The treatment of psychotic behavior is the primary indication for chlorpromazine. Numerous controlled trials have indicated its utility in reducing the delusions, hallucinations, and bizarre behavior that accompanies schizophrenia. Psychotic behavior may be manifested in a number of treatable psychiatric disorders (Table 3A.4).

**Table 3A.4.**  
**Conditions for Which Chlorpromazine May Have Beneficial Effects**

Psychotic disorders, including acute and chronic schizophrenia
Organically induced psychoses (PCP, amphetamine abuse)
Nausea and vomiting
Intermittent porphyria
Intractable hiccups
Tetanus
Surgical restlessness/apprehension
Antihypertensive after open-heart surgery
Schizoaffective disorder
Premenstrual psychotic or dysphoric symptoms

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

The precautions to be considered when using chlorpromazine are numerous as adverse effects can involve most organ systems. Chlorpromazine should not be administered to patients who are comatose or in the presence of large amounts of central nervous system (CNS) depressants (alcohol, barbiturates). Chlorpromazine may impair cognitive ability, and patients may find some usual daily activities, such as safely driving an automobile, to be compromised.

Chlorpromazine can impair body temperature regulation through its actions in the hypothalamus and by suppression of sweating. The extreme result of this effect has been fatal hyperpyrexia. The possibility of heat stroke can be reduced by avoiding combination therapy with other anticholinergic drugs and excessive outdoor activities associated with high temperatures and humidity. Patients who swim may occasionally complain of chills after body exposure in cold water.

Table 3A.5.  
Drug Interactions with Chlorpromazine

Interacting Drug	Effect
Aluminum salts; antacids	Aluminum-based antacids, kaolin, attapulgitte may decrease the absorption of chlorpromazine.
Barbiturates	Hepatic enzyme induction results in decreased chlorpromazine plasma concentrations; additive CNS depression can occur.
Methadone, alcohol	Additive CNS depression can occur.
Propranolol	Pharmacological effects of both drugs may be increased through alterations in the drugs' first-pass metabolism in the liver.
Epinephrine	Hypotension and tachycardia can result. The $\alpha$ -receptor blocking effects of chlorpromazine leave the $\beta$ -adrenergic agonist activity of epinephrine unopposed.
Guanethidine	Inhibition of neuronal uptake by chlorpromazine may decrease antihypertensive effectiveness.
Cimetidine	Uncertain: the absorption of chlorpromazine may be delayed and the metabolites inhibited, producing variability in plasma concentrations.
Anticholinergics	Additive anticholinergic effects; an unsubstantiated decrease in chlorpromazine effectiveness
Cyclic antidepressants	A mutual metabolic inhibition can raise plasma concentrations of either drug or both; additive anticholinergic effects.

## Haloperidol Database

### FORMULATIONS

Haloperidol tablets: 0.5 mg, 1 mg, 2 mg, 5 mg, 10 mg, 20 mg  
Haloperidol concentrate: 2 mg/ml  
Haloperidol injection: 5 mg/ml  
Haloperidol decanoate injection: 50 mg/ml  
Brand names: Haldol (McNeil); various generic brands

### INDICATIONS

Haloperidol is a broadly useful drug in psychiatry. The FDA-approved indications are for use in management of the manifestations of psychotic disorders, for the control of tics and vocal utterances of Tourette's disorder in children and adults, and for the treatment of severe behavioral problems in children. Haloperidol is effective in the short-term treatment of hyperactive children who show excessive motor activity with accompanying conduct disorder. Unapproved uses of haloperidol include prevention and treatment of emesis due to various causes, including cancer chemotherapy, irradiation, and gastrointestinal disorders and in postoperative patients (7). Haloperidol has shown promising effectiveness in the treatment of stuttering and in the treatment of autism in children (8).

Table 3B.1.  
Expected Physiological Effects from Haloperidol Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect and Time Course
Cardiovascular status	
Heart rate	Slight increase
ECG	Similar changes as with chlorpromazine; ST segment depression
Blood pressure	Slight decrease, occasional orthostatic response
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change in most adults.
Hepatic function	
SGOT, SGPT, alkaline phosphatase	Transient benign increases may occur during 1st month. Substantial increases accompanied by increases in bilirubin should prompt further assessment of liver function.
Hematology status	
CBC	Mild and transient leukopenia or leukocytosis; minimal decrease in erythrocyte count. Thrombocytopenia occurs less often than with phenothiazines.
Neuroendocrine status	
Prolactin	Elevated concentrations throughout therapy

<sup>a</sup>For abbreviations, see Table 3A.2, footnote a.

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Haloperidol is contraindicated in severe CNS depression, in comatose states from any cause, and in individuals who have Parkinson's disease or who are hypersensitive to the drug. It may impair mental and/or physical abilities required for operating machinery or driving a car. The ambulatory patient should be warned accordingly. Alcohol should not be used with haloperidol because of the additive impairment of mental or physical functioning and the possibility of contributing to hypotension.

Although haloperidol has a relatively mild hypotensive effect, patients with severe cardiovascular disorders may experience transient hypotension and/or precipitation of anginal pain. If a vasopressor is required, norepinephrine or dopamine rather than epinephrine should be used as the latter leads to unopposed  $\beta$ -receptor stimulation and will possibly induce further hypotension.

Haloperidol may lower the seizure threshold, so anticonvulsant therapy should be monitored closely in patients with seizure disorders. When using antipsychotic drugs in patients with a seizure history, gradual dosage adjustment is recommended to avoid seizures.

Table 3B.3.  
Drug Interactions with Haloperidol

Interacting Drug	Effect
Lithium	Questions about enhanced neurotoxicity have not been fully resolved. Use of the combination should be closely monitored for neurological toxicity.
Phenytoin, barbiturates, carbamazepine, smoking Guanethidine	Hepatic enzyme induction results in decreased plasma concentrations. Due to inhibition of neuronal uptake of guanethidine by haloperidol, the antihypertensive effectiveness may be reduced.
Tricyclic antidepressants	A mutual metabolic inhibition may raise plasma concentrations of either drug. The pharmacodynamic consequences remain to be fully defined.

## Clozapine Database

### FORMULATIONS

Clozapine tablets: 25 and 100 mg  
Brand names: Clozaril; Leponex (Sandoz)

Table 3C.2.  
Expected Physiological Effects from Clozapine Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
Cardiovascular status	
Heart rate	Sinus tachycardia, up to 120 beats/minute
ECG	Occasional flattening of T-wave, shortening of P-Q interval
Blood pressure	Orthostatic hypotension can occur, sometimes severe.
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change in most adults. Occasional apparent diuretic actions.
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Transient increases may occur during first few weeks of therapy unaccompanied by physical symptoms. Increases in bilirubin should prompt further assessment of liver function.
Hematology status	
CBC	Leukocytosis, leukopenia, and eosinophilia may occur. Reversible granulocytopenia can occur. CBC is recommended weekly for the duration of therapy. If WBC is below 3500, then it should be rechecked bi-weekly. WBC below 3000 or granulocyte count below 1500 is an indication for discontinuing therapy.
Neuroendocrine status	
Body temperature	Hyperthermia is common in 10% or more of patients, but is usually mild and self-limited.

<sup>a</sup>Abbreviations: BUN, blood urea nitrogen; AST, aspartate aminotransferase; SGOT, serum glutamic-oxaloacetic transaminase; ALT, alanine aminotransferase; SGPT, serum glutamic-pyruvic transaminase; WBC, white blood cell count.

### INDICATIONS

Clozapine is indicated for use in the management of acute and chronic psychotic disorders in three types of patients. The first group is those patients who are refractory to treatment with conventional neuroleptics. In clinical trials these patients have shown inadequate clinical response to at least two different antipsychotic drugs and have been treated for an adequate duration of time.

Table 3C.3.  
Pharmacokinetic Parameters of Clozapine

Parameter	Range
Bioavailability	Nearly complete absorption; total bioavailability reduced to approximately 70% from presystemic elimination
Time of peak concentration after single dose	Between 1 and 4 hours
Plasma protein binding	90% or above
Volume of distribution	1 to 10 liters/kg (mean of 4.6)
Total plasma clearance	Oral: 11 to 105 liters/hr (mean of 45 liters/hr)
Renal clearance	Negligible
Elimination half-life	Range of 6 to 33 hours; mean of 16
Active metabolites	Uncertain; demethylated metabolites could have some activity.
Therapeutic range	Not established; no correlation has been found in limited studies between plasma concentration and either efficacy or adverse effects. Usual doses produce plasma concentrations with a range of 100 to 600 ng/ml.

Many of these patients will have a history of multiple hospital admissions. Typically, florid psychotic symptoms are present despite doses of antipsychotics at the upper range of recommended doses. In controlled trials, clozapine proved superior to chlorpromazine for this type of patient (2-4). Many patients had also shown unsatisfactory response to haloperidol. During the largest multicenter trial (2), clozapine proved superior to chlorpromazine for improving positive symptoms of schizophrenia during the entire 6-week active treatment period and proved superior for treatment of negative symptoms from weeks 2 to 6.

A second group of patients are those who cannot receive adequate doses of typical antipsychotics to control their symptoms because of intolerable extrapyramidal side effects. As discussed later (see Chapter 3E) some patients do not respond to antiparkinson drugs and are difficult to treat. The low incidence of extrapyramidal symptoms with clozapine makes it an appropriate choice in many of these patients.

Finally, a third group of schizophrenic patients with tardive dyskinesia must continue to be treated because of psychotic symptoms, yet are drug-intolerant. These patients either develop a worsening of dyskinetic movements with continued antipsychotic treatment or are dysfunctional because of their tardive dyskinesia. Some patients' symptoms of tardive dyskinesia were suppressed during treatment with clozapine. However, low doses, less than 250 mg/day, do not seem effective. Guidelines for treating these patients are needed from further clinical research.

Clozapine has been tried as a treatment for abnormal involuntary movement disorders (13, 14). The results have been equivocal. Two patients with Huntington's disease showed a marked decrease in movements, but other patients with Tourette's syndrome showed no improvement. Some patients with tardive dyskinesia had a suppression of their symptoms of tardive dyskinesia while taking

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Agranulocytosis has occurred in patients receiving clozapine (see "Adverse Reactions," below). This drug reaction, reversible upon early detection, is apparently an unpredictable, possibly immunological phenomenon unrelated to dosage. The risk is as high as 1 to 2% of patients treated for a year. Fatalities have occurred but only in patients identified after the onset of symptoms of infection (1). This risk must be balanced against the very poor prognosis for some chronic refractory schizophrenics. State hospitals contain many psychotic patients whose quality of life is dismal and whose prospects for useful interactions with society are limited to custodial care.

The incidence of bone marrow suppression with clozapine is no greater than exists with many chemotherapeutic agents and some other widely prescribed drugs (16). For example, estimates of the frequency of neutropenia associated with sustained-release procainamide is 0.55 to 4.4% (17). However, clozapine's estimated incidence of bone marrow suppression is higher than that of other antipsychotic agents.

Routine frequent monitoring of blood cell counts is the best possible approach to detection of drug-induced hematological abnormalities. However, this is not a fail-safe practice as occasionally granulocytopenia can occur rapidly. Attention should be paid to any symptoms that suggest infection, and appropriate investigation and treatment should be initiated when indicated. Patient fatalities from agranulocytosis usually result from secondary infections.

Clozapine should not be used in combination with other drugs known to depress bone marrow function, including other antipsychotics, or in patients with a history of myeloproliferative disorders.

Unless toxicity requires rapid discontinuation of clozapine, it should be withdrawn gradually. Two patients developed pronounced psychotic symptoms within 48 hours when clozapine was abruptly discontinued (18). Ordinarily, patients do not relapse for 2 weeks or longer after discontinuing antipsychotic therapy, although many patients will relapse within 6 months. These two cases of rapid clinical deterioration suggest that a clozapine-induced supersensitivity psychosis may have occurred.

Like most antipsychotics, clozapine can lower the seizure threshold. Seizures have been reported with clozapine. At doses of 600 mg/day and higher, the risk seems to be greater than with other antipsychotics (11). Generally, there seems to be a relationship between the dose of antipsychotic given and the incidence of seizures. This suggests that patients with a history of seizure disorder should be given the lowest possible dose of all antipsychotics. Anticonvulsant medication should be continued in patients receiving clozapine, but attention should be paid to the possibility that adding clozapine to an existing anticonvulsant regimen may result in a drug interaction. Plasma concentrations of anticonvulsants should be monitored if toxicity is suggested or seizure frequency increases.

**Table 3C.4.**  
**Predicted Drug Interactions with Clozapine**

Interacting Drug	Effect
Alcohol, barbiturates, benzodiazepines	Enhanced sedative effects
Epinephrine	Hypotension and tachycardia can result. The $\alpha$ -receptor blocking effects of clozapine leave the $\beta$ -adrenergic agonist activity of epinephrine unopposed.
Anticholinergics	Additive anticholinergic effects; delirium could occur.
Cyclic antidepressants	Have been successfully coadministered, but highly anticholinergic drugs could lead to delirium.
Enzyme inhibitors (cimetidine, disulfiram, isoniazid)	Could interfere with the metabolism and elimination of clozapine
Enzyme inducers (rifampin, cigarette smoking)	Could hasten the elimination of clozapine and lower its steady-state concentrations

SURVIVING SCHIZOPHRENIA: A Family Manual  
 Torrey, E.F. (1983) p. 117.

THE TREATMENT OF SCHIZOPHRENIA

Table 2

Equivalent Doses of Antipsychotic Drugs

The following list of antipsychotic drugs by drug equivalency is only approximate. Fluphenazine and haloperidol, the most potent (and among the most used) are taken as the baseline. To find out what an equivalent dose of another drug is, multiply by the number indicated. Thus 10 milligrams of fluphenazine is approximately equivalent to 20 milligrams of thiothixene (x 2), 50 milligrams of molindone (x 5), 100 milligrams of acetophenazine (x 10), 150 milligrams of mesondazine (x 15), and 200 milligrams of chlorpromazine (x 20).

Generic Name	Trade (Brand) Names
<b>Baseline</b>	
fluphenazine	Prolixin, Permitil, Moditen
haloperidol	Haldol
droperidol	Inapsine
<b>Multiply x 2</b>	
thiothixene	Navane
trifluoperazine	Stelazine and others
<b>Multiply x 5</b>	
perphenazine	Trilafon, Phenazine
butaperazine	Repose
molindone	Moban, Lindone
loxapine	Loxitane, Daxolin
thiopropazate	Dartalan
piperacetazine	Quide
<b>Multiply x 10</b>	
prochlorperazine	Compazine, Stemetil
carphenazine	Proketazine
triflupromazine	Vespmn
acetophenazine	Tindal
<b>Multiply x 15</b>	
mesondazine	Serentil
chlorprothixene	Taractan
<b>Multiply x 20</b>	
thiondazine	Mellani, Novondazine, Thionl
chlorpromazine	Thorazine and others

## Benztropine Database

---

### FORMULATIONS

Benztropine mesylate tablets: 0.5 mg, 1.0 mg, 2.0 mg  
Benztropine mesylate injection: 1 mg/ml in 2-ml ampules  
Brand name: Cogentin (Merck)

### INDICATIONS

Benztropine is used as an adjunct in the therapy of all forms of Parkinson's disease. It is also used in the control of extrapyramidal side effects caused by antipsychotic drugs (5). It is not used for the treatment of tardive dyskinesia.

### CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Benztropine is contraindicated in children under 3 years of age. It should only be used cautiously in older children. Hypersensitivity to benztropine is a rare contraindication.

Benztropine may decrease sweating because of its similarity to atropine. Therefore, it should be administered cautiously during hot weather, especially when given with other anticholinergic drugs to the chronically ill, those with central nervous system disease, and those who do manual labor in a hot environment. Hyperthermia is a possible consequence of anhidrosis, and fatalities have occurred.

Benztropine should not be used in people with glaucoma, particularly angle-closure glaucoma; pyloric or duodenal obstruction; stenosing peptic ulcers; prostatic hypertrophy or bladder neck obstructions; or myasthenia gravis. Patients taking benztropine who report gastrointestinal complaints should be promptly questioned about the cause and further investigation started, if necessary. Paralytic ileus, sometimes fatal, has been reported in patients taking anticholinergic-type antiparkinson drugs in combination with phenothiazines and/or tricyclic antidepressants.

The subjective effects of antiparkinsonian medications have been perceived as pleasurable by some individuals. This has led to benztropine and similar drugs becoming substances of abuse (9, 10). Trihexylphenidate (see Chapter 3F) seems to be the preferred drug. Single doses of only 2 to 4 times the usual daily dose may produce the disorientation and visual hallucinations typical of anticholinergic delirium. However, a steep dose-response curve (see Chapter 1C) between mild euphoria and toxicity has prevented widespread popularity of this form of substance abuse. Clinicians should take a careful drug history to uncover antiparkinsonian drug abuse. It may be difficult to distinguish between psychopathology and the behavioral effects from mild intoxication.

# F

## Intraclass Comparisons of Antiparkinson Drugs

Parkinson's disease is a neurological disorder characterized by tremor, rigidity, akinesia, and difficulties in maintaining posture and equilibrium. Several causes are recognized. The pathophysiological basis is complex but partly involves a deficiency of dopamine in the basal ganglia area of the brain (Chapter 1B). This results in an imbalance between acetylcholine and dopamine. Some of the drugs that are effective in reversing the symptoms of parkinsonism either increase neurotransmission by acting as dopamine agonists (L-DOPA, amantadine, bromocriptine) or decrease cholinergic neurotransmission by acting as muscarinic antagonists.

Symptoms of parkinsonism may be drug-induced. All of the effective antipsychotic drugs, with the possible exception of clozapine, can produce pseudoparkinsonism and other neurological side effects (1-3). These are collectively known as extrapyramidal symptoms (EPS). The most common are dystonias and akathisia. A comparison is shown in Table 3F.1. The presence of these side effects can seriously undermine the therapeutic goals of antipsychotic drug therapy, prolong hospitalization, and contribute to the patient's inactivity. Some dystonias (e.g., oculogyric crises) can present as serious medical conditions. Akathisia can be distressing and result in maladaptive reactions, even contributing to suicidal behavior. The anticholinergic drugs can reverse or prevent most antipsychotic-induced EPS. L-DOPA, the immediate precursor of dopamine, has not been systematically studied for the treatment of antipsychotic-induced EPS.

Table 3F.1.  
Neurological Side Effects of Antipsychotic Drugs

Reaction	Features	Usual Time of Appearance during Therapy	Treatment
Acute dystonia	Spasm of muscles of tongue, face, neck	1 to 5 days	Antiparkinson agents (IM or IV, then oral)
Pseudoparkinsonism	Bradykinesia, rigidity, variable tremor, mask facies, shuffling gait	5 to 30 days	Antiparkinson agents (oral)
Akathisia	Motor restlessness	5 to 60 days	Reduce dose or change drug; antiparkinson drugs usually help
Tardive akathisia	Motor restlessness	weeks after withdrawal of antipsychotic	Antiparkinson agents (oral)
Tardive dyskinesia	Oral-facial dyskinesia; choreoathetosis	months to years	No adequate therapy; antiparkinson drugs are not recommended

**Table 3F.2.**  
Usual Dosages of Antiparkinson Drugs for EPS

Drug	Brand Name	Dose Range (mg/day)	Equivalent Dose (mg)
Benzotropine	Cogentin	0.5-8	2
Trihexyphenidyl	Artane	2-20	5
Procyclidine	Kemadrin	5-20	5
Biperiden	Akineton	4-8	4
Diphenhydramine	Benadryl	25-200	50
Amantadine	Symmetrel	100-300	100

**Table 3F.3.**  
Medical and Psychiatric Manifestations of Anticholinergic Toxicity

Peripheral
Tachycardia
Dry mucous membranes
Urinary retention
Blurred vision
Constipation
Central
Delirium
Disorientation
Ataxia
Reduced ability to concentrate
Euphoria
Seizures in severe cases
Confusion
Recent memory difficulties
Hallucinations, visual or auditory
Delusions
Irritability
Predisposing factors
High (greater than 450 ng/ml) plasma concentrations of tricyclics
Polypharmacy (two or more drugs with anticholinergic properties)
Advanced age
Concurrent CNS disease

**Table 1F.1.**  
**Major Mental Disorders and Pharmacotherapy**

Major Disorder	Examples: Drugs Used Routinely or Experimentally in Treatment for Either Primary or Associated Symptoms
Disorders evident in infancy, childhood, or adolescence	Mental retardation, conduct disorder, anorexia nervosa, attention-deficit disorder, bulimia nervosa CA, STIM, LI <sup>a</sup> , MAOI <sup>b</sup>
Organic mental disorders	Alzheimer's disease, multi-infarct dementia A-PSYCH, BENZO, HYP
Substance use disorders	Alcohol dependence, cocaine dependence, opioid dependence CA, LI, BENZO, clonidine, disulfiram, methadone, propranolol
Psychotic disorders	Brief reactive psychosis, schizoaffective disorder, schizophrenia A-PSYCH, CA, LI, HYP <sup>a</sup> , BENZO <sup>a</sup>
Mood disorders	Bipolar disorder (manic), major depression CA, STIM, BENZO, HYP, MAOI, A-CONVUL
Anxiety disorders	Panic disorder, agoraphobia, posttraumatic stress disorder BENZO, HYP, CA, MAOI, A-CONVUL <sup>a</sup>
Dissociative disorders	Multiple personality disorder, psychogenic fugue
Disorders of impulse control	Pathological gambling, intermittent explosive disorder LI, A-CONVUL
Personality disorders	Antisocial, borderline, narcissistic, schizotypal LI, BENZO, A-PSYCH

<sup>a</sup>Drug used experimentally.

<sup>b</sup>CA, cyclic antidepressants; STIM, stimulants; A-PSYCH, antipsychotics; BENZO, benzodiazepines; LI, lithium; A-CONVUL, anticonvulsants used as mood stabilizers; HYP, hypnotics; MAOI, monoamine oxidase inhibitors.

**Table 1F.2.**  
**Classification of Mood Disorders**

- |                       |
|-----------------------|
| I. Major depression   |
| A. Single episode     |
| B. Recurrent          |
| II. Dysthymia         |
| III. Bipolar disorder |
| A. Mixed              |
| B. Manic              |
| C. Depressed          |
| IV. Cyclothymia       |

**Table 1F.3.**  
**Target Symptoms for Monitoring Response to Antidepressant Therapy**

Cognitive Symptoms	Physical Symptoms
Dejected mood	Loss or increase of appetite
Self-blame	Psychomotor agitation or retardation
Low self-esteem	Sleep disturbance
Self-depreciation	Loss of libido
Loss of gratification	Gastrointestinal upset
Loss of attachments	Diurnal fluctuation of mood
Loss of sense of humor	
Negative expectations	
Increasing ambivalence	
Delusions	
Increasing dependence	
Hallucinations	
Suicidal ideation	
Loss of motivation	

**Table 1F.4.**  
**Target Symptoms for Monitoring Response to Antimanic Therapy**

Affective Symptoms	Psychomotor Symptoms	Cognitive Symptoms
Irritability	Sleep disturbance	Delusions (e.g., sexual prowess, persecutory, religious, grandiosity)
Labile mood	Pressured speech	
Short attention span	Talkative	Racing thoughts
Euphoria	Flight of ideas	Ideas of reference
Manipulative behavior	Assaultive behavior	Hallucinations
Elevated or expansive mood	Increased activity	Flight of ideas

## Lithium Database

### FORMULATIONS

Lithium carbonate tablets: 300 mg (8.12 mEq of lithium)  
 Lithium carbonate capsules: 300 mg (8.12 mEq of lithium)  
 Lithium carbonate tablets, sustained release: 300 mg (8.12 mEq of lithium); 450 mg (12.18 mEq of lithium)  
 Lithium citrate syrup: 8 mEq of lithium per 5 ml  
 Brand names: Lithium carbonate (Roxane); Eskalith (SKF); Lithonate (Rowell); Lithane (Miles Pharmaceuticals); Lithotabs (Rowell); Lithobid (Ciba)

Table 2A.1.  
 Expected Physiological Effects from Lithium Therapy\* for Monitoring

Parameter	Drug Effect
Thyroid function	
T-4, T-3	Decreases noted within 4 mo with reversal to pretreatment levels within 12 mo of continuous therapy
TSH	Persistent increases noted within 4 mo of beginning therapy
Cardiovascular status	
ECG	Depression of T-waves at upper end of therapeutic concentrations; rarely, inversion
Heart rate, blood pressure	No changes expected in healthy patients
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change in most adults over several years; children have been followed for 3 to 5 yr without changes; values will deteriorate markedly in toxic states.
Urine output	Frequent increases above 2 liters/24 hr correlating with duration of therapy; may begin soon after beginning therapy and frequently, but not always, parallels polydipsia.
Hepatic function	
AST (SGOT), ALT (SGPT)	No effect expected on hepatic enzymes
Hematology status	
CBC	Significant but innocuous leukocytosis within 1 to 3 wk, reversible within 1 wk off of lithium
Neuroendocrine status	
Dexamethasone suppression test	No effects expected
Fasting blood glucose	Short-term (1 yr) decrease, but no chronic effects expected; increases should prompt further patient assessment.

\*Abbreviations: T-4, serum thyroxine; T-3, serum triiodothyronine; TSH, thyroid-stimulating hormone; ECG, electrocardiogram; BUN, blood urea nitrogen; AST, aspartate aminotransferase; SGOT, serum glutamic oxaloacetic transaminase; ALT, alanine aminotransferase; SGPT, serum glutamic pyruvic transaminase; CBC, complete blood count.

## INDICATIONS

Lithium is approved by the Food and Drug Administration (FDA) for treatment of acute mania and for prophylaxis of bipolar affective disorder. Numerous, well-controlled studies have shown that lithium induces improvement or remission in greater than 70% of patients with acute mania. Placebo-controlled trials have also shown that it is effective in manic-depressive patients in preventing both manic and depressive episodes (6, 7). Lithium has also been tried in a variety of other psychiatric disorders, with varying degrees of success.

Table 2A.2.  
Pharmacokinetic Parameters of Lithium

Parameter	Range
Peak concentration from a single 600-mg dose of lithium carbonate	0.45 to 0.85 mEq/liter
Time of peak concentration	0.5 to 2 hr for rapid release tablets; 4 to 12 for delayed release
Total body clearance	Equal to renal clearance
Renal clearance	10 to 40 ml/min
Hepatic clearance	None
Elimination half-life	18 to 24 hr in young adults; 30 to 36 hr in elderly
Plasma protein binding	None
Volume of distribution	0.8 to 1.2 liter/kg
Therapeutic range:	
Antimanic	0.8 to 1.4 mEq/liter
Prophylaxis	0.4 to 1.0 mEq/liter

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

The use of lithium should not be undertaken lightly. As stated previously, lithium toxicity is closely related to serum levels and can occur at therapeutic doses. Facilities for serum lithium determinations are required to monitor therapy. The risk/benefit considerations in preventing the recurrence of bipolar disorder heavily favor the use of lithium for many patients. However, lithium should generally not be given to patients with significant myocardial or cardiovascular disease or in the presence of severe renal disease, organic brain disease, or pregnancy (see below).

Renal damage from long-term lithium therapy is a controversial issue. Morphological changes with glomerular and interstitial fibrosis and nephron atrophy have been reported in patients who underwent chronic lithium therapy for many years (20). However, similar lesions have been found in patients before beginning lithium therapy, so lithium cannot be regarded as specifically nephrotoxic. Nevertheless, the dose of lithium should be kept low to minimize the uncertain risk that long-term lithium use may result in renal damage.

**Table 2A.3.**  
**Drug Interactions with Lithium**

Interacting Drug	Mechanism/Effect/Management
Carbamazepine or haloperidol	Rare neurotoxicity from an unknown mechanism; closely monitor patients receiving these combinations.
Ibuprofen or indomethacin	Decreased lithium clearance possibly from inhibition of renal prostaglandin synthesis; result is increased serum lithium; adjust lithium dose or consider using aspirin.
Naproxen	Decreased lithium clearance by unknown mechanism; monitor lithium serum concentration closely.
Iodide salts	Additive effects in causing hypothyroidism; discontinue iodide salts or give thyroid replacement if needed.
Furosemide, ethacrynic acid or bumetanide	Possible elevated serum lithium from decreased renal excretion; adjust lithium dose if needed.
Theophylline	Increased renal excretion of lithium; monitor serum levels and adjust dose if needed.
Thiazide diuretics	Decreased renal excretion of lithium results in elevated lithium levels, which can lead to serious toxicity; use of a loop diuretic may be preferable.

**Table 2A.4.**  
**Side Effects of Lithium**

Mild and Usually Transient
Nausea, abdominal discomfort, mild diarrhea
Polydipsia, polyuria
Fine hand tremor
Muscular weakness, fatigue, lethargy
Generalized discomfort
Suggesting Early or Moderate Lithium Toxicity
Severe GI distress—nausea, vomiting, severe diarrhea
Anticholinergic-like symptoms—blurred vision, dry mouth
Muscular weakness
Coordination impairment, ataxia
Confusion, drowsiness, irritability
Acute or Severe Lithium Toxicity
Impairment of consciousness, stupor, coma
Neuromuscular asymmetries—nystagmus
Coarse tremor
Epileptiform seizures
Hyperreflexia
Slurred speech, vertigo, somnolence
Arrhythmias, hypotension, peripheral circulatory failure
Respiratory depression

## Imipramine Database

### FORMULATIONS

Imipramine hydrochloride tablets: 10 mg, 25 mg, 50 mg  
Imipramine hydrochloride capsules: 125 mg, 150 mg, 200 mg  
Imipramine hydrochloride injection: 25 mg/ml  
Brand names: Tofranil (Geigy); Janimine (Abbott); SK-Pramine (SKF); various generic brands

Table 2B.1.  
Expected Physiological Effects from Imipramine Therapy for Monitoring\*

Parameter	Drug Effect
Cardiovascular status	
Heart rate	Frequent increase of up to 10 beats/min persisting throughout therapy
ECG	Prolonged QRS greater than 100 msec when plasma concentrations exceed 1000 ng/ml; reduced T-wave amplitude, rarely at usual plasma concentrations
Blood pressure	Orthostatic hypotension is common in up to 20% of treated patients.
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change in most adults.
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Transient benign increases may occur during 1st mo. Substantial increases accompanied by increases in bilirubin should prompt further assessment of liver function. Imipramine- and desipramine-associated hepatitis has been reported.
Hematology status	
CBC	Rare, transient increases in eosinophils; decreases in leukocytes; trivial decreases in platelet count
Neuroendocrine status	
DST, plasma cortisol	Therapy not expected to interfere with DST; frequent normalization of DST with successful antidepressant therapy
Other tests	
EEG	Decreased REM sleep

\*For abbreviations, see Table 2A.1. DST, dexamethasone suppression test; EEG, electroencephalogram.

**Table 2B.2.**  
**Pharmacokinetic Parameters of Imipramine**

Parameter	Range
Bioavailability	Nearly complete absorption; total bioavailability reduced from extensive presystemic elimination to 30 to 70%
Time of peak concentration after single dose	Between 2 and 8 hr
Plasma protein binding	85 to 96%
Volume of distribution	10 to 30 liters/kg
Total plasma clearance	30 to 100 liters/hour
Renal clearance	Negligible
Elimination half-life	6-28 hours, increasing with age after adulthood
Active metabolites	Desipramine, 2-hydroxyimipramine, 2-hydroxy-desipramine
Steady-state metabolite-to-parent concentration ratio	DMI:IMI average of 1.5 2-OH-IMI:IMI average of 0.2 2-OH-DMI:DMI average of 0.5
Therapeutic range for antidepressant effect	180 to 350 ng/ml of combined imipramine plus desipramine in adults; 120 to 250 ng/ml in children

## INDICATIONS

Imipramine is FDA approved for the relief of symptoms of depression and depression accompanied by anxiety. In addition, IMI is the only tricyclic antidepressant with a specific FDA approval for the treatment of enuresis. Imipramine and other tricyclic antidepressants have been tried with some success for various mental and medical disorders listed in Table 2B.3.

Imipramine's use for depression, especially endogenous depression, is its primary indication. These patients will frequently have sleep disturbances, diurnal mood variation, loss of weight and libido, and psychomotor retardation, the neurovegetative signs not consistently present in less ill patients. Of endogenously depressed patients, 60 to 70% should respond well to IMI.

For depressed patients presenting with delusions, there is controversy over whether electroconvulsive therapy should be considered as the treatment of choice (7, 8). The more severe an illness, the more easily recognizable is clinical improvement, and this is true for depression. Therefore, it may be more diffi-

**Table 2B.3.**  
**Conditions for Which Imipramine or Tricyclic Antidepressants May Have Beneficial Effects**

Condition	Efficacy Monitoring Parameters
Anorexia nervosa	Weight gain; improvement in appetite, self-concept
Attention deficit disorder	Decrease in distractibility; increased attention span; improved behavior
Bulimia nervosa	Decreased bingeing episodes
Enuresis	Decreased bed or daytime wetting frequency
Encopresis	Reduction in soiling
Posttraumatic stress disorder	Decreased startle response, anxiety, rumination, nightmares
Panic disorder	Decreased anxiety; fewer panic episodes; less avoidance behavior
Migraine headache	Decreased frequency or intensity or duration
Obesity	Weight loss, decreased craving, self-control
Peptic ulcer disease	Decreased epigastric pain, GI distress
Premature ejaculation	Reports of improved sexual performance

cult to perceive improvement in patients with milder forms of depression without a good assessment of premorbid functioning. However, nonendogenous, or neurotic, depression also responds well to imipramine therapy (9). Schizophrenic patients frequently have a high incidence of depressive symptoms during a postpsychotic state. This syndrome can be confused with akinesia, but IMI has produced good improvement in these patients' affective states (10).

Imipramine has been shown to be effective for treatment of panic disorder. The onset of significant effectiveness may be slow, but 60 to 90% of patients can be expected to show some improvement.

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

It should be remembered that many depressed patients will be suicidal. Unfortunately, the tricyclic antidepressants can be fatal in overdose and, therefore, a large prescription quantity should be avoided in outpatients. The dose of IMI producing fatalities is highly variable. A child has died from an ingestion as low as 350 mg, and adults have survived overdosages between 5 and 10 gm (17).

Patients with open-angle glaucoma can be safely treated with IMI, but those with angle closure should have a referral to an ophthalmologist. IMI has the potential to aggravate glaucoma, especially narrow angle, as its anticholinergic effects can precipitate acute symptoms. In patients over the age of 40, a history of "halos" around lights associated with eye pain should prompt an ophthalmic examination.

During maintenance therapy of patients with bipolar (manic-depressive) disorder, imipramine may accelerate the switch from depression to mania. Monitoring for symptoms of hypomania would be appropriate in these patients. Lithium may be a useful addition to the therapy of these patients but may not always prevent the switch process from occurring (15).

**Table 2B.4.**  
**Drug Interactions with Imipramine**

Interacting Drug	Effect
Barbiturates	Hepatic enzyme induction results in decreased imipramine plasma concentrations.
Methylphenidate, chloramphenicol, phenothiazines, cimetidine, oral contraceptives	Increased plasma concentration through hepatic enzyme inhibition
Thyroid hormone	Possibly increased antidepressant efficacy through an unknown mechanism
Dicumarol	Increased hypoprothrombinemic effect by an unknown mechanism
Clonidine, guanethidine	Decreased antihypertensive effect
Sympathomimetics (epinephrine, phenylephrine)	Enhanced $\alpha$ -adrenergic effects
Monoamine oxidase inhibitors	Increased adverse drug effects are possible. Close monitoring is mandatory. Allow 7 days between starting either one after discontinuing the other, or both may be started together (see Chapter 2D).

**Table 2B.5.**  
**Expected Side Effects of Imipramine Therapy**

Effect	Rare	Less Common	More Common
Dry mouth			X
Blurred vision		X	
Gastrointestinal disorders		X	
Nausea		X	
Vomiting		X	
Drowsiness			X
Ataxia		X

## Trazodone Database

### FORMULATIONS

Trazodone hydrochloride tablets: 50 mg, 100 mg, 150 mg

Brand names: Desyrel (Mead Johnson); Dotazone (Major), various generic brands

**Table 2C.1.**  
**Expected Physiological Effects from Trazodone Therapy for Monitoring<sup>a</sup>**

Parameter	Drug Effect
<b>Cardiovascular status</b>	
Heart rate	Occasional tachycardia accompanying orthostasis
ECC	Rare intracardiac conduction disturbances
Blood pressure	Hypotension upon chronic therapy in susceptible individuals, more frequent in elderly but less frequent or severe than with tricyclic drugs
<b>Renal function</b>	
Serum creatinine and clearance, BUN	Normal values should not change in most adults
<b>Hepatic function</b>	
AST (SGOT), ALT (SGPT), alkaline phosphatase	No changes expected other than minor increases within normal limits
<b>Hematology status</b>	
CBC	Occasional minor decreases in leukocytes and neutrophils, clinically insignificant unless below normal limits
<b>Neuroendocrine status</b>	
Plasma prolactin	Both increases and decreases reported, but little change is to be expected.
DST, plasma cortisol	Therapy not expected to interfere with DST; frequent normalization of DST with successful antidepressant therapy

<sup>a</sup>For abbreviations, see Table 2B.1.

**Table 2C.2.**  
**Pharmacokinetic Parameters of Trazodone**

Parameter	Range
Bioavailability	70 to 90%
Time of peak concentration after single dose	0.5 to 3 hours
Plasma protein binding	89 to 95%
Volume of distribution	1.0 to 2.0 liters/kg; increased in obesity
Total plasma clearance	120 to 200 ml/min
Renal clearance	Negligible
Elimination half-life	3 to 14 hours
Active metabolites	<i>m</i> -Chlorophenylpiperazine
Steady-state plasma metabolite-to-parent concentration ratio	Less than 1.0
Therapeutic range for antidepressant effect	Inadequately defined

## INDICATIONS

Trazodone is FDA-approved for treatment of depression. This indication can be further defined as "major depressive disorder," as described in DSM-III-R (see Chapter 1F). Controlled clinical trials, including double-blinded studies, have been conducted in both depressed inpatients and outpatients (1). Improvement in depression is similar to that observed with the prototype tricyclic antidepressants, imipramine and amitriptyline, with a reported complete remission rate of 46 to 70%. As occurs with all available antidepressants, some patients will be relative nonresponders and might benefit from an alternative therapy

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Although trazodone may cause some cardiac side effects, principally tachycardia, orthostasis, and, rarely, conduction disturbances, its use is associated with fewer and less severe cardiac effects than use of the traditional tricyclic antidepressants (11). Trazodone should not be administered to any patient with a recent myocardial infarction. In patients with cardiac disease, caution should be exercised. Arrhythmias have occurred in some patients with preexisting cardiac disease who took trazodone.

The effects of trazodone treatment for a week on the blood pressure response to tyramine, in comparison to the effects of placebo, were similar (12). This is in contrast to the effects of imipramine on systolic blood pressure after tyramine administration, an effect mediated by norepinephrine. The main cardiovascular effects of trazodone to monitor are blood pressure and pulse rate. Complaints of dizziness should be sought in any patient with a history of orthostasis. Several reports suggest that trazodone may elevate serum digoxin levels. Digoxin concentrations should be monitored when this combination of drugs is used.

Some unipolar depressed patients have been reported to develop manic symptoms when treated with trazodone (13). Thus, trazodone does not preclude this phenomenon, but it may be similar to the tricyclic antidepressants in having a propensity to initiate the switch process in occasional bipolar depressed patients.

Trazodone has been tested in patients with open angle glaucoma and found to decrease intraocular pressure (2). However, studies have not been reported in glaucoma patients with depression receiving chronic trazodone therapy, so caution should be exercised with these patients. As with the tricyclics, those patients with angle-closure disease may be at risk for increased intraocular pressure. However, given trazodone's lack of anticholinergic effects, it may be an appropriate alternative to tricyclic antidepressants in glaucoma patients who have had difficulty in the past with antidepressant therapy.

Table 2C.3.  
Expected Side Effects of Trazodone Therapy

## Phenelzine Database

### FORMULATIONS

Phenelzine tablets: 15 mg  
Brand name: Nardil (Parke-Davis)

Table 2D.1.  
Types of Monoamine Oxidase, Their Substrates, and Inhibitors

	Type of Enzyme	
	Type A	Type B
Substrates		
Serotonin	+	
Phenylethylamine		+
Norepinephrine	+	
Dopamine		+
Tyramine	+	+
Inhibitors		
Clorgyline	+	
Deprenyl		+
Harmaline	+	
Pargyline		+
Tranlycypromine	+	+
Phenelzine	+	+
Isocarboxazid	+	+

**Table 2D.2.**  
**Expected Physiological Effects from MAOI Therapy for Monitoring<sup>a</sup>**

Parameter	Drug Effect
<b>Cardiovascular status</b>	
Heart rate	Slight decrease of approximately 5 beats/minute
EKG	Occasional decreased QTC intervals with normal QRS intervals
Blood pressure	A reduction occurs frequently, especially decreased systolic blood pressure upon standing; an enhanced pressor sensitivity to tyramine and sympathomimetic drugs occurs early in therapy and may persist for weeks after therapy is stopped.
<b>Renal function</b>	
Serum creatinine and clearance, BUN	No changes expected
<b>Hepatic function</b>	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Hepatocellular damage is rare but has been reported in a few patients. No changes are expected outside normal limits.
<b>Hematology status</b>	
CBC	Leukopenia has been reported but is rare.
<b>Neuroendocrine status</b>	
DST, plasma cortisol	May normalize with successful therapy
Fasting blood glucose	MAOIs may lower blood glucose and improve glucose tolerance.

<sup>a</sup>For abbreviations, see Table 2B.1.

## INDICATIONS

Phenelzine is FDA-approved for treatment of depressed patients clinically characterized as atypical, nonendogenous, or neurotic. These patients often have mixed anxiety and depression and phobic or hypochondriacal features. Thus, the target symptoms for monitoring clinical response will differ somewhat from the classical symptoms of endogenous depression. Table 2D.3 compares typical clinical features of these two types of depressed patients. There is current research activity in further defining this heterogenous group of patients (9, 10).

Phenelzine should rarely be the first antidepressant drug of choice, except in patients with atypical depression. Rather, it may be more suitable for use with patients who have failed to respond to either one or more cyclic antidepressants or lithium. Overall, the low degree of cardiac toxicity and apparent absence of central anticholinergic toxicity with phenelzine, as compared to those factors in the tricyclics, may be considered an advantage in some patients.

Reviews of controlled trials of MAOIs, including phenelzine, suggest an improvement rate of approximately 70%. This is similar to the improvement seen with tricyclic antidepressants. Perhaps more importantly, it should be understood that MAOI responders may have different clinical features than have tricyclic responders (11, 12). There is less conclusive evidence of phenelzine's usefulness with severely depressed patients with endogenous features (32, 33).

Phenelzine has several unapproved uses. The antiphobic effects of phenelzine have been well demonstrated, and the drug is most likely to be the agent of choice in the treatment of agoraphobia and social phobias (13, 14). Phenelzine is equal to or better than imipramine in the treatment of panic disorder. Limited research indicates that MAOIs, especially phenelzine, may be used successfully in patients with migraine headache refractory to other treatment (15). Phenelzine has also been effective in the treatment of bulimia (16).

In recent years, there has been wider recognition of posttraumatic stress disorder (PTSD), especially in Vietnam War veterans. These patients frequently have generalized anxiety and panic attacks (17). A favorable response has been noted in patients treated with phenelzine to relieve the anxiety and depressive symptoms associated with PTSD (18). As phenelzine depresses REM sleep in animals and humans, it can be expected to decrease dream activity. Target symptoms may include nightmares and flashbacks when one is monitoring phenelzine therapy in patients with PTSD.

**Table 2D.3.**  
**Target Symptoms Suggested for Monitoring Antidepressant Response in Atypical or Endogenously Depressed Patients**

Atypical	Endogenous
Difficulty initiating sleep	Early morning awakening
Hypersomnia	Diminished sleep
Weight gain	Weight loss
Food craving	Loss of appetite
Agoraphobia	Psychomotor retardation
Panic experiences	Loss of energy
Hypochondriasis	Suicidal ideation
Obsessive traits	Constriction of interests
Psychic anxiety	
Somatic anxiety	

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Phenelzine is contraindicated in patients with pheochromocytoma, congestive heart failure, or a known hypersensitivity to the drug. Phenelzine should be avoided in patients who must take concurrent sympathomimetic amines, guanethidine, or meperidine or who have diets high in tyramine content. These drug-drug and drug-food interactions are explained below.

Like other antidepressants, phenelzine may precipitate a manic reaction in patients with bipolar disorder (22). As lithium has been successfully used in combination with phenelzine (23), it may be useful to prevent rapid cycling in susceptible patients.

Patients have developed pyridoxine (vitamin B<sub>6</sub>) deficiency while taking phenelzine. Patients who complain of numbness of the hands, shock-like feelings in the spine, or other symptoms suggesting a neurological origin, may have this problem. Treatment is easily accomplished with supplemental dietary pyridoxine. The recommended dose is 300 mg daily.

**Table 2D.4.**  
**Drug Interactions with Monoamine Oxidase Inhibitors**

Interacting Drug	Effect
Amine-containing foods	Increased blood pressure; possible hypertensive crisis; can occur up to several weeks after discontinuing the MAOI
Anorexiant and other sympathomimetics: Amphetamine Ephedrine Fenfluramine Methylphenidate Pseudoephedrine Phenylpropranolamine	Elevated blood pressure with possible hypertensive crisis and intracranial hemorrhage can occur. This combination activates large quantities of endogenous catecholamines.
Guanethidine	The antihypertensive effect of this drug may be decreased by an unknown mechanism.
Insulin, sulfonylureas Levodopa	An increased hypoglycemic effect may occur. Enhanced effects of levodopa; possible hypertensive crisis
Meperidine, dextromethorphan	Cardiovascular instability, hyperpyrexia, agitation, and death have occurred.
Tricyclic antidepressants	The effects of both drugs can be increased, leading to enhanced clinical and/or toxic effects (see text).

**Table 2D.5.**  
**Dietary Restrictions Recommended for Patients Taking Phenelzine**

---

Foods high in tyramine content that must be avoided

- Cheese, especially aged cheese (Limburger, Gouda, Edam, Cheddar)
- Foods containing cheese (pizza, fondue, many Italian dishes)
- Wine, particularly Chianti and red wines in general
- Fermented or aged foods, especially meats or aged fish (pepperoni, summer sausage, pickled herring)
- Broad bean pods
- Chicken or beef liver
- Yeast extracts

Foods with moderate tyramine content that are best avoided

- Other alcoholic beverages (gin, vodka, whiskey)
- Avocados
- Yogurt
- Bananas
- Raisins, figs
- Soy sauce

Foods relatively low in tyramine content that can be consumed in moderate amounts

- Bread
- Cottage and cream cheese
- Chocolate
- Coffee, tea, and caffeine-containing beverages
- Other fresh fruits

Protriptyline	Norepinephrine	Weak	Moderate	Moderate
Trimipramine	Serotonin	High	High	High
Trazodone	Serotonin	High	Weak	Weak

**Table 2E.3.**  
**Pharmacokinetic Parameters of Cyclic Antidepressants**

Drug	Oral Availability	Volume of Distribution (liters/kg)	Total Body Clearance (liters/hr)	Elimination Half-life (hr)	Fraction Unbound in Plasma	Active Metabolites
Alprazolam	0.95	1-2	6-140	7-18	0.30	$\alpha$ -Hydroxy
Amitriptyline	0.3-0.6	6-36	19-72	9-46	0.03-0.15	Nortriptyline
Bupropion	0.9	27-60	120-180	10-20	0.20	Hydroxybupropion
Carbamazepine	0.7-0.8	0.8-1.4		10-30; 12 <sup>a</sup>	0.15-0.35	10,11-Epoxyde
Clomipramine	0.4-0.6	9-25	23-122	15-60	0.02-0.10	Desmethyl
Desipramine	0.3-0.6	20-60	78-168	12-28	0.08-0.27	2-Hydroxy
Doxepin	0.2-0.5	10-30	41-60	8-25	0.15-0.32	Desmethyl
Fluoxetine	0.95	12-42	6-42	120+	0.06	Norfluoxetine
Imipramine	0.2-0.7	10-25	32-102	6-28	0.04-0.37	Desipramine
Maprotiline	0.8	16-32	17-34	27-50	0.12	Desmethyl
Nortriptyline	0.5-0.7	15-23	17-79	18-56	0.07-0.13	10-Hydroxy
Protriptyline	0.7-0.9	15-30	8-23	54-120	0.01-0.10	Desmethyl
Trazodone	0.7-0.9	0.8-1.5	7-12	4-13	0.05-0.11	<i>m</i> -Chlorophenylpiperazine

<sup>a</sup>Carbamazepine induces its own metabolism, and patients on chronic therapy will have a decreased half-life.

**Table 2E.4.**  
**Recommendations for Using Cyclic Antidepressant Plasma Concentration Monitoring**

Drug	Concentration Range (ng/ml)	Effect
Imipramine	180–350	This range of combined imipramine plus desipramine concentrations has correlated well in several studies with antidepressant effect in endogenous depression.
	Over 500	Behavior toxicity may occur; there is rarely any justification to exceed this combined concentration.
	Over 1000	Has frequently correlated with severe systemic toxicity requiring medical support; range also applies to other tricyclics.
Nortriptyline	50–150	Range best associated with antidepressant effects in endogenous depression
Amitriptyline	120–250	This combined amitriptyline plus nortriptyline concentration is the target for antidepressant effect.
	Over 500	Frequently associated with anticholinergic delirium
Desipramine	115–250	Target concentration for antidepressant effect

**Valproic Acid** Valproic acid is an anticonvulsant indicated for simple and complex absence seizures. Reports have also suggested that valproate has effects in manic patients similar to those seen with acute lithium therapy (20). It has been reported to be moderately useful in schizoaffective disorder (21). There is much less experience with this drug than with carbamazepine.

Dosage is 1000 to 1500 mg/day, starting with 250 to 500 mg/day. Periodic liver function tests are recommended, as hepatotoxicity has been reported. Other side effects are gastrointestinal in origin, principally nausea, vomiting, and anorexia. Anticholinergic and sedative effects are minor.

**Clonazepam** Clonazepam, an anticonvulsant benzodiazepine, has also been tried for mood stabilization (19). Doses in acutely manic patients, up to 40 mg/day, are substantially higher than the 2 mg/day usually needed for control of seizures. The drug is more sedating than carbamazepine but, if proven effective, could be a safer alternative than lithium or carbamazepine. In doses of 1.5 to 6.0 mg/day it has shown good antipanic effects.

## INDIVIDUAL AGENTS

### Traditional Anticonvulsants

Carbamazepine Carbamazepine (CBZ) demonstrates a remarkable structural resemblance to the tricyclic antidepressants (Fig. 2E.1; compare imipramine in Fig. 2B.1) It is an anticonvulsant agent with prominent antimanic properties (16, 17). It serves as an alternative for patients who are unable to tolerate lithium's side effects or who respond to lithium poorly. CBZ does not produce marked sedation or neuroleptic side effects. Patients with a rapid cycling disorder seem to respond well. CBZ may also be useful to ameliorate aggressive and violent behavior and may be useful for patients with schizoaffective disorders.

Slow increases in dosage are recommended, starting with 200 mg/day and increasing up to 1000 mg/day according to the clinical response. The effective dose range is between 400 and 1600 mg/day. A plasma concentration range of 6 to 12  $\mu\text{g/ml}$  correlates to CBZ's anticonvulsant effects, but a strong correlation of CBZ response with plasma concentration in mania has not been reported. Nevertheless, it seems unnecessary to exceed a steady-state plasma concentration of 8 to 12  $\mu\text{g/ml}$  to achieve good antimanic effects.

Table 2E.5.  
Expected Physiological Effects from Carbamazepine Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
Cardiovascular status	
Heart rate	No cardiac instability expected; less effect on producing orthostatic hypotension than either MAOIs or tricyclics. Rare reports of heart block; decreases in pulse rate should be evaluated.
EKG	
Blood pressure	
Renal function	
Serum creatinine and clearance, BUN	No changes expected
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Transient elevations may occur; some cases of hepatotoxicity have been reported. Baseline indices should be obtained; expect increases in 2-3 weeks.
Hematology status	
CBC	Regular lowering of white count can be expected. Discontinue therapy under any of the following conditions: WBC < 3000/mm <sup>3</sup> . Neutrophils < 1500/mm <sup>3</sup> Erythrocytes < 4.0 × 10 <sup>6</sup> mm <sup>3</sup> Hematocrit < 32% Platelets < 100,000/mm <sup>3</sup>
Neuroendocrine status	
DST, plasma cortisol	False positives can occur. Carbamazepine causes escape from dexamethasone suppression. Carbamazepine enhances vasopressin function and hyponatremia may occur.

<sup>a</sup>For abbreviations, see Table 2B.1.

**Alprazolam** Among the benzodiazepines, alprazolam has been most extensively tested for its antidepressant potential (24, 25) (Fig. 2E.2). Its FDA-approved indications are anxiety and anxiety associated with depression. In clinical trials of depressed patients, dosage has been generally higher than required for antianxiety effects (4 to 10 mg/day). Alprazolam has distinct antidepressant effects equivalent to those of standard tricyclic drugs in controlling acute symptoms for up to 6 weeks, but the efficacy of long-term therapy for maintaining remission of depression is unsubstantiated.

Alprazolam has been conclusively proven to have antipanic effects and is potentially useful for other anxiety disorders, including posttraumatic stress disorder and obsessive-compulsive disorder. Dosage should be started low, approximately 1.5 mg/day or less, regardless of indication. Reports of difficulty in discontinuing the drug suggest the need for gradual tapering of the dose over an extended period.

### Cyclic Antidepressants

**Amitriptyline** Sedation and a high degree of anticholinergic side effects are problematic when using amitriptyline (Table 2E.2). For a patient with a history of a previous response to the drug, it will be the preferred choice for retreatment. However, for many patients, imipramine remains a more suitable first choice among the tricyclic drugs (Chapter 2B). A positive relationship between plasma amitriptyline concentration and response has been noted in several trials (11). A therapeutic plasma concentration range is 120 to 250 ng/ml for amitriptyline, combined with the concentration of its metabolite nortriptyline. However, several large studies that have found no usable relationship between amitriptyline plasma concentration and clinical efficacy for treatment of depression. The determination of plasma amitriptyline concentrations is indicated in selected patients who are nonresponders and when noncompliance or anticholinergic toxicity is suspected. Concentrations greater than 450 ng/ml have been highly correlated with anticholinergic delirium (26).

**Bupropion** This long-awaited monocyclic antidepressant (Fig. 2E.4) has several clinical advantages, as compared to the tricyclic antidepressants, which suggest that it may be a first choice for some patients (29, 30). It lacks any appreciable anticholinergic or sedative effects, and it is probably the safest among all of the cyclic antidepressants, with the exception of alprazolam, for patients with cardiac disease. Orthostatic hypotension occurs to a much lesser degree than with the tricyclic antidepressants. Bupropion produces little or no weight gain or impairment in sexual functioning. However, it has the major drawback of occasionally provoking unexpected generalized seizures. The risk is increased when dosage is escalated sharply, and dosage should be kept under 450 mg for most patients and below 600 mg/day for all patients. Monitoring parameters for this side effect include prodromal signs of seizure activity, including complaints of nervousness, an exaggerated startle response, and psychomotor irritability. Treatment consists of intravenous diazepam or phenytoin and discontinuance of bupropion. As bupropion's active metabolites have half-

lives of greater than 24 hours (31), monitoring should be continued for several days after the drug is stopped.

Bupropion has not received extensive investigation for the presence of a therapeutic plasma concentration range. Golden et al (32) found a curvilinear relationship between antidepressant effect and plasma concentration of hydroxybupropion (HB), bupropion's principal active metabolite. HB concentrations greater than 1250 ng/ml were associated with poor clinical outcome. High metabolite concentrations causing toxic effects involving dopaminergic systems may be related to psychotic reactions seen in occasional patients (33).

Unlike two other antidepressants, imipramine and phenelzine, bupropion lacks efficacy for treatment of panic disorder with phobias. This may be related to its prodopaminergic effects.

**Clomipramine** Clomipramine is similar in structure, effect, and side effects to imipramine. The drug's potent effects on serotonin may relate to its clinical efficacy in depression. Also, there is evidence that it produces a better response in patients with obsessive-compulsive disorder (OCD) than do other cyclic antidepressants or standard anxiolytics (34). It may therefore be expected to alleviate anxiety in depressed patients. Clomipramine may well become the drug of choice in OCD and should become available in the United States in 1990. In well controlled studies, it has demonstrated marked antipanic effects. Daily doses are similar to those of the other major tertiary amine tricyclic drugs (Table 2E.1).

The response to clomipramine in OCD may be slow, requiring 4 to 6 weeks. Sometime a relapse in symptoms has been noted at 4 weeks, followed by further improvement. The overall improvement rate can be expected to be better than 50%. Patients should not be expected to become free of symptoms; however, their symptoms become less bothersome. Ironically, more symptoms may be reported as improvement occurs. Unfortunately, pharmacotherapy must be continuous for improvement to be sustained.

**Desipramine** As the major imipramine metabolite, desipramine has several clinical advantages over its precursor. It is less anticholinergic and sedating. In particular, it is favored as a pharmacological probe in animal and human studies because it possesses the most selective actions on norepinephrine of the available cyclic antidepressants. A plasma concentration range associated with therapeutic effects is between 115 and 250 ng/ml (11); however, this therapeutic range is not as well established as that of imipramine. Studies in people between 60 and 80 years of age have shown that, for optimal antidepressant effect, these patients seem to require plasma concentrations in the same range as are used with younger adults. However, an increased risk of side effects exists for the elderly.

**Fluoxetine** Fluoxetine (Fig. 2E.5) is a selective inhibitor of serotonin uptake with antidepressant effects comparable to those of the tricyclics (35). This neurochemical action suggests that fluoxetine may also be beneficial in the treatment of obsessive-compulsive disorder, but data from double-blind clinical trials to support this use have not yet appeared. Other unapproved uses of fluoxetine for which some data suggestive of efficacy exist include the treatment of obesity, decreasing food craving, and the treatment of alcohol abuse. Its use in the treatment of panic attacks seems to be accompanied by a high incidence of side effects, notably anxiety resembling overstimulation.

Fluoxetine and its active metabolite, norfluoxetine, have half-lives in the range of 7 and 14 days, respectively, a departure from the disposition kinetics of the previously marketed cyclic antidepressants. Thus, steady-state concentrations will not occur for several weeks of continuous dosing. The drug has shown only weak anticholinergic side effects. Common side effects include nausea, nervousness, and insomnia. Rare cases of excessive stimulation, when combined with monoamine oxidase inhibitors (MAOIs), have recently been reported. Such combinations are best avoided at present. Previous reports described a similar "serotonin syndrome" when L tryptophan was administered to patients along with a MAOI.

Recent reports have documented fluoxetine to provoke unexpected seizures in occasional patients. Whether this adverse reaction is dose-related is unknown. The long half-life of fluoxetine and its active metabolite suggest that dosage increases should be made no more frequently than every 1 to 2 weeks to allow full accumulation to steady state. Overall, the drug's advantages of low sedative potential and a lack of anticholinergic and cardiovascular effects suggest that it could be the first choice of antidepressants for many patients.

**Nortriptyline** This demethylated metabolite of amitriptyline has a lower degree of anticholinergic side effects and sedation, as compared with that of its precursor (Table 2E.2). The extent of this difference makes nortriptyline an acceptable antidepressant for some patients when amitriptyline is not. Nortriptyline has another advantage. It has the most established therapeutic plasma concentration range of all available cyclic antidepressants (11). Several studies have replicated a range of 50 to 150 ng/ml as optimal for treatment of endogenous depression. Steady-state plasma concentrations either below or above this range can be adjusted by means of dosage changes if clinical effects do not seem to be as robust as anticipated. However, as with all dose- or concentration-response relationships, some responders will be below and above the accepted target range which usually encompasses 20 to 80% of the responders. Overall, nortriptyline's monitoring parameters are similar to those of imipramine.

Nortriptyline may be the tricyclic antidepressant of choice for patients with significant problems with orthostatic hypotension (37). A pretreatment orthostatic systolic pressure drop of 10 mm Hg or greater may actually predict a favorable response to nortriptyline (38).

**Protriptyline** As can be seen in Table 2E.3, protriptyline has the longest half-life of the available tricyclic antidepressants. In addition, its daily dose is less. This drug has gained the clinical reputation for being "activating" in occasional patients, rather than sedating, as is typical for other members of its drug class. It is similar to the remaining tricyclics in its indications and side effects.

## Heterocyclic Antidepressants

### Brand Names

Amitriptyline	-	Elavil
Doxepin	-	Sinequan, Adapin
Imipramine	-	Tofranil
Protriptyline	-	Vivactil
Nortriptyline	-	Aventyl, Pamelor
Desipramine	-	Norpramin
Amoxapine	-	Ascendin
Maprotiline	-	Ludiomil
Trazodone	-	Desyrel
Bupropion	-	Wellbutrin
Fluoxetine	-	Prozac
Clomipramine	-	Anafranil
Sertraline	-	Zoloft
Adinazolam	-	Deracyn (under investigation)
Paroxetine	-	(under investigation)

## Diazepam Database

### FORMULATIONS

Diazepam tablets: 2 mg, 5 mg, 10 mg  
 Diazepam capsules: 15 mg sustained release  
 Diazepam oral solution: 5 mg/ml  
 Diazepam injection: 5 mg/ml  
 Brand names: Valium (Roche); various generic brands

Table 4A.1.  
 Expected Physiological Effects from Diazepam Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
<b>Cardiovascular status</b>	
Heart rate	No effect or slight increase in patients with lung disease
ECG	No expected effects
Blood pressure	Modest reduction in systolic pressure after IV administration
<b>Renal function</b>	
Serum creatinine and clearance, BUN	Normal values should not change
<b>Hepatic function</b>	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Rare elevation of AST and ALT; jaundice has been reported.
<b>Hematology status</b>	
CBC	Rare leukopenia and eosinophilia
<b>Neuroendocrine status</b>	
Cortisol	No change or decrease in plasma cortisol; potential interference with DST during chronic, high dose therapy
Thyroid indices	These may be altered, but the patient remains euthyroid.
Growth hormone	No change or increase
ACTH	No change or decrease

<sup>a</sup>Abbreviations: ECG, electrocardiogram; BUN, blood urea nitrogen; AST, aspartate aminotransferase; SGOT, serum glutamic-oxaloacetic transaminase; ALT, alanine aminotransferase; SGPT, serum glutamic-pyruvic transaminase; CBC, complete blood count; ACTH, adrenocorticotropic hormone; DST, dexamethasone suppression test.

### INDICATIONS

Diazepam is effective for the management of anxiety disorders or for the short-term relief of the symptoms of anxiety. This Food and Drug Administration (FDA)-approved labeling statement implies efficacy in specific anxiety disorders as well as anxiety associated with medical conditions. The various anxiety disorders were outlined in Chapter 1F. Table 4A.3 lists various medical conditions that may be accompanied with anxiety symptoms amenable to benzodiazepine therapy. The benzodiazepines are the drugs of choice for most anxiety states, but they are not superior to the monoamine oxidase inhibitors or tricyclic antidepressants for treatment of panic disorder and agoraphobia (11).

Diazepam is useful in states of acute alcohol withdrawal (12). It reduces the agitation and associated symptoms of impending delirium tremens. Although

Table 4A.3.  
Conditions for Which Diazepam or Benzodiazepines May Have Beneficial Effects

---

Medical conditions with accompanying anxiety

- Angina pectoris
- Alcohol withdrawal states
- Chronic obstructive pulmonary disease
- Mitral valve prolapse

- Psychomotor agitation
- Eclampsia
- Decerebrate fits
- Tetanus

Neurology

- Postherpetic neuralgias
- Spasticity
- Tetanus
- Status epilepticus

---

chlordiazepoxide has been promoted for this use, it has no inherent advantages over diazepam.

Diazepam has been commonly used as a premedication for numerous surgical conditions. As a preoperative, it is used parenterally before cardioversion and as an adjunct before endoscopic procedures.

Diazepam is used orally as a skeletal muscle relaxant. It decreases the severity of muscle contractions in stiff-man syndrome, a condition characterized by severe spasm of somatic musculature (trunk and abdominal wall) that may last for a few hours or up to a few days. Early studies with cats demonstrated that diazepam had high potency for inhibition of the linguomandibular reflex. It was better in this model of muscle relaxation than either *N*-desmethyldiazepam or oxazepam. This potency difference may account for diazepam's greater popularity as a muscle relaxant than other benzodiazepines. Diazepam is also used parenterally in the treatment of tetanus.

Diazepam administered 5 to 10 mg intravenously is useful in status epilepticus and recurrent convulsive seizures (13). It is also used to treat myoclonic and akinetic seizures and infantile spasms. It may be added to other anticonvulsant regimens in patients with generalized tonic-clonic seizures whose seizures are precipitated by tension and anxiety.

There is some evidence that diazepam may be an effective alternative to anticholinergics for the treatment of akathisia (14). Although this therapy is usually not considered until anticholinergic medications have failed, some evidence exists for successful use of diazepam in dystonic reactions that are otherwise unresponsive (15).

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Unwanted CNS depression can be expected to be worse in patients given diazepam for anxiety who have low serum albumin concentrations, less than 3.0 gm/100 ml (19). This adverse consequence of therapy may be a result of reduced plasma protein binding and increased free drug concentration. The elderly, patients with burns, or those with trauma may be at risk for greater side effects from usual doses due to decreased protein binding.

Table 4A.4.  
Drug Interactions with Diazepam

Interacting Drug	Effect
Magnesium-aluminum antacids	Delays rate and possibly extent of absorption
Rifampin	Increases clearance
Isoniazid	Decreases clearance and prolongs elimination half-life
Disulfiram, cimetidine, oral contraceptives	Inhibits clearance
Nicotine	Cigarette smoking increases clearance and decreases clinical effects.
Phenytoin	Diazepam possibly interferes with phenytoin metabolism.
Alcohol	Additive depressant effects

Diazepam is water-insoluble and is marketed for injection dissolved in propylene glycol and ethanol. It precipitates if diluted for intravenous injection and causes phlebitis at the site of injection relatively frequently. It should not be mixed with other drugs or diluted but should be injected slowly, no faster than 5 mg (1 ml)/min. Diazepam adsorbs to plastic intravenous tubing and, therefore, the delivered dose may be less than that calculated. If patients are to receive diazepam intravenously, equipment for respiratory or cardiovascular assistance should be readily available as rare episodes of apnea have occurred.

Psychological and physical dependence is a risk associated with the chronic use of all benzodiazepines. These problems are more likely to occur with diazepam when therapy is prolonged and doses are excessive. Nevertheless, dependence from normal doses can occur.

When discontinuing therapy, a tapering schedule should be used. This will minimize the possibility of withdrawal symptoms. These are usually mild in character, consisting of flu-like symptoms mimicking cholinergic rebound. However, severe symptoms consisting of tremor and convulsions can occur. Propranolol has been used to attenuate the severity of benzodiazepine withdrawal symptoms, but its use cannot be expected to reduce the incidence of withdrawal symptoms.

**FORMULATIONS**

Buspirone tablets: 5 mg, 10 mg  
Brand names: BuSpar (Mead-Johnson)

**INDICATIONS**

Buspirone has been approved for the treatment of generalized anxiety disorder. Premarketing clinical trials demonstrated that buspirone was superior to placebo and as efficacious as standard benzodiazepines (diazepam or alprazolam) in the treatment of mild-to-moderate anxiety (10-12). Subtle differences between the benzodiazepines and buspirone in clinical trials suggest a basis for discrimination in drug selection for specific patients.

Compared to the benzodiazepines, buspirone may be more effective for anger and hostility associated with anxiety. Buspirone would be preferred in some patients with a history of aggression or loss of impulse control as disinhibition sometimes occurs with benzodiazepine use.

As buspirone has only a minimal effect in producing sedation, patients with psychomotor agitation may be better treated with a benzodiazepine. Also, for patients with a high degree of somatic anxiety and muscle tension, a benzodiazepine may be beneficial because of its sedative and muscle relaxant qualities.

For some patients who have never received an antianxiety drug, buspirone may be preferred because of its lack of sedation. Patients with a history of benzodiazepine use often have specific expectations from antianxiety therapy. These patients may become disappointed with buspirone's slow onset of therapeutic activity.

Buspirone has been shown in double-blind studies to be effective for relief of anxiety in the presence of depression (13); however, other data suggest that buspirone has equivocal effects as an antidepressant. At present, depression does not constitute an indication for buspirone. In anxious patients who do not respond adequately to buspirone therapy in several weeks, underlying depression should be suspected and treated specifically if found to exist.

Buspirone's dopaminergic activity would suggest possible beneficial effects for Parkinson's disease and schizophrenia (14, 15), disorders with a recognized pathophysiological basis involving dopamine. In limited studies, buspirone did not seem to have promising activity for either of these indications. Buspirone was tried in high doses, from 600 to 2400 mg/day, in 10 schizophrenic patients without success (15).

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Most sedatives interact adversely with alcohol and other CNS depressants. Buspirone is an exception. Buspirone can cause drowsiness and fatigue, but these effects are usually minimal and caused no impairment of driving-related skills (16, 17). In addition, buspirone was found to lack euphoriant effects or addictive potential (18). Some patients may experience dizziness if single doses as high as 40 mg are taken. Buspirone may be preferred for patients who are likely to combine antianxiety therapy with depressants like alcohol.

For patients receiving benzodiazepines who are switched to buspirone, tapering of the benzodiazepine must be initiated as buspirone does not block benzodiazepine withdrawal symptoms. It is recommended that the same benzodiazepine dose be kept until buspirone has been titrated up to an acceptable daily dose, around 30 mg/day. At this time, the benzodiazepine dose can be slowly decreased. Similarly, when buspirone must be discontinued, tapering should also be instituted, although a specific withdrawal syndrome has not yet been described.

**Table 4B.3.**  
**Drug Interactions with Buspirone**

Interacting Drug	Effect
Haloperidol	Buspirone may inhibit metabolism and raise haloperidol plasma concentrations.
Trazodone	The combination has resulted in elevation of hepatic enzymes, but no definite pharmacodynamic interaction has been noted. Attempts to replicate this interaction have not been successful.
Amitriptyline, nortriptyline	No kinetic or dynamic interaction reported
Monoamine oxidase inhibitors (phenelzine or tranylcypromine)	Elevations in blood pressure

**Table 4B.4.**

Effect	Rare	Less Common	More Common
Gastrointestinal complaints			X
Nausea			X
Drowsiness		X	
Dizziness			X
Headache			X
Nervousness			X
Skin rash	X		
Sweating/clamminess		X	
Galactorrhea	X		

## Intraclass Comparisons of Anxiolytics

**Table 4C.1.**  
**Pharmacological Comparison of Benzodiazepines**

Basis of Comparison	Clinical Implication
Intrinsic potency	Partly determines differences in daily milligram dose administered to achieve equivalent antianxiety effects (see Chapter 1C)
Absorption rate	Rate-limiting step for entry of drug into the brain; affects onset of acute clinical effects. The greater the lipid solubility, the faster the rate and onset of action.
Plasma protein binding	The smaller the fraction bound in plasma, the greater the amount of drug available to diffuse into the brain.
Volume of distribution	Along with clearance, one of the two major determinants of half-life; a reflection of the extent of drug distribution beyond the systemic circulation (see Chapter 1D).
Hepatic clearance	Determines the extent of drug accumulation at steady state; along with volume of distribution, determines the half-life and therefore the time to achieve steady state and time for drug to wash out of the body after stopping therapy; relates to duration of action (see Chapter 1D)
Predominant metabolism by oxidative pathways (phase I)	Production of active metabolites; predicts prolonged half-lives in elderly, greater likelihood of some drug interactions and influence on disposition from liver disease
Predominant metabolism by conjugation pathways (phase II)	Less influence from ageing, smoking, liver disease, enzyme inhibitors on elimination rate

**Table 4C.2.**  
**Benzodiazepine Anxiolytics and Their Usual Daily Oral Doses**

Medication	Brand Names	Daily Dose Range (mg)
Alprazolam	Xanax	1-4
Clorazepate	Tranxene	15-60
Chlordiazepoxide	Librium, other generics	15-60
Diazepam	Valium, other generics	4-40
Halazepam	Paxipam	60-160
Lorazepam	Ativan	1-6
Oxazepam	Serax, other generics	10-120
Prazepam	Centrax	20-60

Table 4C.4.  
Effects of Ageing on Half-life of Some Benzodiazepines

Drug	Half-life (hours)	
	Healthy Adults	Elderly
Alprazolam	6-16	12-27
Diazepam	20-70	30-200
Desmethyldiazepam	36-96	45-200
Flurazepam (desalkylflurazepam)	35-150	70-290
Oxazepam	5-15	5-20

## INDIVIDUAL AGENTS

### Alprazolam

Among the benzodiazepines, alprazolam has the most proven effectiveness for treatment of panic disorder (24). Clonazepam ranks second, and only limited data exist for the efficacy of diazepam. The usual effective oral daily dose range of alprazolam for anxiety is 1 to 4 mg/day but, for effective treatment of panic disorder, the daily dosage may range up to 6 mg/day. Pharmacokinetic studies suggest that alprazolam should be effective when administered sublingually as the completeness of absorption has been shown to be similar to that with the oral route. This may be useful information for an occasional patient.

Alprazolam is also distinguished by having shown effectiveness for depression and anxiety associated with depression (25). Several multicenter trials found it to be equivalent in many standard measures to cyclic antidepressants. However, the dosage at which antidepressant effects occur, in the range of 4 to 8 mg/day, is generally higher than doses needed for anxiolytic effects.

Alprazolam has been the most thoroughly studied benzodiazepine for antidepressant effects. The possibility exists that other benzodiazepines may also be useful for depression. Adinazolam, another triazolobenzodiazepine, is currently in clinical trials for this indication.

The moderate half-life of alprazolam, in the range of 6 to 16 hours, means that plasma concentrations will fall substantially during a twice daily dosage schedule. This has led to the reemergence of panic symptoms in some patients. Thus, a more frequent dosage schedule may be necessary to maintain the duration of action. Monitoring of daily symptoms (Chapter 1F) will help determine this need.

Like the other benzodiazepines, alprazolam has been implicated as causing withdrawal symptoms when therapy is stopped. There is controversy as to whether alprazolam may be worse than other benzodiazepines in this characteristic (26). The drug should be tapered when discontinued to minimize these effects. Some patients could benefit from overlap with another, long-acting benzodiazepine when discontinuing alprazolam. Diazepam, in a dosage of 10 mg/day for each 1 mg of alprazolam per day, has been recommended with a tapering schedule of 10 mg weekly. Clonazepam (half-life of 45 hours) has proven successful for this situation. Any of the benzodiazepines with long half-lives should help in discontinuing alprazolam. A preferred approach is to use a slow tapering schedule, decreasing the daily dose by only 0.5 mg/week. This usually avoids withdrawal problems in most patients. However, anxiety disorders such as panic disorder are chronic in their clinical course, and reemergence of symptoms may occur during the attempt to discontinue drug therapy. Buspirone will not suppress benzodiazepine withdrawal symptoms and cannot be used for this purpose.

## Clonidine

Clonidine is an  $\alpha_2$ -agonist marketed as an antihypertensive drug. It has been useful in clinical psychopharmacology for moderating the withdrawal from opiate addiction (27). It has been proposed as a treatment for various mental disorders, including schizophrenia, Korsakoff's psychosis, tardive dyskinesia, obsessive-compulsive disorder, and Gilles de la Tourette syndrome, and for reduction of the craving for alcohol, nicotine, and cocaine (28). Most studies have found limited effectiveness for these indications. Studies of clonidine in panic anxiety have suggested only a moderate effect (29). A tolerance to its benefits has also been noted with a decrease in efficacy over time.

There are theoretical reasons for manipulating the noradrenergic system in anxiety disorders (30), and clonidine is likely to continue to be investigated as a psychopharmacological agent. Its physiological effects for monitoring are summarized in Table 4C.5.

The use of clonidine is complicated by side effects. Most prominent are those affecting the cardiovascular system. Mean arterial blood pressure will decrease during therapy. Frequent side effects include sedation, dry mouth, and constipation. Less frequent effects are changes in sleep patterns, nightmares, headaches, and disturbances in sexual function. Of concern is the rebound in blood pressure that may occur upon abrupt discontinuation of clonidine. Within 12 to 24 hours after stopping the drug, restlessness, irritability, and tremor may occur. Behavioral symptoms such as anxiety and nervousness have been noted. Rapid withdrawal should be avoided by tapering the drug when stopping therapy.

Table 4C.5.  
Expected Physiological Effects from Clonidine Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
Cardiovascular status	
Heart rate	Decrease within 30 minutes after oral dose, peak at 2 hours, lasting 24 to 36 hours
Blood pressure	Decrease in systolic and diastolic
ECG	Rebound hypertension if drug is abruptly stopped Rare A-V block; digitalis may predispose patients to this effect.
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change.
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Transient increases during therapy
Hematology status	
CBC	No changes expected
Neuroendocrine status	
Cortisol	No changes expected
Other observations	Acute and sustained decreases in plasma epinephrine and norepinephrine

<sup>a</sup>For abbreviations, see Table 4A.1. A-V, atrioventricular.

## Flurazepam Database

### FORMULATIONS

Flurazepam capsules: 15 mg, 30 mg

Brand names: Dalmane (Roche); various generic brands

Table 4D.1.

Expected Physiological Effects from Flurazepam Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
Cardiovascular status	
Heart rate	No effects are expected unless a slight slowing.
ECG	No expected effects
Blood pressure	Mild and clinically unimportant decrease
Renal function	
Serum creatinine and clearance, BUN	Normal values should not change in most adults.
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Normal values should not change in most adults.
Hematology status	
CBC	Normal values should not change in most adults. Rare case of leukopenia is reported.
Neuroendocrine status	
Cortisol	Normal values should not change in most adults.

<sup>a</sup>For abbreviations, see Table 4A.1.

### INDICATIONS

Flurazepam is approved for the short-term (up to 4 weeks) treatment of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings, and/or early morning awakening. Flurazepam can be used effectively in patients with recurring insomnia or poor sleeping habits. Because the long-acting metabolite accumulates during 2 weeks of continuous therapy, a "carryover" or hangover effect occurs frequently. As a result, flurazepam can be more effective on the second and third nights of administration than on the first night. The slow clearance of the metabolite and its persistence in the body after flurazepam dosing is discontinued explain why sedative effects continue for 1 to 2 nights after the drug is discontinued. This long duration of action minimizes any rebound of REM sleep. Flurazepam is superior to the older barbiturates as a sedative (7). The drug is not approved for the treatment of anxiety although, as a benzodiazepine, flurazepam could be expected to have antianxiety effects.

Although flurazepam is indicated for symptomatic relief of insomnia, the cause of sleep complaints should always be sought. Depression, anxiety, and other mental or medical disorders can result in poor sleep. Reviews of rational sedative-hypnotic prescribing are readily available (8, 9).

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Contraindications include known hypersensitivity to flurazepam and use in pregnancy (see below). Physical and psychological dependence are rare in patients taking flurazepam; however, prolonged therapy with doses greater than those recommended increases the risks.

Benzodiazepines are subject to abuse and dependence. Withdrawal symptoms may occur after the abrupt discontinuance of dosing; however, this problem may be less with flurazepam than other sedative-hypnotics because of the slow elimination of desalkylflurazepam.

Flurazepam may impair physical and/or mental abilities required for operating a motor vehicle or other hazardous machinery. Ambulatory patients should be cautioned accordingly about engaging in such activities while taking this drug.

Flurazepam has the potential for additive effects with alcohol and other CNS depressants. The potential for this interaction continues for several days after discontinuation of the drug, until substantial amounts of active metabolites have been eliminated.

It is recommended that the dose of flurazepam be limited to 15 mg for elderly and debilitated patients because the risk of oversedation, dizziness, confusion, or ataxia is substantially increased with larger doses in such patients (5, 14). Flurazepam should be used with caution in patients with impaired renal or hepatic function and chronic pulmonary insufficiency.

# Methylphenidate Database

## FORMULATIONS

Methylphenidate tablets: 5 mg; 10 mg; 20 mg; 20 mg in a sustained release formulation

Brand names: Ritalin (Ciba); various others

Table 5A.1.

Expected Physiological Effects from Methylphenidate Therapy for Monitoring<sup>a</sup>

Parameter	Drug Effect
Cardiovascular status	
Heart rate	Can be expected to increase 10 beats/minute or more
EKG	
Blood pressure	Slight increases in systolic and diastolic pressure have been noted.
Renal function	
Serum creatinine and clearance, BUN	Normal values are not expected to change.
Hepatic function	
AST (SGOT), ALT (SGPT), alkaline phosphatase	Normal values should not change in most patients.
Hematology status	
CBC	An occasional case of eosinophilia has been noted. A hematological screen is recommended once a year.
Neuroendocrine status	
Cortisol	No effect expected

<sup>a</sup>Abbreviations: ECG, electrocardiogram; BUN, blood urea nitrogen; AST, aspartate aminotransferase; SGOT, serum glutamic-oxaloacetic transaminase; ALT, alanine aminotransferase; SGPT, serum glutamic-pyruvic transaminase; CBC, complete blood count.

## INDICATIONS

The major indication for methylphenidate is in the treatment of ADHD. Before the advent of DSM-III-R, patients with ADHD were frequently diagnosed as having minimal brain dysfunction or hyperkinetic child syndrome. Patients with ADHD are usually children older than 7 years of age, although symptoms will have been present before this age. These children show inappropriate degrees of inattention, impulsiveness, and hyperactivity. These behaviors often lead to difficulties in school performance and maintaining constructive relationships with family members and peers.

Methylphenidate has been proven in double-blind, placebo-controlled studies to improve behavior, concentration, and learning ability in most children with ADHD (8). It has been compared to other psychostimulants and found to be superior to caffeine and amphetamine (9). Methylphenidate has the advantage of producing fewer adverse effects than amphetamine.

Other uses for methylphenidate include symptomatic treatment of narcolepsy and treatment of apathetic or withdrawn behavior due to a variety of causes, including depression. Its effectiveness for these uses is not completely established.

## CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

Methylphenidate should not be used in a patient with a history of marked anxiety, tension, and agitation because it may aggravate these symptoms. It is also contraindicated in patients who are hypersensitive to the drug, patients with glaucoma, and patients with motor tics, a family history or diagnosis of Gilles de la Tourette's syndrome, or anorexia nervosa. In developmental disorders that resemble adult schizophrenia, methylphenidate could exacerbate psychotic symptoms and should be avoided.

Methylphenidate should not be used for severe depression or for the prevention or treatment of normal fatigue states. In patients with hypertension and patients with a prior history of seizures, methylphenidate should be used with caution, if at all.

During prolonged therapy it is advised to have periodic complete blood counts and differential and platelet counts, especially in children. The drug should be administered with caution to adults with a history of drug dependence because such patients may increase the dosage on their own initiative. Chronic excessive use may result in a marked tolerance and psychic dependence.

## Disulfiram Database

---

### FORMULATIONS

Disulfiram tablets: 250 mg, 500 mg

Brand names: Antabuse (Ayerst); various generic names

### INDICATIONS

Disulfiram is indicated as an aid in the management of alcoholism. There are limited data from controlled clinical trials of its efficacy in maintaining long-term sobriety (6). Patients do best who are highly motivated and who feel the need for an external aid in an abstinence program.

The effectiveness of disulfiram depends on the patient's willingness to initiate and comply with treatment. In one study (7), patients who accepted disulfiram tended to be younger and were more likely to be acceptors of most other types of treatment recommendations for problem drinking. A large number of alcoholics refuse to take the drug. Psychological testing has suggested that patients who accept the drug have a strong belief that disulfiram will generally help them to remain sober and will help them to resist the urge to drink (7, 8). It may be beneficial to try to convince skeptical patients that the drug can be helpful. Sources of doubt about the drug's effects and value should be identified, and misconceptions about side effects should be clarified.

### CONTRAINDICATIONS—WARNINGS—PRECAUTIONS

There are several relative contraindications to the use of disulfiram. These include a history of an unusually severe reaction, a history of severe cardiovascular disease, diabetes mellitus, cirrhosis of the liver, hypothyroidism, or a psychiatric history of major affective disorder, schizophrenia, or dementia. A patient with a history of rubber contact dermatitis may be at high risk for an allergic reaction to disulfiram. Pregnancy should be considered a contraindication.

**Table 6A.4.**  
**Drug Interactions with Disulfiram**

Interacting Drug	Effect
Coffee	Decreased clearance; possible increased stimulation
Ethanol-containing beverages, foods, products	Disulfiram-ethanol reaction (Table 6A.1)
Isoniazid	Decreased clearance; exaggerated effects
Benzodiazepines	Decreased clearance; increased sedation
Warfarin	Decreased clearance; enhanced hypoprothrombinemic effects possible
Phenytoin	Decreased clearance; possible toxicity
Cyclic antidepressants	Decreased clearance; increased side effect risk
Metronidazole	Possible precipitation of acute toxic reaction
Marijuana	Synergistic central nervous stimulation?

VOCATIONAL COUNSELING AND PROGRAMMING

**CAREER COUNSELING WITH PERSONS WHO HAVE A SEVERE  
PSYCHIATRIC DISABILITY: IMPLEMENTATION FOR PRACTICE**

**Lynda J. Katz, Ph.D.  
Landmark College  
Putney, VT 05346**

**Unpublished Manuscript**

## INTRODUCTION

Vocational assessment, career counseling and job retention strategies form the structural backbone of vocational rehabilitation programming for persons with severe psychiatric disabilities. Underlying this conceptual framework are five basic premises:

Slide 1

(1) Traditionally, persons with severe psychiatric disabilities have failed to access or benefit from vocational rehabilitation services without a bridge between mental health and vocational rehabilitation resources.

(2) The process of career decision making and work readiness is dependent upon a developmental process which involves the clients' sense of his/her own personal identity, his/her self-concept as a worker, and knowledge of the world of work. Persons with severe psychiatric disabilities by virtue of their illness have experienced major set-backs in the vocational maturation process.

(3) The existence of a helping relationship which draws upon the individual's strengths and engages him/her as a collaborator is essential to the process.

(4) The vocational rehabilitation effort can start at any point in the individual's "career as a patient"

depending upon the individual's desires, needs, and level of adjustment.

(5) Any effective treatment or rehabilitation program or model must be based on an individualized, comprehensive assessment.

In order to effectuate the vocational process a range of options is required. Among these options are the provision of career counseling services which include the use of vocational interest and aptitude measurements, job seeking skills training, work adjustment counseling, and rehabilitation counseling.

Slide 2

Job seeking skills training, conducted on an individual or group basis, prepares individuals to be able to thoroughly complete applications, generate job leads, prepare resumes, organize employment searches, and present themselves well in employment interviews. Attention is specifically paid to handling interview questions regarding disrupted work histories, frequent job changes, or medical status.

Inability to maintain employment, in many cases, is related to impaired interpersonal skills or inability to cope with pressures of employment. Work adjustment counseling includes training in social and/or coping skills with an emphasis upon adapting to stressors in the work environment. Work adjustment counseling also

involves analysis of job performance problems and strategies for remediation. Supportive counseling and long term supportive services are most often necessary for individuals who are apprehensive regarding the transition to employed status after previously having had minimal or unsuccessful employment experiences.

Not all persons with severe psychiatric disabilities, however, will have the ability to pursue vocational or educational goals. Nonetheless, they often present a need to involve themselves in gradual, structured activities in order to improve functional abilities. Sometimes, rehabilitation counseling is a prelude for vocational planning. In other cases, vocational planning functions solely to improve the quality of daily life. Very frequently, this service is appropriate for those persons with chronic, recurrent illness histories or those recently discharged after a psychiatric hospitalization.

In any case, prior to the provision of job seeking skills training or work adjustment counseling, for the vast majority of individuals with debilitating psychiatric disorders the need exists for vocational and career counseling services. Most such persons have had significant difficulty in identifying and implementing realistic vocational/educational plans, and counseling

services must be geared toward formulating feasible goals which are compatible with their particular interests, abilities, and tolerance for stress. Vocational/career counseling in this context will differ from traditional career counseling models because greater attention must be paid to the individual's concerns and anxieties about the future and the prospect of increasingly independent functioning. However, in order to modify a process of career counseling to meet the unique needs of this particular group of persons with major psychiatric disabilities, it is necessary to understand the theory behind career and vocational counseling in general.

#### CAREER COUNSELING THEORY

Career counseling has been defined by Super (1984) among others as a process of helping individuals to develop an integrated and accurate understanding of themselves and the role(s) they may assume in the world of work, to test these understandings against reality, and to convert them into reality in a manner which is satisfying to the individual and to the society in which he/she functions. Inherent in this definition are the notions of self-concept (identity), the realities of the work world, and the implementation of a career plan. The process goes beyond merely deciding upon a career

Slide 3

Slide 4

choice and is dependent upon, among other things, the inherent talents and special abilities which an individual possesses, the instrumental and associative learning experiences from which a sense of self derives, and the environmental opportunities which exist for any given individual.

A number of theories have been articulated to explain the process of career choice and career development, and among the most widely known are the theories of Holland (1959), Mitchell and Krumboltz (1984), Roe (1957), Super (1953). Across all theories but to a varying degree, the issues of critical periods and agents, interests, needs, aptitudes, and the role of the family are dealt with as either determinants of or contributory factors to the career development process. Problems which emerge in this process have been linked to four main factors: (1) the likelihood of a retarded rate of development in general which causes an individual to fail to have the skills necessary to cope with the educational development tasks relevant to his/her age and position level; (2) inadequate emotional adjustment; (3) inaccurate self-evaluation; and (4) frozen behavior between two attractive behavior sequences (Osipow, 1973).

Slide 5

Krumboltz (1983) has further defined a series of specific problems which may arise in the process of career choice and vocational development because of dysfunctional or inaccurate world views and self-observation generalizations. These include the fact that persons may fail to recognize that a remediable problem exists and have adopted the attitude, instead, of "that's the way things are". Second, persons may fail to exert the effort needed to make a decision or solve a problem, preferring the path of least resistance or avoidance altogether. Third, individuals may eliminate a potentially satisfying alternative for inappropriate reasons based on misinformation, overgeneralizations, or false assumptions. Fourth, individuals may choose poor alternatives for inappropriate reasons (parental pressure, issues of prestige, fear of failure). And fifth, persons may suffer anguish and anxiety over their perceived inability to achieve their goals (if I can't be the best, why bother). Finally, Krumboltz identified several processes which may underlie the development of these problematic self-observations and world-view generalizations, including the drawing of faulty generalizations, making comparisons with a single standard, exaggerating the estimate of the emotional

Slide 6

impact of the outcome, drawing false causal relationships, being ignorant of relevant facts, and giving undue weight to low probability events.

Slide 7

These potential problem areas and distorted self-observations and world view generalizations are extremely potent issues when we address the career development and eventual vocational adjustment of individuals who are disabled by virtue of severe and chronic mental disorders. The reasons for this are several and include such factors as learned helplessness, low self esteem resulting from repeated failures, the unpredictable nature of the illness and the resultant sense of lack of control, environmentally-based disincentives, the nature of the individual's anxiety, and his/her tolerance for stress. Anthony, Howell, and Danley (1984) addressed these concerns when they wrote regarding the vocational counseling process with persons who have psychiatric disabilities:

More time is needed to go through the process because of the client's vocational immaturity. More energy is needed to form a collaborative relationship with clients who are used to having things done to and for them rather than with them. More strategies are needed to allow clients

Slide 8

opportunity for reality testing and exploration. More strategies are needed for dealing with stigma against the psychiatrically disabled client. More effort must be devoted to the deliberate refocusing of the helping process on the client's needed skills and environmental supports rather than focusing on client pathology (p. 233).

It is the unique nature of the career counseling process with individuals who are severely psychiatrically disabled which will now be addressed.

#### VOCATIONAL IMMATURITY

The work of Super (1964, 1969, 1972, 1981) as well as Ginzberg, Ginsberg, Axelrad, and Herma (1951) speaks to the issue of vocational choice from the perspective of developmental periods. These periods can span some fifteen years, beginning typically when the child is between the ages of ten and twelve (Fantasy period) to a Tentative or Exploratory period between the ages of 12 and 17 or 18, and to the Realistic period or Establishment phase between the ages of 18 and 24. During these periods specific developmental tasks with respect to a vocational self-concept need to be accomplished. For example, during the Tentative period (Super's Exploratory phase) the adolescent moves away from the arbitrary selection of occupational preferences

Slide 9

and comes to recognize what particular skills he/she may possess, what he/she likes and dislikes, and what values, both intrinsic and extrinsic, may be held. During the Establishment phase, or Realistic period, which Super equates with young adulthood, the individual is engaged in a series of vocational developmental tasks which include formulating ideas about types of work which are deemed to be appropriate, specifying a vocational preference, and implementing a vocational plan. Between the ages of 25 and 35 the individual is settling down within a field of work and using individual talents to demonstrate the appropriateness of career decisions previously made. Finally, between the late 30's and mid 40's the individual seeks to establish him or herself in a given career in terms of well defined skills and seniority. Osipow (1973) comments "(t)he degree to which the individual accomplishes these vocational tasks is a function of the adequacy with which he/she has performed the behaviors appropriate to each phase of his/her development" (p.140). The rate and level of an individual's development with respect to career issues is known as vocational maturity.

Persons who have severe and persistent mental illness are generally beset with the disease process in late adolescence and early adulthood. Those years spent

by their non-disabled peers in the Tentative and Realistic periods are spent by these individuals in and out of psychiatric hospitals with concomitant disruptions in their educational, social and vocational endeavors. So that when we speak of vocational readiness in the context of career counseling with persons with psychiatric disabilities, we must ascertain the level of development which any given individual may have attained. The person who aspires to become an opera star, a concert pianist, or a physician, may still be in the Fantasy period. On the other hand, he/she may have experienced an interruption in the process of beginning to pursue a career in one of these areas. To make assumptions initially regarding the unrealistic quality of a particular individual's career aspirations without understanding his or her level of vocational maturity is an error to be avoided. Understanding the individual's vocational self-concept and judging the level of vocational maturity can only be accomplished through an ongoing assessment process which then enables the practitioner to facilitate appropriate opportunities for growth, exploration, risk-taking, and reality testing.

## THE COLLABORATIVE RELATIONSHIP

It is vital to the process of career counseling with persons who have severe and disabling mental disorders to establish an ongoing collaborative relationship with them. This diminishes the likelihood that the individual will slide back automatically into the "sick patient role," while at the same time reinforces the individual's capabilities through healthy expectations. It is important for the client to understand that the ultimate responsibility for career choice cannot rest with the practitioner. This does not mean that the professional helper takes an inactive role and merely reflects the client's feelings, but rather that the counseling relationship should be one in which both individuals collaborate to resolve the problem of career choice.

A holistic view of the person with a severe psychiatric disability is a sine qua non of this approach. This holistic view is predicated on the following principles.

- The practitioner and the primary consumer are educated about the nature of the particular mental illness which is causing the disability.

Slide 1

Slide 1

- The practitioner and the primary consumer are educated with respect to the psychopharmacologic management of the particular illness involved.

- Time is needed in order to achieve a level of vocational maturity that persons without serious mental illness have had the opportunity to develop over a period of 15 years on the average.

- Individuals with severe and persistent mental illness must come to recognize their strengths and believe in their capabilities so that fears of failure and success can be overcome.

- Both the practitioner and the primary consumer must be knowledgeable about and able to "use" the system.

- The process of psychiatric rehabilitation and successful vocational outcome is highly dependent upon collaboration between consumer and service provider and among service providers themselves.

Integral to the process of establishing this collaborative relationship between the practitioner and the primary consumer are issues of content and process. The counselor/practitioner working with an individual with a psychiatric disability cannot rely solely on a superficial exploration of his/her problems regarding the choosing of a career or vocational objective. At

Slide 1

the same time, the professional helper must refrain from straying so far from career issues that the efforts of the individual's primary therapist are duplicated. For example, if a client has a very poor self-image and disregards his or her assets, these problems can appropriately be addressed under the framework of career counseling. The counselor would not want to focus on these issues exclusively, rather he or she would want to clarify how these problems may have interfered with the client's career aspirations or plans in the past and how the situation might be altered in terms of future planning. Often, the counselor will work on more than one agenda with a client simultaneously. While there may be didactic teaching concerning the career choice process or how a systematic career decision is made, at the same time efforts are directed at addressing related and significant personal and interpersonal issues. For it has now been well established that for persons with psychiatric disabilities, problems on the job and job retention most often relate to personal and dysfunctional interpersonal behavior rather than lack of skills or competency.

#### INTERVIEWING

A significant part of the work of the practitioner who is engaged in career counseling will take the form

of interviewing, particularly at the outset of the process. Interviewing clients with psychiatric disabilities on issues related to vocational rehabilitation can be difficult for a number of reasons. Work identity and self-esteem are often so interwoven that vocational issues become personally threatening or sensitive topics. In addition, the client's symptomatology can make communication on these sensitive issues even more difficult. There are some aspects of the interviewing process which seem to pose particular problems for both experienced and less experienced counselors. The focus of the following discussion will be on the initial series of client interviews because of the role they play in the future course of counseling. Many of these guidelines, however, are applicable to the management of subsequent counseling sessions as well.

The initial interviews are of particular importance for a number of reasons. Quite often they comprise a setting in which clients will be most candid and less prone to conceal information which is painful, but important to discuss. These early interviews are also of special significance because they represent the point in time in which roles are assumed within the therapeutic relationship and assumptions are made which affect the future course of counseling.

Slide 1

Accuracy of perception is critical during these initial meetings because both counselor and client tend to make a series of important judgments during this period. The counselor/practitioner often views the manner in which the client presents him or herself as a sample of that individual's behavior and attitudes. Judgments are made which often include inferences about the client's suitability for rehabilitation and services which might be appropriate. The client makes judgments which often include deciding whether or not further involvement with the counselor and rehabilitation will be beneficial. Thus, it is very important that both the counselor and the client perceive each other as accurately as possible during these initial encounters.

Behavior, in general, tends to be situation specific. The manner in which individuals present themselves during these early meetings, therefore, will be influenced by their understanding of the context in which they find themselves. The following guidelines may serve to maximize the likelihood that individuals with psychiatric disabilities will present themselves in a relatively straightforward manner during these initial sessions. These include (1) clarifying the basic purpose of the interview (2) eliciting the individual's feelings about his/her participation in the interviewing

Slide 1

process (3) discussing and alleviating concerns that the practitioner has a role (unless there is one) in determining eligibility for financial assistance and other types of benefit programs, and (4) encouraging questions throughout the interview. If the client understands the purpose of the interview and if concern about "hidden agendas" is alleviated, he or she will be less likely to skew the manner in which information is presented, and the practitioner will get a much more accurate picture of the situation. Furthermore, as anxiety about the interview is diminished, the client may present him or herself in a more organized fashion.

Errors in Perception. It is also important to accept the fact that the initial impression formulated by the professional about the individual seeking services may be distorted. For example, upon initially meeting a client whose dress and grooming is very poor, it is easy for the counselor/practitioner to begin to build a model of what he or she thinks this individual might be like. This quite often includes the automatic and global assumption that he or she has poor rehabilitation potential. What could be more accurately assumed is that deficits in dress and grooming need to be addressed in order to maximize rehabilitation potential. Conversely, such prototypic thinking can

Slide 1

lead to overestimating the abilities of well-dressed, attractive clients.

When errors are made in perception, they often involve a lack of attention to the context of events. Client and counselor expectations are part of this context. The manner in which a client presents him or herself to the counselor may be related to negative expectations. For example, if the individual with a severe mental disorder fears that the practitioner will pressure him or her into employment, then he or she may be careful to maximize his or her deficits.

Similarly, judgments about clients are affected also by the practitioner's own expectations, as well as his/her previous experience in psychiatric rehabilitation. It is fair to say that, despite the rewards of working in this field, practitioners repeatedly encounter many disheartening situations. The experienced practitioner has seen that in psychiatric rehabilitation the treatment outcome is often less than ideal. Most have become familiar with the revolving door syndrome of repeated psychiatric episodes and have been exposed to highly frustrating experiences in working with clients who have chronic and severe psychiatric disabilities. The counselor works very hard with a client, sees improvement, only to find out that

the individual has decided to terminate his or her medication which results in relapse and the onset of acute psychiatric symptomatology. Moreover, the seasoned rehabilitation practitioner has experienced the very somber reality that a client can make substantial progress and still be unable either to find or to tolerate employment. As practitioners who enter the field with some idealism, we naturally suffer disappointments throughout the years. These negative experiences can affect how we perceive clients, how we handle sessions, and, ultimately, how we judge our clients.

Communication Barriers: Symptoms and Language. In addition to the counselor's and the client's natural tendencies to misperceive matters to some extent, effective communication during the interviewing process is often hindered by client symptomatology and problems of verbal expression. A discussion of some problems related to verbal expression which may occur when interviewing persons with schizophrenia and other psychiatric disorders may prove helpful at this point.

Slide 16

Often times, symptoms seen in clients having schizophrenia involve disturbances in the expression and regulation of emotion. Customary emotional responses that a counselor has learned to expect in working with

less disabled clients are often absent. In most social exchanges, facial expression and fluctuating voice tone can be used as signposts to help understand what the other person is feeling. When interviewing a client with a schizophrenic disorder, these markers may be absent, greatly diminished, or outright confusing. Therefore, emotional rapport may be difficult to establish.

In addition to either the lack of affect or the disconcertingly incongruent affect, the person having schizophrenia, upon interview, may present with an apparent lack of interest in discussing rehabilitation issues. If the individual does engage in conversation, his or her thoughts and verbalizations may be poorly organized and, at times, irrelevant. This disorganization is sometimes most prominent in the earlier segments of an interview when anxiety is highest. It also becomes more problematic if the client becomes fatigued towards the end of a lengthy session.

There may be problems with the symbolic aspect of language as well. This is seen with clients who have a tendency to employ obtuse verbalizations or overly concrete responses. Misinterpretations and difficulty in understanding caused by vagueness of presentation can be experienced by both the counselor and the client.

Difficulties in establishing effective communication result in some very natural feelings which do affect counseling. The practitioner may feel diminished empathy as a consequence of the client's lack of affect and reluctance to express his or her concerns. If the client presents as detached or unmotivated, the counselor may feel subtly rejected or unappreciated, further inhibiting empathetic responses. Continued introduction by the client of material which is unrelated to the situation can result in a range of counselor reactions, from frustration to boredom. Feelings of discouragement with respect to the feasibility of rehabilitation with the client may develop. The client's confused speech may lead the counselor to assume the client does not know what he or she wants. This may pose yet another threat to the pursuit of accurate understanding and the development of rapport. Furthermore, strange or bizarre verbalizations can be disturbing to the clinician, and this may result in distancing which is often readily sensed by the client.

Interviewing Techniques. Guidelines which may be helpful when interviewing clients having schizophrenia include (1) helping the client organize his or her thoughts; (2) when the client is tangential, helping

Slide 1'

him or her return to the central point; (3) providing sufficient time for the client to respond to questions without prolonging the silence; (4) adjusting the length of sessions; (5) remembering that confused verbalizations do not always mean that the client does not have a meaningful opinion; and (6) not getting caught up in debating delusional material.

Slide 18

Helping the client organize his or her thoughts may take the form of paraphrasing the client's statements and then asking if the counselor has understood the point correctly. This is done while conveying that the counselor does not want to put words into the client's mouth. Helping the client return to the central point can be accomplished by making statements such as, "A moment ago we were talking about . . . , and you were telling me that . . . Let's go back to . . ."

While it important to provide adequate response time, the client may have a delayed response pattern because of his/her cognitive or articulatory impairment. Therefore, it is best not to prolong silence to the extent that the client becomes embarrassed over difficulties in responding. Moreover, there may be a need to adjust the length of the session. Some clients need some time to "get warmed up"; others fatigue as

time progresses and then have more difficulty organizing their thoughts.

Confused verbalizations do not in and of themselves indicate a lack of meaningful opinions. Practitioner skill in handling this problem probably differentiates those who work well with persons having schizophrenia from those who do not. And finally, delusional material can not be debated. Debates over delusional material can result in delusional beliefs that become even more entrenched. As trust develops over time, the counselor might suggest alternative perspectives on how the client could interpret events. A frontal attack on delusions, however, is not productive. One can "agree to disagree" on some issues where appropriate. This enables attention to be turned toward issues which are germane to the vocational goal at hand. It is also important to bear in mind, however, that some delusional clients can work or attend school. While it is certainly desirable for these symptoms to abate in order for the process of career planning and career implementation to progress, it is not always necessary.

Interviewing individuals with manic symptoms can pose a different set of problems. Instead of a paucity of speech, which one often encounters with the person who has a thought disorder, there is often verbosity.

Slide 1

The individual speaks very rapidly in a pressured manner with a great deal of detail, wandering from topic to topic. Counselor reactions may include the feeling of "losing control over a session". This may result in anger, especially if the practitioner feels pressured to complete a specific agenda. When interviewing clients with manic symptoms, the professional helper should provide increased structure. Do not hesitate to interrupt, but do it in a spirit of interest in what the client is saying. Guidelines are actually similar to those used to compensate for the disorganization which can occur when interviewing clients who have a schizophrenic disorder. If necessary, the practitioner may want to slow down his or her own speech. This may result in a reciprocal slowing of the client's speech which can help the counselor not to feel bombarded. Asking the client to speak more slowly is quite straightforward, but it is sometimes neglected.

Many illnesses, like schizophrenia, are thought to derive from a biochemical imbalance. And, often the resultant symptoms cannot be entirely controlled. It is important to bear in mind that these symptoms can function to influence and/or control what occurs in the counseling relationship. This takes place either through the counselor's reactions to the symptoms or the

client's use of these symptoms to avoid discussion of issues which are relevant but potentially painful. The client may use symptoms to distance the practitioner if he or she feels the threat of too much intimacy. This does not necessarily mean that these symptoms have a psychodynamic base, but rather that clients learn the impact their symptoms can have on others. Quite reasonably, then, they will sometimes use symptoms to control relationships when they feel threatened.

Finally, it is within these early meetings that the interpersonal relationship between client and practitioner begins to be defined. Quite often the individual seeking services wants to place the helper into a role(s) which replicates that of family members or significant others. Typically the assumption of these roles by the counselor is not in the client's best interest. Awareness of this issue can often emerge early in the counselor-counselee relationship, and the counselor must be cautious about sliding into such roles inadvertently.

In a similar vein, some practitioners assume that a client will "fall apart" if provided with direct feedback regarding his or her interactions with others. Typically, these fears are unfounded; nonetheless, clinicians may censor their reactions. The result of

this is usually unsuccessful as feelings can often color both verbal and nonverbal behavior, whether they are expressed or not. Most importantly, the client is deprived of accurate feedback which is essential if he or she is to learn how to develop reciprocal, positive relationships with others. The very aspects of a client's behavior which the practitioner finds obnoxious, but which he or she refrains from addressing, are those behaviors that most likely will harm the client's relationships with others. In particular, relationships on the job, in school, or in work settings with co-workers and supervisors, may suffer. These relationship issues will become a focus of the career counseling process as the vocational rehabilitation process unfolds and the ultimate goal is achieved.

#### STRATEGIES IN THE CAREER COUNSELING PROCESS

One way to better understand the process of career counseling is to view it as a series of stages Crites (1981). While stages have been delineated for ease of understanding, it is recognized that career counseling is a more fluid and dynamic process. Moreover, although the first stage describes a focus for the helping person, this does not mean that he/she dominates the process. Rather, the practitioner structures the sessions in order to obtain an

understanding of the client and his or her perceptions, attitudes, and concerns. It is important to recognize the connection between the practitioner's role and that of the client in order to understand the therapeutic aspects of career counseling. The following discussion adapts the work of Crites to the process of working with individuals with major psychiatric disorders.

#### CLARIFICATION AND INFORMAL ASSESSMENT

The first stage in the career counseling process involves a series of steps or strategies aimed at (1) clarifying the individual's concerns and perceptives on his/her problem (2) determining the individual's expectations of the career counseling and vocational readiness process (3) understanding the individual's perceptions with respect to his/her previous educational and/or occupational experiences and (4) helping the individual to reformulate his or her concerns through an awareness of those factors which have contributed to the present dilemma, which problems can be resolved, and how to begin to utilize a decision-making (problem-solving) approach in those areas where remediation is possible.

Clarification of the problem. An understanding of the individuals perception of problems related to the career/counseling process is essential. How does

Slide 2

he/she describe current needs, conflicts, and difficulties? Can the individual articulate problems regarding the choice of what he/she might like to do in the occupational arena? Does the individual verbalize the ideas and values of others--the therapist, a parent, a spouse? Often the well meaning counselor assumes to know what the client may need and proceeds to act accordingly. In this case career counseling will be ineffective or the client will terminate the process before the counselor's goals are achieved.

DIANE I

Eliciting the client's perspective on the problem of career choice is important for several reasons. First, clients often have good insight and may be aware of what processes will facilitate problem resolution, e.g. what has worked for them in the past in other circumstances. Second, it is important to understand the client's frame of reference and his or her manner of viewing the specific situation and life in general, even if the counselor objectively feels the client lacks insight. For example, a client may project his or her career failures onto others, an unsupportive parent, a teacher who actively disliked him or her, a counselor who gave bad advice, etc. Even though there may be background information available which suggests that these perceptions are not accurate, the counselor will

need to understand how and why the client views the situation as he or she does, or the counselor will never connect with the client. Asking the client about his or her assessment of the problem serves an additional positive function within the counseling relationship. It indicates an interest in understanding the client, demonstrates that his or her opinions on the issues are valuable, and helps in establishing the collaborative relationship early on.

PATRICK

Expectation of treatment or rehabilitation. Here the concern is with the outcome(s) the client desires. What are the specific educational or vocational goals that the client wishes to achieve in order to resolve his or her current dilemmas? Often the client comes to the counseling session and states, "They told me you'd get me a job." We are thus reminded of Anthony et al. (1984) earlier comments regarding "clients who are used to having things done to and for them rather than with them". Expectations here are based on what the client has come to believe is a way of life, following directions, passively accepting advice and counsel, having had little or no opportunity to develop personal career aspirations. Personal ownership of goals is a foreign and unfamiliar concept.

At other times the individual with a major psychiatric disorder has only a vague notion of what he or she would like to achieve. In the words of one client, "to go to school and get a good job." Expectations are of the norm and what is socially appropriate, but with no real specificity. For these individuals coming to recognize that the career counseling process can assist with this noble but overwhelming goal is a legitimate end in and of itself.

Perceptions of previous work or educational experiences. A review of the individual's educational and vocational history as well as his or her current activities constitutes a semi-structured but informal assessment strategy. Such a process helps the client and the counselor to gain a common perspective on the problem through an exploration of the client's educational and vocational experiences, undertaken in a chronological sequence. This process helps the practitioner/counselor begin to get an understanding of the client's assets, limitations, interests, and experience.

If the client has a work history, it is important to review each job to find out what aspects he or she liked or handled well, as well as what aspects were not as positive. The reasons why the client left each

educational or employment endeavor should be explored. The nature and quality of relationships with peers, coworkers, and supervisory staff is also important to understand.

This longitudinal view of the individual's educational and/or work experiences often provides the practitioner with a more objective basis for understanding a particular individual's vocational problem and for identifying his or her strengths. It also may help the client become more aware of patterns in his or her vocational history. For example, the client may feel he or she has failed in most endeavors, but may alter that perspective when reviewing the actual history in greater depth. Or, a client may learn that he or she has never really taken responsibility for career choices, but instead has relied only on the guidance of friends and family and has found him or herself in occupations for which he or she was not well suited.

Reformulating concerns and identifying resolvable issues. Only after a climate of trust and rapport have been established can the practitioner begin to help the individual client recognize and deal with issues and concerns that have come to the surface during the early part of the Clarification and Informal Assessment stage.

Harry Stack Sullivan (Perry & Gawel, 1970) underscored the importance of a client getting something back for what is given in the interview. This should occur even in the initial sessions when information is gathered. Initial impressions of the factors involved in the client's specific career problems should be shared, yet qualified as initial impressions. Along with this tentative formulation, the counselor will want to speak of strategies that can be used in future sessions. This procedure provides a much needed sense of "hope" while at the same time helping the client to begin to learn about systematic career decision-making. Frequently, as counseling progresses, issues related to self-concept or personal skills become more prominent, and it becomes apparent that these have an important bearing on the career choice problem. The career problem may then be reformulated to reflect these dimensions.

In assisting clients to alter dysfunctional or inaccurate beliefs, self observations and world view generalizations (Mitchell & Krumboltz, 1984), practitioners need to be sensitive to why individuals may be resistant to altering, changing or even revealing them, even if alternative beliefs may be more adaptive. Mitchell & Krumboltz go on to explain that society

reinforces individuals who give socially acceptable reasons for their behavior and punishes those who engage in the same behavior for unacceptable reasons. Also, many individuals have extreme fears about the consequence of examining important beliefs. With these cautions in mind, the counselor, but only after trust and rapport exist, (1) can examine the assumptions and presuppositions underlying expressed beliefs ("I'm too stupid to go to school . . . I've only ever been fired from my previous jobs . . . My parents will never understand . . . I'll be happier if I sit in my apartment alone all day . . .") (2) can look for inconsistencies between words and actions, and (3) then can identify specific barriers to the vocational or educational goal with which the individual can relate.

Finally, Mitchell and Krumboltz (1984) recommend the use of specific cognitive restructuring techniques to facilitate the reformulation of concerns and the identification of resolvable issues utilizing problem solving strategies. Specifically:

- (1) direct instruction about the role of cognitions in subjective stress and behavioral deficits;
- (2) monitoring one's personal thought patterns;
- (3) modeling of a rationalistic evaluation process and modification of personal thought patterns;

Slide 2

- (4) feedback on reported changes in thinking patterns and behaviors; and,
- (5) performance assignments and rehearsal tasks to improve discrimination and evaluation of performance-relevant cognitions.

#### FORMAL VOCATIONAL ASSESSMENT

Stage two in the process of career counseling with individuals who have major psychiatric disabilities involves the use of vocational interest, values, and aptitude measurement tools. Vocational assessment enables both the primary consultant and the practitioner to better understand the consumer's interests, abilities, and work environment preferences as related to various career options (Katz, Beers, Geckle, & Goldstein, 1989). Very often a client holds either a very self-depreciating or aggrandized view of his/her abilities. Vocational assessment provides a more objective method of identifying strengths and deficit areas.

To a great extent, an individual's ability to integrate into the world of work is contingent upon the ability to formulate a realistic occupational goal. Vocational assessment procedures are instrumental in the formulation of realistic goals and can provide a profile

of characteristics relevant to career decision-making. A core battery of tests is often useful in providing the kinds of information needed to help a particular individual make realistic choices about career or vocational endeavors. Such a battery frequently includes the use of interest inventories, ability measures, and inventories of the clients' values that surround the work role or work environment. Information derived from testing enables a systematic exploration of careers that might be particularly advantageous and provides information concerning fields to avoid and/or types of academic remediation that might be beneficial. Assessment provides a relatively objective base of information. This is important because individuals with long standing psychiatric illness may not have very accurate assumptions about their abilities. That is, they may overestimate or underestimate them.

The vocational assessment serves an important and natural role in career counseling, but judicious timing is necessary if the assessment is to be beneficial. If undertaken prematurely, results can be misleading. There may be an increase in the client's defensiveness and the results might undermine his or her self-esteem. There is a need to determine whether the client's symptomatology will significantly affect the information

that is derived from the assessment. This is important because a vocational assessment serves as a sample of opinions and abilities. The sample must be representative because generalizations are derived from it. When individuals are in an acute phase of their psychiatric illness, testing may need to be delayed. Other individuals experience the presence of symptomatology on a fairly consistent basis. Under these circumstances, formal assessment procedures may be timely, but the impact of the symptoms must be recognized and the results interpreted accordingly. The results may provide a picture of how the individual is performing at a particular point in time but may underestimate future levels of performance. Consideration also must be paid to the client's feelings regarding formal testing procedures. The optimal time for a formal vocational assessment is when the individual presents a desire to resolve questions about future plans by learning more about his or her interests and abilities.

It is important to bear in mind that although the results of the vocational assessment can provide an important base of knowledge, the results can also be misleading. Just as clients often believe the answers to career planning lie solely in test results,

practitioners may hold similar misconceptions. Test results are best understood in the context of a more general appraisal of an individual's overall functioning. Therefore, it is necessary to examine results carefully, always keeping in view the client's life circumstances and general adjustments. For example, it is misleading to identify high mental ability and not to determine whether it is available for the client's use.

Finally, the results of a formal vocational assessment must take into account other important factors related to academic or career success. An individual's social skill repertoire, tolerance for specific stressors, and capacity to sustain goal directed behavior are highly significant. As formal vocational testing may tell us little about these factors, testing results must be interpreted cautiously unless during the earlier stages of career counseling these issues had been clarified. Thus, formal vocational testing and measurement has an important role in career counseling, but it is not the crux of it.

Slide :

DIANE

#### CAREER EXPLORATION AND SYSTEMATIC DECISION MAKING

The major task to be undertaken during this third stage is to gather information about the world of work. The objectives of the systematic career decision process

Slide

are not only to resolve the client's career indecision, but also to teach and model how these kinds of decisions are made. This is important because, hopefully, the client will incorporate these skills into his or her repertoire for future use. Systematic career decision-making focuses upon identifying a career which is congruent with the client's interests, abilities, values, and tolerance for stress. As part of this process, career exploration strategies are essential.

Career exploration can involve the use of resource material to learn about specific careers. The Occupational Outlook Handbook, the Dictionary of Occupational Titles, and other references which may include computerized and videotaped sources of information can prove helpful (Zunker, 1986). In addition, volunteer work might be done in a setting related to client interests; site visits, informational interviews, and shadowing are often helpful techniques as well. The desire to work in a hospital laboratory service, for example, without a direct knowledge of what kinds of job duties and responsibilities are expected of laboratory staff can be based on faulty assumptions or preconceived notions. One can read about using microscopes and other highly specialized instruments, but the actual process of experiencing the laboratory

setting itself--testing body fluids, the importance of universal precautions, adherence to rigid testing procedures--can be the most valuable ingredient in the decision making process. Similarly, the process of trying to decide upon a career option that involves years of education or specialized technical training can be facilitated by encouraging the individual to pursue a single course of study in a high interest area.

This active career exploration promotes independent functioning as well as providing the client with detailed information regarding the nature and demands of specific occupations of interest. In their article describing "The Choose-Get-Keep Model" of supported employment for persons with psychiatric disabilities, Danley and Anthony (1987) make several comments which are highly pertinent to the career exploration and decision making process:

The assumption of psychiatric vocational rehabilitation is that with increasing time and different vocational experiences, the clients' interests and values often change. Unfortunately, clients' occupational choices following the onset of the disability are oftentimes based on former values and skills rather than on a comprehensive picture of their current values and skills. It may

in fact be desirable to create new occupational experiences, short of a supported vocational placement, to clarify interests and values. The truth is that they can when they are stimulated by new knowledge gained first hand from relevant vocational experiences (pp. 7; 28).

#### IMPLEMENTING THE CAREER PLAN

The counselor's task during the fourth and final stage of the career counseling process is to assist the client in developing a specific plan whose focus is the implementation of his or her career choice. This includes indentifying subgoals of manageable proportions. Subgoals are important because many clients with long term mental illness have difficulty getting started as they are so overwhelmed with the magnitude of the task in terms of time, energy, and resource commitments. Their dismay is often manifest as problems in organizing their efforts, in remaining goal focused, or in handling anxiety. Some may want to tackle much at once to make up for "lost time".

The technique of reviewing provides an opportunity to determine whether obstacles have occurred or may occur and to plan effective interventions and means to assist the client in the transition to increased and

Slide 2:

sustained activity and social contact. Reviewing can be used also as a time for "trouble shooting". Reviewing is important throughout the process of career decision making as well as during the process of implementing a career plan. It enables the client to experience feedback, both positive and negative, and to learn to self-monitor his or her own reactions to this feedback. Self-monitoring can then be exercised "in vivo" because there has been a previous opportunity to learn how to utilize this inner resource. It is important to recognize, however, that the success of self-monitoring depends not only on the client's ability, but also upon the counselor's willingness to provide support and consensual validation when appropriate.

Motivation. When assisting a client with the implementation of his or her career plan or vocational objectives, one of the most common traps practitioners fall into involves labeling a client as unmotivated and then terminating him or her until the individual "shows more motivation." This is not to say that discontinuing the process of career planning and implementation is never indicated, but rather, that problems which involve motivational issues are part and parcel of the vocational rehabilitation process and need to be understood

Slide 2

accordingly. That is, motivational issues are to be expected and are most probably the norm. It is unfortunate that "resistance" and motivational problems are not acceptable in the rehabilitation setting; in more classic psychotherapy, resistance to the treatment process is acknowledged as an expected part of working toward change. Such acceptance, however, is often not seen in rehabilitation settings. Clients are rather automatically labeled as unmotivated when they fail to implement established rehabilitation plans. By labeling a client as unmotivated we act as if motivation (or lack of it) were a personality characteristic, and then this label is used to justify the withdrawal of services. We act as if we knew what the term "unmotivated" means.

Lack of motivation needs to be understood within the context of the client's frame of reference. With some exceptions, motivation is situational. If one examines the thoughts of the classic "unmotivated" client, one will find negativistic thinking, anxiety, and/or the desire to avoid further losses. This might be thought of as a fear of getting better. The bottom line is that few people are motivated to enter situations which they feel they will be poorly equipped to handle. Most people are afraid of change even when they want it. So, rather than label a client as

unmotivated, counselors must identify the factors that contribute to the individual's avoidance of rehabilitation activities and work with him or her to resolve these concerns.

BILL

Unrealistic Career Goals. In addition to motivation, the other commonly seen problem in the process of implementing a career plan is that of unrealistic career goals. Unrealistic career aspirations may be related to symptoms; for example, a patient having a bipolar disorder may be grandiose. Second, unrealistic career aspirations might be related to the given environment in which the client has had a long-standing "career", i.e., wanting to be a psychiatrist or a social worker. The client expresses a desire to model these persons because he or she has spent the majority of his or her adult years involved with them on a variety of levels.

Slide 2'

Third, unrealistic career aspirations may be related to sustaining fantasies. When a client is very dissatisfied with him or herself, perhaps due to an awareness of his or her limitations, fantasy life is likely to increase. There may be an escape into daydreams about being an accomplished, highly regarded person. While these fantasies bring comfort, they also prevent the client from being able to implement a viable

career plan. A realistic career plan could result in positive benefits such as improved self-esteem, financial independence, or less need to withdraw and fantasize. Although it is important not to encourage a client to pursue an overly demanding career endeavor, it is equally important not to destroy precipitously a client's sustaining fantasy because the fantasy serves a protective function. The counselor needs to refrain from striving for realism at "any cost" and simultaneously, to avoid colluding with the patient's hiding from reality.

A gradual approach toward facilitating realism of career choice is best. Often, entry level positions or limited training programs related to the highly valued career can be recommended without removing the possibility of further career advancement in the future. It is essential never to discourage abruptly a highly valued career plan. It is far easier for a client to relinquish a valued but unrealistic goal if viable alternatives are presented.

Finally, it is frequently the case that discussion of the values and influences which have led an individual to have very strong feelings about a particular career can help free the client from the consuming pursuit of an unrealistic goal. Sometimes

such exploration reveals that a client is aspiring to an untenable career plan because of factors in his or her relationship with family members, i.e., excessive competition with a sibling or expectations of a parent who cannot accept the client's disability. These problems often lend themselves to group treatment providing the group is structured to promote candidness.

#### CAREER COUNSELING WITH WOMEN AND OTHER MINORITY GROUPS

As a final concern we would be remiss in our discussion of vocational and career counseling issues with persons who have major psychiatric disorders if we did not give special recognition to the career development problems which are unique to women and ethnic minorities among this larger population. While these concerns demand equal time, we can only refer the reader to a number of excellent reviews on the topic of women and ethnic minorities and the career development process Gottfredson (1978); Fox and Hesse-Biber (1984); Leony (1985); Orum (1986); Matthews and Rodin (1989); Ogbu (1989); Scarr, Phillips, and McCartney (1989), briefly summarize the major concerns which have an impact on persons with psychiatric disabilities, who are also members of these traditional minority groups.

Women. First, while there have been long held assumptions that the primary roles of women were those of housewife and mother and that the theories and concepts of career development used to describe and explain males would generalize to women, this is no longer the case. Women whose adult lives will not include work outside of the home have become the minority. Sex differences have been demonstrated to account for the restricted range of occupational alternatives available to women and the fact that women are socialized to pursue stereotypically female traditional occupational roles regardless of their capacities and talents. Moreover, women's career development has always involved one more step than that of men. Before a woman can decide on a career choice, she must sequentially decide whether or not to make outside employment a focus of her life Fitzgerald and Betz (1983).

Women with major psychiatric disorders face these same issues as they aspire to achieve a career or vocational objective just as all women with disabilities appear to do Slappo and Katz (1989) There must be a particular sensitivity on the part of the practitioner to these women who in many instances have failed to achieve an internalization of a self-concept which

acknowledges the right to choose between equally or not so equally attractive alternatives. They also may face the process of career decision making or vocational goal achievement as single parents or caretakers of elderly parents. These additional responsibilities are affecting more and more women in society at the present time and will continue to do so in the future. Women with major psychiatric disorders are not immune to the same stressors which face their non disabled peers.

Ethnic and Racial Minorities. Second, there has developed an increased interest in the career aspirations and adjustment of racial and ethnic minority citizens in this country. This recent interest is due in large part to the uneven distribution of races and sexes in the labor market, the high unemployment rate of minority adults and minority youth, and since 1975 the creation of an "underclass" among Afro-american, Hispanic, and American Indian communities on account of a continued state of economic crisis Smith (1983). Of concern also is the increasing growth of ethnic minorities with disabilities who enter into the vocational rehabilitation system Wright and Emener (1989).

These authors and others have addressed issues surrounding career decision making and vocational

opportunities which are specific to an identified ethnic or racial minority group. Therefore, we will only make several salient comments, which again relate to the career counseling process with persons who also have major psychiatric disorders. It is important, first of all, to appreciate the cultural relativity of the notion of the centrality of work in the lives of all people (MOW International Research Team, 1981). This is a tradition of Western-European culture in particular (Katz & Feroz, In Press) for American Indians work is necessary only to provide enough money to get through the day or the week, to meet the necessities of life. It's value is greatly diminished in the presence of the concern with oneness with nature. For Polynesian-Americans work can come and go, but it is the stability of the family which takes preeminence in the value system of the culture and, therefore, dictates the meaning which work as a career shall ultimately have.

Second, the concept of the dignity of all work is highly questionable since we can no longer pretend that a free and open labor market exists. We must appreciate the need for certain individuals of ethnic and/or racial minority status to separate their personal self-concept from that of their work self-concept. The practitioner is faced, then, with the problematic nature of

determining what is meant by career or vocational maturity in the context of these several and diverse cultural populations and what role career counseling will or will not have. Decision making will, of necessity, need to be based on individual client values rather than on the pre-determined values of the practitioner who, more often than not, is a product of the mainstream culture. The dilemmas created by these disparate value systems are real and must be addressed as ethnic and minority groups are the fastest growing population within the United States today.

#### CONCLUSION

An attempt was made to address those salient aspects of the career counseling process with persons who have a severe psychiatric disability and how adaptations to the traditional practice of career and vocational counseling might be implemented. Specific concerns discussed were those of (1) the concept of vocational maturity and the developmental stages wherein the self-concept of worker emerges; (2) the nature of and necessity for a collaborative relationship between the practitioner and the primary consumer; (3) stages in the career counseling process; (4) the role of formal vocational measurement; (5) aspects of the interviewing process in light of particular symptoms and

communication barriers; (6) the implementation of a career plan and the impact of motivation and unrealistic career goals on the plan; and finally (7) special concerns which arise with women and ethnic and racial minority groups in the career counseling process.

### FIVE BASIC PREMISES

1. NEED FOR A BRIDGE BETWEEN MH AND VR RESOURCES
2. VOCATIONAL READINESS IS DEPENDENT UPON A DEVELOPMENTAL PROCESS
3. NEED FOR A HELPING RELATIONSHIP
4. VR TIMING IS AN INDIVIDUALIZED PROCESS
5. NEED FOR INDIVIDUALIZED, COMPREHENSIVE ASSESSMENT

## RANGE OF OPTIONS

- CAREER COUNSELING INCLUDING VOCATIONAL INTEREST AND APTITUDE MEASUREMENT
- JOB SEEKING SKILLS
- WORK ADJUSTMENT COUNSELING
- REHABILITATION COUNSELING

## CAREER COUNSELING

### **CAREER COUNSELING IS:**

**A PROCESS OF HELPING INDIVIDUALS TO DEVELOP AN INTEGRATED AND ADEQUATE UNDERSTANDING OF THEMSELVES AND THE ROLES THEY MAY ASSUME IN THE WORLD OF WORK, TO TEST THESE UNDERSTANDINGS AGAINST REALITY, AND TO CONVERT THEM INTO REALITY IN A MANNER WHICH IS SATISFYING TO THE INDIVIDUAL AND SOCIETY IN WHICH HE/SHE FUNCTIONS.**

- KNOWLEDGE ABOUT ONESELF
- KNOWLEDGE ABOUT CAREERS
- KNOWLEDGE ABOUT HOW TO MAKE A SYSTEMATIC CAREER DECISION

- **RETARDED RATE OF DEVELOPMENT IN GENERAL**
- **INADEQUATE EMOTIONAL ADJUSTMENT**
- **INACCURATE SELF-EVALUATION**
- **FROZEN BEHAVIOR BETWEEN TWO ATTRACTIVE BEHAVIOR SEQUENCES**

- **FAILURE TO RECOGNIZE A REMEDIABLE PROBLEM EXISTS**
- **ELIMINATING A POTENTIALLY SATISFYING ALTERNATIVE FOR INAPPROPRIATE REASONS**
- **CHOOSING POOR ALTERNATIVES FOR INAPPROPRIATE REASONS**
- **SUFFERING ANGUISH AND ANXIETY OVER PERCEIVED INABILITY TO ACHIEVE GOALS**

## DISTORTED SELF-OBSERVATIONS AND WORLD VIEW GENERALIZATIONS

- LEARNED HELPLESSNESS
- LOW SELF ESTEEM
- UNPREDICTABLE NATURE OF THE ILLNESS
- ENVIRONMENTALLY-BASED DISINCENTIVES
- NATURE OF THE ANXIETY
- TOLERANCE FOR STRESS

More time is needed to go through the process, because of the clients' vocational immaturity. More energy is needed for a collaborative relationship with clients who are used to having things done to and for them rather than with them. More alternative vocational environments are needed to allow clients opportunity for reality testing and exploration. More strategies are needed for dealing with stigma against the psychiatrically disabled clients. More effort must be devoted to a deliberate refocusing of the helping process on the client's needed skills and environmental supports rather than focusing on client pathology.

Anthony, Howell & Danley (1983)

DEVELOPMENTAL PERIODS

FANTASY

EXPLORATORY/TENTATIVE

REALISTIC/ESTABLISHMENT

**COLLABORATIVE RELATIONSHIP BASED ON  
HOLISTIC VIEW OF THE PERSON**

- **EDUCATED ABOUT THE NATURE OF THE PARTICULAR MENTAL ILLNESS**
- **EDUCATED WITH RESPECT TO THE PSYCHOPHARMACOLOGIC MANAGEMENT OF THE PARTICULAR ILLNESS**
- **TIME TO ACHIEVE A LEVEL OF VOCATIONAL MATURITY**
- **RECOGNIZE STRENGTHS AND BELIEVE IN CAPABILITIES**
- **KNOWLEDGEABLE ABOUT AND ABLE TO "USE" THE SYSTEM.**

### PROCESS/CONTENT ISSUES

- SUPERFICIAL EXPLORATION OFTEN UNSATISFACTORY
- NEED TO WORK ON MORE THAN ONE AGENDA SIMULTANEOUSLY

## CHARACTERISTICS OF THE INITIAL INTERVIEW

1. LEVEL OF CANDIDNESS
2. ASSUMPTION OF ROLES
3. JUDGMENTS ABOUT BEHAVIOR

1. CAREFULLY CLARIFY THE BASIC PURPOSE OF THE INTERVIEW.
2. ELICIT CLIENT'S FEELINGS ABOUT THE REFERRAL.
3. DISCUSS AND ALLEVIATE CONCERN THAT YOU HAVE A ROLE (UNLESS YOU DO) IN DETERMINING ELIGIBILITY FOR FINANCIAL ASSISTANCE.
4. ENCOURAGE QUESTIONS THROUGHOUT THE INTERVIEW.

## ERRORS IN PERCEPTION

- **AUTOMATIC AND/OR GLOBAL ASSUMPTIONS**
- **RELEVANCE OF EXPECTATIONS**

## COMMUNICATION BARRIERS

- SYMPTOMATOLOGY
- VERBAL EXPRESSION
- REGULATION OF EMOTIONS
- FLAT OR INAPPROPRIATE AFFECT
- SYMBOLIC USE OF LANGUAGE
- DIMINISHED EMPATHY

1. **HELP THE CLIENT ORGANIZE HIS THOUGHTS.**
2. **WHEN THE CLIENT IS TANGENTIAL, HELP HIM RETURN TO THE CENTRAL POINT.**
3. **PROVIDE SUFFICIENT TIME FOR THE CLIENT TO RESPOND TO QUESTIONS WITHOUT PROLONGING THE SILENCE.**

4. ADJUST THE LENGTH OF SESSIONS.
5. REMEMBER THAT CONFUSED VERBALIZATIONS  
DON'T ALWAYS MEAN THE CLIENT DOESN'T HAVE  
A MEANINGFUL OPINION.
6. DON'T GET CAUGHT UP IN DEBATING DELUSIONAL  
MATERIAL.

1. PROVIDE INCREASED STRUCTURE.
2. DON'T HESITATE TO INTERRUPT; DO IT IN A SPIRIT OF INTEREST IN WHAT THE CLIENT IS SAYING.
3. IF NECESSARY, SLOW DOWN YOUR OWN SPEECH.
4. ASK IF THE PERSON WILL SPEAK MORE SLOWLY.

## CLARIFICATION AND INFORMAL ASSESSMENT

1. CLARIFYING THE INDIVIDUAL'S CONCERNS AND PERSPECTIVES
2. DETERMINING THE INDIVIDUAL'S EXPECTATIONS OF THE PROCESS
3. UNDERSTANDING THE INDIVIDUAL'S PERCEPTIONS WITH RESPECT TO HIS/HER PREVIOUS EDUCATIONAL AND/OR OCCUPATIONAL EXPERIENCES
4. HELPING THE INDIVIDUAL TO REFORMULATE HIS OR HER CONCERNS

## SPECIFIC COGNITIVE RESTRUCTURING TECHNIQUES

1. DIRECT INSTRUCTION ABOUT THE ROLE OF COGNITIONS IN SUBJECTIVE STRESS AND BEHAVIORAL DEFICITS.
2. MONITORING ONE'S PERSONAL THOUGHT PATTERNS
3. MODELING OF A RATIONALISTIC EVALUATION PROCESS AND MODIFICATION OF PERSONAL THOUGHT PATTERNS
4. FEEDBACK ON REPORTED CHANGES IN THINKING PATTERNS AND BEHAVIORS
5. PERFORMANCE ASSIGNMENTS AND REHEARSAL TASKS TO IMPROVE DISCRIMINATION AND EVALUATION OF PERFORMANCE-RELEVANT COGNITIONS.

## FORMAL VOCATIONAL ASSESSMENT

- ENABLES BOTH THE PRIMARY CONSUMER AND THE PRACTITIONER TO BETTER UNDERSTAND THE CONSUMER'S INTERESTS, ABILITIES, AND WORK ENVIRONMENT PREFERENCES
- PROVIDES A MORE OBJECTIVE METHOD OF IDENTIFYING STRENGTHS AND DEFICIT AREAS
- INSTRUMENTAL IN THE FORMULATION OF REALISTIC GOALS AND CAN PROVIDE A PROFILE OF CHARACTERISTICS RELEVANT TO CAREER DECISION-MAKING.
- ENABLES A SYSTEMATIC EXPLORATION OF CAREERS THAT MIGHT BE PARTICULARLY ADVANTAGEOUS AND PROVIDES INFORMATION CONCERNING FIELDS TO AVOID AND/OR TYPES OF ACADEMIC REMEDIATION THAT MIGHT BE BENEFICIAL.
- JUDICIOUS TIMING IS NECESSARY IF THE ASSESSMENT IS TO BE BENEFICIAL.

**RESULTS OF A FORMAL VOCATIONAL ASSESSMENT  
MUST TAKE INTO ACCOUNT AN INDIVIDUAL'S SOCIAL  
SKILL REPERTOIRE, TOLERANCE FOR SPECIFIC  
STRESSORS, AND CAPACITY TO SUSTAIN GOAL  
DIRECTED BEHAVIOR.**

**CAREER EXPLORATION AND SYSTEMATIC DECISION MAKING**

## IMPLEMENTING THE CAREER PLAN

- IDENTIFYING MANAGEABLE SUBGOALS
- REVIEWING
- SELF-MONITORING

**MOTIVATIONAL ISSUES**

**MOTIVATIONAL ISSUES ARE THE NORM.**

**MOTIVATION IS A SITUATIONAL PHENOMENON.**

## UNREALISTIC CAREER GOALS

- SYMPTOM-RELATED
- MODELING
- SUSTAINING FANTASIES
- VALUES AND INFLUENCES

## Basic Interviewing Skills

W. Russell Johnson

---

Dr. W. Russell Johnson is a clinical psychologist in private practice in Oklahoma City. He specializes in marriage and family counseling and in helping families of children with special problems. He received his doctoral degree from Vanderbilt University in 1975. He teaches university-level courses and maintains an active speaking schedule.

This chapter focuses on the special dynamics of the interview process and discusses important diagnostic aspects of the interchange between interviewer and interviewee. Special problems encountered in interview situations are discussed along with particular techniques, such as the mental status examination. The emphasis is on using the interview as a specialized diagnostic tool in order to clearly understand each patient for proper diagnosis and treatment planning.

In a certain sense each of us is an experienced interviewer to the extent that we are experienced communicators, since, as Pope (1979) points out, "an interview is a conversational encounter between two individuals [p. 3]." An interview is indeed a communication interchange, primarily (but not exclusively) directional from interviewee to interviewer. Communication is something with which each of us has abundant experience, although some are more facile communicators than others.

Much attention is paid to teaching interviewing skills in mental health training programs because good interviewing is definitely a skill, arguably either inbred or learned, artistic or scientific. As a skill important for a mental health professional, interviewing is taught with emphasis on the listening and understanding aspects of communication. In fact, it is usually the overanxious, inexperienced interviewer who spends a significant portion of the interview speaking rather than listening.

It is clear that the mental health interview is more than simple communication.

although the interpersonal skills and experience one accumulates from a natural history of talking with other people will prove invaluable to the perceptive interviewer. The interview is indeed "a special instance of interpersonal relations [Sullivan, 1954, p. ix]." Not every mental health practitioner will be a good interviewer, because just as people bring various experiences; social preferences and interpersonal styles with them to the interview, they have varying potentials for the sensitivity and deductive reasoning skills required of the truly good interviewer.

Matarazzo (1965) points out that interviewing is one of many techniques through which one person exerts influence over another. Historically educators and priests as well as psychotherapists have utilized the techniques of the interview, a term that originally meant "a meeting of persons face to face [Zubin, 1962, p. 403, quoted by Matarazzo]." Too often interviewers pay too much attention to what the patient or client is saying at the expense of noticing how and what they themselves are communicating. Others are preoccupied with their own anxiety about their interview behavior ("What do I say next?") and neglect the patient in the process.

Even though interviewing is essentially the patient talking about himself or herself to the interviewer, the process of communication is dyadic and includes both verbal and nonverbal factors. The influence of communication on relationship and the implications for the initial interview are discussed by Bernstein, Bernstein, and Dana (1974), who state that "each relationship contains the potential for bringing into play the infinite range of emotions — positive, negative, ambivalent [p. 1]." The reciprocal nature of the interpersonal dynamics of the interview situations must be considered by interviewers, who must understand the person being interviewed. Good interviewers respond to both their own and the interviewee's communication with perspective and balance, keeping in mind the importance of understanding how they themselves communicate in the process of trying to understand the patient or client.

We interview in order to understand people and we accomplish this end through the medium of communication, a specialized kind of communication. Particularly in this sense, but also in less formalized areas of communication, we are aware of many factors that infringe on the process and consequently on the degree to which the purpose of the communication is achieved. Expectations, mood, social attitudes, intelligence — these are only some of the factors that influence interview dynamics. Most often, too, the initial interview is the patient or client's first encounter with a mental health professional; therefore, whatever myths or inaccurate attitudes the patient brings to the interview will be both informative and intrusive. The interviewer must recognize these and tactfully deal with their emergence.

There is essentially no single "correct" way to interview, nor can interviewing easily be taught. Good interviewing requires much practice, careful scrutiny of one's work, and most important, an appreciation of the fact that the interview is a human relationship. There are at least three variables that affect the interviewer-

interviewee interaction: (1) content, (2) style of communication, and (3) quality of the interaction.

*Content* is the actual interview data, the information presented by the client or patient, his or her history, presenting symptoms, and so forth. Much of this information is gained during the interview, although some very useful information can be obtained from reviewing previous medical, school, employment, or psychiatric records, conducting interviews with family members, and having the patient complete a history form or write an autobiography. *Style of communication* refers to the verbal and nonverbal messages given by the patient. An alert, perceptive interviewer will learn as much or more from the way a person communicates as from the content of what is said. *Quality of the interaction* includes patient and interviewer variables — attitudes, expectations, previous experiences, mood, and other factors that directly affect the interpersonal relationship during the interview.

The initial interview is in very many respects like psychotherapy. The characteristics of a therapy interview in which patients speak openly and revealingly about themselves are the same as those that are relevant to a good initial interview. An interviewer or therapist who is intelligent, caring, and perceptive can elicit a successful interview or therapy session. However, while it is desirable for patients to speak freely, it is well to keep in mind that what patients do not say verbally is often revealed in other ways and is vitally important to a clear understanding of them as individuals. Truly successful interviewers and psychotherapists are intelligent people who rely on their life experience, perceptiveness, and general knowledge of theory to understand patients and clients rather than engaging in the academic exercise of fitting the patient or client to a particular theory. Real interviewing, like real psychotherapy, requires commitment and thinking; therefore, it is infinitely more risky than academic exercising, and consequently more effective.

## PRELIMINARY CONSIDERATIONS

### Purpose of the Interview

Although it is true that there is much similarity between a good interview and a good psychotherapy session, the purpose of the initial interview is not therapeutic *per se*. While a patient may derive cathartic or insightful benefit from the relatively concise investigation of the areas touched on in the interview, the purpose of the interview is primarily information gathering and understanding.

Skillful interviewing allows patients and clients to reveal themselves in the

context of a dyadic relationship. In order to foster the patient's self-revelation, the interviewer should refrain from following a structured format. Although haphazard questioning should be avoided, the interview must be loosely enough structured so that the interviewer can pursue avenues of inquiry that present themselves during the course of the interview. As MacKinnon and Michels (1971) point out, "The interview is most effectively organized around the clues provided by the patient and not around the outline for psychiatric examination [p. 28]." Interviewers generally start interviews with the general goal of understanding patients in their individuality, but may also have a more specific goal depending on what they want to know about a particular patient. Immediate and unfolding impressions of the patient, as well as topics introduced by the patient, guide the skillful interviewer. The process of a good interview can best be described as hypothesis formation and hypothesis testing. Impressions of the patient are formed and investigated and the interview is not completed until the interviewer understands the patient.

Keeping in mind that understanding the patient is the overriding purpose of the interview, our understanding is often guided toward a specific end, depending on circumstances. The setting in which the patient or client is seen often generates certain guidelines, as will be seen in the following list of specific interview purposes.

**Diagnosis.** Hospitals, mental health clinics, social agencies, and veterans hospitals all have requirements for diagnostic classification that must be met. Third-party payers such as insurance companies and welfare agencies have diagnostic requirements with which one should also be familiar. In most cases a DSM-III (APA, 1980) diagnosis is sufficient, although some companies will require elaboration of the diagnosis. A conceptual diagnosis reflecting the psychological processes underlying the patient's problems and incorporating both etiology and prognosis is often useful. Of concern also is the question of whether or not the patient actually has any psychiatric problems at all that merit a diagnosis. The fact that a patient is in a psychiatric setting and is being interviewed does not mean that he or she has a psychiatric condition or actually fits a diagnostic category. Too many interviewers feel compelled, as if by the thrill of the hunt, to find the elusive diagnosis in every patient.

An invaluable and yet often traumatic experience for the mental health professional is the brief hospital consult. In this situation the professional is often asked to interview a patient for twenty to thirty minutes and arrive at a diagnosis. Here the interviewer must pay special attention to verbal and nonverbal clues, efficiently make and check hypotheses, and arrive at an accurate diagnostic impression. Under such circumstances, most psychologists want to administer a battery of tests, social workers want to take a thorough history, and psychiatrists want to conduct a series of in-depth interviews. Relatively few professionals feel comfortable making judgments about psychopathology on the basis of one brief interview.

yet in the practical working world such practice is often a necessity. There are times when important decisions must be made as expeditiously as possible.

**Patient management.** Whether in an inpatient or outpatient setting, decisions must be made regarding treatment planning. Initial interviews must help the interviewer decide on diagnosis and plan an appropriate treatment strategy. If psychotherapy is selected, the interviewer must decide among individual, group, or family therapy, or a combination; who the therapist is to be; how often therapy sessions should be scheduled; and so on. A good intake interview includes an understanding and explanation of the patient's presenting complaints, conceptualization of the psychopathology, diagnosis, treatment recommendations, and prognosis. The interviewer must ensure that the interview is sufficient to provide this information.

**Outpatient treatment versus hospitalization.** This purpose is significant enough to be considered singly, although it is essentially subsumed under patient management. Relevant questions for the interviewer to keep in mind are: Can the patient manage the daily affairs of living on his or her own? How much support is there in the patient's environment? What other alternatives are available? What are the patient's financial resources? How willing is the patient to be hospitalized? Is the patient capable of determining a rational course of action and judging what is in his or her own best interest?

**Deciding on a test battery.** When interviewing a patient with whom a psychological evaluation is scheduled, the psychologist will want enough information to enable selection of an appropriate test battery. Intellectual and achievement tests may be selected on the basis of an assessment of the patient's intellectual status. If the clinician thinks the patient manifests organic symptomatology during the interview, a neuropsychological battery might be called for. Particular personality and projective techniques should be selected based on the cooperation of the patient, his or her intellectual and motivational level, and the particular questions to be answered. The interviewer should always find out what questions the referring person wants answered. What is the patient's perception of the purpose of testing? Is the patient cooperative, manipulative, honest, hostile, withdrawn? Impressions formed during the initial interview will help with both test selection and management of the testing situation. For example, does the patient have questions regarding confidentiality? If so, the examiner would be well-advised to clear these up before they interfere with the patient's level of cooperation during the testing session. Who will give the patient feedback regarding the test results? Does the patient expect the examiner or the referring person to talk with him or her afterwards? Clearing up questions such as these prior to testing can eliminate problems with cooperation and motivation that otherwise might cloud the test results.

**Disposition.** Particularly in an inpatient setting, an interview is often conducted with patients prior to discharge in order to assess their current functioning and assist them in making plans for readjustment to living outside the hospital and for follow-up outpatient visits. An important related question concerns the family's perception of the patient's status and their willingness to readmit him or her into the family structure.

**Test feedback.** When conducting an interview for the purpose of giving test feedback to a patient or client, the psychologist is normally doing most of the talking, which makes this situation different in this respect from the other interview situations we have discussed. There are several principles the interviewer must keep in mind: (1) Give information to patients commensurate with their capacity to understand and utilize the information. The most eloquently worded explanation will be useless if it is not phrased in such a way that the patient can understand and use it. (2) Give the patient the essential information without elaborate or unnecessary details. A concise message containing the important elements will be easily understood and appreciated by most patients. (3) Take plenty of time so that the patient can ask clarifying questions. (4) Particularly if the patient is a minor, consider carefully what information regarding the test results he or she can accept and utilize. There is no point, out of the context of psychotherapy, in confronting patients with troubling information except as it encourages them to enter treatment. (5) Again, if the patient is a minor, arrange to give feedback to his or her family. In the case of an adult, feedback may be given to family members as long as it is in the best interest of the patient, and in most instances should be done only with the patient's (or his or her legal representative's) written permission. It is particularly important to involve family members in a feedback interview when patients are incapable of making good decisions for themselves and the family will be called upon to decide upon treatment in the patient's behalf. (6) The referring person is entitled to some form of test feedback. Those involved in primary care of the patient should be given as detailed a report as is possible.

**History taking.** The interview designed to elicit historical information alone is a specialized technique usually performed by social workers. However, other mental health professionals often wish to obtain a history as part of their initial interview. These interviews normally involve a more structured format than the diagnostic interview, although a good interviewer can take a history while seemingly engaging in pleasant conversation with the patient. Certain areas of prime interest will be investigated in more detail, depending on the purpose for obtaining the information.

A thorough history should include the following categories of information as

obtained from the patient.\* The interviewer should make a special effort to note the patient's own words, as this method often reveals salient information about the patient's thoughts, attitudes, and emotionality.

1. *General information:* demographic data (name, age, sex, occupation, marital status, address, telephone numbers, religious preference); a list of close relatives, and the name of the referral source.
2. *Patient's narrative:* chief complaints, the patient's description of problem history, duration and severity, previous therapy, the kind of assistance presently sought, the patient's evaluation of present general health, and the interviewer's impression of the patient's reliability as an informant.
3. *Personal information:* height, weight, interests, hobbies, and friends.
4. *Medical history:* data from birth to the present: list all illnesses, surgeries, and medications.
5. *Occupational data:* current and previous employment.
6. *Sex information:* past and current sexual interests and behaviors.
7. *Menstrual history (females only):* age at menarche and current description of menstrual periods.
8. *Marital history:* data relevant to present and previous marriages and children.
9. *Family data:* information about natural parents, stepparents, and siblings.
10. *Alcohol and other toxins:* information about alcohol and drug use, poisons ingested, nicotine, glue, and paint.
11. *Family mental history:* information about psychiatric treatment for any family members.

### Interview Data

MacKinnon and Michels (1971) identify several factors which constitute the data of an interview, which all interviewers should keep in mind.

**Content and process.** *Content* is the verbal and nonverbal substance of an interview, including both the information provided by the patient and the interviewer's interventions. It includes what patients and clients say as well as the nonverbal messages they give. A patient might tap his or her fingers rapidly on the arm of a chair, for example, while talking about looking for a new job. *Process* refers to the implicit meaning of content in the context of the interviewer-interviewee relationship. Content is what happens and process is what it means. Process is not inferred at the conclusion of the interview. It is ongoing, and develops with the interview as a continuous and integrated whole. Communication in an interview is a two-way process: the interviewer's reactions to the patient are part of the content, whose meaning gives important process information.

\*Another outline for the psychiatric history is given in Menninger, K. A. *A manual for psychiatric case study*. 2nd Ed. New York: Grune & Stratton, 1962.

**Introspective and inspective data.** *Introspective* information is that provided directly (usually verbally) by patients, their accounts of their own feelings and experiences. *Inspective* data, on the other hand, is the information contained in the nonverbal behavior of the patient and the interviewer.

**Affect and thought.** It is important to distinguish between emotional reactions (*affect*) and intellectual productions (*thought*). Many patients, when asked how they feel about some aspect of content, will state their thoughts — intellectualized responses devoid of any personal revelations of feeling. While the interviewer notes the patient's verbal description of feeling, he or she also takes into account paralinguistic and nonverbal information. In examining a patient's thinking process it is important to look at content, rate of production, and organization.

### The Interviewer

It is vital that clinicians as interviewers be aware of the way they present themselves to patients so that they can understand the patient's behavior in the correct context. Interviewer directiveness has been shown to reduce patient self-exploratory statements (Bergman, 1950), to increase defensiveness in patients who were more defensive or more aggressive before treatment, but to decrease defensiveness in those who had felt a greater need for autonomy (Ashby, Ford, Guernsey, and Guernsey, 1957), and to improve outcome for patients exhibiting external locus of control (Abramowitz, Abramowitz, Roback, & Jackson, 1974). Pope (1979), in his review of the literature in this area, suggests that interviewer directiveness is a reflection of the type of patient being interviewed, with more dependent patients evoking more directiveness on the part of the interviewer.

Interpretations on the part of the interviewer have been shown to meet with various interviewee responses. Pope's (1979) review of these studies suggests that interpretations can decrease patient verbal productivity (Kanfer, Phillips, Matarazzo, & Saslow, 1960) unless used as verbal conditioning reinforcers, in which case they increase productivity of preselected words (Adams, Butler, & Noblin, 1962; Adams, Noblin, Butler, & Timmons, 1962; Noblin, Timmons, and Reynard, 1966). Other research has demonstrated that interpretations of moderate depth are more productive than either shallow or deep interpretations (Shaffer & Shoben, 1967; Speisman, 1959), and some authors (Bernstein, 1965; Fisher, 1956) advise against deep interpretations in the interview.

Several studies indicate that high levels of interviewer activity enhance positive therapeutic outcome (Rice, 1965) and facilitate patient perception of empathy and warmth in the interviewer (Lennard & Bernstein, 1960; Truax, 1970; Pope, Nudler, VonKorff, & McGee, 1974). Other factors such as ambiguity of interviewer statements (Pope & Siegman, 1965; Pope & Siegman, 1968; Siegman & Pope, 1965), interviewer affect statements (Isaacs & Haggard, 1966), and inter-

viewer expressiveness (Wexler & Butler, 1976) have been shown to increase patient activity and expressiveness in an interview.

The point of this research evidence for clinical practice is that it suggests how interviewers can affect interviewee variables to enhance a productive interchange by manipulating their own behavior during the interview. As mental health professionals, we must be aware that we have a tremendous effect on patients and clients; we must be aware of that effect so that we can properly interpret a patient or client's behavior.

The interviewer's appearance and manner are the most readily influential characteristics. An interviewer whose physical presentation elicits confidence from the client or patient will have a more successful interview than one whose appearance leaves his or her professional status in doubt. The interviewer's dress and grooming should exemplify self-respect and competence. Many patients will feel that interviewers cannot respect them and take them seriously unless they manifest these attitudes toward themselves. The interviewer's posture, handshake, and overall bearing will affect the patient either favorably or unfavorably.

Pope and Siegman (1972) found that interviewers who were perceived as experienced elicited more productive (verbose) responses in shorter response times than did inexperienced interviewers, but that these responses might involve little self-disclosure. Pope, Nudler, Norden, and McGee (1976) and Pope, Nudler, VonKorff, and McGee (1974) compared interviewer experience levels and found a mixture of facilitating and inhibitory effects due to status (experience). It was clear in these investigations that a factor such as social compatibility influenced the interview interaction in such a way that the novice interviewers engaged in a less formal, more conversational dialogue with patients than the experienced interviewers. Pope (1979) concluded that "the social proximity between interviewer and interviewee may be more salient in some situations than the expertise and experience of the interviewer [p. 265]."

In this writer's experience, it takes skill to make a conversational interview — one that the patient is likely to report in pleasant terms — a productive interview as well. Interviewers should be mindful of the fact that disturbing material sometimes must be discussed, albeit in a nonthreatening manner, in order for an interview to reveal pertinent information about the patient. Accurate understanding is a more important goal than pleasant conversation, even if the interviewer is personally anxious to keep unpleasant topics from being discussed. It is evident that whatever other factors are operative, the interview is basically a special case of an interpersonal communicative relationship between two people. As interviewers we will do well to be mindful of the fact that we are personally part of that communicational dyad, that we are what Sullivan (1954) calls "participant observers [p. 19]." This means that the communication is two-way during an interview. Sullivan observes that "to the extent that he [the interviewer] is unconscious or unwitting of his

participation in the interview, to that extent he does not know what is happening [p.19]."

### The Interviewee

There are several often-overlooked factors that the interviewer should consider in evaluating and understanding an interview with a patient or client, for these factors can have a significant effect on the content and process of an interview. It has long been clear that the expectations patients bring with them to the interview greatly influence the behavior they exhibit while talking with the interviewer. There is evidence that patients' expectations of a therapy encounter depend on the psychotherapeutic approach they anticipate will be used (Lennard & Bernstein, 1960) and on the professional status of their therapist-interviewer (Chance, 1959; DeHaan, 1962). Male and female patients might expect interviewers to behave in different ways (Apfelbaum, 1958), and a patient's socioeconomic status is often an important determiner of expectations (Heitler, 1973; Strupp & Bloxom, 1971). Overall and Aaronson (1963) suggested that middle-class patients expect the therapist to assume less direction, authority, and responsibility than did lower-class patients. Jacobs, Muller, Anderson, and Skinner (1972) found a significant tendency for patients who had improved after psychotherapeutic treatment to have had more positive self-reported pretherapy expectations of the psychotherapy encounter than had unimproved patients.

Evidence has indicated that patients' role expectations influence their behavior during therapy (Jacobs, Muller, Anderson, & Skinner, 1972; Kelley, 1955). Several efforts to utilize role induction procedures in order to align patients' expectancies with the realities of therapeutic interactions have met with success (Heitler, 1973; Hoehn-Saric, Frank, Imber, Nash, Stone, & Battle, 1964; Marian, Jacobson, Johnson, & Morrice, 1970; Sloane, Cristol, Pepernik, & Staples, 1970; Spiratas & Holmes, 1971; Strupp & Bloxom, 1971; Yalom, Houts, Newell, & Rand, 1967). This writer (Johnson, 1975) demonstrated that patients' expectancies of active or passive participation could be altered in a positive direction, but that altered expectancies are not quickly translated into behavior in one interview. Thus even though patients' expectancies are directly changeable in an ongoing therapy situation, patients probably behave within one interview in accordance with their preconceived expectations. For this reason, the interviewer does well to pay attention to clues to such expectations and to evaluate to what extent they influence the patient's observable behavior.

Also, patients and clients respond to their perception of the interviewer and the interview situation itself. The interviewer must be aware of these factors in order to assess their possible influence. For example, on one occasion the present writer, then a student interviewer working in a hospital, was obliged to conduct an interview of a neurotic adolescent and her parents in an undesirable location, due to a shortage of office space during a period when offices were being moved.

Growing concern was evident on the parents' faces as we left the reception area, took the elevator to another floor, and walked through several corridors to a distant part of the hospital in order to find a private interview room. An explanation of the situation comforted the parents and the interview progressed smoothly, but the outcome would undoubtedly have been quite different if the interviewer had not been perceptive of the patients' reactions to a change in setting that contradicted their expectations.

Equally important is the presence of anxiety that normally is evident in most people in a new situation. Anxiety is often heightened in the psychiatric interview situation, particularly if patients are aware that diagnostic and treatment decisions will be made based on their "performance" during the interview. Many patients draw the analogy of a job interview or a consultation with a medical doctor.

Some patients evidence better relationship skills than others (Isaacs & Haggard, 1966), while some are simply more likable than others and tend to produce desirable interview behavior and to be disclosing and verbally fluent during the interview (Pope & Nudler, 1973). All of these factors should be considered by the interviewer as potential influencing factors on patient behavior and its interpretation during an interview.

Finally, the interviewer should be aware that any psychopathology that is manifest in the patient's behavior will itself affect the course of the interview. Pope (1979) illustrates this process with several examples. The schizophrenic, he notes, will often relate to the interviewer's questions in an autistic or irrational manner and, if stressed, can "retire behind an impermeable wall of speech that is not readily understandable [p. 431]." The obsessive patient, on the other hand, will appear to be the most rational and articulate of patients until the interviewer realizes that he or she has been seduced into an intellectual contest and has become "an accomplice of the interviewee in banning any expression of personal feelings [p. 432]."

## THE SETTING

The importance of a patient's expectations as they relate to the interview process was discussed earlier. One thing that patients and clients universally expect, and rightfully so, is to receive professional care from a person who takes his or her job seriously. Patients and clients hold this expectation because they want to be taken seriously, and regardless of how it sounds to anyone else, their problems are serious business to them. Indeed, many patients begin the interview by implicitly asking to be taken seriously — "I hope you won't think I am crazy."

Many patients have little if any experience with mental health professionals. They do, however, usually have some experience with physicians. One influence of this prior experience is normally that the patient expects all health professionals

to be just that — professional. It is the clinician's responsibility to provide the patient with a comfortable, pleasant atmosphere in which to talk about his or her problems, concerns, and aspirations. This task is made difficult by the very atmosphere of certain settings in which interviews must be conducted. Hospitals, prisons, rehabilitation centers, and the like do not engender feelings of privacy and confidentiality in patients. Therefore special measures must be taken in order to generate an atmosphere conducive to an open, self-disclosing interview. A private room, preferably not a corner in a large conference or recreation room, where one can arrange to be undisturbed by patients, staff, and visitors, is highly desirable.

The aesthetics of the interviewing room should convey a professional atmosphere of comfort and security. The setting in which one works might impose certain limitations on furnishings for the office; nonetheless, in most situations the furniture available can be placed in a comfortable, conversational arrangement, and paintings and other accent pieces can be selected to convey the appropriate mood.

The purpose of the interview is to help clients and patients reveal themselves so that the interviewer can understand them. Interviewing the patient while sitting behind a desk not only destroys the conversational mood, but also inhibits a full view of the patient. Generally the best arrangement is to sit facing the patient with both participants in chairs that are approximately the same height. Sitting the patient significantly lower or higher than the interviewer unnecessarily imposes an additional variable on the interview process.

Attention should also be paid to other aspects of the environment, such as temperature, ventilation, and lighting. In addition, the room should be relatively quiet and the clinician should arrange to be undisturbed during the interview. It is difficult to convey a feeling of confidentiality if other people are coming in and out during the interview, or if telephone calls constantly interrupt.

It is a good idea not to sit between the patient and the door. Sooner or later the interviewer will interview a psychotic patient who impulsively decides to leave the room by storm or whose "voices" are so frightening that he or she flees in panic, oblivious to the unsuspecting interviewer sitting directly in the way.

Equally as important as the appearance of the interviewing room is the clinician's personal appearance. The patient's confidence in the professional will directly influence the degree to which he or she speaks freely and openly during the interview. The interviewer should not only be well-groomed, but should also dress appropriately for the setting in which he or she works. Although everyone has the right to personal standards, it is well to remember that the professional engages in a special relationship with another person and therefore has a special responsibility. The clinician demonstrates respect for himself or herself and for the patient by dressing in a professional manner, and by doing so fosters the cooperation of the patient. It is inaccurate to interpret as pathological a patient's negative reaction or reticence to talk if it is a justifiable response to the interviewer's inappropriate appearance or behavior.

Psychologists' professional organizations encourage the provision of an approp-

riate setting for the conduct of work with patients and clients as a professional responsibility. The American Psychological Association, for example, states in the *Standards for Providers of Psychological Services* (January 1977 revision):

Physical arrangements and organizational policies and procedures should be conducive to the human dignity, self-respect, and optimal functioning of users (patients), and to the effective delivery of service. The atmosphere in which psychological services are rendered should be appropriate to the service and to the users, whether in office, clinic, school, or industrial organization (p. 111).

Special mention should be made of the interview conducted in a hospital setting. Whether patients are hospitalized on a medical or a psychiatric ward, they are usually in a state of mind characterized by feelings of helplessness and dependence. Patients react to these feelings in various ways, depending on their personality and any psychiatric conditions they may be experiencing. Typically patients have not requested the consultation, and often interpret any psychiatric intervention, even a simple interview, to mean that their physician or family considers them to be "crazy." Thus the interviewer often encounters a defensive or hostile patient. In this regard, much depends on what patients were told about their hospitalization and how they were prepared for the interview. The interviewer is well advised to investigate these factors before seeing the patient. If the patient has not been informed about the interview or has been inaccurately informed, this must be cleared up with the patient at the start of the interview.

It is also a good idea to review the patient's hospital chart and to talk with nursing personnel and others who have had frequent contact with the patient prior to actually conducting the interview. Much can be learned through these procedures that will prove invaluable during the conduct of the interview. It is both courteous and desirable to talk also with the referring person prior to seeing the patient.

A significant problem in hospital interviews is the patients' reluctance to talk openly about themselves because of the lack of privacy engendered by the hospital setting. Patients are constantly observed and their behaviors noted while they are hospitalized, and they understandably react. The perceptive interviewer will note this reaction in the patient, empathically acknowledge it, and endeavor to keep the interview as private as possible. It is often advisable with particularly wary patients to discuss with them the nature of confidentiality in the hospital, telling them who has access to information about them and what use may be made of it. In conducting the interview, use of a private interview room is desirable. If the patient must remain in bed, draw the curtains and speak in a relatively soft voice. Ask other patients and visitors to leave the room so that you can converse privately with the patient.

At the conclusion of the interview, a note must be put in the patient's chart.

either in the Progress Notes or on a special consultation sheet used by many hospitals. The interviewer should be thoroughly familiar with hospital policies and procedures before interviewing the patient. The chart note should be concise and well organized. If the hospital uses a system such as the Problem-Oriented Medical Record (POMR), the note must be in that format. The note should include significant interview data, assessment, diagnosis, prognosis, and treatment recommendations. A personal communication by telephone and/or letter with the referring person is also highly advisable.

A further word is in order regarding the POMR system, since it is enjoying increasing acceptance in mental health settings. The POMR is a record-keeping system that emphasizes the route from problem identification to problem solution. There are essentially five phases to the system:

1. *Initial evaluation.* A good initial evaluation provides for goal-setting for the patient, family and staff, diagnosis, treatment plan, and anticipated length of treatment.
2. *Data base.* The data base includes history and results of present medical and psychiatric examinations.
3. *Problem list.* A problem is defined as anything important enough (to the patient, family, or staff) to do something about. The POMR system requires that all problems be numbered and listed so that treatment plans can be clearly formulated and progress noted.
4. *Treatment plans.* Treatment goals and the methods used to attain the goals are listed separately for each problem.
5. *Progress notes.* Daily progress notes are written for each problem listed on the problem list. The S-O-A-P format is used as follows:
  - a. *Subjective:* what the patient, family or staff say about the problem.
  - b. *Objective:* results of studies or direct observations regarding the problem.
  - c. *Assessment:* current formulation of the problem and evaluation of treatment effectiveness.
  - d. *Plans:* what is to be done to solve the problem.\*

In the next section of this chapter we shall examine the phases of the interview and discuss ways to handle each phase in a skillful manner.

---

## PHASES OF THE INTERVIEW

### The Beginning

**The appointment and the waiting room.** The experienced interviewer realizes that the interview begins at the time the appointment is made. Much can be learned about patients from a receptionist's description of their behavior on the telephone. For example, this writer recently saw a twenty-year-old man with the presenting complaint of anger over a smothering family and the desire for independence. His mother had called to make his appointment, at his request.

A well-coached receptionist can also provide an interviewer with an accurate account of the patient's behavior in the waiting room. How patients describe the purpose of the interview, how they relate to the receptionist, other people in the waiting room, and any family members accompanying them, and how they respond to a request to supply the receptionist with the usual name, address, and telephone information all provide the interviewer with valuable insights.

**The referral.** Discussion with the referring person prior to interviewing the patient is not only good etiquette, but also offers the interviewer an opportunity to learn something of the background of the patient, why he or she was referred, and what his or her preconceptions and attitudes toward the interview are likely to be. Experienced interviewers prefer to have every scrap of available information about the patient at their disposal, both for hypothesis formation and for validation of hypotheses.

**Initial observations.** The good interviewer begins observing as soon as he or she lays eyes on the patient. Notice how patients sit and how they respond to your initial greeting. When you call the patient's name and introduce yourself, notice his or her handshake, eye contact, and any comments he or she makes. Notice posture, facial expression, voice quality, grooming, and gait as you greet patients and escort them to your office.

If the patient is a child or adolescent accompanied by parents, or an adult accompanied by spouse or family, greet the patient first, even if you have spoken with another family member on the telephone to arrange the appointment for the patient. Ask the patient to introduce the other family members to you, noticing speech patterns, nonverbal behavior, and the order of introductions. Remember that the welfare of the patient is your first concern — greeting patients first gives them that message. Do not run the risk, especially with an uncooperative patient who is being interviewed involuntarily, of further alienating the patient by giving the impression of being in alliance with the patient's family.

Be sure to start the interview on time. If you begin the appointment early, some patients will interpret this as overeagerness on your part and will question your

motives. If you start quite late, some patients will feel you are uninterested in them. It is advisable to avoid having to deal with these unnecessary complications. If you are going to be late starting the interview, ask the receptionist to inform the patient.

**In the interviewing room.** It is normally a good idea to show the patient into the interviewing room and invite him or her to be seated. Some interviewers like to provide several possible seating arrangements and watch patients make their choice. What can be learned in this situation is how readily patients make a decision and whether or not they need to ask the interviewer for guidance. Some degree of awkwardness upon entering a new room is perfectly normal; therefore, interpretations of the patient's behavior in this situation must be made carefully.

When patients are accompanied by family or friends, it is usually a good idea to offer to see them alone before talking with their family. In the case of a particularly uncommunicative patient, this interview might be brief. Seeing the patient first is respectful and reassures him or her that the interviewer has the patient's best interest at heart. It is not a good idea to ask a patient's permission to talk with their families (they might refuse), but it is advisable to inform them of your intention to talk with their family and ask them how they feel about your doing so.

It is often a good practice to offer to bring in the family at the conclusion of the interview with the patient, thereby seeing the whole family together after having established a relationship with the patient. Comparison of the patient's behavior while talking alone with the interviewer and his or her behavior while the family is present is usually very enlightening for the interviewer. Some families ask to talk with the interviewer privately, which is usually permissible and most often means that they have particular questions, concerns, or information that they do not wish the patient to hear.

If the patient's family is with him or her, it is advisable to talk with them one way or another. Their presence indicates that they are concerned and that they have something to say. Additionally, they can provide clarifying information and correct any false impressions that the patient may have given the interviewer. For example, occasionally patients will try to "con" the interviewer into believing that they have problems (or that they have none). Information from the patient's family can help validate or invalidate the patient's perceptions and statements.

### **The Middle**

**The presenting complaint.** Most patients expect some direction from the interviewer at the beginning of the appointment. Many patients feel so overwhelmed by their problems that they seem not to know where to begin, and some will verbalize these feelings. Most often, though, the interviewer becomes aware of this feeling in the patient's tone of voice, facial expression, gestures, and other nonverbal behaviors.

A good starting point is to briefly let the patient know what information you have received from the referring person — for example, "Dr. Smith told me that you have felt low in energy lately." This kind of statement informs patients that you already know something about their problems and that you are interested enough to have spoken with the referring person. Patients then have a starting point from which to elaborate on their problems. Some interviewers prefer to start by telling the patient to "begin wherever you want to," to "tell me what concerns brought you here today"; others simply sit in silence and let the patient take the initiative.

All patients want to "tell their story" in their own way, and it is important that the interviewer let them do just that. The sequence in which patients tell their story, the problem areas they emphasize, the words they choose, the affect they display, the way they explain their understanding of their problems — all these aspects of patients' stories give the interviewer valuable information.

The best rule is to start with general questions and see how effectively patients can structure their responses. Often psychotic patients will tell an incoherent, illogical story, depressed patients a short story — the way patients present themselves tells the interviewer a lot about them. General questions such as "Tell me about yourself," "Describe your family life," "What problems brought you here?" give patients the opportunity to structure the answer in their own (revealing) way. More specific questions can be asked as needed. As Pope (1979) points out, "Self-disclosing and expressive communication is fostered by interview conditions of sufficient ambiguity to permit a communicational interaction to develop. Whatever the orientation of the interviewer, he must find a balance between enough ambiguity to permit the interviewee to speak freely and expressively and enough structure to conduct the communication into channels that are considered important by the interviewer [p. 98]."

The basic principle with which you should conduct every interview is to let the interaction flow naturally. Do not structure the interview with an outline or a predetermined format. Talk about the areas needed in order to understand each particular patient.

**The most common mistakes.** Inexperienced interviewers share one attribute — they tend to make the same mistakes.

1. *Talking too much.* Many interviewers who are anxious (often more so than the patient) exhibit their anxiety by talking incessantly. Often they feel that they must ask *all* the right questions, which usually comes out as asking too many questions. The good interviewer says very little and lets the patient do the talking. If you begin to feel anxious while conducting an interview, that is the time to be quiet.

2. *Trying to help.* Good samaritans have no business conducting initial interviews. The initial interview is not psychotherapy; it is for the purpose of understanding the patient, not helping *per se*. The interviewer must pay attention to listening and looking and leave the helping until later. The first interview is the

worst time to give advice, however much you are impressed with your insights into the patient's problems. Too much too soon is deadly and absolutely *not* helpful to patients, even though you err with the most altruistic of intentions.

3. *"Tell me a little about . . ."* Every student this writer has observed has asked patients to say "a little" about something or the other, and then has expressed surprise when the patient did not say very much. Listen to what you ask patients before you render a diagnosis based on their responses. An appropriate answer to the question "Can you tell me something about your childhood?" is "Yes, I can."

4. *Rephrasing questions.* How many times have patients heard, "Tell me about your marriage, how do you feel about it? Do you and your wife argue?" This anxious young interviewer asked three questions in the same breath, and then was uncertain how to interpret the patient's response. Patients who are not confused when they start the interview may well leave very confused if you ask several questions at once. Ask only one question at a time. If the patient requires clarification, then rephrase.

5. *Asking multiple choice questions.* Questions that can be answered with a simple "yes" or "no" do not encourage a patient to elaborate. "Tell me about your wife" is preferable to "Do you love your wife?" By the same token, questions that suggest a choice of answers usually elicit uninformative responses. "Tell me about your job" is preferable to "Do you like your job or not?" and to rapid-fire short questions such as "Where do you work? Do you like it? What do you do there?"

**Develop rapport.** Rapport between two people exists when they have established a mutual purpose in the context of a comfortable relationship. Regardless of an interviewer's theoretical orientation, the value of interest, empathy and a sincere effort to understand the patient in fostering cooperation in an interviewee is inarguable. Some authors speak of "accurate empathy, nonpossessive warmth, and genuineness" as basic factors that underlie all successful psychotherapy (Truax & Carkhuff, 1967). Since rapport must be developed quickly in the initial interview, it is well for the interviewer to facilitate the same kind of responsive rapport he or she would develop in a psychotherapy situation. Interviewers who naturally exhibit these qualities will easily communicate well with most interviewees and will be better interviewers in the long run than those who learn to "perform" these qualities.

A discussion of confidentiality often hastens the development of rapport, particularly with children and adolescents. Some young people view the interview as proof that they are "in trouble" and assume that whatever they say and do will be reported directly to their parents or to school authorities.

**Questioning.** Many poor interviewers are unsuccessful simply because they conduct an interrogation rather than an interview. Questioning should be done in a way that makes the patient feel free to open up. Good questions often utilize the

patient's own words — for instance, asking a patient to "Tell me more about . . ." a situation he or she has just described, or asking for clarification by simply saying, for example, "You said you disliked your employer. Tell me more about that." This kind of questioning is open-ended so that patients can respond by *structuring their own answers*.

It is very important to clarify terms that the patient introduces. Inexperienced interviewers take it for granted that they know what patients mean when they complain that they are "depressed" or have "bad nerves." In a recent example brought to the attention of this writer, "bad nerves" referred to a delusion that the patient's nervous system was rotting away. Clarification of contradictions should be accomplished in a nonjudgmental way.

Some patients wander from topic to topic, thereby demonstrating a thought process disorder, and should, after a short period of time, be given more structure. Once tangentiality, for example, is demonstrated, no purpose is served by permitting the patient to go farther afield. The patient will feel more comfortable and you will obtain more useful information if you give the patient a reference point, by saying, for example, "Go back to what you said earlier about your son," or "I'm having trouble following you, start again."

**Look for changes.** As patients tell their story and respond to questions, watch for points of change, conflict, or confusion. Many patients who deny a precipitating event, for example, tell a story in which at the time they became depressed they experienced the death of a loved one or a change of fortune on the job. Inquiry into their experience of these change points in their lives can provide valuable information regarding the etiology of their problems. Also, themes that are repeated by the patient, such as feelings of failure or anxiety in heterosexual relationships, are usually indicative of important material.

**Elicit affect.** When there are verbal or nonverbal signs of affect, help the patient clarify what he or she feels with statements such as "That must have been pretty sad," or "It sounds like you feel angry about that." The way in which the patient responds to the interviewer's probe will illuminate the patient's degree of insight. On occasion, encouraging a patient to talk further about a subject that you noticed elicited nonverbal expression of affect will illuminate important feelings.

If a patient exhibits a depressed mood and you have reason to suspect suicidal thinking, be sure to talk with the patient about suicide, possibly by asking, "Have you ever thought of hurting yourself?" For a more thorough discussion of suicide, see Chapter 8 of this volume.

**Delusions and hallucinations.** Delusional patients may talk about their delusions, in which case it is important that the interviewer encourage the patient to talk about them without agreeing with or validating the delusions, either explicitly or implicitly. It is advisable to ask for more information by asking the patient to explain

the delusion, such as "Why is the FBI looking for you as opposed to someone else?" A good check for reality testing is to ask the patient why the anxiety, marital conflict, or whatever is happening to him or her. It is permissible to respond to patients' queries as to whether you see or hear their hallucination by saying that you do not see or hear it but asking the patient to describe it to you in detail.

**Empathy.** Empathy implies understanding, not necessarily agreement. The interviewer can identify a patient's affect without openly evaluating it. Many patients look for validation of unjustified feelings and attitudes and can easily entrap an unsuspecting interviewer who intends to empathize. For example, one patient complained bitterly that his parents had verbally and physically abused him as a child and talked of how angry he felt about the mistreatment. The student interviewer took the patient at his word and "empathically" responded, "Your parents certainly sound terrible. I can see why you are so angry." The student later discovered that the patient exaggerated the abuse in order to justify his drug abuse and disregard for his family. An empathic statement would have been "You seem to feel angry because you believe you were abused." Empathy reflects accurate perception of patients' feelings, but it should not imply concurrence with their reasoning.

**Taking notes.** Some interviewers feel apologetic about taking notes during an interview, believing that their full attention should be directed toward the patient. At the other extreme, overanxious interviewers write down practically everything a patient says, fearing that otherwise they will miss a vital piece of information. A middle course is preferable. Many patients reveal too many details for an interviewer to recall accurately. Sketchy notes taken during an interview can be filled in afterwards to ensure that important topics, dates, and names are correctly remembered. In addition, most patients perceive note taking as a sign that the interviewer is interested in them and takes seriously what they are saying.

**Silence.** Ideally the patient is more anxious during a period of silence than the interviewer, and consequently will break it by resuming the conversation. All too often, however, interviewers interpret a patient's silence as an indication that they should ask another question. If this happens, the interviewer is likely to miss important information about the patient out of concern that a proper interview be conducted. Most beginning interviewers (and some not-so-beginning ones) conduct terrible interviews because they are too concerned with their own "performance" and their demonstration of either exquisite skill or (they fear) exquisite stupidity. When this happens the interviewer is too self-absorbed to concentrate on understanding the patient.

If the patient is silent because he or she is obviously wrestling with a problem, it would be a mistake for the interviewer to break the silence by asking another question. Instead the interviewer should wait for the patient to resume talking. If

the patient appears to be withdrawing into an uncommunicative fantasy, or obviously intends to remain silent, the interviewer should respond with something such as "You fell silent after you said [the patient's last comment]," or "Are you uncomfortable because something is difficult to discuss?" If possible, help patients identify the feelings they are experiencing, thereby reassuring them that you want to discuss even difficult feelings with them. At times psychotic or depressed patients will become silent and will speak no further. On these occasions the interviewer should discontinue the interview and resume at a later time.

**Restless patients.** Occasionally an overly anxious or manipulative patient will want to get a drink of water or go to the rest room in the middle of the interview. Usually telling the patient that you are almost finished and asking him or her to postpone the trip to the water fountain or to the rest room until the end of the interview will be acceptable. Patients on certain medications experience dryness of the mouth to the point that they have difficulty talking without frequent use of a glass of water. Giving these patients water facilitates the interview process.

Some patients may pace the room restlessly. There is no point in insisting that they sit calmly; they would if they could. In most instances these patients will talk nonstop while they move around the room, and the interview data is readily available.

Under no circumstances should an interviewer attempt to physically prevent a patient from leaving the room. If structuring of the situation and a calm, reassuring voice do not settle the patient down, chances are that physical efforts will result in injury, most likely to the interviewer.

**Verbal behavior.** *How* patients say something is just as important as *what* they say. Pope (1979) refers to Miller's (1973) example of a patient who enthusiastically says, "Oh, isn't that wonderful!" and another patient who says the same sentence sarcastically: "Oh, isn't *that* wonderful!" (p. 22). Verbal signals such as tone of voice (Davitz & Davitz, 1959; Pittenger, Hockett, & Daheny, 1960; Pope, Blass, Siegman, & Rahe, 1970; Vetter, 1970), rate of speech (Chapple & Arensberg, 1940; Goldman-Eisler, 1952; Saslow & Matarazzo, 1959), and speech disturbances (Mahl, 1961) have been demonstrated to give invaluable information about a patient.

Pope and his colleagues (Pope & Siegman, 1965; Siegman & Pope, 1965, 1966) have demonstrated that interview topics which are anxiety-arousing for patients are disruptive to their speech patterns. Talland and Clark (1954) discovered that the more anxiety aroused by a topic, the more helpful and intimate it was to discuss it in terms of understanding the intimate problems of the patient, even though patients are usually less willing to disclose themselves on high-anxiety topics than low-anxiety ones (Jourard & Lasakow, 1958; Jourard & Friedman, 1970).

Several types of resistiveness have been identified: refusal to talk, superficiality, and use of disqualifying remarks (Watzlawick, Beavin, & Jackson, 1967). Pope

and his colleagues (Pope, Blass, Siegman, & Rahe, 1970; Pope & Siegman, 1968; Pope, Siegman, & Blass, 1970; Pope, Siegman, Blass, & Cheek, 1972) have investigated the effects of interviewee superficiality and resistiveness, their terms for two primary modes of patient resistance. The effect of such resistance is to inhibit patients' self-disclosure and discussion of psychologically relevant material.

**Nonverbal behavior.** Elaboration on the message contained in a verbal statement is provided by patients' nonverbal behavior, including their eye contact (Miller, 1973), physical distance (Sommer, 1974), gestures (Miller, 1973), facial expression (Dittman, 1973; Ekman, 1975; Frijda, 1953, 1958; Thompson & Meltzer, 1964), and body movements (Birdwhistell, 1963). Ekman and Friesen (1974) demonstrated that facial expression is the most salient of all body cues but that it is the easiest to deceptively manipulate. Their evidence suggests that body position, of which people are normally less aware than facial expression, is more honestly expressive of feelings and attitudes. The implication for the interviewer is to observe facial cues and validate them with those from the body. Accumulated research suggests that the voice is most easily made to deceive, then the face, and lastly the hands, feet, and body. Verbal and facial messages may be contradicted by those emanating from the hands, face, and body (Pope, 1979).

There is no doubt that patients say as much or more nonverbally as they do with the spoken word. The good interviewer not only notices nonverbal behavior, but also, on occasion, may call it to the attention of the patient and tie it to the topic at hand. For example, "I noticed that you began to tap your fingers as you started talking about your father." The reason for mentioning the behavior in this way is to further draw patients out, to clarify feelings, and to understand patients' reactions to their own behavior. A good interviewer can learn much about a patient or client by effectively mirroring some statement or behavior and carefully observing the patient's reaction. The interviewer must remember, however, that some patients are threatened by direct comment on their nonverbal behaviors, often to the point of seriously disrupting the interview. Therefore, this type of confrontation must be utilized with judgment. Overly anxious patients, those who have difficulty disclosing personal information, or those who evidence suspiciousness should not be so confronted in the initial interview.

### **The End**

Terminating an interview is problematic for many interviewers, usually because they are unsure what to tell the patient or how to best answer the client or patient's questions. Many patients anticipate a patient-doctor relationship in line with a medical model, meaning that they expect "answers" to their problems and that the "doctor" will take the lead during the interview (Johnson, 1973). This expectation poses difficulties for the interview process and is often particularly thorny at the termination of an interview. The interviewer must keep in mind that patients

rightfully expect him or her to share impressions and recommendations with them. This information must be given to patients in understandable terms and must be explained so that they get the message, without giving the impression that "answers" to their problems are being provided. Time must be allowed for answering whatever questions the client or patient has.

At the conclusion of the interview, the interviewer may summarize the process by identifying the basic points brought out by the patient. The interviewer can then briefly encapsulate the meaning of the patient's communications and provide recommendations. The cardinal rule is to communicate in language the patient can understand, or if the patient is too withdrawn or intellectually incapable, in language his or her family can understand. In the situation in which the patient's family must provide follow-up for him or her on the interviewer's recommendation, the interviewer must be alert to and supportive of their intention to do what is best for the patient. Such families often feel guilty that they are doing something unpleasant to the patient and often hold frightening misconceptions about mental health treatment. It is the responsibility of the interviewer to make recommendations that are realistic for the individual patient and that the interviewer genuinely believes will be helpful. For example, if psychotherapy is recommended, you must suggest therapists whom you believe are competent to help the patient. The interviewer also has a responsibility to make recommendations as indicated for treatment other than psychotherapy — for example, medical evaluation or religious counseling.

Some patients ask for a prognostic statement, such as "Is there any hope?", "Am I crazy?", or "Have you ever treated any cases like mine?" In these situations encouraging reassurance is often helpful, along with a restatement of the necessity for following through on the interviewer's recommendations.

It is important to leave time for patients to ask whatever questions they have. Not only do they appreciate this courtesy, but it also gives the interviewer an opportunity to evaluate the patient's understanding of the recommendations. Interviewers often make the mistake of giving the double message of sitting forward in their chair, indicating eagerness to terminate the interview, while asking if the patient has any questions.

Most patients can be relied on to make their own arrangements for recommended treatment. Occasionally there are patients who do not appear to be capable of making their own arrangements and who have little or no family support. In these cases structured, step-by-step procedures are helpful, for example, the interviewer may make telephone arrangements for appointments while the patient is still there. Recommendations can be written down for a patient, if necessary.

Novice interviewers often assume that the very fact that a patient is being interviewed in a mental health setting implies that he or she must have some psychopathology, if only the interviewer is astute enough to discover it. The interviewer then searches for a diagnosis that somehow fits and almost invariably recommends psychotherapy. While it is true that most people who are seen for an

initial interview have some concerns, they might not need psychotherapy or exhibit any true psychopathology. Interviewers should not feel compelled to find emotional disturbances where they do not exist. Some people will come to a counseling office when their real problem is medical, financial, or religious.

## SPECIAL PROBLEMS

### The Depressed Patient

The most common complaint in any mental health setting is depression. The interviewer must quickly learn that patients mean different things by the word "depressed." It is always advisable to ask patients what they mean by the term. In order to investigate the nature of the patient's feeling of depression, the interviewer should inquire about somatic functions, activity and energy level, and what the patient does for fun. Many depressed patients report that they feel listless, do not sleep well, and do not enjoy anything that they used to enjoy. The interviewer must be careful not to simply take patients at their word when they say they are depressed.

The depressed patient often seems relatively uncommunicative and may manifest such a helpless, dependent attitude that a friend or family member immediately takes charge and offers to talk to the interviewer for the patient. The patient's nonverbal communication of depression may be so obvious that a logical starting point for the interviewer is to comment on the patient's appearance of depression. It is not a good idea to challenge the patient's depression. The interviewer should express interested concern without agreeing or disagreeing with the patient's statements.

One problem that often arises with depressed patients is their hopeless feeling that it is useless to talk about their problems because no one can help them. Conversely, they often are so dependent that they seem to want the interviewer to tell them what to do or to solve their problems for them. An interested, professional manner and supportive encouragement is the best approach.

After patients have talked about their depression sufficiently, it is a good idea to inquire about their premorbid adjustment. Any information obtained about precipitating events is helpful. Suicidal thoughts should be explored if they are present (see Chapter 8).

### The Schizophrenic Patient

The schizophrenic often appears flagrantly bizarre, but not always. The alert interviewer can observe subtle signs of borderline psychosis. For example, the schizophrenic usually has difficulty coping with most everyday tasks and rarely finds real pleasure in anything. Schizophrenics typically display minimal affect.

thus the interviewer must be alert and try to elicit the accompanying thoughts as well as the meaning the affect has for the patient.

The schizophrenic might have trouble describing a chief complaint, and if asked, "What brought you to the hospital?" might answer, "A car." His or her confused thinking demands that the interviewer provide more structure than usual, and agitated schizophrenics or paranoids often need reassurance about the purpose and nature of the interview.

Schizophrenics often talk about bizarre or impossible topics, and usually their train of thought is difficult to follow. Interviewers should not make the mistake of giving such patients the impression that they understand the patient's logic or that they agree with or share the patient's delusions or hallucinations. It is at times reassuring to psychotic patients that the interviewer does not share their distorted view of reality. For example, a patient who loosely associates one thought with another might be told, "I don't understand the connection between your parents' divorce and your changing jobs," or "I lost you when you started talking about changing jobs." Certain patients who appear to be sensitive or paranoid might assume that you understand their illogic, even if they do not. It is usually best not to argue with them, as they can become agitated unnecessarily. Most psychotic patients will offer some explanation of their "logic," or state that they do not understand it either. A few patients will ask if you hear the voices, too. A reasonable approach is to answer that you do not hear the voices but that you are interested in the patient's description of them. Statements by a patient such as "My mind is being controlled from outer space," or "I believe Christ is coming soon; He told me so," can be handled by asking for further explanation. It is often helpful diagnostically to ask patients to explain how it is possible for their mind to be controlled or for Christ to speak directly to them. In all of these situations it is important to understand the patient's train of thought and the meaning to them of what they say.

If, during the interview, the patient becomes silent, call his or her name and try to engage him or her in discussing nonthreatening material. Many schizophrenics withdraw when asked a question about a disturbing subject. Give the patient plenty of time to formulate an answer and remember that even catatonic patients are aware of everything that goes on around them during their period of silence.

### **The Manipulative Patient**

The manipulative patient often catches the unsuspecting interviewer off guard with seductive behavior, angry outbursts, questions about the interviewer, and the like. These situations are best dealt with by maintaining a professional demeanor, reminding the patient of the purpose of the interview, and commenting on the patient's remarks in an appropriate manner. Patients may ask, "Have you ever felt like this?" or "Do you think I'm crazy?" as a way of eliciting reassurance. These questions are best handled by reminding patients that you are interested in understanding their feelings and experience. Nonthreatening interpretations of

affect are also appropriate, such as "You seem to feel that you are all alone with this problem."

Many patients want to concentrate on blaming others for their problems and try to induce the interviewer to give them advice that undoubtedly will not work, thus setting the interviewer up for blame. Patients often want the interviewer to agree with them about their perceptions and feelings, and in essence want to feel better without having to make changes in their own lives. The interviewer must be careful not to be seduced into agreeing with or feeling sorry for the patient and thus being manipulated into giving advice or telling the patient simply what he or she wants to hear.

### The Seductive Patient

One type of manipulative patient deserves special mention because of the harm that can be done if the situation is not handled well by the interviewer. Some patients are sexually suggestive or seductive, either as a defensive maneuver to avoid dealing with sensitive material or as a manifestation of their characteristic way of dealing with people. In either case the seductiveness must not be encouraged, for to do so would be injurious to the patient. It is never appropriate to take advantage of the person in conflict who comes to you for assistance.

For example, this writer became aware of problems a male student interviewer was having in terminating a counseling relationship with a female patient who had entered therapy because of unsatisfying heterosexual relationships. The problem quickly became evident when the counselor, who had recently been divorced, played a tape of a recent session. The clinking of ice in glasses could be heard, and there were references to cards and letters the patient had sent to the counselor proclaiming that she felt warmly toward him and was distressed that he was completing his training and planning to move out of state. The counselor was to a large extent unaware that his divorce and subsequent loneliness had left him vulnerable to flattery, and that he had so enjoyed this patient's attention that he had actually encouraged her seductive behavior toward him. The patient had brought martinis to the session he had tape-recorded, and instead of discussing her feelings and behavior in a constructive way, he had enjoyed the drinks with her.

As another example, this writer recently saw a hysteric adolescent girl on hospital consult. She was seductively attired in a nightgown and lying on top of her bed. The solution was to politely ask her to put on her robe and come to an office down the hall for the interview, thus creating a less intimate setting.

It is rare that a clinician would decide to confront a patient directly about seductive behavior in an interview situation, since that tactic is more appropriate for the therapy situation. Nonetheless, the interviewer must be alert to his or her own attitudes and emotional reactions and to those of the patient so that an appropriate response can be made. The simplest approach is to keep the interview on a professional level and to avoid appearing overly friendly or encouraging. If

the patient's seductiveness is interfering with the progress of the interview, a statement reminding the patient of the purpose of the interview and of your role as the interviewer should suffice. Keep in mind that some naive seductive behavior is pathognomonic of certain patients, for example, hysterics, and would be impossible to eliminate during the course of one interview. Also, such patients can easily become offended if you suggest too strongly that they are behaving seductively. Most behavior of this type can be kept within reasonable limits by a gentle reminder of the purpose of the interview and by not allowing the patient to pursue indefinitely topics that lend themselves to seductive or suggestive behavior. Once the presence of a seductive process has been established, you can steer the interview toward more factual areas for a time and thus defuse the situation.

## THE MENTAL STATUS EXAMINATION

The Mental Status Examination used to lie primarily in the province of psychiatry, but it is such a useful tool that practitioners in other mental health disciplines have begun to appreciate and use it. The examination amounts to an organized method of classifying and reporting information received during a diagnostic interview. It is not an outline to be rigidly followed during the interview; such a formalized procedure would defeat the interview's purpose. In practice most information relevant to the Mental Status Examination is produced during the course of any good interview. If certain hypotheses (for example, schizophrenia or organic brain dysfunction) are still unconfirmed toward the end of the interview, selected items from the outline may be asked directly.

Although the Mental Status Examination is useful in all interview situations, it is particularly helpful when one is conducting a brief hospital consult and must arrive at a diagnosis and recommendations. In the hands of a skilled interviewer, the Mental Status Examination assists in a thorough exploration of relevant topics. The Mental Status Examination is best learned after one has some experience and has become comfortable interviewing a variety of patients representing various diagnostic categories.

We shall discuss the categories of the Mental Status Examination\* in an order conducive to writing a logically formulated report or chart note. The actual use of the examination should be performed in an order consistent with the progress of any particular interview. The outline which follows has been developed by Dr. John Rush and adapted for inclusion in the present volume by this writer. An out-

\*Another outline for the Mental Status Examination, attributed to F. T. Meigs, is quoted in Rosenbaum, C. P., & Basbe, J. E. *Psychiatric measures: Crisis, clinic, consultation*. New York: McGraw-Hill, 1975. A brief form of the Mental Status Examination is given by Kahn, R. L., et al. Brief objective measures for the determination of mental status in the aged. *American Journal of Psychiatry*, 1960, 77, 326 - 328.

line for recording the results of a Mental Status Examination was developed by the present writer based on the Patient Evaluation Report presented in Meldman, McFarland, and Johnson (1976) and appears as Appendix 5 at the end of this chapter.

### **I. Appearance and Behavior**

This category contains all information pertinent to the patient's conduct and manner of presenting himself or herself during the interview.

1. **General description.** Demographic information, such as name, age, race, sex, marital status, children, and occupation, along with a description of salient physical characteristics (height, weight, posture), grooming, and dress.
2. **Motor behavior.** Gait, hyperactivity, eye contact, peculiar or identifying movements, tics.
3. **Expressive mannerisms.** Verbal or nonverbal expressions that appear to be relatively characteristic of the individual patient (for example, lip-smacking, "you know," gestures).
4. **Attitude of patient.** Data relevant to the patient's attitude toward the interviewer and the interview situation (for example, compliance, defensiveness, cooperativeness, hostility, friendliness, seductiveness).

### **II. Sensorium**

This category contains information relevant to the functioning of the central nervous system. Any questions of organic brain dysfunction due to any cause would be investigated here.

1. **Level of consciousness.** Any impairment in general alertness, responsiveness, or consciousness, whether consistent or fluctuating.
2. **Orientation.** *Time* (month, day, year, approximate time of day), *place* (the name of the place where the patient is), *person* (the patient's name), and *present situation* (the patient's awareness of the fact that he or she is being interviewed). Orientation must not be inferred; it must be tested by direct questioning. The interviewer should not be uncomfortable asking for the patient's full name at the beginning of an interview. Asking time, place, person, and present situation questions requires a tactful approach, but is necessary if organicity is suspected.
3. **Attention and concentration.** Normal attention is usually inferred if the patient can attend to the interviewer's questions and comments and does not evidence easy distractibility. The patient who frequently asks that questions be

repeated does not exhibit normal attention. Concentration is tested with "serial sevens" — the patient is asked to count backwards from 100 by sevens. The procedure should be described as starting with 100, subtracting 7, and subtracting 7 from each consecutive answer. An example — "100, 93, 86" — is advisable.

**4. Memory.** Memory must be tested in three spheres:

a. *Immediate.* Tested by asking the patient to recall news events, visitors, activities, or meals that occurred within the past twenty-four hours. Do not ask anything that you cannot verify as accurate.

b. *Recent.* Tested by asking the patient to recall personal events (verified) or news items that happened within the past two weeks.

c. *Remote.* Tested by asking the patient to recall events that occurred longer than two weeks ago. Examples are significant news events such as the year of President Kennedy's assassination or man's landing on the moon. Most patients will answer by recalling their personal activities at the time they learned of the event.

### III. Thought Process

Both production and continuity of thought must be considered in evaluating a patient's thought process. Psychotic patients have difficulty maintaining a logical, coherent, smooth-flowing thought pattern and will seem hard to follow because their train of thought is unclear. Circumstantiality, tangentiality, blocking, and loose associations should be noted in this category. Formal testing of thought process is unnecessary because the patient's speech during the interview will make evident any problems in this area. Schizophrenic patients may demonstrate a thought process disorder by exhibiting tangentiality, for example: a schizophrenic man may be talking about his mother and all of a sudden be giving details about his job. A tangential patient often leaves the interviewer wondering how the patient achieved the topical switch unnoticed.

### IV. Thought Content and Intellect

Several areas are included in this category, each of which gives valuable insight into the patient's problem.

1. **Characteristic topics and issues.** What does the patient like to talk about? What topics keep coming up? Note should be made of these areas of interest, conflict, or preoccupation because they give the interviewer clues to what is going on in the patient's mind. This writer recently saw a patient who began an interview by talking about how badly he felt because he drank too much, but during the course of the interview he spent a great deal of time discussing problems with his wife, thus giving an insight into the marital conflict that turned out to be the true source of his drinking problem.

2. **Relationship to reality.** In determining the nature of a patient's psychosis, it is important to assess the degree to which he or she is unaware of reality. Autistic thinking, delusions, and hallucinations should be noted with special reference to their content, the manner in which they are expressed, and the affect demonstrated by the patient.
3. **Concept formation.** The interviewer should note whether or not the patient can easily form generalizations and abstractions. Questions useful for this determination are items in the form of the Similarities subtest of the WAIS and proverb interpretation. Most clinicians interpret bizarre responses as indicative of psychosis, concrete interpretations as suggesting an organic process, and low-level abstractions as revealing intellectual deficiencies. Examples are: "An orange and a banana are alike because they both reflect light" (bizarre); "The grass is greener on the other side of the fence because the farmer fertilized and watered it" (concrete); "Liberty and justice both have to do with government" (poor abstraction). Relatively simple abstraction items and familiar proverbs are more useful in the interview situation than obscure, highly intellectual items.
4. **Morbid preoccupations.** Persistent or intense reference to death, suicide, destruction, gruesome descriptions, dead or decaying matter, rotting corpses, and the like are often thought to be indicative of a psychotic preoccupation or severe depression. If the patient brings up such a topic, the interviewer should encourage exploration so as to uncover the nature of the preoccupation. Inquiry is also needed to determine that the subject is indeed a preoccupation. Depressed patients may indicate that they once thought of suicide or once had a disturbingly morbid dream, but may have no symptoms of an actual preoccupation. If a patient mentions thoughts of hurting himself or herself or of suicide, the interviewer should prompt a discussion of the issue, since many patients lose their suicidal intent after discussing it in detail — the mystique wears off when discussing the particulars. It is also wise to ask what plans the patient has made for suicide. Carefully worked-out plans and procurement of the means of suicide (such as guns or pills) often indicate serious risk. Patients who talk about friends or family members who "will be sorry" usually intend a suicide attempt rather than death, because they want attention. These are high-risk patients because through miscalculation they are often accidentally successful suicides.
5. **General intellectual evaluation.** Observation of the patient's vocabulary will allow the interviewer to judge whether the patient is below average, average, or above average intellectually. A general rule of thumb used by many clinicians is that the use of three-syllable words indicates average intelligence. Intellectual

level is important in understanding a patient's pathology and how well he or she can be expected to understand it. It is also important for treatment planning. How well can the patient utilize verbally oriented psychotherapy? Would bibliotherapy be useful? Or does the patient need a more concrete, experiential approach? What goals can be set for discharge in terms of self-sufficient living and occupational success?

6. **Insight and Judgment.** Evaluation of insight and judgment is important in determining treatment approach, reality orientation, self-awareness, and self-sufficiency. It is usually thought that patients exhibit insight if they are generally aware of what is wrong with them. Patients who deny apparent problems, project blame or responsibility, or believe that their problems are caused by X-rays from outer space, for example, do not demonstrate insight. Judgment is shown in patients' awareness of what should be done about their problems. The patient who asks to see a doctor because he or she is having hallucinations exhibits good judgment. The patient who talks back to the voices he or she hears rather than seek help does not.

## V. Perceptual Disturbances

Any impairment in perception should be noted in detail. It is thought that auditory hallucinations are usually due to functional psychoses, whereas visual or olfactory hallucinations usually stem from organic or chemically induced psychoses (Dette & Jarecki, 1971). Patients withdrawing from drugs may experience auditory hallucinations in the form of sounds or voices, but in contrast to the schizophrenic's hallucinations, these are experienced as externally rather than internally produced (Bilz, 1959). Any aberration in the patient's perception of reality is reason to hypothesize a psychotic process. The interviewer must then take pains to distinguish the type of psychosis, whether functional, drug- or alcohol-induced, or organic. The diagnostic differentiation here is crucial for determination of proper treatment.

## VI. Emotional Regulation

1. **Mood and affect.** Identification of the patient's prevailing emotional tone (mood) and the individual expressions of affect must be noted. For example, a male patient might seem predominantly depressed but exhibit anger when describing getting fired from his job. Both verbal and nonverbal cues must be taken into account, for it is rare that patients will directly define what they are feeling. Some patients even deny obvious affect. The interviewer should be observant for mood and affect cues and follow them up with further observations and questions. For example, a female patient whose voice quivers when she describes the death of her father might not directly identify the anger that accompanies the sadness unless the interviewer notices her clenched fists and comments that she appears to be feeling more than sadness.

2. **Subjective and objective evidence.** Both must be noted. Subjective evidence includes direct verbal expressions made by patients ("I feel sad"), which are based on their perception and experience of their own feelings. Objective evidence is that which can be identified by any observer (crying, voice quality, clenched fists) as denoting a particular feeling quality.

3. **Appropriateness.** Affect that is appropriate or inappropriate to the content being discussed is noted. Appropriate affect is observed when, for example, a patient expresses regret that she did not get a job she had particularly wanted. Inappropriate affect is seen when a patient laughs when describing her mother's death. The fact that such behavior is indicative of conflict is precisely the reason for noting it.

4. **Ambivalence.** The presence of two or more conflicting feelings experienced at the same time in relation to the same object (person, place, situation) is noted as ambivalence. For example, a patient states that he loves his father, who is a no-good, despicable bum. It is not ambivalent if the patient says he loves his father and later in the interview states that he hates him. The conflicted feelings must be experienced simultaneously, indicating in this example the patient's indecisiveness regarding his feelings toward his father.

5. **Depersonalization, derealization.** The presence of a perception that one is not real, as if one is outside of and observing oneself (depersonalization), or that one's environment is not real (derealization), is indicative of serious emotional conflicts and is noted in the particular way the patient experiences it.

## VII. Volition

A general assessment is made of the patient's ability to willfully direct a course of action and follow it through to completion. Can the patient, for example, hold an eight-hour-a-day job? Is the patient able to express spontaneity and flexibility? These issues are important in diagnosis, treatment planning, and discharge planning.

## VIII. Somatic Functions

Disturbances in *sleep, appetite, weight, or sexual functioning* are important because they often signal psychological dysfunction.

It is noted by most clinicians that difficulty in falling asleep is usually indicative of acute dysfunction, and early morning awakening of a chronic dysfunction. The patient who takes more than thirty minutes to fall asleep is probably experiencing a short-term, reactive type of problem. The chronically dysfunctional patient complains that he always wakes up long before the alarm rings. Anxiety and excitement usually accompany difficulty falling asleep, whereas sadness and

psychomotor retardation accompany early morning awakening (Detre & Jarecki, 1971). Many professionals find that difficulty in waking up is often a symptom of depression.

Psychiatric difficulties, particularly those that are acute, disturb the ordinary functions of daily living. Appetite disturbances are common, particularly loss of appetite, as are concomitant weight fluctuations. Some patients complain that when they feel depressed, for example, they overeat. When inquiring about appetite and other somatic functions, the interviewer should take care to ask questions in a way that does not lead the patient to an answer. "How is your appetite?" is preferable to "Have you lost your appetite since you have felt depressed?" "Tell me about your sleep" is better than "Do you have trouble falling asleep?" Patients who want to exaggerate or mask illness can easily pick up clues to specific symptoms from leading questions. It is always best to begin questioning in an area of interest by asking a general, nonleading question. More specific questions can be asked later if necessary.

Loss of libido or other sexual disturbances often accompany psychological problems. Most beginning interviewers are more reluctant to explore this area than are their patients. A question such as "How is your sex life?" will introduce the subject if the patient has not done so. Obviously a short answer such as "Fine" tells you nothing, and you must ask further questions. Often this subject is easily raised when the patient is talking about marriage or dating relationships. As with most items on the Mental Status Examination, the interviewer should be flexible, introducing the topic of sexual functioning at any point in the interview that seems most natural.

## SUMMARY

The mental health interview is presented in this chapter as a special kind of communication interchange, in which the interviewer must be sensitive not only to what patients say and how they say it, but also to what the interviewer explicitly and implicitly communicates to the patient. In order to accomplish an effective interview, interviewers must determine the purpose of the interview with each interviewee. They must be aware of both interviewer and interviewee factors that affect the course of communication. Consideration must be given to the setting in which the interview takes place, since various environmental characteristics have different effects on the process and content of the interview.

The interview is discussed in three basic sequential stages — beginning, middle, and end — in order to highlight important variables at each phase of the interview. There is also a section concerning the special interview problems presented by the depressed patient, the schizophrenic patient, the manipulative patient, and the seductive patient, and suggestions are made for dealing with each situation. The chapter concludes with a discussion of the Mental Status Examination as a useful tool in various interview situations.

JOB DEVELOPMENT AND PLACEMENT

## JOB DEVELOPMENT AND PLACEMENT

Joseph Marrone, M.Ed.

Job placement and job development are the parts of the rehabilitation process that involve getting people to work and getting them to stay on the job, a particular concern with persons having a psychiatric disability. On one hand, job placement is something to which everyone can relate because everyone has some of his or her own experiences in this area. On the other hand, there is very little magic in this topic. Job development and placement involve a lot of hard work. You hear many experts discuss the same general principles, but when you try to put these principles into practice it still seems hard. With time it may get easier, but it might not stay easy. The focus of this section is on the job placement problems of persons with long term mental illness.

A number of issues arise as special problems with job placement in general, but especially with persons having a psychiatric disability. For example, "How do I know when someone is job ready?" What happens if I am in charge of job placement and I am told that the client is job ready, but I have doubts? What is the specific information concerning social security that might help clients in terms of returning to work? Finally, there is the issue of self-control. This might be called the "Lizzie Borden Syndrome." People are not worried about hallucinations or medication compliance issues with persons with psychiatric disabilities. Instead people worry, "Is this person one of those crazy people who's going to take an ax or shoot someone?" No one, or very few people certainly, explicitly says this, but you can often sense their fear.

Effective placement has very few magical techniques or answers. It is a

lot of hard work, trial and error, and hypothesis testing. To do effective placement you must focus on the principles behind the activities. Basically, this section introduces these concepts and focuses on answers to specific questions.

There are differing views of the mental health worker's role as an advocate. Some people say, "Isn't it good that the counselor was that involved in advocating for his or her client?" Others might say, "This rehabilitation counselor's crazy! Where did she get the idea of computer programming?" Part of this conflict of ideas has to do with systems and bureaucracies. There are also some underlying reasons why the mental health system's view of clients and their placement differs from that of the vocational rehabilitation system's view, and it is important to understand these reasons. The Resource Manual includes articles in which these issues are addressed. While there are service issues and premises regarding job placement which are important to review, a counselor's values are also an influential factor. It is necessary to be clear about the counselor's values regarding job placement especially with persons who have psychiatric disabilities.

S.1

## **PERSPECTIVES ON THE JOB PLACEMENT PROCESS**

Three different perspectives on the job placement process will be covered in the following discussion: client centered, employer centered, and system oriented factors. The client centered aspects of job placement include the teaching of job seeking skills and the operation of job clubs. Also of concern is what you teach a client to say about him or herself -- the issue of passing. Olshansky's article in the Resource Manual discusses passing. If the client is not going to pass, how do you explain the psychiatric disability in

ways that an employer can tolerate? How do you provide support to the client and the family concerning this very stressful issue? And, how do you use follow-up as a strategy for prevention, as well as for crisis intervention?

In examining the employer centered point of view, the counselor begins to think about advocacy. In essence, changes in employer attitudes through advocacy lead to an environmental modification for clients with long term mental illness. Marketing is another employer centered aspect of job placement. Every vocational rehabilitation agency in the country is involved in marketing. Table 1 lists some basic marketing strategies. On-the-job training (Table 2) and targeted job tax credits are also employer centered issues. Another issue is how to deal with employers who say, "I want to hire a handicapped person. Get me somebody in a wheelchair. I don't want one of those crazy people." Addressing this might involve talking to the employer regarding concerns about a specific client as opposed to marketing agency services too broadly.

S.2

S.3

S.4

S.5

**Table 2**

**On-the-Job Training Works for the Employer and the Agency**

---

**You Get:**

- A pre-screened, motivated, skilled worker trained to your own specifications
- Payment for your company's services as a trainer
- Targeted job tax credit from the time the VR payment ends
- Back-up and support services from VR at your request

**The Worker Gets:**

- A skill
- A job
- A salary

**Who Would You Consider For OJT?**

If one of our clients is not as fully qualified for a job in your company as other applicants, yet you do believe he or she can learn the skills required on the work site, you may want to consider entering into an OJT arrangement with us.

**How Does It Work?**

Once you have identified the job in your company and a client of ours suitable for OJT, the rest is simple. You would sit down with one of our staff and the client to agree on what skills need to be taught, who will do the teaching, how it will be done, the amount of time needed for the training (usually less than 6 months), and minimum acceptable standards of performance which will signify successful completion of the training.

You and the VR staff member will also arrange a mutually acceptable payment (in an amount up to a maximum of \$22.00 per day over the length of the training) for your company's services.

**What Is Your Commitment?**

- Provide the training as agreed upon
  - Maintain a good faith effort to retain the trainee as a regular employee provided that he or she performs at the level specified in the training agreement.
-

System or environmental issues might involve the financial incentives under Social Security called 1619A and B or Social Security rules for Impairment Related Work Expenses (IRWE). The essential question is how can clients continue their benefits?

Effective job placement begins with a placement plan for a client that specifically deals with who is doing it, when is it being done, and how is it being done. When counselors set up a plan that describes placement, measurable performance criteria is the section that is often omitted. When you get to placement, the goals tend to be fairly clear, "I want to get a job as a \_\_\_\_\_." What is almost always neglected, however, is who is responsible for that specific activity. Getting the job is not an activity, it is an outcome. Everybody, whether overtly or covertly, always thinks somebody else is doing it. The client comes in and says, "I thought that was your job." VR counselors have the standard rap, "I can't get you a job. You have to get a job yourself. I can only help." So, in terms of the placement plan, mutual responsibilities are an issue. Transitional employment and supported work will be discussed as a system modification especially useful for placement of persons having psychiatric disability. Where do these techniques fit in terms of the total placement concept?

It is important to keep in mind that we are dealing with clients who have a lot of problems, sometimes the least of which is their disability. These problems may be related to social, economic, or political issues. Billie Holiday said, "You got to have a little love in your life and a little food in your stomach before listening to any damned fool's sermon about how to behave." When we talk about motivation and follow through, we need to remember this idea as a context. Persons who are in human service agencies need to be

aware of the full scope of these issues when they think about job placement.

### **SOME SPECIFIC PROBLEMS OF JOB PLACEMENT**

**Problem:** "My clients with psychiatric disabilities complain that the plans are too slow for them. They don't want to go through the evaluation. They want to get out on a job. Then you don't hear from them for 3 months. Next, you find out that they lost a job."

This is a frequent scenario. A client is frustrated and impatient, so he or she goes out and gets a job, only to lose it in a couple of months. Then he or she calls you up. What comes to mind? Do you say, in your head, "I told him so," or "I wish she hadn't done that"? Or do you say, "Gee, that's good, he worked for three months"? What is your gut reaction? The client has a right to be impatient, and you, too, are impatient because you couldn't help him or her more. What are you calling job readiness? Is job readiness when the client thinks he or she is ready? The counselor might not agree.

**Problem:** "I've been having problems when I work with a client toward a specific goal. That is, I have to amend the goal several times in the course of my work with the person because of crises or because of a number of other factors that come up. For example, I am now working with a client who has manic depression. We started out with the goal of training because she had all the background necessary to get into a clerical training program. She stayed in the clerical training program at OIC for about 3 months and then she began to have family problems. She lost her public assistance. She has one child and she had babysitting problems. There was nobody else; so she had to drop out. Because of the fact she was in crisis, she was then referred back to her therapist for a period of 2 or 3 months. When she came back to me again, we had to start all over. At that particular point she was not interested in going back to training, feeling it was too stressful. We also felt that she could not go back, so we tried an on-the-job training slot."

This scenario presents the issue of the cyclical nature of the disability. What you have to deal with is the fact that you have a plan going, a crisis occurs, and then you start back at square one. That's tough, but it is one of the key characteristics of a psychiatric disability.

**Problem:** "Sometimes I have difficulty in terms of selling or marketing the client because of the questions I get regarding the disability. It is easy to get into limitations in terms of physical disability, but not with psychiatric problems."

One of the things we advertise to employers is that we have all this information about our clients, and then, all of a sudden, we become reluctant to disclose some of that information. In this case you are not only in a bind about societal expectations, but also about what your own agency is marketing.

**Problem:** "I feel that if a client gets a job on his or her own, even if he or she only holds it for 3 months, it says a lot about the client. Whether or not the job was realistic and whether or not the client was complying with a treatment plan can eventually be used in working with the client if he or she comes back to the agency. I think it is a good sign that a client has the where-with-all and the self-esteem, a feeling of self-worth, so he or she can go out and find employment, whether it is realistic or not."

It is fine to say that the way you learn things is to try them, but how do you minimize the disruption of 35 failures? It is one thing to say look what you have learned, but it is still very hard on the ego. Trying shows real strength. The problem is how do you keep that motivation, how do you keep that ego strength?

#### **PREMISES REGARDING PLACEMENT**

The premises about placement described in Table 3 relate to a value system, not just to techniques or skills.

S.6

**Table 3**

**Premises Regarding Placement**

---

- System vs. individual placement skills
  - Interviews generate job offers (1 in 7)
  - Myth of the ideal worker
  - Advocacy as environmental modification
  - Persons with chronic mental illness want to and can work
  - Vocational choice as hypothesis testing:
    - Situation specific assessment data
    - Information gathering
    - Not only one correct choice
  - Employer relations are a means not an end
  - Action + Words = Values
- 

**System vs. Individual skills.** Job placement is much more a function of the system than of individual skills. Simply put, this means that people get jobs based on getting to where jobs are as quickly as possible. In other words, the quicker the client gets to the job openings and the more job openings for which he or she applies, the better the chances of success. There is a much higher degree of success using this strategy than there is in simply learning good job seeking skills. This does not mean that job seeking skills are unimportant. This does not mean that marketing is unimportant. It means that, in terms of designing a system both for your clients and your agency, you need to focus on what is most important. If you had only two clients, you could go out and pound the pavement. When you are talking about a system for yourself, you need to make some choices. One of the choices counselors are encouraged to make is to develop a broad based system. Get people to jobs as quickly as possible rather than doing lots of job seeking skills, lots of job clubs, lots of individual marketing, or lots of visits to employers. This doesn't mean that the other activities are less

important. It means that an efficient system generates more success for clients than skills-building per se.

Interviews generate job offers. Interviews are the one aspect of a system that will lead to jobs. This does not necessarily mean sitting down in the personnel office for a formal 45-minute interview; but talking to an employer is what generates jobs. For persons who are disabled, as well as for the general population, roughly every seven to ten job interviews lead to a job. Now for some clients that means 40 interviews, for others that means one. If you follow a vocational rehabilitation system serving several hundred people over a year's time, this statistic holds up fairly well. So your goal should be to get clients job interviews. One of the main implications here is that you err on the side of sending a client to the interview before job readiness is certain. This does not mean that you ignore screening clients. It does mean that there is large gray area which contains those judgment calls. "Now, will I blow this for both the client and the employer if I send someone who's not ready or doesn't do well in the interview? On the other hand, I don't want to keep someone away from an opportunity." Interviews produce jobs.

The father of the job club, psychologist Nathan Azrin, operated on this idea. The belief that interviews produce jobs was the focus of all the job club activities. Azrin based his model on two major premises. First, get people to as many interviews as possible. What you are looking for is an interview not a job. Employers will turn you down for a job; but fewer will turn you down for an interview. The second premise is that clients need a lot of support when seeking jobs and we need to build up a support structure to

operate during the difficult time of the job hunt.

**Myth of the ideal worker.** Hiring often is not done to find an ideal worker or even done in a logical manner. One of the assumptions in traditional job placement training is that if the vocational counselor does his or her homework and the client does the homework of identifying skills and knowing the job, that the hiring process will be logical. You present a neat package to the employer. What employer can argue with that logic? But most of us deal with employers who are not always logical. This does not necessarily mean that they are not good employers. It might mean that they do not have the time, they are not trained in personnel selection, or they are not interested.

We have all probably been employers ourselves from time to time. Have you ever had your house painted or hired a plumber? In one way or another, you have been in the employment business. What you look for when you hire someone, whether it be a plumber, a painter, or a person to sell cookies, is the best person available, not the ideal person. If you have more time, you look for someone who is recommended and can do the job well at an affordable price. It does not matter that there might be 40 better plumbers. You just care that the work gets done well enough for you. When we talk about hiring in the abstract, we must be careful not to create the ideal employment candidate, one who has no limitations. In fact, hiring is not that ideal.

**Advocacy as environmental modification.** In an average group of clients, about 25% will interview worse than their job skills indicate. Over the last

few years, one of the new ideas in rehabilitation has been to view employer advocacy as an environmental modification. Sometimes rather than teaching interviewing skills, we need to find an employer to whom we can say, "Give this person a chance. I will tell you right now he interviews poorly." This, however, is easier said than done. Five years ago most vocational rehabilitation counselors would have said the client was not job ready because of the lack of interviewing skills. The interview was an essential part of the job, and if the client could not interview, then he or she was not job ready.

There are many ways to address the lack of this specific skill. One way to help the client mitigate the effects of a poor interview is to avoid it all together. Any personnel journal will tell you that the employment interview is the least reliable predictor of work performance. Everyone knows that, so why do it? Employers know no better way. They are comfortable with the system and it keeps personnel departments in business. The counselor needs to be aware of these facts. The process is not logical. Maybe it is reasonable to change the expectation of the employer since the interview does not predict much anyway. This might be preferable to constantly putting the client into situations where performance is poor.

Persons with psychiatric disability want to and can work. Counselors need to believe that clients who have chronic mental illness want to and are able to work. If you do not believe this, you are in the wrong line of work. Rehabilitation counselors believe people want to work. Financial disincentives are a real issue, but most people do not decide whether to work based on how much they get from welfare or Social Security.

**Vocational choice.** The process of job choice or the narrowing down of job options is, in fact, hypothesis testing. It is very natural to go through a narrowing process, but the only way really to learn is to try the job. I asked several vocational rehabilitation counselors how they obtained their jobs. Did they know they could do placement or be rehabilitation counselors? Most of them did not. Even if you have a masters degree in rehabilitation counseling, you do not really know that you can become a successful rehabilitation counselor. Even if you are a rehabilitation counselor, you might not want to work for vocational rehabilitation. So the process of job choice involves experimentation and is not narrowed down to only one right answer. One of the major issues in vocational counseling generally, but especially with persons who have chronic mental illness (who do not have a lot of success, who are scared, who will probably need a lot more support than you or I might) is to convince clients that they are able to choose from alternatives, to test the choice out, to return for further evaluation, and to move ahead. Hypothesis testing is the hardest part of vocational counseling. When a client comes for vocational counseling, he or she wants you to choose something. Then the client wants you to prove that it is the right choice. Job choice is often paralyzing. Most of us experienced this as we finished school. We have the fantasy that our decision is going to put us on a track that we can not get out of for the next fifty years!

Often the focus of the rehabilitation goal is wrong. There is nothing in the rules of the vocational rehabilitation system that prohibits changes in the vocational goal. If you've read the regulations, you know you can amend an IWRP; you can change a vocational goal. But if your supervisor says, "Well, you need some rehabs," this becomes a real issue. We should not hold the

client hostage to our values. In fact, we need to develop some preliminary hypothesis testing.

Focusing on one goal at a time makes sense for practical reasons. That, in fact, gives you more flexibility. The more specific you are about a goal and the reasons for it, the more flexibility you have if that doesn't work out. You say, "We went here, and we are moving to the next logical step, here." Sometimes the next step might be to address a different goal not related to the first, but the progression is logical.

On the videotape you see that Sam went through a little bit of this hypothesis testing. Apparently he had come up with the idea of computers. He tested this idea out in his own head, just in passing. So you need to view the process of job choice as a process of elimination and as hypothesis testing. It is not a lot of data gathering that comes up with one choice that is honed in on by the client as the solution to everything. It is very logical and natural for people to change job choices. We all do. We should not hold our clients to different expectations and vocational development processes than those we hold for ourselves.

## THE PLACEMENT PLAN

Even though the IWRP is set up to accommodate a placement plan, few people ever actually do it. A placement plan is used to organize your time and structure your own activities, and to make sure that as many people, including the client, are involved, as possible. This one sheet specifies who is going to do what, when, with whom, and when evaluation occurs. Who is going to call how many employers? How many companies are you going to look for in the Yellow Pages? When are you going to meet to discuss this?

The placement plan helps the counselor use the limited time more efficiently. We said this is what we are going to do. What did we do, what didn't we do? Who else can help?

One of the fascinating things that we discovered at our placement unit was that after 6 months the clients, even clients with whom we thought we had done well, were very disappointed in a many of the services. Clients were surprised that they had to compete on interviews with other clients. They said, "I thought you were going to get me a job. I went to an interview and five other people got hired, not me." If we secured an interview or a job by looking in the Yellow Pages and then calling, clients would say, "Well, I could have done that myself. I was expecting something different from you." We realized, however, that we had made some assumptions about how we would go about our business. Both staff and clients needed to be clear about this. So we developed a simple letter regarding what the agency would do in placement, what the client would do, and how we would go about working together. For example, the client was told that we would be using the Yellow Pages or want ads and that he or she would be competing with others from the same agency. Although some counselors believe that only one client should be sent for the job interview, in reality, it is a good idea to show employers that you have a source of potential workers. Also, the process of going for interviews can help to desensitize some anxious clients.

Knowledge about the world of work is over-rated. There are too many jobs out there for anybody to know about all of them. You can start right now and spend the rest of your life, but you still won't know enough about all the jobs that exist. There are certain kinds of jobs, however, that many clients get and it would make sense to know about these. More important

than becoming an encyclopedia of knowledge is thinking about the kind of job a client wants to do. What is important to have the client or counselor check out what is involved in the work? You may need to call up employers, for example, and find out if they will hire those with a high school degree or only those who have gone through a certain type of vocational training.

That is the way you get knowledge - with a little bit of a detective approach about some specific vocational choices. It is not a wise use of your time to try to become an expert about many different jobs. That is an impossible task. You should, however, know the difference between the service industry and the manufacturing industry. You should know about federal government employment and some of their basic jobs, and who the big employers are in your area.

Placement planning goes on throughout the rehabilitation process. Rehabilitation counselors often do not make use of employer's reports and the work history as sources of diagnostic information in order to assess a client's job functioning or job readiness. In the initial interview, counselors get more information about the exact medication level than they do about the client's previous job or why the client left. One reason for this is that employers are often reluctant to give counselors information. In spite of this we need to make a concerted effort both to contact previous employers, who are an important source of diagnostic information, and to take a much more thorough work history. This history goes beyond finding out where a client has worked.

The client does not always give functional data. The client may tell the outcome, but not the reasons for the outcome. Was he or she fired for low production or for absenteeism? People think of fired for absenteeism as a specific reason. What is your definition of absenteeism? What do you think

is too much absenteeism? I do not know what too much is. I know some employers people who would fire you for being out one day in 6 months. I know others who allow employees to take a day a month and never notice. So even knowing that a persons was fired for absenteeism doesn't reveal the functional data that rehabilitation counselors need in terms of job placement.

Why was Sam fired? He was fired for absenteeism, but no one seemed to have a big problem with his absenteeism. Was his absenteeism different than the person who was fired for being absent the same number of days because he or she decided to sleep late? In this case Sam's absenteeism raised a different issue. When you are assessing a client, know what information is useful in order to help him or her get back to work. However, there are some practical limits to this. I can tell you about counselors I have supervised who would be willing to spend days trying to speak to the psychiatrist who treated their clients three times over 4 years ago. However, these same counselors would assume that because these clients worked a short term job at a hamburger stand 6 months ago it would not be worthwhile to check that out. They would not even give that job experience a second thought.

It is a question of intent and approach. If we are assessing work disability and work readiness, then the most accurate way to measure this is to look at the client's functioning at work. This does not mean he or she cannot change the behavior; but the best assessment data available is previous performance in a similar environment. What is more environmentally specific to a client's role as a worker than to assess the client's capacity to be a worker. I would venture to say that work in a hamburger stand often tells more about a person's work behavior than their functioning at a rehabilitation facility. Even when we do an evaluation and get some good assessment data,

no vocational evaluator is going to say that there is an exact match. An evaluator says, "I can give you some information about the person's ability or the person's interests. I can't really give you environmentally specific information about how this person is able to use those abilities, or how that interest is going to play out. You get that from a real work environment."

## REHABILITATION AND MENTAL HEALTH PERSPECTIVES

Rehabilitation counselors view work as a means for clients to maintain and regain their health, not as an activity to pursue after health is regained. Now once again, the vocational rehabilitation system imposes some limits on that, but the point is a rehabilitation counselor believes that productivity is important. Sometimes people need to be productive or to feel productive before they are able to comply with treatment. In other words, treatment compliance should not be the prerequisite to getting a job. If you have a history of treatment compliance as the main issue in losing jobs, then that is different. But too often we get into a sequential process that says you need to do this and this before we'll get you a job. Sometimes the client needs to work on feeling productive, whether in a job, in a workshop, or in a supported work experience, before he or she is able to work on other problems.

The other issue which relates very much to job placement, is that rehabilitation counselor believe in the technique of hypothesis testing. We believe that you gather some data, you try it out in vivo, and then you use what you learn to move ahead. That is different than in traditional medicine where the emphasis is on technology and cure. Our goal is to put safety nets around that hypothesis testing process and help the client obtain data he or she can use to make intelligent choices. Ultimately we ask the client to take

S.7

S.8

some risks. The VR system reinforces the notion that clients go through this process in a nice lockstep fashion, but we all know that does not really happen. It is important to see that the hypothesis testing process is not something we do because we don't know any better; it is something we value as a way clients learn behaviors in real situations. They do not learn behaviors because a counselor sits them down and tells them how to act. Clients learn behaviors and skills by being given information, practicing, and obtaining feedback. Then they move ahead. In this way rehabilitation functions as an adult learning process.

### **EVALUATING JOB READINESS THROUGH FUNCTIONAL ASSESSMENT**

What data do you use to decide if a person is job ready? What kinds of information do you use? Motivation, skill level, attitude, appearance, training -- those are all things you need to know. How did the client act in past jobs? These are all useful, very specific pieces of information. The one thing that they all have in common is that they are all a client's characteristics. In other words, you define work readiness by looking at the set of characteristics the client presents.

You have all probably seen or used work readiness check lists. No one is ever work ready. The lists I've seen describe the classic ideal candidate. Rehabilitation counselors need to think about job readiness as a specific form of functional assessment. Job readiness is a dynamic that basically tries to match the client and the job and the employer. Someone is job ready for a specific job at a specific place of employment. No one is job ready to be a welder, for example. The kind of a welder and the setting need to be defined.

In Washington, D.C., many counselors deal with the federal government. Clients placed in one department and doing a good job could never get hired and could never do the job if they were in another department with another supervisor. So functional assessment in job readiness does not just get data about the client, but also involves collecting data about the employer and the job. In managing your cases it does not make sense to think of a client as job ready unless you have a specific job and a potential employer in mind. You obviously do not know every employer, but you should have a handle on the type of employers in your labor market. Most of our clients have reasonable requests. "I'd like a job - not at minimum wage. I cannot support a family on minimum wage. I need a job with medical benefits." Those are the kinds of things on which we need to focus. And to do this you need to make an assessment of the client, the job, and the employer.

The major categories of this assessment are seen in Figure 1. Job readiness is assessed by looking at the client in terms of his or her abilities, values, and tolerances; by looking at the needs and values of the employer; and by evaluating the job in terms of abilities and tolerances required.

S.9

**Figure 1. Assessment of Job Readiness.**

The client. Ability means what the person can do. We tend to use ability as a positive factor, but I think it is a neutral factor. Ability is a measure of performance in a certain environment. We tend to use the word ability as synonymous with a lot of ability, i.e., as a measure of performance above a certain level of achievement.

Here is an oversimplified case. Suppose someone wanted to be an electronics assembler and is in a sheltered workshop producing at 20% of the norm. Many people would say that the client does not have the ability to be an electronics assembler -- the level of ability is below that required in order to be an electronics assembler. Interestingly enough, most people get placed from sheltered workshop facilities when they produce at about 60 - 70% of

the industrial norm. When you establish the competitive norm at 100%, you assume that is where the client has to function in order to get the job. If the client's ability to perform is at 20%, you could then develop a strategy to increase that person's level of ability, either through learning strategies, modeling, motivational techniques, or coercion. The point is at this stage you do not make a judgment that the client does or does not have the ability to be an electronics assembler. You measure the person's ability along a scale and then you work on skill teaching or on behavior modification. Whatever intervention strategy you use, you need to look at measuring ability along a scale and not at defining ability as performance above a certain point.

Rehabilitation counselors need to look at client values as well as client abilities. What does the client want to do? What does he or she say about work? A client has all the skills to be a dishwasher. He or she could get the job but is not interested. Often we tend to negate the importance of client values or to see values only in terms of the problems they create. We say, "If only the client weren't so picky." All the staff in my placement department were complaining about a client with a wife and three children who turned down a job at \$4.00 an hour with no benefits. "Who does this guy think he is, what does he expect us to do?" I looked at them and said: "Am I crazy or are you crazy? Since I'm in charge, we're defining it as you're crazy." When they stopped and thought about it they were embarrassed. Rehabilitation counselors have placement pressures as part of their job, but they also need to be very conscious of the client's values and needs. We all have to compromise sometime and that includes clients. However, you need to respect your client's values and factor them in when you assess job readiness.

**The employer.** Let's move to the needs and values of the employer. Needs are simpler to define. What is the job the employer has available? What is he or she looking for? Employer values deal with attitudes. Some employers do not like disabled people. Some employers do not like black people. Some employers do not like white people. Be aware of the fact that part of the equation of job readiness has to do with the employer, not just with the job. Part of the counselor's job involves working with the employer to change (or soften) his or her values if they interfere with the client's employment chances.

**The job.** Finally, the specific job is evaluated. One aspect of the job deals with abilities. What kind of skills are needed to be an electronics assembler or a welder? Tolerances identify the kind(s) of environment in which the client can use the skills that he or she has and wants to use. Most of you do not have the luxury of getting an employer to change the office setting. It is important to see not only what the client can do and what the client wants to do, but also what the different environments are in which the client can function. Similar jobs are done in many different environments. You can probably all share stories about your supervisors, "I've got a hard one!"; "I've got someone who lets me do whatever I want!"; "I've got someone I like!", etc. The job is determined by not only the particular skills needed but also by where the job is done. So counselors need to look at job readiness as a dynamic that is situation specific. If somebody asks you if someone is job ready, you say, "For what job? What employer? Be as specific as possible."

Sometimes you do not have all the pieces of the puzzle and that is all

right. Our jobs require going on with uncertain knowledge. If you define job readiness totally in the bailiwick of the client, you will be very limiting to your client. You can't change anything about the client's job history or I.Q. You could probably change their way of dressing or possibly their job seeking skills. But to the extent that we focus only on the client, then all the pressure is on him or her and, in a sense, off of us. Once we add the employer and the job to the equation, it gives us more control over job readiness. Job readiness becomes something to work on and it becomes part of a functional assessment.

In summary, there is no such thing as generic job readiness. It is similar to the concept of handicap. Unless you tell me the environment, I cannot say whether John Jones is handicapped. You need data on the environment in which the client is going to function. We need to see the client not as someone who is disabled, but as someone with a work handicap. When you select sources of data in terms of deciding job readiness, you need to make sure that you concentrate on the client, the employer, and the job. We certainly should have information about the client and the job in any assessment, even though to some extent the employer is often an unknown.

Exercise 3: Marketing Sam to an Employer

The following is a role-play exercise that involves practicing marketing strategies:

(C) - Vocational Rehabilitation Counselor  
(E) - Employer

(E): Well, what can I do for you today?

(C): Well, first of all, thanks very much for seeing me. I'll only take a few minutes of your time. Basically, what I'm here for is to talk to you about the janitorial positions that you have open and the reason I am here is that I work for an organization who helps employers like yourself recruit for a variety of positions including the janitorial jobs you have open. The way we go about assisting in recruiting is by hooking employers into a pool of qualified applicants that we're involved with. Our goal is to help people who have had some problems in the past in terms of working to get back on their feet, get them the skills they need to go back to work, and help them present those skills to employers. Very specifically, I believe I have a person who fits the bill in terms of the janitorial job that we spoke about.

(E): Can you tell me a little bit more about this person?

(C): Sure, I'd be happy to. He's someone who has over five years janitorial experience in 3 or 4 settings, most recently at a nursing home. He has some specific skill training both in high school and that our organization has helped him to get in terms of basic janitorial skills, in terms of the mopping, the sweeping, the use of the various chemicals and equipment. And he's got very good work references from his previous jobs that I would be happy and he'd be happy to share with you. He's also someone that I've worked with over a fairly long period of time, so I would be able to give you a lot of the good information that I found out about him in terms of his reliability, punctuality, his willingness to work as he demonstrates by showing up to work every day.

(E): Well, I have two questions. He sounds very good but I'm a little concerned. How come he isn't here for an interview on his own?

(C): Well, he would be happy to come in to see you and that's one of the things I had hoped we would be able to arrange. But the reason I'm in is because I know about the openings you have and part of my job is to seek out openings in the community and also to make employers in the community aware of our services. So I thought I'd take the opportunity to introduce myself; but I certainly would like to set up an appointment with you and for him, and I hope we can do that before I leave.

(E): And your agency works with people with disabilities, and I'm a little concerned at this point, over what his disability might be.

(C): Well, we work with people who have a variety of problems, whether it's medical, learning, psychiatric, whatever, whose problems have interfered with their working. What our services primarily do is to help people get the help they need to get back to working and get back to the stage where they were. I certainly have some constraints in terms of confidentiality of information as I'm sure you can appreciate from your position. However, this particular person is someone who I've known for 2 1/2 years who had had some problems that had affected his job relating to the time he was getting divorced. He had, as you can well imagine, some problems in terms of dealing with his family issues. However, one of the things we've worked on is getting him back on his feet. He's worked very hard on working things out for himself. He's demonstrated his ability to get back to work, to get some additional training. Many of the situations I've seen him in have required him to show up for work every day, to show up for appointments with me on a regular basis and all the contexts I've seen him in show him to be very reliable, show him to be very punctual. So he's someone simply who has had some problems and we've helped him in terms of the work he's had to do to put them behind him.

(E): Well, that sounds pretty good. I think that one of the problems that we have when we are thinking about people for these positions in the janitorial department is that I need to tell the supervisor that somebody is going to be pretty reliable. I've had some problems with the supervisors, because there have been people who have been incredibly incompetent or who have had various problems and have not shown up after a week or two on the job. With somebody I recommend to be interviewed by the supervisor, I like to feel that this person really has a good job background and that they sound pretty reliable.

(C): Well, this person fits the bill. Certainly reliability is one of the key things in any employee that I am sure that you look for and frankly, that I look for. One of the things that I'm very pleased about with Sam Smith is the fact that I can really tell you in very specific terms, once again, about his reliability in showing up for work on time and his ability to follow through on instructions in all situations where I've had first hand knowledge. Also, I've been able to review his references so I would be very happy to vouch for them as well.

(E): One thing I do want to say, I realize that a lot of this is confidential. But we've had some problems in the past with people on medication, psychiatric problems, and I don't know whether you can tell me this straight out, whether or not this client is on some kind of medication, or that he's being followed, if he is, because that has been a problem in the past. I'll be honest with you, we've had some problems with some of our employees before.

(C): What kind of problems have come up around that?

(E): Well, some people have been taking the medication, you know, and then they stop taking it for one reason or another, and then don't show up for work or get very abusive when they were on the job, and there's been a number of problems with that.

(C): Sam has had no problem at all in terms of showing up for work, in terms of, once again, following through on any instructions, in terms of completing training well. I will tell you even though as you mentioned it's a sensitive area, that he has sought out the help he's needed. In terms of any of the problems you've mentioned, it's not a problem that Sam has and I would have no problem recommending him, in terms of the job. It certainly hasn't come up in the situations that you talked about.

(E): Okay, okay. Anything you would like to ask me about the position?

(C): Well, I would like to know some more specifics. I read the job description and certainly don't have to waste your time going over that again but I wonder if you could give me some more specifics in terms of the particular work environment, the size of the work crew he would be working with, the hours.

(E): Well, as you know, it's a general janitorial position and it's a dayshift. It's from 8:00 to 4:00 and he actually would be working fairly independently, even though he's officially on a team. Very often people do work independently cleaning restrooms and doing just general sweeping and mopping, so he would be working independently.

(C): Well, that's good.

(E): Can he work independently?

(C): Certainly, part of the specific training that we've helped him arrange for himself and part of what we try to focus on, (many of our people are trying to help companies recruit) is that need, because a lot of jobs require following instructions but being able to carry them out independently, and Sam is one of the people who has been able to demonstrate that ability. I'm sure he would fit your particular need very well. So he wouldn't have to have a supervisor standing over him at all times, giving him instructions - he can follow things through. No, certainly, not so much because of Sam but because of your particular needs, I would assume that the supervisor in terms of the initial training would really want to make very clear to any employee, including Sam, what the particular needs are and what would be demonstrated to the supervisor and to the employee himself, that he was doing the job very well. But if the supervisor were able to demonstrate that, as I'm sure he's had to do with other employees, I think Sam is very good about following through. Certainly if it's a particular issue in terms of communicating certain kinds of information, one of the areas of expertise I have and our organization has, is helping work-site supervisors, who might not be very familiar in terms of personnel terms, in breaking down the instructions to a job in ways that are easier for people to understand, but Sam has demonstrated that ability before.

(E): If there were any problems, once, we were ready to hire Sam for a company, what could we do? Could we call you in as his counselor to come trouble-shoot a little bit?

(C): Well, first of all, I should state that based on my experience, I wouldn't expect any problems beyond the natural problems that occur with any new

employee. But if something came up that you were having a problem with, that you thought I could be helpful, feel free to give me a call. I would be happy to come right out. One of the things I would be doing normally with any of the people we help companies recruit is checking in with them over several months after they get a job to make sure things are working out okay. If you would, or the supervisor would appreciate, I would be very happy to not just check in with Sam but also with the supervisor to see if there is anything I can do. It would really be up to the supervisor.

(E): Basically, he would be working fairly independently, but he is part of a team too. How well does he work with other people? As part of his day, he'd be working with some other crew members, how is he?

(C): Sure, I understand that. Well, his previous jobs, in terms of the nursing home, and in terms of Woolworth's, have involved working in a variety of settings. Sometimes he's about the only person responsible for a floor, so he's shown no problems in either area. I'd say in looking at my own particular experience with him, certainly he's had to work with me in a team format, obviously different than what you're looking at, but he's certainly very cooperative, part of the training that we've helped him arrange for himself involves group training and group instruction in terms of janitorial work. He's, once again, performed very well, gotten very good evaluations, has gotten along very well with both his coworkers and his supervisors, so I expect that translates very well to your job.

(E): Okay, I think that's pretty much about it. The only other thing, and this is kind of a minor issue, that we've found some problems in, is that very often a lot of our people work in the janitorial department, we're kind of off the beaten track when it comes to public transportation. Any plans made on how Sam would get here? Does he have a car?

(C): Right now, Sam takes public transportation; but one of the things that once again that we assist people with is some help in terms of paying for transportation. I've researched it myself. You're certainly not right on the line, but Sam has commuted to jobs that have involved longer commutes, and longer walks from the bus stop and Sam would be very happy to do this and he's told me he's interested. Once again he's demonstrated his interests and I'm sure you'll see that when you meet him. In the future, once he gets on his financial feet again, then he'd be able to go buy an auto. He does have a driver's license.

(E): Great! I have another appointment right now and Sam sounds like a pretty good candidate and I would like to refer him to our supervisor in the janitorial department.

(C): Excellent, would I be able to make that appointment now or should I call the supervisor?

(E): Why don't you call the supervisor directly? I'll talk to the supervisor this afternoon and maybe you can give him a call tomorrow morning. Give him a call between 9:00 and 9:30. Well, thank you for coming in.

(C): Thank you for your time, Ms. Walsh.

**Exercise 4: Interview Situations: Practice in Job Seeking Skills**

Look over these example responses to hypothetical employer questions.

Following each response is a rating and an indication of the response representing passing or full disclosure. Think of other ways to answer these questions.

1. Why did you leave your last job?

a. I didn't get along with my boss at all. He expected way too much of me and when I tried to complain about it he told me to leave. (Poor)

b. I didn't make a good job choice. It turned out to involve things I wasn't good at or even qualified to do. I was asked to leave and I understood. I wasn't happy in the job and I've never had that kind of trouble in previous jobs. If you check my references I think you'll find I'm qualified for this job and I was always productive in my other work. (Good, Passing)

c. At the time of my last job, I was dealing with a lot of problems around the break-up of my marriage. My work suffered and the company had no choice but to let me go. I did seek out help and I worked through the bad times. I think if you check with my employers before that point, you'll see my work record is very satisfactory. You don't have to worry about that problem getting in my way again. (Good, Full Disclosure)

2. Looking at your work record, I see you haven't worked in the last 2 years. What have you been doing during that time?

a. Well, I was sick so I had to go to the hospital but now my doctor says it's okay for me to work again. (Poor)

b. Well, to be honest with you I was having some family problems at home that were really affecting my job. Rather than let that go on, I decided I had to take care of one thing at a time. I sought some counseling help and with a lot of hard work I was able to resolve the problems. Now I really believe I'm ready to go back to work. For the past couple of months, I've been doing some volunteer work just to make sure of myself but I know now I can give 100% to this job. (Good, Full Disclosure)

3. Have you ever been hospitalized for any physical or mental illness?

a. That's none of your business. I know my rights. I don't have to answer that. (Poor)

b. I certainly don't have any problems that would interfere with my ability to do this job now, but I don't see how that specific question relates to the job. Could you tell me how it does? (Good)

4. Why have you held so many jobs?

a. Well, I went through a divorce. I was very depressed and my parents had to get me hospitalized a few times but the doctor says I'm okay now. (Poor)

b. I had a series of jobs at the same time I was going through a divorce. I found I kept going back to work without resolving that problem. Now I've worked on the problem, I've resolved it, and I'm currently working in a special program for people who have had these kind of problems before. You can check the high quality of my work with this employer. (Good, Full Disclosure)

c. Well, to tell you the truth, most of the jobs I had, my bosses weren't patient enough with me. You know, some people expect an awful lot from minimum wage jobs these days. (Poor, Passing)

d. Well, I wasn't sure what job area that I wanted to stick with and I thought the best way to explore possibilities was to try things out. I want to make it clear that I left all of my jobs with adequate notice and often I was one of the employees who had the longest time on the job there. (Good, Passing)

5. Why do you feel you're ready to work now?

a. Well, I've been evaluated as part of a program that works with people like me. My doctor and my counselor think it's okay. (Poor)

b. Well, I've worked very hard over the last two years on developing the skills I need to handle this job. I got more training in janitorial work. I worked a minimum of 20 hours a week for the last 6 months and worked without being late or missing a day and my supervisor there would be happy to provide you with a complete work reference. I've sought out help when I needed to and I've learned how to get assistance quickly when I need it before my problems get too much for me to handle. (Good)

6. Why were you in the hospital?

a. Well, you wouldn't believe the kinds of problems I had. Everyone thought it would be a good idea for me at the time. (Poor)

b. Well, I had problems dealing with the divorce from my wife but I decided to seek help. I got it and now I've demonstrated by being active in my rehabilitation program that I can tackle work again. I really look forward to showing you I can do that job. (Good)

7. This job involves a lot of stress. Would this be a problem for you?

a. I don't think so. What kinds of stress? I'll give anything a shot. (Poor)

b. Not at all. I worked very hard in controlling my emotions well and I've succeeded. I've demonstrated by the work I've done on a daily basis in my

rehabilitation program and the effort I expended to get myself back to being able to work that I can handle large amounts of stress. Feel free to check any of my references on this point. (Good)

8. Well, we work as a team here. I wonder how well you'd work with other people.

a. Well, as long as everyone is patient and understanding, I don't see any problems. (Poor)

b. Well, actually, I really enjoy working on a team and all of my other jobs have involved sharing tasks with the other employees. In fact, that's one reason that attracted me to your company. Also, I had to put in a lot of hard work with lots of different people to get myself back to where I am today. I can put what I've learned in that area to good use when I become part of your team. (Good)

**SESSION GOALS:**

1. VALUES
2. NEED FOR ADVOCACY
3. RISK-TAKING ON CLIENT BEHALF
4. SYSTEM > SKILLS
5. PRACTICAL TIPS
6. PROMOTE DISCUSSION
7. ENGAGE "TOUGH" QUESTIONS - SPECIFIC CASES
8. EDUCATE REGARDING THE REALITIES OF MOST HIRING PROCESSES
9. YOUR CLIENTS ARE NOT SO BAD
10. NO "MAGIC"
11. CONTROL WHAT YOU CAN - DON'T SWEAT THE REST

COMMON QUESTIONS:

1. "THE WHOLE TRUTH"?
2. IF TRUTH, HOW TO PRESENT IT?
3. ECONOMIC DISINCENTIVES?
4. MOTIVATION?
5. ATTENDANCE/PUNCTUALITY?
6. JOB READINESS?
  
7. THE "HOPELESS CASE" - CAN YOU TOP THIS?
8. HOW MUCH TO TELL SUPERVISORS/CO-WORKERS?
9. HOW TO COUNTER EMPLOYER OBJECTIONS DUE TO:
  - a) POOR AGENCY HISTORY?
  - b) POOR EXPERIENCE WITH A PARTICULAR CLIENT?
  - c) POOR EXPERIENCE WITH A PARTICULAR PSYCHIATRIC DISABILITY?
  
10. JOB SEEKING SKILLS?
11. STRESS?
12. GETTING ALONG WITH OTHERS?
13. HOW TO EXPLAIN WORKSHOP, TE, SE?
14. UNREALISTIC GOALS?
15. HOW TO DEAL WITH LOSS OF SUPPORT?

## PREMISES REGARDING PLACEMENT

- PERSONS WITH CHRONIC MENTAL ILLNESS WANT TO WORK.
- PERSONS WITH CHRONIC MENTAL ILLNESS CAN WORK.
- JOB READINESS IS DYNAMIC; ON A CONTINUUM.
- VOCATIONAL CHOICE AS HYPOTHESIS TESTING.
  - \* SITUATION SPECIFIC ASSESSMENT DATA
  - \* INFORMATION GATHERING
  - \* NOT ONLY ONE CORRECT CHOICE
- INTERVIEWS GENERATE JOB OFFERS (1 IN 7).
- MYTH OF THE IDEAL WORKER.
- EMPLOYER RELATIONS ARE A MEANS NOT AN END.
- ACTION + WORDS = VALUES

## REHABILITATION PRINCIPLES

- PRODUCTIVITY IMPORTANT TO PHYSICAL AND MENTAL WELL BEING
- PERSONAL CONTROL AND RESPONSIBILITY (ONCE GIVEN MEANINGFUL OPTIONS)
- PLATEAUS
- PERSON AND ENVIRONMENT
- HOPE AND SUPPORT

## ASSESSMENT AND JOB READINESS

### CLIENT

ABILITIES - WHAT CAN (S)HE DO  
VALUES - WHAT DOES (S)HE WANT TO DO  
TOLERANCES - IN WHAT ENVIRONMENT CAN (S)HE DO IT

EMPLOYER

JOB

NEEDS

ABILITIES

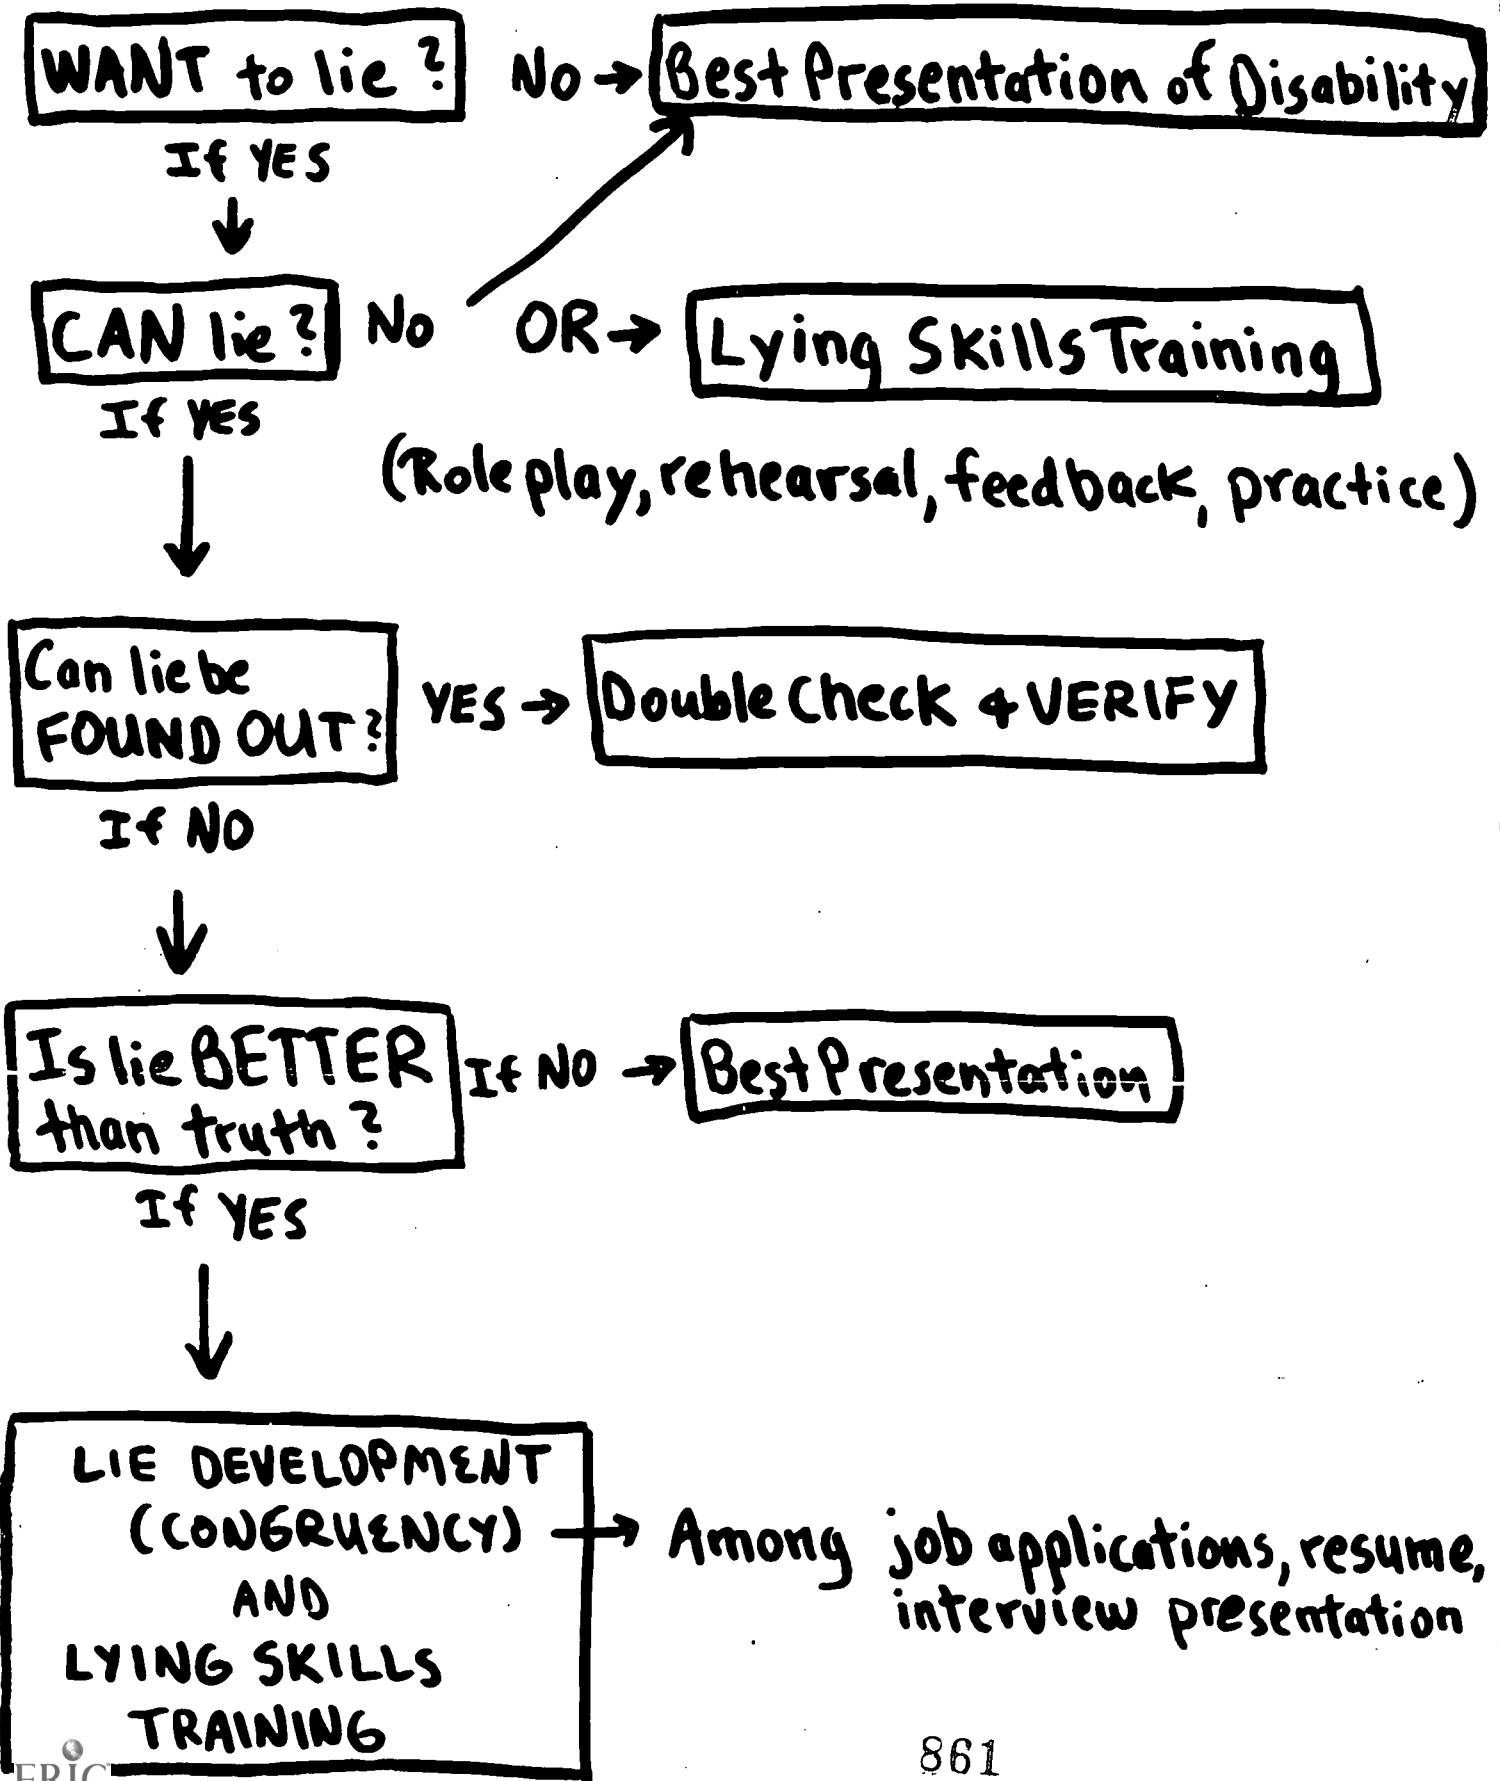

VALUES

TOLERANCES

## CLIENT-CENTERED APPROACHES

1. SCREEN IN, NOT OUT
2. SUPPORTS
3. JSS-JOB CLUB, PLUS
  - PRE-WRITTEN APPLICATION
  - LIST OF 3-5 ASSETS
  - DON'T VOLUNTEER NEGATIVE INFORMATION
  - "YES, BUT. . ."
  - STRESS CONTROL - 1ST PERSON & ACTIVE VERBS
  - PAST PROBLEMS VS. PRESENT CAPABILITY
  - FOLLOW-UP PHONE CALL
4. "PASSING" VS. "OPEN"
5. PREVENTIVE FOLLOW-UP

# LYING DECISION TREE

## **DEALING WITH A PSYCHIATRIC DISABILITY**

- **STRESS POSITIVE ASPECTS OF CURRENT FUNCTIONING**
- **DON'T VOLUNTEER NEGATIVE INFORMATION**
- **AVOID MEDICAL TERMS OR JARGON**
- **CONNECT DISABILITY WITH SIGNIFICANT LIFE EVENT**
- **DESCRIBE CLIENT IN TERMS OF QUALIFICATIONS FOR JOB, NOT DISABILITY**
- **STRESS CLIENT'S CONTROL**
- **PAST PROBLEM VS. PRESENT CAPABILITY**
- **CLIENT PATHOLOGY ≠ CLIENT WORK SKILLS**

## **ON-THE-JOB TRAINING WORKS FOR US AND YOU**

### **YOU GET:**

- **A PRE-SCREENED MOTIVATED SKILLED WORKER TRAINED TO YOUR OWN SPECIFICATIONS**
- **PAYMENT FOR YOUR COMPANY'S SERVICES AS A TRAINER**
- **TARGETED JOB TAX CREDIT FROM THE TIME THE OVR PAYMENT ENDS**
- **BACK-UP AND SUPPORT SERVICES FROM OVR AT YOUR REQUEST**

## **HELPFUL HINTS FOR MORE EFFECTIVE PLACEMENT**

1. **STRESS KNOWLEDGE OF CLIENT, BOTH WORK SKILLS AND PERSONAL QUALITIES.**
2. **SUPPORT AND FOLLOW-UP AVAILABLE TO EMPLOYER AS WELL AS CLIENT.**
3. **TALK UP "PERSONAL SERVICE" -- FREE RECRUITMENT AND SCREENING.**
4. **ASK HOW EMPLOYER USUALLY HIRES PEOPLE.**
5. **DOES THE EMPLOYER PROVIDE ON-THE-JOB TRAINING?**
6. **FIND OUT EMPLOYER'S NEEDS IN TERMS OF HARD-TO-FILL JOBS, HARD-TO-FIND PEOPLE.**
7. **STRESS PLACEMENT SUCCESSES. DESCRIBE OTHER CLIENT SUCCESSES.**
8. **ASK EMPLOYERS ABOUT AFFIRMATIVE ACTION CONCERNS.**
9. **STRESS CONTINUOUS CONTACT WITH AND COMPREHENSIVE KNOWLEDGE OF CONSUMERS AND CONSUMER-ORIENTED ORGANIZATIONS.**
10. **MENTION OTHER WORK PROGRAMS AVAILABLE-OJT, TEP, SUPPORTED EMPLOYMENT.**
11. **MENTION TARGETED JOBS TAX CREDIT.**
12. **ASK FOR REFERRALS AND PERMISSION TO USE EMPLOYER AS A REFERENCE.**
13. **ADVERTISE YOUR PRODUCT - BROCHURES, MEDIA.**
14. **BE WHERE THE EMPLOYERS ARE.**
15. **CONTACT LOCAL CIVIC ORGANIZATIONS.**

SOME SPECIAL CHARACTERISTICS OF SE PROGRAMS FOR PEOPLE WITH SEVERE PSYCHIATRIC DISABILITIES

1. THE ISSUE OF STIGMA WITH THE ATTENDANT GREATER NEED FOR EMPLOYER ADVOCACY.
2. THERE IS OFTEN PERSONAL DISCOMFORT ON THE PART OF THE PROVIDER STAFF.
3. PEOPLE WITH PSYCHIATRIC DISABILITIES PROBABLY HAVE A GREATER SENSE OF LOST POTENTIAL.
4. GREATER WORRY ABOUT LABELING.
5. PARENT EXPECTATIONS CAUSED BY GUILT AND SOCIAL STIGMA.

QUALITY SERVICES IN SE FOR PEOPLE WITH PSYCHIATRIC DISABILITIES

1. INTEGRATION AND VISIBILITY
2. NON-STIGMATIZING SUPPORT
3. PREVENTION, NOT REMEDIATION, IS THE KEY.
4. COMPREHENSIVE INVOLVEMENT WITH PROVIDER FOR OTHER THAN SE.
5. REHAB PLANNING IS COMPREHENSIVE IN NATURE.
6. COOPERATION AMONG SERVICE PROVIDERS.
7. ACTIVE INVOLVEMENT OF CLIENT AND SIGNIFICANT OTHERS.
8. OPPORTUNITY FOR CAREER MOBILITY.
9. PROGRAM CLIENTS ARE THE PRIMARY CONSTITUENCY OF THE SE PROGRAM, NOT THE EMPLOYER.
10. ZERO REJECT - EASY IN AND OUT
11. OPPORTUNITY TO OPT OUT OF THE "FAST TRACK"

## EFFECTIVE COLLABORATION BETWEEN VR AND MH

- A. TEAMWORK - WHAT IS IT?
- B. ELEMENTS OF EFFECTIVE COLLABORATION AMONG AGENCIES
  - 1. JOINT LEARNING
  - 2. NETWORKING
  - 3. AVOIDING TURF ISSUES
  - 4. VALUING MULTIPLE RESOURCES
  - 5. ACCEPTING AMBIGUITY
  - 6. SHARED RISK TAKING
  - 7. CLIENT GAINS, NOT THE RELATIONSHIP ITSELF IS IMPORTANT
  - 8. RELATE TO PEOPLE, NOT AGENCY
  - 9. DEFINING WHOSE NEED IS BEING MET
  - 10. APPROPRIATE VS. INAPPROPRIATE CLIENTS, "READINESS"

GOAL: To Help the Trainees Gain An Appreciation Of  
What Line Staff In Each Agency Have To Deal  
With As Part Of Their Internal System Structures

VIII WHAT DMH CASE MANAGERS SHOULD KNOW  
ABOUT VR AND VICE VERSA

A. ABOUT VR

- 1) The VR system is based on eligibility. Eligibility for VR services involves access to the professional services of a VR counselor for the purposes of vocational planning. The counselor has resources at his/her disposal to provide or pay for services. However, simply put, being eligible for VR does not mean the counselor agrees to provide any specific services except counseling and placement.
- 2) The VR system is vocationally focused. This does not mean that the only services provided are vocational ones, but rather that every service requested has to be judged on the basis of whether it will aid in the achievement of that client's vocational goal.
- 3) VR services are individually based. Even though there is a tendency in VR systems, as with all large systems, to make clients fit the system, not the other way around. But the core of the VR model is that the client is entitled to an individual program of services, based on his/her unique needs. In fact, the much maligned IWRP is the legislative prototype predating the other federal/state alphabet soup designations such as IEP, ICSP, IHP, etc.
- 4) VR service funding is client-driven, not system/slot driven. This is a bit of an overstatement but nonetheless, the premise of most VR service delivery is the identification of individual client needs which are provided through individual purchase of service funds. This is very different from the way most MH & DMR services are provided. Adding pressure to this purchase system is the practice of MRS counselors handling individual caseload budgets.
- 5) VR services have always been closure and outcome focused (i.e. the most important goal measured is job placement). Even more so now, with the introduction of the MCS system which gives different weights to various types of employment outcomes for different types of people. DMH day services nationwide have historically been concerned more with dispositions and clients served than specific successful outcomes. VR counselors feel regular pressure to achieve their goals, which itself is not problematic. However, what tends to happen is problems in achievement often get addressed by changing the client mix (i.e. more "appropriate" clients) rather than improving individual skills or modifying the system.

BEST COPY AVAILABLE

- 6) The VR system as a whole has been under great stress nation-wide over the last few years. What for many years has been a small, non-controversial, stable, self-contained service network has been under greater scrutiny than ever before. There are questions about whether the VR model is useful for severely psychiatrically and developmentally disabled clients. Whether VR should broaden its scope or leave vocational services for such people to DMH and DMR? Whether Supported Employment will dilute the clear vocational focus that has been in place for 60 years? Whether S.E. should be an allowable VR service (Title 110 funds) or separately delivered through Title VIC funds? The residual tremors from these tensions are felt to some extent by every level of VR staff.

## B. ABOUT DMH

- 1) DMH (Rule 74) has eligibility criteria also, but these criteria are based on categorical definitions which are much less susceptible to individual DMH Case Manager judgement than VR eligibility criteria are to VR counselor judgement. The variability from VR office to office, VR counselor to counselor, which often frustrates outsiders is a sign of this flexibility. VR counselors used to making these sorts of determination get frustrated by case management staff who insist they have little control over the eligibility determination process.
- 2) DMH systems have always had a more "cradle to grave" focus on service delivery. And, especially since the advent of the CSP movement, they have not had the luxury of focusing on just one type of service need. Residential, treatment, advocacy and protection, and vocational services all fall somewhere within the current DMH case management purview. Therefore, it is difficult for DMH case managers to develop a specific area of expertise, beyond the generic one of "case management", given the wide range of client needs to which they must attend. When VR people are "stumped" on vocational options, DMH case managers often then feel without allies in this regard.
- 3) Historically, most DMH day service delivery, because it has served broader needs and been of a much larger scale than VR, has been purchased on a contractual basis. Generally, a certain number of slots (or FTE's) have been agreed upon with a program provider and when these slots were filled, a waiting list was developed. Also, many times, service providers have been able to control entry into DMH contracted day slots; whereas most often in VR service delivery, referrals come from the VR counselor to the service provider. The magnitude and scope of DMH service delivery cannot be overemphasized as a

crucial factor in system tendencies. DMH has had to ensure that certain types of mandated services (in-patient, day treatment, emergency services) are available to a vast array of people with mental health needs. This system focus has often led to categorical dispositions (certain kinds of people need certain services) rather than individual planning and program development).

- 4) Because of the vagaries of the concept of mental illness and the lack of clearly effective treatment strategies, the provision of DMH services has tended to be more process and problem focused than based on successful interventions. Much disagreement exists even within the mental health field itself as to what works. There has also been much societal pressure to make sure that mentally ill people do not pose either danger or embarrassment to themselves or others. These widely disparate problems and controversies have led to the development of a large, sometimes unwieldy, amorphous service system which spends much more time attending to client problems than on solving them. This is not an indictment of the staff but rather a reflection of the political and social realities which all mental health systems live under. There is an expectation that VR services will produce successful employment outcomes; there is no expectation that DMH services will "cure" mental illness.
  
- 5) Some of the stresses the DMH system has been under, nationwide and locally, parallel that of the VR agency. They have been asked to focus more time and attention on those people with severe and persistent mental illness (i.e. severely disabled people). DMH staff have been asked to expand their capacity to affect people's lives by delivering other than traditional mental health treatment services (e.g. vocational services). DMH and VR staff have both been given overlapping mandates in the employment arena - a situation which provides a safety net for clients but causes a great deal of uncertainty in the minds of staff. In addition, DMH staff are part of a more visible, more politically charged, larger service network than VR staff. They are often subject to public policy pressures (national/state magazine cover stories on deinstitutionalization, homeless people, "violent ex-mental patients", etc.) that most VR staff are immune from due to the fact that VR agencies are smaller, deal with less sensational problems, and have a tighter focus.

GOAL: To Assist Trainees In Gaining An Understanding  
Of The Essential Components Of Effective Teamwork  
Between V.R. & M.H.

VII EFFECTIVE COLLABORATION  
BETWEEN V.R. & M.H.

A TEAMWORK - WHAT IS IT?

- Effective collaboration between systems involves the concept of teamwork. A definition of teamwork offered here has been developed by Naomi Brill:

A team is a group of people, each of whom possess particular expertise; each of whom is responsible for making individual decisions; who, together, hold a common purpose; who meet together to communicate, collaborate and consolidate knowledge from which plans are made, actions determined and future decisions implemented."

- A rehab team must include the client and significant others as an integral part of the team.
- Teaming up should not be a way to avoid individual responsibility, delay action or stake out agency turf.
- It should be a way to bring multiple resources to bear on client problems, gain fresh perspectives and ensure clear communication among all parties involved.

B ELEMENTS OF EFFECTIVE COLLABORATION AMONG AGENCIES

- 1) Joint Learning - There is rarely one single reservoir of expertise available, particularly in the field of S.E. for people with severe psychiatric disabilities. While some people do have greater skills and knowledge than others in various areas, there should be an expectation that VR-MH collaboration around S.E. will result in both organizations needing to (re)learn different ways of thinking about severely psychiatrically disabled clients.
- 2) Networking - Collaboration by definition involves a network among the team members. However, related to Number 1 above, is the need to expand the knowledge base available in the team by reaching out to people and entities that could shed some light on ways of dealing with thorny client and/or system issues. This expanded network may include providers, consumers, similar service systems, university-based TA, etc.

- 3) Avoiding Turf Issues - A third element of effective teamwork is the need to avoid turf issues. Turf issues are defined here as issues related to maintaining the system status quo and avoiding any change in one's own operations. Positive collaboration involves identifying client related problems that need to be addressed and finding ways to ensure that one's own agency can assist in this endeavor, not look for ways out of the effort. Differing mandates are very real but there is much flexibility built into the VR law as well as Rule 74 for counselors and case managers to find resources to become more, not less involved.
- 4) Valuing Multiple Resources - There is built in overlap among many legislative mandates as noted above. While very real issues abound in the funding arena (Who's going to pay for what client and for how long?), there are other needs which people entering SE often have (housing, public assistance advocacy, clinical changes necessitated by a work schedule, etc.). An effective team values many of the services team members bring to the problem resolution (knowledge, skills, time, energy, as well as money).

In the realm of DMH - VR collaboration around SE, both VR and MH staff bring personal/professional resources to the meeting table. VR people should bring a perspective on individual vocational development, a knowledge of the vocational services system and experience in case management with clients working out individual service plans. DMH Case Managers should bring extensive knowledge of serious mental illness, a broad based overview of non-vocational parts of the human service delivery system (e.g. residential or treatment options) and presumably a closer working relationship with the total array of DMH caregivers offering assistance to the client.

- 5) Accepting Ambiguity - There are many unanswered questions about S.E. for severely psychiatrically disabled people as well as VR counselors' and DMH Case Managers role' in the process. Added to this mix is a large amount of role overlap and differing pressures from each system on its own staff (for DMH Case Managers—the pressures of the ICSP and Rule 74); (for VR Counselors—the pressures of the IWRP and the MCS). Finally, the problems that many clients bring to their SE placement are not often easily resolvable. No one can work effectively as part of a team if that person expects clear answers to all the questions about roles, funding and client needs, before feeling comfortable in moving ahead.
- 6) Shared Risk Taking - Related to Number 5 above, both DMH and VR staff must understand that the collaborative efforts are a form of shared risk taking. When roles cannot be clearly defined or client problems solved completely, there is a tendency to want to point fingers. Collaboration means sharing the risks, sharing the problems and sharing the rewards. An effective team effort will allow each of the members to take on some risks (i.e. flexible eligibility decisions, extended funding, extra work) but will also provide a vehicle for maintaining a tolerable amount of stress on any one person's particular job duties.

- 7) Client Gains. Not the Relationship Itself Is Important - There is no magic in a good relationship developed among service providers. People must keep the goal of better services to our clients in mind. Effective teamwork is precluded by bickering and personal animosity among team members. However, all too often good relationships among professionals are developed at the expense of client goals.

Our clients want services that challenge our capacity to deliver them. Both VR & MH staff work under a layer of bureaucracy that generally reinforces "safe" decisions. VR counselors and DMH case managers probably all have too many clients and too little time in the day. If the premium is on good relationships, not client service, there is a tendency to not want to put your peer in a difficult spot - not want to push him/her too much. There can be a desire to avoid testing the relationship by working with clients who are considered marginal in one or both systems. Advocacy is sometimes considered "bad form" and a reflection of not understanding the other person's needs. The test of an effective inter-agency collaborative relationship is services being delivered to people formerly excluded, not the collegial relationship flourishing, per se. A good professional relationship will stand the stress of such tensions just as a solid personal one will.

- 8) Relate to People. Not Agency - Having stated Number 7 above because it is often omitted in discussions of the subject, I will need to state my belief that a well-functioning team is built on relationships among people, not agencies. This concept is equally valid for engaging the client as an active member of the rehab team as well as for working with other professionals. In the case of client involvement, VR & DMH staff must develop a personal identity in the client's mind set, not totally dependent on that staff's professional function (i.e. some one must be seen as John or Mary - not just as the "DMH man" or the "VR lady"). The way to accomplish this engagement in the early stage is to opt for frequency of contact over length (i.e. a 1/2 hour visit to a program weekly is preferable to a whole day spent monthly).

With regard to personal relations among professional team members, time needs to be spent on niceties often considered extraneous to the important business at hand. Habits like always rushing in late (or out early) of group meetings, frequently taking phone calls, insisting on your agenda prevailing, never having a chance to gossip or exchange small talk (about the Twins, Vikings, weather, families, etc.), often talking about the pressures you and your agency are under, not returning phone calls promptly, and making every request for you to do something a major imposition are all signals that the other members of the group are not valued by you. Such behavior makes it difficult for the other team members to develop a personal bond that can transcend any particular problem the group needs to confront.

9) Defining Whose Need Is Being Met

As was mentioned several times before, both VR and DMH have responsibilities and legislative mandates which run separate courses and overlap, particularly most recently in the provision of employment services to people with severe psychiatric disabilities. Of necessity, there exist demands imposed on professionals by their respective systems which to the extent that these requirements pose demands on the other team members, can cause tensions. For example, the need for each system to define eligibility using different criteria. Or the need to develop both an ICSP and an IWRP.

There is no simple way around these barriers. A strong personal relationship which can be imposed upon can help both staff's needs, particularly where information already on hand in one system is needed by the other. Also, a clear, up front explanation of what the need is why it is important and how the other party can help is essential. If the requesting party defines the need as "paperwork" or "something my supervisor wants", the other professional can be hard pressed to understand why (s)he should be bothered to help.

The same principle holds in trying to get a client to provide information or come in for evaluations. If no good reason is given and no outlining of the positive consequences of this activity are made, the VR or MH professional appears to be little more than a bureaucratic automaton and should not be surprised when others view him/her in the same light.

10) Appropriate vs Inappropriate Clients "Readiness"

First, refer to Marrone's Rule Number 6 on the opening page. Not only is it deleterious to client interests to think of someone as an "inappropriate referral", it is usually infuriating to the person making the referral. If we cannot help someone obtain what they want from us (e.g. an SE job) it is not necessarily the system's "fault", but it certainly is a limitation it has in delivering services. A customer who goes to a store which is out of the product (s)he wants or doesn't like the price, is not labelled an "inappropriate customer". The store management either obtains the product, lowers the price or accepts the fact that it is not interested in that customer's business. If enough customers leave the store, management generally rethinks its policy - not laments how difficult the customers are these days.

An effective team needs to understand differing mandates and priorities but seeks to expand the limits of what it can do by using all the resources at its disposal. Team members must stretch the limits of acceptability and appropriateness to their furthest boundaries if severely psychiatrically disabled people are to gain access to employment. Besides, the humanistic rationale for this approach, there is a technical reason. The capacity to predict vocational success from data available at time of referral is spotty at best. Usually what is clear are the barriers to successful employment. What is unclear is the susceptibility of these barriers to effective rehab interventions. Diagnostic information is not a good predictor of employment functioning.

Because of the flexibility built into the VR and the new DMH Case Management system, there is a human tendency to protect oneself from being overwhelmed and being put on the spot by being quite cautious over who gets "let in" because it is difficult to get extricated once involved. Since the DMH Case Management system is fairly new, no clear track record has emerged in this record.

VR, being the more mature system, has a set of traditions. All too often, the VR system - which has an extremely flexible client-driven service design - gets presented by VR staff as an incredibly rigid, restrictive system. The most important referral questions for a referrer to ask are "Does this person want to consider the possibility of work for themselves" and "Is the situation the person is in uncomfortable enough for them that they are willing to go through some effort to change?". There are certainly guidepoints which DMH referral people can use, as outlined in the article on "Serving Psychiatrically Disabled People Within The VR System" by Joe Marrone. However, the crucial questions are those two above. Assessing whether a person meets the VR legal eligibility criteria is the VR staff's job, not the referral agency.

The traditional "tight" description of VR services was brought to mind by a recent workshop I conducted in Connecticut. The room we used was off of a swimming pool area and contained "Rules for Pool Use". Reading this list reminded me of a typical VR informational talk I have heard given many times. The list included 14 rules - all of them began with "No" or "Don't" and I had to read to Number 9 before swimming was mentioned!

An expansive presentation of the possibilities in the VR system of delivering SE services to people with severe and prolonged mental illness would communicate a message of "Come on in, have fun and swim", not "Don't bring glass containers into the pool area".

# FUNCTIONAL LIMITATION FACTORS RESULT FROM IMPAIRMENT AND MUST SERIOUSLY LIMIT THE FUNCTIONAL CAPACITIES

## 1. Physical Mobility

- . Limited personal mobility
- includes, but not limited to, ambulation, transportation, accessibility.

## 2. Dexterity and Coordination

- . Limited dexterity and coordination
- includes, but not limited to, basic life skills, independent self-care, ability to write or successfully manipulate objects.

## 3. Physical Tolerance

- . Limited physical tolerance
- includes, but not limited to, endurance, speed, or fatigue.

## 4. Personal Behaviors

- . Inappropriate behaviors
- includes, but not limited to, interpersonal relationships, attendance, punctuality, grooming, hygiene, or social responsibility.

## 5. Capacity to Learn

- . Limited learning capacity
- includes, but not limited to, reduced capacity to retain or learn at an acceptable rate through traditional means due to difficulties with visual or auditory processing, cognitive integration, retention or retrieval of information, or reduction of sensory receptivity.

## 6. Repeat Hospitalizations

- . The severity of the impairment caused repeated hospitalizations.

## 7. Environmental Interaction

- . Limited ability to perceive or interact with the environment
- includes, but not limited to, communication, safety, health.

## 8. Life Planning

- . Inability to determine the direction of one's own life
- includes, but not limited to, limited ability to think through choices to a logical conclusion.

**3005.01 Purpose and Legal Authority**

Statistical reporting under the State-Federal Program of Vocational Rehabilitation is sponsored by the Rehabilitation Services Administration (RSA) and conducted under the auspices of the National Center for Social Statistics (NCSS) acting as the collecting and processing agency for RSA-sponsored reports. This section contains copies of the required statistical reports and instructions for preparing them.

Section 101(a)(10) of the Rehabilitation Act of 1973 and Section 401.21 of the Proposed Regulations dated May 28, 1974 which implement the Act, relate to the submittal of reports.

**3005.02 Caseload Statuses**

There are 15 status classifications under the caseload status coding structure coded in even numbers beginning with 00 and ending with 30 (excluded is code 04). Reporting on all statistical forms is based on one or more of the caseload statuses.

Status 00. REFERRAL. This status represents entrance into the vocational rehabilitation process. A referral is defined as any individual who has applied to or been referred to the vocational rehabilitation agency by letter, by telephone, by direct contact, or by any other means; and for whom the following minimum information has been furnished: (1) name and address, (2) disability, (3) age and sex, (4) date of referral, and (5) source of referral.

It should be noted that it is not intended to include in the definition of "referrals" those individuals included in long lists of persons who are "screened out" by criteria established in a cooperative agreement between the vocational rehabilitation agency and another agency. However, all those cases not screened out by the established criteria should be recorded and reported, not just the cases which appear to have good vocational rehabilitation potential after counselor investigation.

All cases must be recorded and reported as referrals for Form SRS-RSA-101 and Form SRS-RSA-300 purposes as soon as the above basic, minimum information is available. Recognition of this basic principle by all

counselors and all State vocational rehabilitation agencies is essential. Referrals should be recorded on these forms even though the counselor may close out the referral almost immediately as not being eligible for services.

Status 02. APPLICANT. As soon as the referred individual (Status 00) signs a document requesting vocational rehabilitation services, he is placed into Status 02 and is designated as an applicant. Generally, the document will be an agency application form, but a letter signed by an individual who provides the minimum basic referral information and requests service should also be considered as a basis for placing the individual in Status 02. This is important, since the applicant must be notified in writing if his request for VR services has been denied, and the only certain basis for determining that the individual has knowledge of having been referred is by the existence of a document signed by the individual.

While the individual is in Status 02, sufficient information is developed to make a determination of eligibility (Status 10) or ineligibility (Status 08) for vocational rehabilitation services, or a decision is made to put the individual into extended evaluation (Status 06) prior to making such a determination.

Status 06. EXTENDED EVALUATION. An applicant should be placed in this status when the counselor has certified the applicant for extended evaluation. Individuals placed in this status may not remain in the status longer than eighteen consecutive months from the date of certification but may be moved from this status to either Status 10 or 08 at any time prior to the expiration of the 18-month period if it is determined that, either (a) there is a reasonable expectation that the individual can benefit in terms of employability (Status 10), or (b) there is no reasonable likelihood that he can benefit in terms of employability (Status 08). No time allowances can be made for interruptions during this period regardless of the nature of, or reason for, the interruptions.

Prior to or simultaneously with acceptance of an individual for services for purposes of determination of rehabilitation potential (extended evaluation), there will be a certification of: (1) the presence of a physical or mental disability, (2) the existence of a substantial handicap to employment, and (3) the inability to make a determination that vocational rehabilitation services may benefit the individual in terms of employability. An individualized written rehabilitation program is required concurrently with or reasonably soon after execution of the certificate of eligibility for extended evaluation services.

Status 08. CLOSED FROM REFERRAL, APPLICANT, OR EXTENDED EVALUATION STATUSES. This status has been provided to furnish a means for identifying all persons not accepted for vocational rehabilitation services, whether closed from referral status (00), applicant status (02), or extended evaluation (06). All persons processed through referral, applicant, and/or extended evaluation, and not accepted into the active caseload for vocational rehabilitation services, will be closed in this status. A certificate of ineligibility is required for a closure in Status 08, except when the client becomes unavailable for services. A copy of the Form SRS-RSA-300, properly completed, dated, and signed is sufficient certification of ineligibility for these cases, provided case documentation includes specific detailed reasons for the closure action. See Page 75 for additional instructions concerning closure of cases.

#### ACTIVE CASELOAD STATUSES

An individual who has been certified as meeting the three basic eligibility requirements is accepted for vocational rehabilitation services, designated as an active case, and placed in Status 10. Eligibility for vocational rehabilitation services is based upon: (1) the presence of a physical or mental disability; (2) the existence of a substantial handicap to employment; and (3) a reasonable expectation that vocational rehabilitation services may benefit the individual in terms of employability.

After an individual has been accepted and his case placed in the active caseload, the case study is completed, an individualized written rehabilitation program is developed,

and the appropriate services are provided, including follow-up prior to case closure to insure the suitability of employment.

The following statuses are designed to provide counselors, district supervisors, and State agency management personnel with a uniform method for recording individual case progress and caseload management information. It may be noted that there are no national reporting requirements for applying these statuses to cases in extended evaluation. However, any large-volume agency desiring to establish case progress identification for their evaluation cases can easily do so by prefixing the following statuses with a "6" to signify status changes during extended evaluation.

Status 10. INDIVIDUALIZED WRITTEN REHABILITATION PROGRAM DEVELOPMENT. While a client is in this status, the case study and diagnosis is completed to provide a basis for the formulation of the individualized written rehabilitation program. A comprehensive case study is basic to determining the nature and scope of services to be provided in order to accomplish the vocational rehabilitation objective of the individual. The counselor and client formulate and plan the rehabilitation services necessary to the solution of the client's problems, and those services are clearly outlined to him. The individual remains in this status until his rehabilitation program is written and approved.

Status 12. INDIVIDUALIZED WRITTEN REHABILITATION PROGRAM COMPLETED. A case is placed in this status when the individualized program has been written and approved. The case remains in this status until at least one arrangement has been made to supply a necessary service and the service has been actually initiated. In those instances where the program as written and approved provides for counseling, guidance, and placement only, the client may be moved immediately after program approval into Status 14 since counseling is a continuing process.

THE IN-SERVICE STATUSES (Statuses 14, 16, and 18). These service statuses are provided for case progress designations to indicate the kind or kinds of services given to the client to prepare him for employment.

In those instances where a client receives restoration and training services simultaneously, the client should be identified by the service which is running for the longer period of time. In those instances where both services run concurrently for the same time period, the counselor must use his professional judgment in assigning the case to the status which is most important to that particular case.

Status 14. COUNSELING AND GUIDANCE ONLY. It is intended that this status be used only for those cases having an approved program which outlines counseling, guidance, and placement as the only services required to prepare the client for employment. It is not to be used to reflect the counseling and guidance which take place during the course of program development or provided by the counselor during the progress of training, or physical or mental restoration. However, within the context of the meaning and intent above, in those instances where there has been a breakdown in the case progress after other services have been provided, and it has been determined by the counselor that substantial counseling and guidance is essential to the successful placement and rehabilitation of the individual, the client may be entered in this status, provided that a program amendment has been written and approved after consultation with the client and that this is the only additional service required to prepare the client for employment.

Status 16. PHYSICAL AND MENTAL RESTORATION. A client is placed in this status if he is receiving any physical or mental restoration services such as medical, surgical, psychiatric or therapeutic treatment, or is being fitted with an appliance. A case remains in this status until physical and mental restoration services are completed or terminated.

Status 18. TRAINING. A client is placed in this status if he is actually receiving academic, business, vocational or personal and vocational adjustment training from any source such as a public or private school, a commercial or industrial establishment, a rehabilitation or other facility, by an individual

teacher or instructor, or by correspondence. Clients remain in this status until the training is either completed or terminated.

Status 20. READY FOR EMPLOYMENT. A client is placed in this status when he has completed preparation for employment (counseling, guidance, treatment, fitting of an appliance, training, etc.) and is ready to accept a job but has not yet been placed, or has been placed but has not yet begun employment. For example, "June graduates" with teaching contracts, who will not begin employment until September, should be placed in this status for Federal reporting purposes.

Status 22. IN EMPLOYMENT. A client is placed in this status when he has been prepared for, been placed in, and begun employment. He must be observed in this employment for a minimum of <sup>60</sup> days prior to being closed rehabilitated (Status 26) to insure adequacy of employment in accordance with the needs and limitations of the individual. Homemakers and unpaid family workers should be included in this status while they meet the observation criteria.

Status 24. SERVICE INTERRUPTED. A client is recorded in this status if services are interrupted while he is in one of the Statuses 14, 16, 18, 20, or 22. Such cases are then held in this status until the client returns to one of the aforementioned statuses or until the case is closed.

#### ACTIVE CASELOAD CLOSURE STATUSES

A client remains in the active caseload until he has completed his individualized written rehabilitation program or until it has been terminated. Cases closed from the active caseload are classified in one of the three following categories.

Status 26. CLOSED REHABILITATED. Cases closed as rehabilitated must as a minimum (1) have been declared eligible, (2) have received appropriate diagnostic and related services, (3) have had a program for vocational rehabilitation services formulated, (4) have completed the program insofar as possible, (5) have been provided counseling as an essential rehabilitation service, and

(6) have been determined to be suitably employed for a minimum of 60 days. See page 75 for additional instructions concerning closure of cases.

Status 28. CLOSED OTHER REASONS AFTER INDIVIDUALIZED WRITTEN REHABILITATION PROGRAM INITIATED. Cases closed in this category must have met the criteria (1), (2), and (3) above, and at least one of the services provided for by the program must have been initiated, but for some reason one or more of criteria (4), (5), and (6) above were not met (closures from Statuses 14 through 24). Included here are cases which are transferred to another State rehabilitation agency, either within the State, or in some other State. Also included here are those cases for which a rehabilitation program for counseling and guidance only was written, approved, and initiated. See page 75 for additional instructions concerning closure of cases.

Status 30. CLOSED OTHER REASONS BEFORE INDIVIDUALIZED WRITTEN REHABILITATION PROGRAM INITIATED. Cases closed in this category are those cases which, although accepted for rehabilitation services, did not progress to the point that rehabilitation services were actually initiated under a rehabilitation plan (closures from Status 10 or 12). Included here are cases which are transferred to another State rehabilitation agency, either within the State, or in some other State. See page 75 for additional instructions concerning closure of cases.

Status 32. POST-EMPLOYMENT SVCS -  
Client is eligible for OUR services for  
up to one year after being closed in  
Status 26.

SAMPLE VR REFERRAL  
LETTER

December 1, 1997

Robert Shields, Rehabilitation Counselor  
Office of Vocational Rehabilitation  
State Office Building  
300 Liberty Avenue  
Pittsburgh, PA 15222

Dear Mr. Shields:

This letter is to verify that [redacted] (WPIC# [redacted], ESN [redacted]), carries the DSM-III-R diagnosis of Bipolar Disorder, Manic in partial remission (296.45), which was originally made in 1982. Treatment for Mrs. [redacted] includes bi-weekly individual psychotherapy sessions with Caroline Haak, LSW, of the Comprehensive Care Program (CCP), Western Psychiatric Institute and Clinic (WPIC), and pharmacological treatment with Lithium 900mg daily, Trilafon 10 mgs every day, and Cogentin 4mg every evening under the direction of Dr. James Jacobson. Mrs. [redacted] will also be seen for vocational rehabilitation services by Maribel Baez, B.A. and Michelle Geckle, M.Ed., CRC, in the Psychiatric Rehabilitation and Assessment Services (PRAS) Clinic of WPIC.

Mrs. [redacted] is a woman of 53 years who worked as a secretary for 25 years. She lost her job in 1985 and since that date has been working in part-time and temporary secretarial positions. Since 1992, Mrs. [redacted] has had serious difficulties finding a job as a secretary as a result of her lack of skills with computers. She completed a developmental career job-seeking skills training program via [redacted] in January 1995 (i.e. interviewing skills, resume, job seeking) and has continued to actively seek employment but without response to date.

Mrs. [redacted] is doing well with her treatment and is highly motivated to improve herself educationally and vocationally. She is most interested in obtaining education/skill training in the computer field, i.e. word processing, data base management, which in combination with her 25 years of secretarial experience, should qualify her for competitive employment.

Functional limitations secondary to Mrs. [redacted]'s mental illness include, but are not limited to, episodic distractibility, irritability, rapid speech, mood swings, insomnia, cognitive confusion and increased activity. Mrs. [redacted] has not had a manic episode since May 1992 and her symptoms are well controlled with medication and therapy. She is supported by SSDI and resides in the [redacted] housing project.

Mrs. [redacted] applied (12/5 [redacted]) for the Information Sciences Program at Bidwell Training Center, Inc. and met all entry requirements except for Reading Comprehension level. She hopes to improve this skill via classes at Bidwell and be accepted for the [redacted]

February 1961 training program.

Any assistance which you may provide Mrs. [redacted] will be greatly appreciated. She could particularly benefit from assistance with transportation costs associated with school. Please do not hesitate to contact me if I may be of any further assistance to you.

Sincerely,

Lynda J. Katz, Ph.D.

# **UNDERSTANDINGS**

## **ELIGIBILITY CRITERIA**

To be eligible for vocational rehabilitation services you must have an impairment which results in a substantial impediment to employment; you must be able to benefit in terms of employment outcome and you must require services to prepare for, enter, engage in or retain gainful employment.

## **YOUR RESPONSIBILITIES**

It is your responsibility to cooperate in carrying out the rehabilitation program and to make reasonable efforts to attain your rehabilitation objectives and goals. Continuation of services is dependent upon your meeting your responsibilities.

## **YOUR RIGHTS AND REMEDIES**

It is your right to be fully consulted regarding any amendment or change to your rehabilitation program. You may discuss a problem or grievance with your rehabilitation counselor at any time upon scheduling an appointment. You may file a request for an impartial hearing before an Impartial Hearing Officer. The request must be mailed to the Director of Program Operations, OVR, Room 1310, Labor and Industry Building, 7th and Forster Streets, Harrisburg, PA 17120-9975. The request shall state the reason for the appeal, and the action, services, or relief you want; and be sent within thirty (30) days of the decision with which you are dissatisfied.

If you are not satisfied with rehabilitation services or the denial of services, you may contact the Client Assistance Program (CAP) in Philadelphia at 215/557-7112 (voice or TDD), in Pittsburgh at 412/363-7223 (voice or TDD), or toll free 1/800/742-8877 (voice or TDD). CAP staff can give advice and provide clarification or assistance with the services provided by OVR or other agencies. CAP staff can work with you and OVR staff to give you information and to resolve problems.

If your status is changed from eligible to ineligible, you will be given the opportunity for full consultation in such a decision. Ineligibility decisions will be based upon factors which are recorded in the official case record, and the decision will be certified by the appropriate OVR staff member. If ineligible because you cannot benefit from OVR services, you will be given the opportunity to participate in an annual review of that decision.

## **ANNUAL REVIEW OF PROGRAM**

At least once each twelve months there will be a review of your rehabilitation program at which time you will have the opportunity to jointly develop its terms with your counselor.

## **CONFIDENTIALITY**

All information acquired as part of the rehabilitation process shall remain the property of OVR. It is strictly confidential. Information shall be used only for purposes directly related to the administration of your rehabilitation program. This information will not be shared with anyone except Pennsylvania OVR staff or other agencies with whom the agency has a written cooperative agreement without your informed written consent or that of your representative, unless required by law.

I have participated in the development of this rehabilitation program and I understand and accept its provisions.

OR STATISTICS FOR SUB SAMPLE**
- 4) VOCATIONAL OUTCOME DATA  
PROVIDED**

## ***SUMMARY OF FINDINGS***

- 1) IF OUTCOME EQUALS COMPETITIVE EMPLOYMENT RATE, 2 STUDIES YIELDED SIGNIFICANT RESULTS (AT THE END OF FOLLOW-UP PERIOD)***

***BELL AND RYAN (1984)  
MARX, TEST, STEIN (1973)***

**2) IF CRITERIA IS JOB STARTS IN CE, 4 STUDIES MIGHT QUALIFY**

- **SOME OVERALL ADVANTAGE TO EXPERIMENTAL GROUP**
- **STUDIES HAVE METHODOLOGICAL LIMITATIONS**

**CONCLUSION: NONE OF APPROACHES HAVE DEMONSTRATED EFFICACY IN HELPING CLIENTS ACHIEVE AND MAINTAIN CE OVER ANY SUSTAINED PERIOD OF TIME.**

**3) IF CRITERION IS PAID EMPLOYMENT (TE/SE)**

**8 OF 10 STUDIES INDICATE THAT:**

**(A) WHEN CLIENTS ARE GIVEN INTENSIVE SUPPORT AND ARE**

**(B) PLACED IN JOBS NOT TOO DEMANDING THEY OFTEN FUNCTION AT A LEVEL BEYOND USUAL EXPECTATIONS**

**- INTENSIVE SUPPORT -  
- POSITIVE EXPECTATIONS -**

**CONCLUSION:**

**GIVEN THE ADDITIONAL FINDING THAT EMPLOYMENT SUCCESS IS OFTEN NOT MAINTAINED AFTER TREATMENT ENDS, THEN SE PROGRAMS MAY BE THE BEST WAY TO INCREASE EMPLOYMENT RATES.**

# **FINDINGS FROM 24 CONTROLLED STUDIES:**

**(Bond, 1992)**

- 1. Vocational Rehabilitation programs have been consistently, although modestly, successful in helping clients obtain and hold jobs.**
- 2. Few studies find an experimental effect for competitive employment rates.**
- 3. Subjects in experimental (VR) conditions had significantly less hospitalization in over half the studies, BUT also received additional services not provided to control subjects.**

4. Sheltered workshops are ineffective in producing competitive employment.
5. Clients with better work experience and better psychological adjustment benefit most from enriched vocational programs.
6. Clients with little/no work experience did most poorly regardless of type of vocational training provided.
7. Persons with mental illness have a good chance of retaining community employment as long as **I N T E N S I V E   S U P P O R T  
C O N T I N U E S .**

# **FIVE (5) CURRENT APPROACHES TO VOCATIONAL REHABILITATION:(Bond, 1992)**

## **1. BOSTON UNIVERSITY'S MODEL**

- \* Extended pre-vocational preparation period**

- \* Two intervention strategies:**

- (1) Client skill development**

- (2) building supports needed for functioning in a specific environment**

- + Emphasis on client choice & career development ("Choose - Get - Keep" model)**

- + Well Articulated Model**

- Has not been empirically validated**

- Does lead to > satisfaction with career choices but no evidence this leads to better employment outcomes.**

## **2. JOB CLUB MODEL - (Azrin, 1979)**

- \* Intensive behavioral counseling program focused on job finding**
- \* Job finding viewed as involving interpersonal skills, a social info. network, and motivational factors.**
- + Stresses client responsibility**
- + More direct strategy for higher functioning clients**
- + Positive empirical findings - produces as high as 90% employment rate**
- Inadequate for lower functioning Clients**
- Job retention rate is unclear**

### **3. ASSERTIVE COMMUNITY TREATMENT (ACT) MODEL - (Stein & Test, 1980)**

**\* Assertive outreach & service coordination to help clients in their natural environment**

**+ Closest to individual placement model of SE**

**+ Adaptable for small & rural programs**

**+ Promising controlled research**

**- Cost effectiveness is unclear**

**- Underdeveloped voc. capacity**

#### **4. PSYCHOSOCIAL REHABILITATION (PSR) & TRANSITIONAL EMPLOYMENT (TE) - (Fountain House)**

- \* Principles of normalization & gradualism**
- \* Address client's basic needs & stress client responsibility well-defined**
- + Well-defined model, national network**
- + Long track record, refined methods**
- Step to competitive employment hard, clients develop an institutional dependency on prevocational work crews**
- Null findings from controlled studies**
- Narrow, rigid stance toward employment options; job belongs to agency, not member (only 15% of TEP's convert to permanent jobs)**

**5. JOB BANK EXTENSION OF TE -  
(Thresholds, Rise, Incentive Community  
Enterprises)**

**\* Range of type & level of job  
opportunities & cooperating employers**

**\* Skill training programs & "supported  
education" options**

**+ Eclectic - Menu of Employment  
Options**

**+ Network & Cooperate with many  
Employers**

**- Takes Years to Establish**

**- Better Suited to Urban than Rural**

**- No Published Evaluation Studies**

## 6. SUPPORTED EMPLOYMENT (SE)

*Bellamy, Wehman (1986), Place-Train.  
(Developmental Disabilities). Federal  
Guidelines (1987)*

- \* "Place-Train-Plus": Advocacy, job development & placement, on- and off-site training ("coaching"), ongoing supportive services*
- \* Competitive employment, integrated work setting, ongoing supportive services*
- + Reconceptualization of problem from client (disability) to societal focus (unemployment)*
- + Normalizing experience - real work for real pay*
- + Zero reject - even the most severely disabled can work*
- + Time unlimited, diverse supportive services*
- Mixed results from evaluations of demonstration projects; 45-50% CE rate deteriorated after support withdrawn to base rate*
- Used primarily with persons with mild or moderate mental retardation (72%) vs. long-term mental illness (14.6%)*
- Nature, funding mechanisms, and responsibility for long-term support often problematic.*

## INDIVIDUAL PLACEMENT & SUPPORT (IPS)

- Becker and Drake (1993), C.M.H. Journal  
NH - Dartmouth Psych. Research Center; Pitt
- \* Eclectic - "the best of the rest"
- \* CMH Center employment specialists - trained in  
MI, VR, employment and community resources
  - + Rehab is MH's business
  - + Client preferences
  - + CE, integrated settings, follow-along supports
  - + Continuous assessment, empirical research
  - + Rapid job finding
  - + Trusting, ongoing relationship

Favorable initial results:

	<u>% Employment</u>
CMHC day treatment program:	8
IPS:	55

GOAL: To Inform Trainees About Factors That Go Into The Provision of Quality S.E. Services for Severely Psychiatrically Disabled People In A way That They Can Identify When Examining Program Options.

V WHAT ARE QUALITY SERVICES IN S.E. FOR PEOPLE WITH PSYCHIATRIC DISABILITIES?

There are many indicators that can be examined to assess "high quality" supported employment services. Materials put out by Paul Wehman et al (Virginia Commonwealth University), Tom Bellamy et al (University of Oregon), Bill Anthony et al (Boston University), Frank Rusch, John Tracht et al (University of Illinois) and Tom Powell et al (Corporation for Supported Employment in Connecticut). Quality services for people are quality services, period.

However, there is no denying that people with severe psychiatric disabilities do have some unique needs and face special barriers. What I have intended to do in the following section is to highlight some areas which are particularly important creating work opportunities for people with psychiatric disabilities - some of which are exactly the same as for any type of person but play out more prominently for these people; others which are essential to consider because of the stereotypes society holds of mentally ill people; others because of the nature of psychiatric disabilities. The intent here is not to label programs that do not meet these criteria as "bad" programs but rather to help identify potential gaps and problem areas when these are not met.

1) Integration and Visibility

There needs to be a concerted effort to ensure that supported employees are part and parcel of the regular work force and everyday society. Even more than concerns for numbers of clients at any worksite, there is a responsibility to be concerned that meaningful integration (i.e. to the extent the client wishes) occur in areas such as lunch, after hours socializing, employee training, etc. Because people with mental illness often have problems in developing meaningful interpersonal relationships (both because of their own behavior and societal stigma) the SE provider may need to provide advocacy with employers to insure this occurs - not settle for just a steady work opportunity. Also, a provider must recognize the very real stigma attached to mental illness and be prepared to confront it even with employers who agree to provide SE jobs. One obvious way to combat stigma is the recognition that "front of the house" jobs (sales, waiters, etc.) do more to confront social stereotypes than "back of the house" functions (e.g. stock room, dishwashing, etc.).

2) Non-Stigmatizing Support

Because there does exist societal fear, stigma and guilt associated with mental illness the nature of the support of the provider must allow for non-obtrusive interventions when needed. This may involve breakfast, lunch or dinner meetings, "undercover" (to employer), observations (e.g. job coach as customer), phone contact at night, etc.). Such "invisibility" is not always possible and/or even desirable. It is not a value in and of itself, but service providers should include it within the menu of options.

3) Prevention, Not Remediation, Is the Key

Almost by definition, the supports inherent in the concept of S.E. must of course be available to the worker quickly when crises do occur. But supports are best seen as preventive measures. All people undergo stress in making major life changes. The assumption must be that difficulties will arise for the client early on and intermittently throughout the job. A system of supports needs to be built in that is not totally dependent upon a client's identifying a need before an intervention is made. Sometimes clients lack the judgement to recognize problems early on; often employers do not give good feedback to employees with clear performance expectations, but rather give a sudden termination notice. Support, no matter where delivered, needs to be quite intensive during the 1st month and a minimum schedule of program initiated contacts needs to be maintained - obviously more if problems arise. The schedule I would recommend is the 1st, 2nd and 3rd days of employment, the end of the 1st week; at least 3X the next week and 2X a week for at least the next 2 weeks; and then at least weekly thereafter. Once again, these supports can be individual meetings, phone contacts, group meetings, on and off-sites, etc. They can range from 10 minutes - 2 hours in length. What is crucial is they do occur and they are not dependent upon the identification of a "problem" for them to occur.

4) Comprehensive Involvement With Provider For Other Than S.E.

This concept reflects an ideal which may not always be feasible but because of the nature of a particular local service delivery system needs to be kept in mind. The nature of support is personal and caring, not technical assistance. It is difficult for people to provide the level of support people need during a difficult period in their lives (i.e. starting work) when there is no meaningful relationship behind the provision of that support. When persons want to seek solace, they do not look under "S" in the Yellow Pages (for support or solace); they turn to someone they know and trust (lover, spouse, family members, etc.) if that resource is available. I believe the most effective service delivery models of S.E. for persons with severe mental illness are the psychosocial clubhouse and the Fayerweather Lodge concepts where people can form caring relationships to use when needed. Sometimes these services don't

exist in a given area or clients do not choose this option. In that case, an independent S.E. provider must develop a mechanism for ensuring that relationships are developed between job coach and S.E. workers before a job site is obtained. A relationship that transcends the work place contact.

5) Rehab Planning Is Comprehensive in Nature

Programs that have experience in offering work opportunities for people with severe mental illness have consistently found that non-work areas of people's lives cause as much, if not more, work for the job coaches and support staff as work problems do. When developing a plan for S.E., it is essential that rehab counselors, case managers, program providers, clients and significant others include in the plan of action, strategies for dealing with other facets of the clients' life (treatment, housing, family problems, etc.). When running a S.E. program, providers and agency staff cannot arbitrarily divide problems as work and non-work related problems. A person's life impinges on his (her) work and vice versa. While work is important, it is not a panacea for solving problems associated with severe mental illness.

6) Cooperation Among Service Providers

Related to Number 5 above, such comprehensiveness in planning cannot be achieved without working at cooperation among service providers and significant others involved in the client's rehab. There are some issues which have to be confronted head on and will be addressed in another section on "Teamwork". But particularly VR counseling and MH case management staff must understand that there will be stress and strains associated with joint planning and programming.

Several dangers exist. Much emphasis in the literature has been placed on client "splitting" but there is a phenomenon entitled the "Stanton-Schwartz" syndrome wherein two helpers' disagreements "split" the client. It is not necessary to always agree nor even to avoid presenting competing alternatives for clients. It is necessary to be clear on the rationale for alternatives and not make the client choose among people, as opposed to courses of action.

Traditionally, VR people have placed a higher value on convening meetings among caregivers than others. However, they often take the perspective of laying out the limits of their responsibility at these meetings (i.e. "We're only a vocational agency") rather than the possibilities. On the other hand, DMH Case Managers often feel too busy to participate and/or can be impatient in looking at goals and outcome measurements for success - they just want to give a client a chance or even just obtain a disposition. Both stereotypes have grains of truth which both VR and DMH people must recognize, in order to dispel - not just resent the other's viewpoint.

GOAL: To Help Trainees Sort Out Some Of the Soocial Needs That Impact On A SE Program Serving People With Severe Psychiatric Disabilities.

VI WHAT ARE SOME SPECIAL CHARACTERISTICS OF S.E. PROGRAMS FOR PEOPLE WITH SEVERE PSYCHIATRIC DISABILITIES

While the similarities outweigh the differences (insofar as the core values are concerned) there are a few special considerations that are very clear differences in SE as it has developed for mentally retarded persons as opposed to SE for persons with severe and prolonged mental illness.

1) The Issue of Stigma with the Attendant Greater Need For Employer Advocacy

Psychiatrically disabled people are feared, stigmatized, rejected and discriminated against more overtly than mentally retarded people. There is more social acceptance of this attitude towards people with mental illness than for others. An S.E. program for this group must accept an advocacy role (occasionally adversarial) with employers. Program providers must not participate in employment discrimination (i.e. not screen out clients for reasons employers are not legally allowed to) and must see community education as a part of their roles.

2) There Is Often Personal Discomfort On the Part of the Provider Staff

Staff of providers are not immune to societal stereotypes and biases against psychiatrically disabled people. In fact, many psychiatrically disabled people are difficult to relate to for a variety of reasons. The nature (cyclical) of the illness is such that staff will not have a sense of easy completion; there is always the uncertainty of a psychiatric exacerbation; and clients with psychiatric disabilities are much harder to market as employees to business people.

A SE program that serves severely psychiatrically disabled people probably needs to spend more time in recruiting staff due to the "burnout" factor, aggressively counter erroneous stereotypes propogated within its own staff (e.g. "these people can fly off the handle at any time") and be extremely vigilant about what gets communicated to the public at large and potential employers via brochures, TV and radio spots, and face-to-face meetings.

3) Psychiatrically Disabled People Probably Have a Greater Sense of Lost Potential.

I do not wish to overstate this point in relation to mentally retarded people. But, SE programs for people with psychiatric disabilities often are dealing with people who have been exposed to vocational development activities through adolescence, whose progress was then hindered by the development of the mental illness. People with severe psychiatric problems have probably had some (albeit usually unsuccessful) work experiences in the outside world. They have probably been encouraged more than mentally retarded people to think about career options and to have experienced a sense of loss at not attaining them. While many SE jobs are probably more stimulating and socially enhancing than work offered to mentally retarded people in rehab facilities or developmental achievement centers, the reverse is frequently true in terms of psychiatrically disabled people's pre-SE vocational experiences.

4) Greater Worry About Labelling

Once again, as with Number 3 above, there is a tendency to exaggerate this difference in programs serving mentally retarded vs mentally ill people. There does appear to be greater self-consciousness as a rule about the need for overt manifestations of support, particularly on the job site when doing SE for persons with severe mental illness. Hence the concern about non-obvious support interventions as opposed to the 1-1 job coach model so prevalent in many of the current SE programs developed out of the mental retardation field. This is not to say that 1-1 on site support is not needed or wanted by many psychiatrically disabled people (the Fountain House TEP model and others dispel that notion) but rather program providers cannot take for granted the concept that the job coach/support person will be seen as more of a help than a hindrance. Client resistance to this 1-1 approach needs to be appreciated as a natural (and probably acceptable) skepticism and accepted, if at all possible. Certainly, it should not necessarily be seen as unrealistic concerns, pathological manifestations, or lack of motivation.

5) Parent Expectations Caused By Guilt and Social Stigma

Any parent of a disabled child or adult has totally warranted concerns about the nature and quality of services offered to his (her) son or daughter - no matter what the disability label. In the case of clients with mental illness, for a long time, parents, particularly mothers, have been scapegoated as causative factors (the schizophrenogenic mother) in the development of the disease. So this natural skepticism is augmented by societally reinforced guilt and the stigma that mental illness holds. It is to combat

these attitudes, in addition to advocate for better services for mentally ill people that the National Alliance for the Mentally Ill has grown exponentially over the last few years.

Parent expectations for even non-disabled children are often unburdened, as they should be, by "realistic" limitations. In the case of SE for people with severe psychiatric problems, these expectations may run counter to the options that programs may have to offer. Also, as noted before, in the case of adults, client and parent needs are often complementary but never identical. This tension is exacerbated by the need for confidentiality and client control of his (her) own rehab. process.

Program providers need to give credence to parent concerns while not seeming to back away from their primary relationship responsibility - which is the client one. Program staff should not minimize differences of opinion nor try to imply parents should be realistic and accept what is there. They also should be clear when they are acting on the client's wishes, as opposed to deferring to the parents when disagreements occur.

Bond, Gary R. (1992). Vocational Rehabilitation. In R. P. Liberman, M.D. (Ed.), Handbook of Psychiatric Evaluation (pp. 244-275). New York: Macmillan Publishing.

## CHAPTER 11

# VOCATIONAL REHABILITATION

Gary R. Bond

This chapter provides a glimpse of the past, present, and possible future of vocational programming for persons with severe mental illness. To use a historical metaphor, the post-deinstitutionalization period can be divided into three eras: the rule of imperial institutions, the dark ages, and a renaissance. The first era started in the 1950s and extended into the 1960s. Vocational programs were implemented in hospitals, sheltered workshops, and halfway houses (Black, 1988). However, the optimism that prompted these facility-based efforts was soon overtaken by a deeply felt pessimism about the employment potential for psychiatric patients.

The 1970s and early 1980s were the "dark ages," in which vocational rehabilitation for persons with severe mental illness was not considered the mission of either community mental health centers (CMHCs) or comprehensive rehabilitation centers. During this time, psychosocial rehabilitation (PSR) cen-

ters, such as Fountain House (New York) (Malamud & McCrory, 1988; Vorspan, 1988), Thresholds (Chicago) (Dincin, 1975), Horizon House (Philadelphia) (Cnaan, Blankertz, Messinger, & Gardner, 1988), and the Club (Piscataway, NJ) (Lehrer & Lanoil, 1977) developed transitional employment (TE) programs. These programs were seen either as "maverick" or as "model" programs, depending on one's ideology. They existed as isolated fiefdoms within pervasively nonvocational mental health systems. Adaptations of TE are only now becoming part of the services within community support programs (CSPs) in CMHCs.

Now we may be on the verge of a renaissance in the form of the supported employment (SE) movement (Wehman & Moon, 1988). SE represents a paradigm shift in vocational thinking. By advocating the placement of clients with minimal prevocational training in community employment and the provision of time-unlimited support, SE

has led to explorations of employment possibilities for persons with severe disabilities. Whether these explorations shall result in enduring social inventions remains to be seen.

Vocational approaches for persons with severe psychiatric disabilities will be examined against this historical backdrop. Three general questions guide this chapter: (a) What vocational approaches are effective? To be deemed effective, a program must result in paid employment outcomes for its clients. (b) What exactly do these programs do? We urgently need clear, operational descriptions of program services. (c) For whom are different vocational approaches successful? An appreciation of the potential of vocational programs has been muddled by vague sample descriptions. We need to develop more precise and appropriate taxonomies to describe clients successfully served by various programs.

### A LOOK AT THE PAST: PRIOR RESEARCH

The research literature on the effectiveness of vocational approaches in psychiatric programs was examined, including the rare occasions in which researchers reported client-treatment interactions. Researchers have not built a cumulative knowledge base, and it was therefore necessary to impose an external structure on a scattered literature.

#### Method

##### *Inclusion Criteria*

Evaluation studies were included if they met five criteria: (a) The study was conducted after 1955; the approximate date for the inception of deinstitutionalization. (b) The program evaluated had an explicit vocational component. Several studies have shown that nonvocational approaches with emphases on insight and improved social functioning do not generalize to better work functioning (Gunderson et al., 1984; Vitale & Steinbach, 1965; Wilder, Levin, & Zwer-

ling, 1966). (c) The sample studied consisted solely of clients with psychiatric disabilities. Or, if a mixed disability sample was used, statistics were reported on a psychiatric subgroup. (d) Random assignment, or a close approximation, was used. Subject as own control, ex post facto matched group, and single-subject designs were excluded. (e) Employment outcomes were reported. Twenty-four studies were located that met the requirements, as listed in Table 11.1.

##### *Typology*

Vocational programs were grouped into the seven categories briefly described below. The last three approaches (the job club, assertive community treatment, and psychosocial rehabilitation) are discussed further in the section, *A Look at the Present: Current Popular Approaches*, p. 251.

1. *Hospital programs* included those in which the participants were inpatients, regardless of whether the vocational programming occurred in the community or in-hospital.
2. *Halfway houses* included programs in which the primary site of rehabilitation was conceptualized as a community residence. The best-known model was the Fairweather Lodge, which provides a structured setting for living, employment, and peer support (Fairweather, Sanders, Maynard, Cressler, & Bleck, 1969).
3. *Sheltered workshops* included programs in which training and employment were provided by securing subcontract work from industry (Black & Kase, 1986). The vocational activity generally occurred in segregated facilities. Programs included comprehensive rehabilitation centers offering training to a range of disability populations (Weinberg & Lustig, 1968) and workshops specifically designed for clients with psychiatric disabilities (Meltzoff & Blumenthal, 1966).
4. *Vocational counseling* included programs in which the primary activity evaluated

Table 11.1. Controlled Studies of Vocational Programs for Persons with Severe Psychiatric Disabilities

PROGRAM TYPE	STUDY	SAMPLE SIZE		FOLLOW-UP PERIOD (MONTHS)	EXPERIMENTAL COMPARISON
		EXPERIMENTAL	CONTROL		
Hospital programs	Paquette & Lafave (1964)	140	140	Not stated	Halfway house and vocational training vs. custodial
	Becker (1967)	25	25	8	Intensive social/vocational program vs. custodial
	Walker et al. (1969)	14	14	6	Community transitional employment (TE) vs. hospital job placement
	Marx et al. (1973)*	19	20	5	Progressive inpatient vs. regular ward
	Kuldau & Dirks (1977)	41	48	18	Day hospital and workshop vs. rapid discharge
Halfway house	Ryan & Bell (1985)	31	26	6	Hospital and community job placements vs. traditional inpatient
	Fairweather et al. (1969)	57	48	12	Lodge vs. aftercare
	Lamb & Goertzel (1972)	28	20	24	High expectation halfway house vs. low expectation family care
Sheltered workshop	Velasquez & McCubbin (1980)	36	36	6	Community residence vs. waiting list
	Meltzoff & Blumenthal (1966)	33	36	18	Day treatment with workshop vs. psychotherapy
	Soloff (1967)	55	91	12	Sheltered workshop vs. state hospital or recreation therapy

	Weinberg & Lustig (1968)	20	18	24	Sheltered workshop vs. vocational counseling
	Griffiths (1974)	14	14	18 (mean)	Sheltered workshop vs. aftercare
Vocational counseling	Briggs & Yater (1966)	74	60	13 (mean)	Vocational counseling vs. no treatment
	Purvis & Miskimins (1970)	99	50	not stated	Group and individual counseling vs. no follow-up
	Kline & Hoisington (1981)	10	10	6	Career exploration at a psychosocial rehabilitation (PSR) center vs. PSR only
Job club	Azrin & Philip (1980)	19	6	4	Job club vs. vocational lecture
Assertive community treatment	Marx et al. (1973)*	21	20	5	Assertive community treatment (ACT) vs. hospital
	Field et al. (n.d.)	18	18	18	Job developer + ACT vs. sheltered work + ACT
	Stein & Test (1980)	57	59	12	ACT vs. short-term hospital and aftercare
Psychosocial rehabilitation centers	Beard et al. (1963)	163	69	12	PSR with TE vs. waiting list
	Wolkon et al. (1971)	106	185	12	PSR vs. aftercare
	Dincin & Swift (1969)	160	76	24	PSR + TE vs. PSR day program only or no services
	Dincin & Witheridge (1982)	46	44	9	PSR + TE vs. social club
	Bond & Dincin (1986)	56	54	15	PSR + rapid placement vs. PSR + gradual placement

\*This study is listed twice. It had two hospital control groups, which have been treated as separate experiments in the ensuing analyses.

was verbal interaction, in either a one-to-one or group format. Vocational counseling typically involved identification of client needs, development of a rehabilitation plan, and career selection (Farley, Schriener, & Roessler, 1988; Rubin & Roessler, 1978).

5. *Job club* included programs in which a behavioral approach was used to help any unemployed group acquire and use the skills needed to obtain jobs (Azrin & Besalel, 1979).

6. *Assertive community treatment (ACT)* was an approach consisting of helping clients in their natural environment with frequent home and community visits, and assisting clients to obtain funding, housing, and jobs on a time-unlimited basis (Stein & Test, 1980).

7. *Psychosocial rehabilitation (PSR) centers* included programs that evolved from the clubhouse model developed by Fountain House in New York (Beard, Propst, & Malamud, 1982; Dincin, 1975). They provided an accepting peer-oriented clubhouse. They also offered a continuum of vocational opportunities, ranging from prevocational work crews, usually unpaid work opportunities within the center, to TE, which consists of temporary community jobs employing clients under an arrangement between the PSR agency and a community employer.

### Outcome Measures

Six variables measuring paid employment were examined: employment status at the end of the follow-up period (either *paid* or *competitive* employment), *duration* (number of weeks worked), *earnings*, *job starts* (i.e., any community employment at any time during study period), and *intensity* (i.e., full-time competitive employment status). Paid employment included competitive, transitional, and sheltered employment.

### Findings from 24 Controlled Studies

#### Study Characteristics

The classification of studies is shown in Table 11.1. The median publication dates for the studies reviewed in each of the seven voca-

tional program categories showed an approximate temporal progression from institutional to industry-integrated approaches: sheltered workshop (1967), hospital programs (1971), halfway houses (1972), vocational counseling (1970), PSR (1971), ACT (1980), job club (1980). The mean study sample size was 104 subjects and the mean study follow-up period was 12.5 months. The studies had various methodological problems, including vague descriptions of both experimental and control treatment conditions, low statistical power, brief follow-up periods, ambiguities about when vocational programming was terminated, and high dropout and refusal rates (Bond, 1988).

### Vocational Outcomes

Vocational programs have been consistently, although modestly, successful in helping clients obtain and hold jobs, as shown in Table 11.2. When meta-analytic techniques (Rosenthal, 1984) were used to evaluate the findings for this group of studies, the experimental condition showed greater vocational gains than controls on all six of the vocational outcome variables, as shown in Table 11.3. However, it is also true that none of the 13 studies reporting competitive employment outcomes found an experimental effect when examined individually.

### Hospital Outcomes

Clients assigned to the experimental conditions had significantly less hospitalization than controls in over half the studies examining this outcome. However, in addition to vocational programming, these experimental groups received other services not provided to the control group. The studies were designed this way because they were not intended to evaluate the vocational intervention in isolation from all other services. Thus, this set of comparisons does not directly test the efficacy of vocational programs in preventing rehospitalizations.

Table 11.2. Frequency of Significant Findings on 7 Outcome Measures Favoring Experimental Conditions Among Studies Reported in Table 11.1\*

PROGRAM TYPE	OUTCOME VARIABLE						
	PAID EMPLOYMENT	COMPETITIVE EMPLOYMENT	FULL-TIME EMPLOYMENT	JOB STARTS	DURATION	EARNINGS	HOSPITAL ADMISSIONS
Hospital-based	2/3	0/3	2/4	2/3	2/3	2/3	2/5
Halfway house	1/2	-	0/1	-	2/2	-	2/3
Sheltered workshop	-	0/4	-	1/2	0/2	-	1/1
Vocational counseling	0/1	0/1	-	-	0/1	-	-
Job club	-	-	-	1/1	-	-	-
Assertive community treatment	2/2	0/3	1/2	-	1/2	1/2	2/3
Psychosocial rehabilitation	0/4	0/2	1/1	1/2	1/2 <sup>b</sup>	0/2	2/5
Total	5/12	0/13	4/8	5/8	6/12 <sup>b</sup>	3/7	9/17

\*The first number in each pair is the frequency of studies significantly favoring experimental condition. The second number is the total number of studies examining a particular outcome variable.  
<sup>b</sup>Control group in one study had worked significantly more weeks than the experimental group.

Table 11.3. Meta-Analytic Results for 24 Controlled Studies Reported in Table 11.1

VARIABLE	OVERALL Z-SCORE	NUMBER OF STUDIES
Paid employment	6.0**	12
Competitive employment	2.9*	13
Full-time employment	4.1**	8
Job starts	5.7**	8
Duration	4.3**	12
Earnings	2.8*	5
Rehospitalization	6.2**	14

Note: All z-scores favor the experimental conditions; \* $p < .01$ ; \*\* $p < .001$ .

### Client Factors

Three studies used prior work experience to classify clients (Bond & Dincin, 1986; Kuldau & Dirks, 1977; Ryan & Bell, 1985) and one study stratified clients on their general psychosocial adjustment (Meltzoff & Blumenthal, 1966). A simple dichotomy was used in each case; for example, Bond and Dincin (1986) classified clients as *work-experienced* if they had been employed continuously for at least 1 year before admission, and classified the remainder as *work-inexperienced*. All four studies found that clients with more work experience (or better adjustment) benefited significantly more from the enriched vocational programs than did controls. Clients with little or no work experience did poorly regardless of the vocational training provided.

### Discussion of the Literature Review

Early reviews by Anthony and his colleagues (Anthony, Buell, Sharratt, & Althoff, 1972; Anthony, Cohen, & Vitalo, 1978) documented a lack of differences in employment rates for clients attending vocational programs compared with baseline rates for this population. The current review qualifies this conclusion. It shows that these programs *have* succeeded in placing clients in jobs and in helping clients retain these jobs. The consistent deficiency of these

programs has been their failure to prepare clients for future competitive employment outside the support provided by the rehabilitation program. Thus, the success of vocational programs has been in helping clients adjust to a specific vocational environment, which has sometimes been sheltered or transitional employment. Given what is known about the psychiatric population, it is not surprising that these skills have not generalized to new environments. Extrapolating from these data, one hypothesis is that clients have a decent likelihood of retaining community employment positions as long as they continue to receive intensive support.

Research on the effectiveness of sheltered workshops for persons with severe mental illness stopped in the United States after 1968. This was in contrast to the half-dozen active research programs in the 1960s (Black, 1988; Criswell, 1970). The reason that this line of research was abandoned is quite simple: Sheltered workshops have been ineffective in helping clients with psychiatric disabilities achieve competitive employment.

Among disability populations, clients with psychiatric disabilities do especially poorly in sheltered workshops (Ciardiello, 1981). The larger issue, however, is the poor track record these facilities have for placing in competitive employment clients with *any* disability. A national survey found that only 10% of workshop clients were placed in competitive employment annually (Green-

leigh Associates, 1975). Bellamy, Rhodes, Bourbeau, and Mank (1986) have estimated that clients with mental retardation (MR) who are placed in day activity and work activity centers require an average of 47 years to "graduate" to competitive employment.

This points to the need to "triage" the vocational needs of the psychiatric population in a more meaningful way than has been done in the past. For example, the generally positive results from controlled studies of hospital-based programs illustrate the capacity for institutionalized patients for work, and to a greater extent than is sometimes acknowledged. Industry-integrated programs for long-term patients are possible, and should be encouraged when discharge is not a current option (Forman, 1988). At the other end of the continuum, the evidence is compelling that many clients with prior work experience can benefit from high expectation programs. Another subgroup not adequately served by existing programs consists of well-educated clients who aspire to more than entry-level jobs (Collignon, Noble, & Toms-Barker, 1987).

Finally, the subgroup that is perhaps least understood and who may benefit the least from existing programs are clients with little prior work experience. The current experimentation with "supported education" may prove to be an optimal pathway to employment for clients not suited for traditional programs (Unger, Danley, Kohn, & Hutchinson, 1987).

Overall, experimental clients had a *lower* hospital rate than controls in the studies reviewed. The inference, therefore, is that most clients who receive vocational programming within a comprehensive rehabilitation program have no greater risk of rehospitalization than those who are not involved in a vocational program. This conclusion is somewhat at odds with that reached by Test (1984) and Hogarty et al. (1986) for high expectancy programs in general. There are, in fact, examples in the literature (Goldberg, Schooler, Hogarty, & Roper, 1977; Lamb &

Goertzel, 1972) in which some clients had poorer outcomes in high expectancy programs. Further research is needed to delineate client and treatment combinations in which high expectancy vocational programs are contraindicated. One characteristic of successful programs may be that they attend to the warning signs of relapse (Herz, 1984) and provide additional support or crisis intervention at those times. Successful programs may also assist clients in a graded, incremental trajectory of rehabilitation as well as in avoiding too many major life changes at the same time.

Comparison between different vocational approaches is difficult, because of the different populations each typically serves (Black, 1988). Research is needed to determine, for example, whether clients served by sheltered workshops differ systematically from those attending PSR programs, as has been sometimes argued. Such research would clarify whether different success rates are a result of sampling differences. Only a few of the studies reviewed used "grand prix" designs (Gottman & Markman, 1978) that pitted one approach against another. This research strategy has the unfortunate side effect of heightening competitiveness in a field in which cooperation is an essential ingredient of success. Perhaps quasi-experimental designs (e.g., Lam, 1986) are a partial answer.

### A LOOK AT THE PRESENT: CURRENT POPULAR APPROACHES

Table 11.4 lists five vocational rehabilitation strategies currently being used in the United States. Although a few controlled studies have been conducted on these models, as described in the last section, many gaps remain in our knowledge. The following summaries are impressionistic, and the conclusions may well change as more data accumulate.

Table 11.4. Current Vocational Approaches in Psychiatric Rehabilitation

PROGRAM APPROACH	EXAMPLES	STRENGTHS	WEAKNESSES
Boston University psychiatric rehabilitation model	Transitional Employment Enterprises, Boston	Well articulated Emphasis on client choice	Lengthy prevocational preparation Not empirically validated
Job club	Brentwood Job Club, Los Angeles	Stresses client responsibility Most direct strategy for higher functioning clients Positive empirical findings	Not suitable for lower functioning clients Job retention unclear
Assertive community treatment	Program for Assertive Community Treatment, Madison, Wis, Harbinger, Grand Rapids, Mich	Closest to Wehman's Individual Placement Promising controlled research Adaptable to small programs Wide range of clients served	Cost effectiveness not clear
Psychosocial rehabilitation/transitional employment	Fountain House	Clear model National network Long track record	Null findings from controlled studies Step to competitive employment hard
"Job bank" extensions of transitional employment	Thresholds Rise, Minneapolis, Minn, Incentive Community Enterprises, Mass	Menu of job options Eclectic — both Place-Train & Train-Place Wide range of clients served	Takes years to establish More suitable for urban areas No published evaluations

## Boston University's Psychiatric Rehabilitation Model

At the Boston (BU) Center for Psychiatric Rehabilitation, Anthony and his colleagues have been developing a conceptually grounded rehabilitation approach that has roots in both client-centered therapy and skills training (Anthony, 1980; Farkas & Anthony, 1989). Unlike the other four current approaches described in this section, the Boston University (BU) psychiatric rehabilitation model has developed in an academic setting.

In a quasi-experimental evaluation of the BU psychiatric rehabilitation model, Goering, Wasylenki, Farkas, Lancee, and Ballantyne (1988) examined 2-year outcomes for 82 clients, comparing experimental subjects to historically matched controls. The experimental treatment was a case management program, using case managers trained according to the Boston model. The rate of paid employment was 20% for the experimental group, compared with 13% for controls, a nonsignificant difference. However, using a measure of "instrumental role," defined as ability to function as worker, student, volunteer, or homemaker, significantly more of the experimental subjects than controls were rated as successful.

Danley and Rogers (1989) have further articulated the vocational aspect of the BU model as entailing a *Choose-Get-Keep* sequence. Transitional Employment Enterprises (TEE), an agency experienced in providing vocational training to a range of vocationally disadvantaged clients, adopted the *Choose-Get-Keep* model in a new project designed for persons with severe mental illness (Trotter, Minkoff, Harrison, & Hoops, 1988). The BU model emphasizes extended exploration of career options before community placement. Accordingly, TEE's program included two phases of preemployment training, averaging 2 to 6 months, before clients graduated to the job-seeking phase. An evaluation of their program showed that 35% of program participants obtained com-

petitive employment. Role functioning in nonvocational life domains did not predict successful placement.

The strength of the BU model is its focus on client choice, an emphasis that has been overlooked in many vocational programs. One effect of this counseling focus has been to enable clients to feel more satisfied with their vocational choices (Goering et al., 1988). Other studies suggest that a focus on career development increases client involvement in the rehabilitation process (Farley et al., 1988; Kline & Hoisington, 1981). Career exploration seems especially appropriate for addressing "career immaturity" that characterizes a significant subset of clients with severe mental illness (Ciardiello & Bingham, 1982). Poor job retention rates occur partly because clients are placed in jobs they do not choose. Often these are dead-end jobs that they find demeaning.

One indication that client preferences have been neglected is their absence in the empirical literature. The next generation of evaluations will undoubtedly examine quality of life, quality of the work place, and client satisfaction (Schalock, 1988).

A drawback to the BU model is its untested assumption that extended prevocational career exploration will lead to better outcomes. What has been shown to date is that career exploration leads to greater satisfaction with choices. However, satisfaction with choices is different from success in employment, as noted by Bolton (1988): "Vocational interests are relatively independent of the abilities that determine occupational success" (p. 180). More research is needed to determine how success and satisfaction can be jointly maximized.

## Job Club

The job club is an intensive behavioral counseling program based on Skinnerian principles. The focus is on job finding with clients taking ultimate responsibility for obtaining jobs. Job finding is viewed as involving interpersonal skills, a social information

network, and motivational factors (Azrin & Philip, 1980).

The emergence of the job club in the 1980s as a major VR activity is consistent with the mounting evidence that the only counselor activities associated with successful VR closures are services in close proximity to the job search itself (Vandergoot, 1986). According to past surveys, rehabilitation professionals typically spend less than 10% of their time on placement-related activities, thus partially explaining low competitive employment rates for clients with severe disabilities (Vandergoot, 1986).

Azrin and Philip's (1980) initial study with a heterogeneous sample of unemployed persons reported extraordinary success rates for job club participants. For job club clients who had been in a mental institution, the employment rate was 90%, compared to 33% for controls. Job club clients "with mental problems" achieved a 94% employment rate. A replication reported that 42% of the job club members were placed in employment, compared with 13% of controls (Keith, Engelkes, & Winborn, 1977). Unfortunately, this study did not report separate statistics for different disability groups. Eisenberg and Cole (1986) compared veterans with mental illness participating in a job club with a demographically matched control group. During a 5-month follow-up period, 61% of the 26 experimental subjects had found employment, compared with only 10% of the controls, a significant difference.

A series of uncontrolled studies on the Brentwood Job Finding Club by Jacobs and his colleagues (Jacobs, Kardashian, Kreinbring, Ponder, & Simpson, 1984; Jacobs et al., 1988) provides the most extensive information on the application of the job club to the psychiatric population. A study with a Veterans Administration (VA) psychiatric population found that 56% of those entering the program obtained a job; 68% of those employed who were located after 6 months were still employed (Jacobs et al., 1984). In a subsequent study, 51%

of all participants found vocationally productive placements (Jacobs et al., 1988). However, a third study obtained a more heterogeneous sample than the preceding two studies. In this last study, which included referrals from community-based treatment and residential care programs, the success rate dropped to 29% (Jacobs et al., 1988). VA referrals had a 37% success rate, compared to a 17% success rate for non-VA referrals. Moreover, only 12% of clients diagnosed with schizophrenia or bipolar disorder achieved employment, compared to 45% of the remainder, who had diagnoses of substance abuse, anxiety disorder, or depression. Recipients of Supplemental Security Income (SSI) had significantly poorer outcomes. Poor work history and poor interviewing also were negatively associated with employment. Thus, the job club is an excellent option for clients who are not overly disabled, but it is apparently an inadequate response for clients with severe psychiatric disabilities.

One drawback to the job club model is that it does not address job retention. Similarly, the job club literature has generally not reported job retention statistics beyond a short follow-up period. Moreover, documentation of program dropouts has been weak.

A logical extension of the job club model is use of behavioral strategies to improve job retention. Mueser and Liberman (1988) report a successful case study of a behavioral approach to helping a client acquire the social skills necessary to retain a job. A large sample controlled study of this individualized approach applied to vocational issues would be a major contribution to the literature.

### Assertive Community Treatment

ACT includes programs in which assertive outreach and service coordination is used to help clients in their natural environment.

The prototype is the Program for Assertive Community Treatment (PACT) in Madison, Wisconsin, developed by Stein and Test (1980). Unlike facility-based models, PACT provides in vivo training in the activities of daily living.

ACT is widely regarded as a promising, commonsense approach. Its demonstrated efficacy in increasing community tenure is substantial. It is flexible, in that it can be adapted to both small and large programs. It is also well suited to rural communities (Rutkowski & Howick, 1986). Because the approach is individualized, clients with a wide variety of characteristics are appropriate for referral. ACT programs provide time-unlimited support, which is believed to be important for job retention. The ACT philosophy of defining client services as the responsibility of a single core team avoids the fragmentation that has hampered vocational initiatives.

Harbinger, a Michigan ACT program, was evaluated in a controlled study of 91 clients (Mulder, 1982). The study results are difficult to evaluate because of compromises made in the randomization procedure, the lack of a fixed follow-up period, and lack of details in the final report. However, it is the only controlled study outside of Madison of an ACT program with a vocational focus. Harbinger placed clients in volunteer positions in community businesses. Follow-up interviews were completed on 90% of Harbinger clients and only 56% of control clients. The difference in employment rates—26% for Harbinger clients and 18% for controls—was not significant. The mean annual earnings from employment was \$537 higher for Harbinger clients than for controls.

Another controlled study of ACT found no differences in employment status between ACT clients and controls (Hoult, Reynolds, Charbonneau-Powis, Weekes, & Briggs, 1983). However, the description of the ACT program did not include any mention of a vocational emphasis.

Unfortunately, few ACT programs have developed their vocational capacity as extensively as the PACT program in Madison, so it remains unclear how easily the vocational aspect of the ACT model can be replicated. Finally, the cost effectiveness of the ACT model's individual placement approach to employment remains an open question.

### Psychosocial Rehabilitation and Transitional Employment

PSR developed out of a self-help group for ex-psychiatric patients (Dincin, 1975). Accordingly, it deemphasizes the patient role and stresses the client's own responsibility for rehabilitation. Clients are referred to as *members*, and the rehabilitation process stresses principles of normalization. Status distinctions between staff workers and members are often blurred. PSR programs attempt to address basic needs of members for housing, recreation, social support, and employment. Most PSR programs emphasize the principle of gradualism (Dincin, 1975). According to this principle, clients may move through a continuum in each of several critical life domains (such as employment, independent living, and socializing) in the process of achieving full integration in the community.

A key element in the vocational continuum is TE. Beard et al. (1982) have listed 18 formal characteristics of TE, including the following: The positions are temporary, and they "belong" to the PSR agency, not the members. Members typically work half-time, in entry-level jobs in community settings. Job failures are accepted as part of the vocational process, and members may work many different TE positions.

PSR is a well-defined model with a strong national network. These are valuable characteristics for implementation and community acceptance. The long history of PSR suggests that it has survived a trial-and-error process during which its methods have been refined.

Several recent surveys suggest the extent

to which the PSR model has been disseminated. Stratoudakis (1986) has reported 178 clubhouses modeled after Fountain House. Rutman and Armstrong (1985) surveyed 114 TE programs and found that among clients completing TE, 35% were employed and 16% were on another TE placement. One of the key findings was a fair degree of fidelity in emulating the Fountain House model among those programs surveyed.

One drawback to PSR programs is that clients develop an institutional dependency on the prevocational work crews (Bond & Boyer, 1988). Some studies have suggested that PSR clubs have difficulty moving the majority of clients beyond prevocational activities. A Maryland survey of 28 PSR centers found that only 5% of their clients were placed in competitive employment in a 12-month period (Connors, Graham, & Pulso, 1987). A case study of one PSR program found that clients had alternating cycles of progress and regression, and that they returned more frequently to prevocational crews than to any other program component (Turkat & Búzzell, 1982). Clinical impressions suggest that the step from TE to competitive employment may simply be too large for some clients.

The nonexperimental evidence on the efficacy of the PSR and TE models is equivocal: Some reports suggest competitive employment rates exceeding 40% for graduates (Rehab Brief, 1986; Ruffner, 1986). To what degree these figures are affected by self-selection is hard to judge. Moreover, none of the controlled studies of PSR have shown positive results for employment.

Another criticism of Fountain House and other clubhouses following its paradigm is that they have traditionally taken a fairly rigid stance to the kinds of agency-employer relationships they will undertake. For example, the TE model stipulates that jobs belong to the PSR agency, not the member. Consistent with this principle, Rutman and Armstrong's (1985) survey reported that only 15% of TE participants converted their TE

position into a permanent job. Thus, the disadvantage of a clearly defined model is a tendency to rule out other options.

### Job Bank Extensions of Transitional Employment

A label for the final type of vocational approach is approximated, although inadequately, by the term *job bank*. This approach is characterized by expansion of vocational services into a wide array of options, partly as a function of community business opportunities. The job bank capitalizes on relationships with a variety of cooperating employers. Employment specialists therefore already have a list of available employment possibilities when they begin vocational planning with a new or returning client. The menu of job opportunities the job bank affords its members distinguishes it from all the other models described above. Clients have the advantage of a range of options in terms of types of jobs, work schedules, duration of employment, and hours worked per week. Moreover, such programs offer relatively easy entry, exit, and reentry to new jobs.

Three agencies that exemplify this eclectic approach are Thresholds (in Chicago), Rise (in Minneapolis) (Barrett & Lavin, 1987; Prieve & DePoint, 1987), and Incentive Community Enterprises (in Massachusetts) (Campbell, 1988). Unlike Fountain House, these agencies have experimented widely with different vocational options. These agencies are pragmatic, and they have avoided a rigid ideology regarding the single "best" agency-employer arrangement.

For example, over the past 30 years many innovations have transformed the Thresholds vocational program from a clubhouse approach based on Fountain House to a complex and eclectic set of vocational strategies. A partial list of strategies includes a factory enclave (Bond, 1987; Forman, 1988), arrangements with local food services industries to supply them with trainees, supported

employment opportunities, a mobile job support team, and special arrangements with community employers in which Thresholds, in essence, functions as an employment agency. In the realm of supported employment, Thresholds staff have been examining supportive roles for coworkers. A recent program development has been the Community Scholars Program, a "supported education" approach in which clients are assisted in the completion of university and technical school coursework. Thirty-six clients had enrolled in the Community Scholars Program by the end of 1988 (Thresholds Community Scholars, 1990). Thresholds also continues to have a strong TE program. In a 1986 survey of 135 agencies offering TE to persons with severe mental illness in the United States, Thresholds ranked first in the number of members on job placement, first in the total annual wages paid to members, and fourth in the total number of employers (Thresholds Newsletter, 1987).

The Rise program provides a similar range of options: enclaves, typically for lower functioning clients with multiple disabilities; training programs for data entry and for nursing assistant certification; and conventional TE (Barrett & Lavin, 1987; Prieve & DePoint, 1987).

## Discussion of Current Approaches

These five vocational approaches vary on a number of critical dimensions. None emphasizes traditional psychometric assessment. The BU model employs a functional assessment approach that explores the skills necessary for a client to be successful and satisfied in the environment of choice (Anthony, Cohen, & Danley, 1988). The job club uses behavioral assessment to identify specific skill deficits in job acquisition. ACT stresses community-based assessments and job tryouts (Bond, 1987). PSR programs have used prevocational work crews as a context for situational assessments (Bond &

Friedmeyer, 1987). The job bank agencies use a combination of strategies. Among the five approaches discussed, ACT is most similar to the individual placement SE approach, to be described in the next section.

With regard to prevocational training, the approaches vary from the BU model, which stresses extensive prevocational exploration, to the job club, which consists of only 20 hours of training prior to the job search. Empirically, PSR programs appear to have extended prevocational preparation for most clients. ACT and job bank programs are individualized and in theory are flexible about preparatory time.

As we look toward the future, Wehman's (1986) *place-train* paradigm may affect both the conceptualization and implementation of psychiatric vocational programs. Of the five current approaches presented, only the BU approach explicitly stresses the desirability of extended preparation in protected environments. Accordingly, programs adopting BU principles have not encouraged rapid entry of clients into community employment (Bond, 1990a).

Important comparative issues remain unanswered. What are the self-selection biases to the respective approaches? Clients with prior work history appear to do better, regardless of vocational approach, but are some approaches more adaptable? How easily can each approach be implemented in new areas? The clubhouse has had the widest dissemination. Is it incompatible with medically oriented CMHCs? How has the clubhouse been adapted? Aspects of the ACT approach have similarly been widely adopted, but the inclusion of a vocational counselor on the ACT team, as found in some Wisconsin CSPs, is rare. With regard to ongoing support, which approaches actually provide the necessary intensity of intervention? Only the job club approach explicitly excludes ongoing support from its program description. How cost-effective is each approach? Which approaches do clients

prefer? This is only a sampling of questions that merit attention.

## A LOOK AT A POSSIBLE FUTURE: SUPPORTED EMPLOYMENT

### Definition of Supported Employment

Supported employment as defined by 1987 federal guidelines consists of three elements: (a) competitive employment (defined as employment paid at commensurate wages with an average of 20 hours of work per week), (b) an integrated work setting, and (c) the provision of ongoing support services (Wehman, 1988). The guidelines stipulate three types of integrated work settings, which have become known as (a) the individual placement approach, (b) the enclave, and (c) the mobile work crew (Moon & Griffin, 1988). These guidelines also state that SE is intended for "individuals who, because of the severity of their handicaps, would not traditionally be eligible for VR services" (Wehman, 1988, p. 5).

In the federal guidelines, TE is listed explicitly as a type of SE. Its inclusion in the SE guidelines was *political*, and not a conceptually elegant decision. The prospects for VR funding to SE programs explains the lobbying activity on behalf of the TE language.

*Historically*, TE has evolved quite differently from SE, although the motivations for the development of each are related. As previously described, TE was originally developed by Fountain House for persons with severe mental illness. By contrast, SE developed out of the normalization movement for persons with MR.

*Definitionally*, the chief distinction between SE and TE is that TE is *time-limited* whereas SE is not. Edelstein (1988) has noted three assumptions of TE not shared by SE: (a) prevocational training should precede placement, (b) clients should be able to func-

tion at the competitive production levels at the time of placement, and (c) follow-up supports are not permanent and ongoing.

*Philosophically*, there are points of convergence and divergence (Anthony & Blanch, 1987; Bond, 1987). Both SE and TE stress the importance of placing clients in real work settings, and both deemphasize traditional assessment approaches. TE, however, minimizes the importance of the job match for a TE client, because the TE work experience is valued as an opportunity to work and to earn money in an integrated setting. Because the job is temporary, the specific content of the job is less important.

### The SE Movement

Wehman, Kregal, and Shafer (1989) have documented the growth of SE services in 27 states that received federal SE funding. According to their survey, these states reported serving 9,633 SE clients in 1986. By 1988 this number had grown to 24,817. The vast majority (72%) of 1988 SE clients had a primary disability of MR. However, 14.6% had long-term mental illness. Individual placements accounted for 65% of the 1988 placements, followed by the enclave (20%), the work crew (6%), and small businesses (4%). The most popular SE occupations have been custodial (35%), food service (23%), manufacturing (12%), and clerical (3%). The majority of clients (73%) met the federal guidelines by working at least 20 hours per week, although 40% of the individual placement clients did not. Hill's (1988) surveys suggest that SE programs have not fulfilled the intent of federal guidelines in that most SE recipients are only mildly or moderately disabled. Wehman (1988) has acknowledged this discrepancy.

To summarize, SE is a popular movement at present, probably fostered in part by economic conditions that brought a demand for new workers in the service sector. Campbell (1988) notes that supported employment involves a reconceptualization of the problem from a client to a societal focus. The prob-

lem is defined in terms of unemployment, not disability. Following this logic, the solution lies with local industries, *not* with human service organizations.

Although SE can be conceptualized as a program model, the existing literature has focused largely on the systems aspects implied by its introduction. This emphasis is not accidental because adoption of SE requires a radical shift in thinking in both the VR and MH systems. Moreover, the proponents of SE have been politically astute and sensitive to the problems of assimilation of new models into the existing VR system. Despite Wehman's assertions that SE is a movement for all disabilities, in most states it has remained focused mainly on the MR population. We now turn to efforts directed specifically at the psychiatric population.

### SE for Persons with Severe Mental Illness

In 1978 a cooperative agreement was made between the Rehabilitation Services Administration and the National Institute of Mental Health to improve vocational services for the chronically mentally ill. This agreement led many state vocational rehabilitation (VR) and mental health (MH) departments to follow suit (Stratoudakis, 1986). Additionally, supported employment legislation provided funding for SE demonstration projects. In some states this funding resulted in projects targeting the psychiatric population (Rehab Brief, 1987).

Statewide SE projects aimed at the psychiatric population are a recent phenomenon, and virtually no statistical data on them are available. The early results from these demonstration projects have been mixed.

In 1983 Pennsylvania funded 33 "industry-integrated" projects at a cost of \$2.5 million. During the first year of operation, 920 clients were served and 174 were placed. However, only 47 clients were rehabilitated, using VR criteria for successful closure. The second year brought a large increase in successful closures (Forbrich, 1986).

In 1983, the Ohio DMH initiated a study of vocational services for persons with severe mental illness (Saveanu & Roth, 1986). Over a 4-year period, 2,323 clients were rehabilitated, at an average per-client cost of \$2601. Of the 7,164 clients referred, 71% were accepted for rehabilitation services. This is an encouraging rate because of the history throughout the United States of screening out clients believed to be too severely disabled. The fact that only 20% of the referrals came directly from the CMHCs suggested a major gap in the full implementation of the interagency agreement. In a survey of VR and MH practitioners, each tended to blame the *other's* system for implementation problems (Saveanu & Roth, 1986).

Indiana provided \$1.2 million targeted for 10 vocational projects during 1986-1987. The guidelines for these projects included the requirements that they be "industry integrated, complement existing services, and lead to competitive employment" (Indiana, DMH, 1985, p. 1). The success in implementation of the 10 projects was mixed. Five were judged moderate successes, and five had major implementation problems.

### Outcome Findings from an SE Demonstration Project

Nichols (1989) evaluated one of the 10 Indiana demonstration projects. It used an individual placement approach provided by Morgan County Rehabilitation Services (MCRS), a comprehensive rehabilitation center in central Indiana. The sample consisted of 25 clients who were followed for an average of 66 weeks after admission to the program. The clients were mostly referred from local CMHCs. Although the target population was intended to be clients with severe mental illness, the sample characteristics suggested that this population was less impaired than typical CSP clientele. For example, only 36% were SSI or Social Security Disability Income (SSDI) recipients and only 32% had a diagnosis of schizophrenia. Nevertheless, the majority of clients were

severely disabled, as suggested by an average of three prior psychiatric hospitalizations and an average of only 1 month of employment in the preceding year.

During the study period, 80% of the clients were employed at least once, and 52% were employed at the end of the study period. Nineteen clients were employed at least once before the last month of the study period. They averaged 30.7 weeks of employment, earning an average of \$2,616. They also averaged 28 hours of employment per week with an average hourly wage of \$4.00. The average number of hours worked per week varied widely; 36% averaged fewer than the 20 hours per week stipulated by the federal definition of SE.

The 19 clients achieving competitive employment received an average of only 19.4 hours of job coaching, or approximately 40 minutes of job coaching per week of employment. Clients also averaged 75.9 hours of attendance in an employment support group. Number of hours of job coaching was negatively correlated with average number of hours worked per week. Thus, clients who worked full time had far less job coaching than those who worked only a few hours a week, as might be expected.

The "VR process" was a major interest in this study. MCRS conceptualized their program as consisting of two major phases, a *prevocational* phase and a *placement* phase. The prevocational phase was further sequenced into: *VR referral* (the time required for establishing the client's eligibility for VR services), *vocational evaluation*, and *work adjustment* (consisting of sheltered workshop and TE placements). Periods of time in which clients temporarily dropped out of the vocational program were classified as *hold* time. Hold status occurred for a wide range of reasons, including medication problems, attempts by clients to find jobs on their own outside the rehabilitation program, concerns about losing Social Security benefits, and requests by staff at the CMHC. Once in the placement phase, clients began the job search in collaboration with the job de-

veloper. The placement phase consisted of three types of activities: searching for jobs (*search*), working (*job*), and periods of inactivity (*hold*).

The average duration in each of the program phases for the sample of 25 clients is displayed in Figure 11.1. Time was apportioned as follows: prevocational phase (28%), searching for a job (19%), hold status (19%), and competitive employment (36%). The length of time spent in the various preparation phases was either unrelated, or negatively related, to vocational outcomes, after controlling for time in program. Thus, these data do not support the notion that an extended preparation time enhances one's job retention.

The obstacles to employment can be clarified by examining the apportionment of time across the various phases. Clients averaged 18.4 weeks in the prevocational phase before starting the job search. This delay is noteworthy, because the program was conceptualized as a rapid placement approach. Moreover, MCRS was the most committed of the 10 Indiana demonstration projects to reducing the administrative and other barriers to community employment. Specifically, MCRS streamlined the VR eligibility process and deemphasized both vocational evaluation and prevocational preparation. Thus the prevocational phase was *shorter* than in the other projects. Even so, the 4-month preparation period may be less than optimal.

After clients entered the placement phase, the process of vocational rehabilitation was not linear. Three factors influenced the stability of job tenure: hold status, job changes, and hospitalizations. Clients averaged 12.9 weeks in hold status, 91% of which occurred *after* they entered the placement phase. Twelve clients held two or more jobs. Three of the 25 clients were hospitalized during the study period.

Demographic and diagnostic variables had little bearing on either the rehabilitation process (as measured by length of time in the program components and amount of job

Figure 11.1. Average duration in SE phase. Average number of weeks spent in each vocational program phase for 19 clients with severe mental illness. Note: Values are weeks in each phase. SE = supported employment; VR = vocational rehabilitation; Voc Eval = vocational evaluation; Prevoc Hold = prevocational hold. (Adapted from Nichols, 1989.)

coaching and number of support groups attended), or on outcomes. SSI and SSDI recipients, however, had significantly poorer outcomes compared to nonrecipients.

### Discussion of Supported Employment

The debate on the merits of SE for the psychiatric population has been obscured by a lack of hard data, conceptual confusion, and the confluence of *program* and *systems* issues. The Pennsylvania, Ohio, and Indiana projects suggest that systems change is slow. Others have also concluded that cooperation between VR and MH programs is problematic (Dellario, 1985; Noble & Collignon, 1988).

The Nichols study shows that achievement of competitive employment is difficult even when rapid placement is an objective. The barriers included both client resistance and administrative barriers. Client resistance became more salient when clients were closer to actual employment than when they were engaged in prevocational activities. As other studies have found, client resistance was also greater when clients were receiving Social

Security benefits. Long-standing administrative barriers included those imposed by both the VR system, with its cumbersome eligibility process, and the MH system, with the lack of referrals.

Future research should differentiate SE approaches for clients with psychiatric disabilities from the approaches used with the MR population. One difference already widely reported is a different conception of job coaching with the psychiatric population than with MR clients. Quantitatively, clients with severe mental illness receive far less job coaching at the job site. For example, the average of 19.4 hours of job coaching in the Nichols study for an average 30-week employment period is far less than the 113-hour average during an initial 12-week training period for MR clients reported by Hill (1988), or the average of 233.2 hours reported more recently by Wehman et al. (1989). Supplementing the job coaching in the mental health system is case management. The empirical literature suggests that the consistency of follow-along support is instrumental in job retention (Bond, 1987), although this has not been shown directly for supported employment. Wehman (1986) has

described SE as a *place-train* model. For the psychiatric population a more apt term may be *place/follow-along*, because the support does not typically involve job coaches training clients in job-specific skills.

The nonlinearity of the rehabilitation process observed in the Nichols study has also been noted by Strauss, Hafez, Lieberman, and Harding (1985). Insofar as SE provides time-unlimited support and allows for flexible arrangements in the number of hours clients work, it is well suited to the frequent and unpredictable variations in status characteristic of the psychiatric population. The finding that clients in the Nichols study were given a second and third opportunity for competitive employment is consistent with the Fountain House philosophy of tolerating job failures (Beard et al., 1982).

### ONE FUTURE DIRECTION FOR RESEARCH: THE TIMING OF PLACEMENT

Wehman (1986) has hypothesized that a place-train sequence is more effective for persons with severe disabilities than the conventional train-place approach. This hypothesis should be tested directly, especially because it goes against the conventional VR wisdom. Not all experts agree that Wehman's hypothesis applies to the psychiatric population. In particular, the BU model represents a dissenting viewpoint (Anthony & Blanch, 1987).

One fact is apparent. If clients are to have rapid entry into integrated work experiences, employment specialists must take an assertive approach to both the VR and MH systems. To date, the main evidence that a place-train model is effective is based on demonstration projects showing reasonable placement and retention rates for MR clients who have had little prior competitive employment within the traditional sheltered workshop programs. The Thresholds accelerated placement study (Bond & Dincin, 1986), although conducted between 1980 and 1983 and therefore somewhat dated, offers

the only direct experimental evidence on a rapid placement approach with any severely disabled population. For this reason it is described in some detail.

## Method

### Design

The design compared two vocational approaches designated as *accelerated* and *gradual*. Clients randomly assigned to the accelerated condition were placed in a TE position (typically an enclave) 1 month after admission to Thresholds. Clients in the gradual condition attended prevocational work crews for a minimum of 4 months before they were eligible for TE.

### Sample Characteristics

The study eligibility criteria for clients were the following: (a) 18 years of age, (b) unemployed, (c) stated goal of employment, and (d) minimum attendance of 40 hours during the first 4 weeks at Thresholds.

In the sample of 131 clients accepted into the study, the mean age was 24.5. Modally, the clients were males (69%), whites (75%), and high school graduates (80%). Diagnoses, obtained by the client's case worker from the most recent hospital records, indicated 55% with schizophrenia, 19% with a major affective disorder, and 26% with a personality disorder. The sample averaged 3.2 prior psychiatric hospitalizations. At the time of admission, 61% were receiving government assistance (either SSI or SSDI), 31% were supported by their parents, and 8% stated they were self-supporting. The median number of years in prior competitive employment was 2 years. The median length of unemployment immediately prior to admission was 9 months.

### Predictor Variables

Client background variables were obtained during an interview conducted 1 month after program admission. In addition

to demographics, three employment variables were coded: work experience, months employed, and months unemployed. Work experience was a dichotomous variable distinguishing between clients who had worked 1 year continuously in competitive employment and those who had never done so. Months employed was defined as the time in paid employment before admission. Months unemployed was measured between the termination from the last job held and date of admission (with a value of 70 months assigned to those who had never worked).

Two types of staff ratings were obtained. At study admission, a research assistant made ratings on the Global Assessment Scale (GAS) (Endicott, Spitzer, Fleiss, & Cohen, 1976). A situational assessment, based on staff ratings of client work performance in prevocational work crews and TE placements, was obtained for 84 clients an average of 5 months after program admission (Bond & Friedmeyer, 1987). (Situational assessments were not obtained for early program dropouts.)

At study admission, clients made self-ratings of general capacity to cope with problems on a 7-point Coping-Mastery scale (Pearlin & Schooler, 1978). Clients also completed the Work Performance Inventory, a 22-item inventory of common obstacles to job retention (e.g., symptoms, lack of education, work conditions, work stress) adapted from Westermeyer and Harrow (1987).

Dropout status was coded as a 3-point scale, based on whether a client dropped out during the first 4 months in the program, dropped out between the fourth and ninth months, or was an active client of the program for the entire 15-month study period.

### *Vocational Outcome Variables*

Three outcome variables were examined for 107 clients located for interviews 15 months after study admission. Employment status was based on the client's status at the time of the follow-up interview. A 5-point

scale was used: (a) competitive employment, (b) individual TE placement, (c) group TE placement, (d) prevocational work crew, (e) unemployed. Weeks worked was defined as the total number of weeks of paid employment over the final 11-month period. Earnings referred to all wages earned during that time.

### **Findings from the Accelerated Placement Study**

As shown in Table 11.5, the two most potent predictors of vocational success were dropout status and situational assessment ratings. The correlations for the dropout status variable are probably underestimates, in that employment information on many of the early program dropouts could not be obtained at follow-up. The third largest correlation in Table 11.5 was between assignment to experimental condition and weeks worked during follow-up.

Among the employment history variables, work experience was modestly correlated with vocational outcome, and length of unemployment was negatively correlated with earnings. Reception of government assistance was negatively correlated with outcome. Finally, education showed a marginal correlation with outcomes. Except for those variables already mentioned, client characteristics were not helpful in predicting vocational success. Hospitalization history, global functioning, and client's self-report were not correlated with outcomes.

### **Three Conditions Enhancing Vocational Success**

The pattern of correlations suggested a post hoc representation of the findings based on the intuitive notion that the pathway to employment consists of a series of successive hurdles. The findings were organized around a division of the sample into five subsamples defined by an *approximate* chronological hierarchy, based on clients' progression through the program. This is diagrammed

Table 11.5. Predictors of Vocational Outcomes in Thresholds Study by Bond &amp; Dincins, 1986

PREDICTOR VARIABLE	SAMPLE SIZE	15-MONTH EMPLOYMENT STATUS <sup>a</sup>	WEEKS WORKED	EARNINGS
<i>Demographic Variables</i>

Note: Categorical variables were coded as follows for calculating Pearson correlations:

<sup>a</sup>Higher scores indicate better functioning.

<sup>b</sup>Sex: Male = 1, Female = 2.

<sup>c</sup>Race: White = 1, Black or Latino = 2.

<sup>d</sup>Income assistance: Self-support = 1, Parental support = 2, Government assistance = 3.

<sup>e</sup>Dropout status: Active for 15 months = 1, Terminated between 4 and 9 months = 2, Terminated within 4 months = 3.

\* $p < .05$ .

\*\* $p < .001$ .

in Figure 11.2. The first variable, labeled *persistence*, was defined by duration in the Thresholds program. Two subgroups of dropouts were defined: those who dropped out within 4 months and those who dropped out between 4 and 9 months. The second variable, labeled *performance*, was defined by staff ratings on the situational assessment. Among clients active for at least 9 months, those who scored below the median on the situational assessment rating were classified in this third group. The third vari-

able, labeled *placement*, was defined by the experimental condition. Two groups were identified among clients who were active for at least 9 months and who scored above the median on the situational assessment: those who were randomly assigned to the standard gradual program with prevocational preparation, and those assigned to the accelerated TE program.

The three variables were not statistically independent. Although persistence and placement were uncorrelated, performance

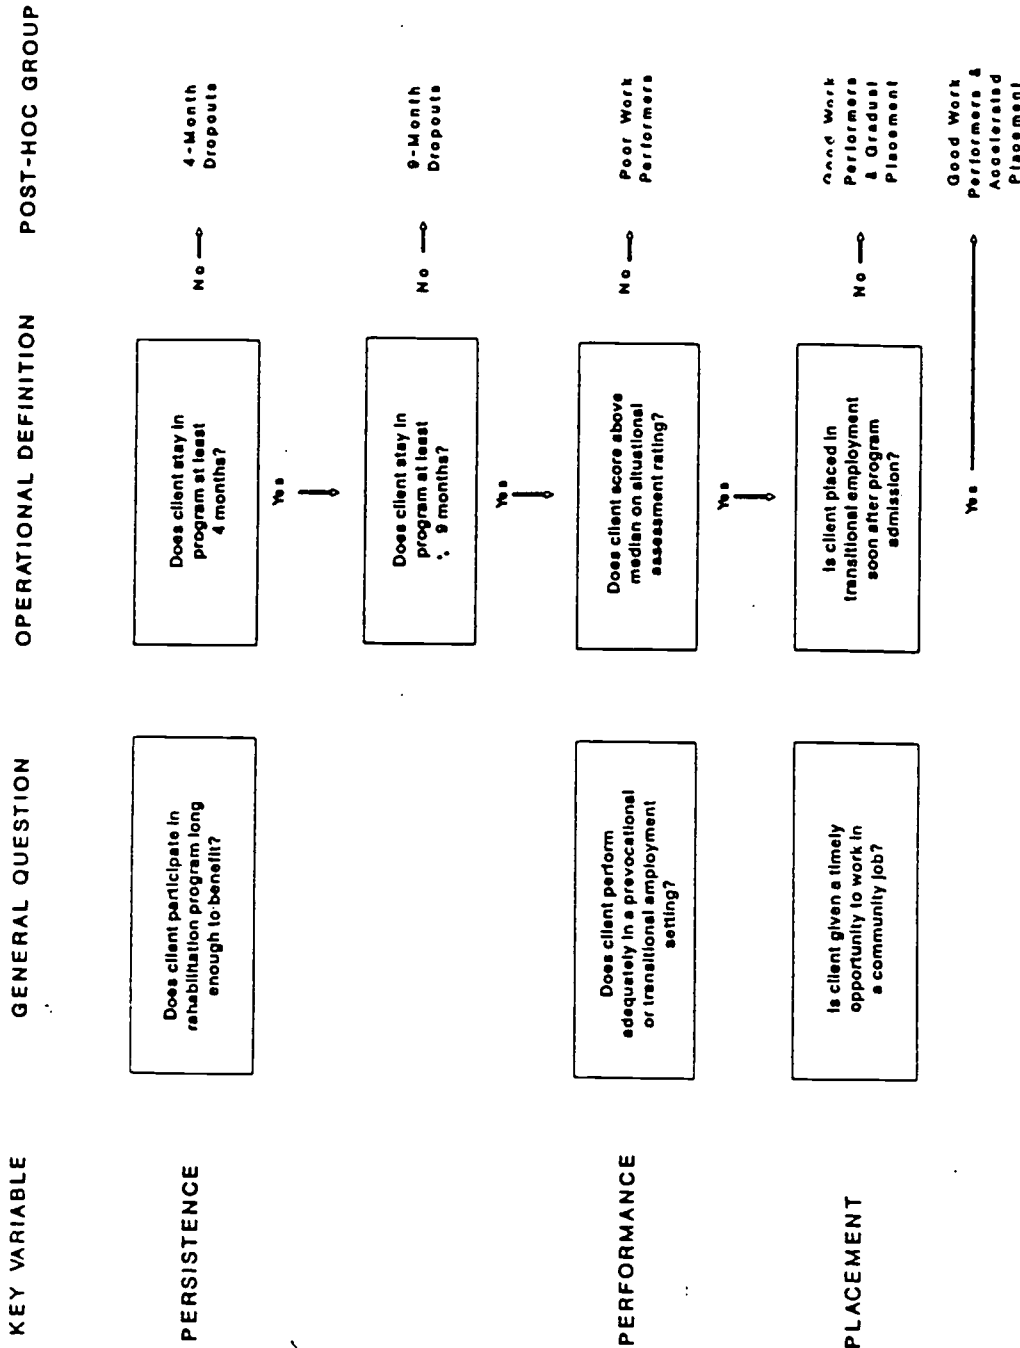

Figure 11.2. Three conditions for employment success among persons with serious mental illness.

was related to both persistence and placement. Dropout status was correlated with poorer performance on the situational assessment ( $r(82) = -.26, p < .01$ ). More surprising was the finding that accelerated clients had higher assessment ratings than did gradual clients ( $t(75) = 2.00, p < .05$ ).

*Persistence* appeared to be a critical precondition for successful rehabilitation. As seen in Table 11.6, dropout status identified two subgroups of unsuccessful clients. It is logical to ask further if any client characteristics predict dropout status. In the current study, however, the only predictor variable listed in Table 11.5 that was correlated with dropout status was educational level ( $r = -.27, p < .001$ ). More educated clients were less likely to drop out.

*Performance* in the vocational domain (as measured by the situational assessment) is a second condition for employment success. In the current study, various global indicators of role functioning, including a rating of global functioning and client's self-assessments, were not predictive of outcomes. In contrast, those who received low ratings on the situational assessment had poor vocational outcomes regardless of their accelerated or gradual vocational programs assignment.

Months employed prior to study admission was the only client background variable among those listed in Table 11.5 that was correlated with situational assessment ratings ( $r = .19, p < .05$ ). Thus, client background information yielded little predictive information on a client's actual work performance.

*Placement* was also important for enhancing employment outcomes. Among the subgroup of clients who demonstrated adequate work performance, those in the accelerated TE program were compared to clients in the standard (gradual) program. Accelerated clients had better vocational outcomes than gradual clients: over twice as many accelerated clients were competitively employed and had worked significantly more weeks.

## Discussion of the Accelerated Placement Study

From the standpoint of program planning, the findings from the preceding analysis are cause for optimism. The identified factors are all within the control of rehabilitation programs, at least in principle, as discussed below.

### *Persistence*

Several studies have shown that clients who persist, that is, clients who attend PSR programs for an extended period, have the best employment outcomes (Barry, 1982; Bond, 1984; Dincin & Kaberon, 1979; Malamud & McCrory, 1988; Rehab Brief, 1986). Persistence is typically a characteristic attributed to clients and not to programs. However, assertive outreach can increase client participation in rehabilitation (Stein & Test, 1980). No research has yet directly tested the viability of assertive outreach as a means to increase attendance in vocational programs.

Assuming that assertive outreach does increase persistence among clients who otherwise would drop out, a second question is whether reluctant clients so encouraged will benefit from vocational rehabilitation. SE proponents have advanced an idealistic "zero exclusion model," which states that all clients are assumed candidates for employment until proven otherwise (Wehman, 1988). Although this study was not designed to evaluate a zero reject model, its findings can be reexamined in terms of this perspective. Specifically, we examined the outcomes for the subgroup of 30 clients who persisted beyond 9 months but who performed poorly on the situational assessment (see Table 11.6). This subgroup would be viewed by the VR system as poor employment risks. Consistent with that view, they did not have any better vocational outcomes than did program dropouts. Thus, persistence alone provides no guarantee of success in competitive employment.

Table 11.6. Employment Outcomes for the Five Subgroups Identified in Figure 11.2

CLIENT SUBGROUP	WEEKS WORKED <sup>a</sup>	EARNINGS <sup>b</sup>	EMPLOYMENT STATUS AT 15 MONTHS					
			COMPETITIVE EMPLOYMENT	INDIVIDUAL TRANSITIONAL EMPLOYMENT	GROUP TRANSITIONAL EMPLOYMENT	CREWS		
						PREVOCATIONAL	UNEMPLOYED	UNKNOWN
A: 4-month dropouts (N = 19)	5.2	\$559	0%	0%	0%	5%	53%	42%
B: 9-month dropouts (N = 35)	10.0	\$913	3%	0%	0%	11%	60%	26%
C: Poor work performance (N = 30)	16.1	\$731	3%	0%	13%	53%	23%	7%
D: Good performance and gradual preparation (N = 21)	23.1	\$1625	14%	19%	19%	33%	5%	10%
E: Good performance and accelerated placement (N = 26)	39.7	\$2140	39%	19%	15%	15%	12%	0%

<sup>a</sup>According to the Newman-Keuls test for post hoc comparisons, the following subgroups differ at  $p < .05$ : A, B < D, E; C, D < E.

<sup>b</sup>According to the Newman-Keuls test for post hoc comparisons, the following subgroups differ at  $p < .05$ : A, B, C < E.

Clients who do become engaged in rehabilitation but who have limited vocational skills represent a large and important segment of the total population of persons with serious mental illness. Finding appropriate vocational options for this subgroup remains a vexing problem. At a commonsense level, it appears that some form of systematic skills training may be necessary for these clients to achieve employment success.

### Performance

The priority of current vocational performance over work history is an affirmation of the Fountain House principle that every consumer deserves a chance to work, regardless of past problems (Beard et al., 1982). The intent of prevocational and TE programs is to improve client work habits and attitudes. We have surprisingly little literature to show that a client's work performance and attitudes in psychosocial rehabilitation settings does improve over time (Growick, 1976). It would be relatively easy to determine whether situational assessment ratings in PSR programs typically show a steady progression, or whether, as is more likely, a nonlinear path to improvement is more common.

Clients working on the prevocational crews had lower situational assessment ratings than did those on TE. Possibly clients in the prevocational crews felt that little was expected of them, as suggested by frequent reference to poor attendance on their rating forms (Bond & Friedmeyer, 1987). The monetary incentive in TE also may have made a difference in performance (Lehrer & Lanoil, 1977).

A further speculation is that the TE job coaches gave higher ratings because they expected more of their clients in an integrated setting. This possible explanation is reminiscent of the finding from educational studies in which teachers' expectations have been experimentally demonstrated to affect student performance (Rosenthal & Jacobson, 1968).

In a similar vein, Kiernan and Brinkman (1988) have also noted an interaction between work performance and the work site. One implication is that community-based assessments may be more ecologically valid indicators of a client's potential than are those obtained in artificial settings (Menchetti & Rusch, 1988).

From a programmatic standpoint, it would seem logical to provide skills training in order to improve client performance in prevocational and transitional work settings. The efficacy of skills training has been examined in over 50 studies (Anthony, Cohen, & Cohen, 1984; Liberman, 1988), yet most PSR proponents have adamantly maintained that an experiential learning approach is superior to more structured approaches. In any case, research has not yet closed the causal chain that hypothesizes that clients can be taught vocational skills and thereby achieve success in community employment.

### Placement

The provision of job opportunities is a simplistic addition to the rehabilitation model, yet one that has not been fully appreciated. A study using a similar research paradigm but with individual supported employment placements as the accelerated condition is now in progress (Bond, 1990b). Early anecdotal evidence makes it clear that many clients clearly *prefer* early placement over gradual work preparation *including group TE programs* in CMHCs. This unexpected pattern suggests a strong client aversion to prevocational training programs that are considered progressive in many CMHCs. It is reminiscent of recent survey findings on supported and transitional housing: Most clients prefer to live in their own apartments with adequate support from professionals, despite the opinion of most professionals who think the majority of clients need structured group homes (Blanch, Carling, & Ridgway, 1988).

## SUMMARY

Like Dickens' *Christmas Carol*, we have examined the past, present, and possible future of vocational programs for persons with severe mental illness.

The limitations of sheltered approaches for most clients with psychiatric disabilities have been widely documented. Although it is customary to note that sheltered alternatives are appropriate for some clients, to operationalize this assumption has proved difficult. Too often the belief that some clients are more suited to sheltered settings has been used to justify wholesale exclusion of clients from competitive employment. Clients themselves are often reluctant to enter vocational programs. Clients who have self-defeating attitudes perhaps are influenced by rehabilitation workers who believe that psychiatric disabilities are a barrier to employment (Bingham, 1988).

The opposite viewpoint, that clients simply need an opportunity in competitive employment, with supports, is also an insufficient formulation. In the accelerated placement study (Bond & Dincin, 1986), for example, there was a subgroup of clients who did not succeed in TE, even though they attended the rehabilitation program for over a year. Multiple vocational options are necessary to address the spectrum of clients who are admitted to CSP programs.

Although prognostication is a risky business, some observers are predicting expansion of SE services for persons with severe mental illness. A recent comprehensive national survey of SE practices in rehabilitation facilities (NARF, 1989) notes that "individuals with chronic mental illness are receiving more attention nationally" (p. 39), although the survey showed only 11% of the individuals served in surveyed SE programs had chronic mental illness. Another recent survey (Tashjian, Hayward, Stoddard, & Kraus, 1989) showed a large discrepancy between the percentage of clients believed by mental health workers to have access to SE

and TE programs (70%) and the percentage of clients actually receiving these services (11%). How much and how fast expansion occurs will depend on many factors, including solving the problems of short-term and long-term funding. SE requires attention to systems issues and financing at the program level, whereas VR has historically funded most of its services on a case-by-case *client* basis. The funding problems are not insurmountable, but they require new thinking.

This chapter has argued that our future includes the incorporation of the *principles* of supported employment. It is already clear that Wehman's provocative model, developed for persons with mental retardation, must be modified considerably for persons with severe mental illness. That adaptation is already being attempted across the United States.

Because current programs with vastly different philosophies have adopted the label of *supported employment*, the term has lost its meaning. In place of labels and slogans, we need empirical benchmarks: Whom does your program admit? What is the dropout rate? What self-selection occurs? What is the average duration in each program phase? What do vocational staff do? What are your employment rates? How long do clients hold jobs? How satisfied are they with the jobs they have?

Supported employment has in no sense been "proven." It conforms with a number of working hypotheses, but has not been examined within a rigorous evaluation framework. Several scenarios for the future of SE for persons with severe mental illness are possible, including the following: (a) SE is implemented only under special conditions, such as in agencies that have charismatic administrators, or in communities where the local VR and MH politics are somehow bypassed. (b) Its evolution is heavily influenced by the characteristics of the local communities and economies. For example, the job bank model may become the dominant model in some large cities, whereas the indi-

vidualized placement model may evolve in less populated areas. (c) Administrators conclude that SE is not cost effective or that the funding dilemmas are insoluble. In the short term, SE programs appear costly and inefficient. As Wehman (1989) notes, "It usually takes 2 to 3 years for the full benefit and placement outcomes of supported employment to accumulate" (p. 8). Questions about economic feasibility have already surfaced in the Pennsylvania and Indiana projects described above, in which the placement rates were low during the early stages of implementation. In fact, in both states, demonstration sites only first began to make genuine progress during the second year of implementation. In the case of Indiana, the projects were funded for only 2 years, thus severely hampering their development from the outset.

The intent of this chapter has been to generate hypotheses. We are still at an early stage of program description (Brekke, 1988), and better classification of vocational approaches will need to be developed in the future. Some process and outcome variables have been suggested in this chapter that may contribute to a consensus battery of measures that all investigators might use.

Time has been a motif of this chapter. In the past, extensive resources have been directed to prevocational activities, with little demonstrable impact. Conversely, few resources have been directed to the post-placement period (Tashjian et al., 1989), resulting in disappointing rates of job retention (Solberg & Raschmann, 1980). It is time to reverse these priorities.

# Creating Positive Vocational Outcomes for People with Severe Mental Illness

**Joe Marrone**

Joe Marrone is currently the Coordinator of Technical Assistance at the Training and Research Institute for People with Disabilities at Children's Hospital in Boston, Mass.

---

*Abstract: This article is meant to serve as a practical guide to the various vocational alternatives currently in use in the psychiatric rehabilitation field. It presents both benefits and drawbacks to the service recipient, of each of the models described. A perspective is offered on some parallel developments in employment services for people with mental illness and those with developmental disabilities. Finally, consideration is given to using links with the public Vocational Rehabilitation system as part of the array of vocational options presented to clients of rehabilitation service organizations.*

The topic of creating positive vocational outcomes for people with major psychiatric disabilities has generated much heat, but a great deal less light, over the last 10-15 years. People with severe disabilities are often "at the end of the labor queue [and] need special assistance in overcoming institutional barriers and re-establishing or establishing a lasting labor connection" (Levitan and Taggart, 1982, p. 127). In particular, the rehabilitation field has not proven itself overwhelmingly successful in helping people with severe psychiatric disabilities achieve stable employment at competitive levels (Anthony & Blanch, 1987; Anthony & Jansen, 1984; Bond & Boyer, 1988; Bond & McDonel 1991; Ciardello, 1981; Hirsch, 1989; Levitan & Taggart, 1982; MacDonald-Wilson, et al, 1991). The literature includes unemployment estimates for people with serious mental illness as high as 80% (Anthony & Blanch, 1987; Tessler & Goldman, 1982; Wasylenki, et al, 1985.) The most recent figures available from the Rehabilitation Services Administration on the performance of the VR system nationwide, for fiscal year 1990, shows a successful rehabilitation rate of VR clients with "Psychotic Disorders" of 48%, compared with successful closure rates for all disability groups of 60-65% (Rehabilitation Services Administration, 1991).

A variety of vocational rehabilitation approaches have been developed in recent years that appear to show promise. These include: the psychosocial rehabilitation approach, perhaps best exemplified by the Fountain House clubhouse model and its attendant Transitional Employment (TE) programming; the psychiatric rehabilitation movement, as popularized through the Boston University Center for Psychiatric Rehabilitation; the

Community Support movement, perhaps best exemplified through the Assertive Community Treatment model developed in Madison, Wisconsin; the Fairweather Lodge movement as demonstrated through the creation of Community Lodges throughout the United States; and the Supported Employment methodology which has "grown up" politically out of the Developmental Disabilities field, primarily through the University of Oregon & Virginia Commonwealth University ( Bond & Boyer, 1988; Bond & McDonel, 1991; Cook & Engstrom, 1985; Fairweather, 1980; MacDonald-Wilson, et al, 1991; Malamud & McCrory, 1988; Russert & Frey, 1991; Vorspan 1989). However, the specific capacity of the panoply of vocational placement models developed over the years, to positively affect vocational outcomes is still, in many respects, unproven (Bond, 1990; Bond & Friedmayer, 1987; MacDonald-Wilson, et al, 1991).

Clearly, there continues to be a paucity of "hard" data to justify the use of any one option over another to produce enduring vocational success in community-based psychiatric rehabilitation. Indeed, one of the reasons for this dearth of information is that there is no clearly accepted definition of vocational success, which is used consistently, either in research or program evaluation activities (Bond, 1990). However, the public/private service delivery system faces the immediate need to assist individuals with severe psychiatric disability to (re)enter the workforce of their local communities. They do not have the luxury of waiting until all the research issues are resolved. Service providers usually need to establish and update the research and data base as they help people through service delivery.

It is the intent of this article to provide an overview, for the interested practitioner, client, family member or advocate, of the "pro's and con's" of major community rehabilitation models which pertain to vocational outcomes for people with serious mental illness. The goal is not to provide a substantive research review. Several of the sources cited above, particularly those developed by Bond and colleagues, do an excellent job in this area. Rather, the following analysis is meant to serve as a practical guide to considerations in developing and using the approaches described. When research data are available, this is identified. In most instances, however, what are noted are administrative/clinical indicators for use in setting up and referring people to programs. These facts are presented in a form that should give the rehabilitation professional, consumer, and/or advocate, a way of selecting alternatives that best fit the needs of the person for whom the service is intended.

## **Models of Vocational Programming**

### *Work Units in a Clubhouse Program*

Work units in a clubhouse setting are specific work units set up to get

tasks accomplished which the clubhouse needs to get done. In many ways, work units form the centerpiece of the clubhouse approach to rehabilitation with people with long term mental illness (Vorspan, 1989). This pattern of service delivery based on staff-member side-by-side functioning is commonly referred to as the "work-ordered day". Work units are meant as vehicles for members & staff to work productively together. One of the tenets of clubhouse administration is that staffing should always be such that the work of the club could not be accomplished without the active contribution of the members as well as the staff (Beard, et al, 1982.) In some respects, this structure was developed as a counterpoint to the view, prevalent in the 1950s, of psychiatric treatment as psycho-dynamic "talk" therapy. It emphasizes the value of "productivity," (Whitehead & Marrone, 1986) so essential to the rehabilitation philosophy, while, less consciously, using the concept of developing a person's capacity to nurture and support others as a way of enhancing self esteem.

The traditional types of work units that exist in clubhouse programs are kitchen/cafe, janitorial/housekeeping, clerical (attendance, record-keeping, and fiscal), and public relations (newsletter, tours, public speaking). Sometimes units are created to do maintenance/repair functions, community volunteer activities, fund-raising, and odd jobs in the community.

The "essential" purpose of work units in a clubhouse setting is to benefit the consumer through his/her contributions to keeping the club functioning. Work units are not:

- Volunteer work (any more than cooking for your family is)
- Specific skills training (any more than cooking meals at home helps you learn to run a restaurant)
- A means of assessing or achieving "generic" work adjustment, a vaguely defined concept that, some have argued, doesn't fit the realities of behavior (Anthony & Jansen, 1984).

Except in large programs, specific assignment to a work unit is not crucial. Someone may spend part of a day or a week in one unit, then move on a regular schedule to other units. Some programs may use a members' meeting each day to divide the tasks of the units. Consumer choice needs to be at the core of the process, though methods, such as direct suggestion and use of peer pressure, are often used. Clinically, the method of unit designation is irrelevant. However, it creates an administrative problem if staff cannot count on certain duties getting done each day (e.g., if no one volunteers to cook lunch one day, what will be eaten?)

*Transitional Employment (TE)*

Transitional Employment (TE) is also a core component of a pure clubhouse model (Malamud & McCrory, 1988). However, many programs that call themselves "clubhouse programs" do not include TE in their service mix—because they do not see it as crucial, they cannot find jobs for their members, or they can't find a way to fund it. A "purist" view of the clubhouse approach would insist that the absence of a TE component is antithetical to its value base analogous to calling oneself a behaviorist while focusing solely on client affect in counseling. Since the development of the TE concept (in the mid-1960s at Fountain House in New York City,) several variations have been developed. In many ways, the TE concept used some of the same principles that were later popularized in the Supported Employment (SE) movement of the 1980s in the Developmental Disabilities field (Bond, 1987). Because of the increased emphasis on the employment aspect of community integration, free-standing TE programs, have become increasingly popular over the last 5 or more years.

TE, in its Fountain House roots, grew out of the intuitive sense that "in vivo" learning was a good way for people to acquire good work habits, as well as out of the belief that members-- by virtue of their skill deficits, lack of a good work history, and status as ex-mental patients-- would almost always have great difficulty in securing employment (Beard, et al, 1982.) In addition, it was assumed that people with major mental illness needed a chance to practice work skills in a setting more "practical" than a clubhouse environment, while less demanding than a typical full time job. The major components are:

- 1) The responsibility for job development lies in the program, not the individual client.
- 2) The program accepts the responsibility of recruiting, hiring, & training members for each job. Thus program staff go out & learn the job first and teach the client individually (similar to a "job coach" in Supported Employment).
- 3) The employer gives up the option of screening the client out via the interview process.
- 4) The employer agrees to pay workers directly, not through the program, and at least minimum wage.
- 5) Most full-time jobs are broken up into two part-time jobs.
- 6) There are time limits on individual consumer tenure in each TE job (usually 6 months). In the "pure" clubhouse model, consumers may switch TE jobs in 4-8 months, but stay in the TE program. In recent years, funding restrictions have led some programs to limit consumers to one TE experience. Thus, the

sense that gets created- that consumers should be able to work competitively unsupported, after one TE experience- is a major bastardization of the concept.

- 7) The program, not specific clients, are seen as "owning" the job.
- 8) Because of the above characteristics, the great majority of TE jobs are entry level, experience high turnover, quick training, minimum wage and provide no benefits (by extension, boring & low status).
- 9) The agency establishes a regular support mechanism away from the job, usually in the form of a weekly or bi-weekly dinner meeting, to enable fellow TE workers to "compare notes" and often to allow potential TE workers to hear about the experience first hand.

Originally, it was not viewed as important to provide TE in an area of vocational interest to a consumer, because the point was to learn about work, not acquire specific work skills. However, the confluence of heightened consumer clout, more people spending greater amounts of time in the community, advances in treatment, use of supported employment approaches, and an increased awareness of the importance of values/interests in skill acquisition has moderated this view somewhat. Unfortunately, the practical realities of the kinds of jobs employers are willing to make available as part of TE (i.e., easy to train, entry level) preclude a really extended range of vocational options. For the foreseeable future, these are usually limited to food service, janitorial, groundskeeping, messenger, and entry level clerical jobs.

While remaining aware of the dangers of generalizing, TE usually is most appropriate for people without much work experience, or who haven't worked in more than two years, or who are unsure whether paid work is an option they wish to pursue. Other considerations concerning TE, which are not value-based, but rooted in the realities of service delivery are that it:

- works best in an urban or suburban setting as opposed to rural areas;
- is fueled better by a service-driven, rather than a manufacturing economy;
- requires jobs which can be taught fairly quickly; and
- requires a steady flow of new clients & new jobs, if a program is willing to provide multiple TE opportunities to its clientele.

BEST COPY AVAILABLE

The major advantages of a TE approach, particularly vis-a-vis supported

employment, include the following:

- 1) It provides a sense of "graduation" & completion to the worker, often the first successful adult experience in his/her memory.
- 2) For the worker who is having trouble, the time-limited nature of the experience allows for a sense of "light at the end of the tunnel." For the worker who "fails," having to quit or be replaced, the finiteness of the program enables one to think through the experience as having made it one sixth, one fourth, one third, etc. the way through.
- 3) In the author's experience, employers often need more education about the TE concept, since it is different from the typical employment endeavor. Once convinced, they are much more willing to take risks and tolerate a consumer with poor job skills. This appears to be due to the fact that the program has established its "ownership," thus its responsibility for the job; and probably most comfortably for the employer, [s]he will not get "stuck" with a poor performer as a natural cycling out process occurs.
- 4) Because TEs are usually part-time, each job can serve two people at a time and four people a year.

Some of the deficits associated with TE are the following:

- 1) By definition, the work experiences are transitional. For people with major mental illness, transitions in relationships and in settings, often pose great difficulty. Each transition, even if it is to a similar job, requires increased supports available for the consumer.
- 2) Skills in one environment do not translate well to a different environment (Anthony & Jansen, 1984; Anthony & Farkas, 1982; Forsyth & Fairweather, 1961). So transferring the skills learned (social, life adaptive, or job specific) on one TE to a different TE, or an independent competitive job, is not often easily done.
- 3) TEs are not usually developed for "white collar" situations. Convincing a potential worker to see this routine, low status position as a stepping stone, not a dead end, can be difficult. It requires the provider's taking on the responsibility of demonstrating "good faith," through words and action, and creating an expectancy of success in its consumers.
- 4) Also, as noted previously, if the provider offers multiple TE

opportunities, these need to be in an economic environment that can support this endeavor. Competent marketing staff also need to be available. There is conflict among TE providers about whether to have specific TE job development staff (most common & often more efficient) or insist, in the case of clubhouse providers of TE, that all staff participate in development and on-the-job support activities. The rationale for the latter approach is to try to ensure that TE is seen as an integral, not a tangential, program component, and to maintain the intense support relationship developed between staff & member in the club setting.

### *Volunteer Work Experiences*

Volunteer (i.e., unpaid) work experience options occupy a controversial niche in the array of vocational opportunities for people with long term mental illness. These, more than any of the other concepts covered, vary greatly in their utility, based on the match between individual consumer's needs and the specific form the volunteer work experience takes. The major dispute centers around whether it devalues a person to work without pay as a condition of his/her rehabilitation. In addition, the issue of whether an unpaid (or piece rate paid) worker is being exploited by an employer is of great concern, not only to rehabilitation providers, but, probably more ominously, to the U.S. Department of Labor.

Questions to examine when deciding whether volunteer work is viable in a particular situation are:

- 1) Does the position meet the requirements of the Fair Labor Standards Act, administered through the Wage and Hour Division of the U.S. Department of Labor?
- 2) Is this part of a formal volunteer program (e.g., something set up through hospitals, schools, non-profit agencies, etc.) or the Federal Unpaid Work Experience Program (Section 501 of the Rehabilitation Act of 1973, as amended)?
- 3) Are other people being paid to do the same tasks as the volunteer?
- 4) Is the "employer" making money from the volunteer worker's labor?
- 5) How will this role affect the ego of the consumer? People beyond teenage or early 20s, particularly those with work experience, are usually not best served through volunteer options. Unless that is the work role they prefer, for financial and/or personal considerations. Or, they are seeking re-entry to

- a professional level environment, in which they can currently not compete, due to their psychiatric illness. Others may find that it leads to diminished self-esteem.
- 6) If the goal is to move towards paid work experience, does the program have tight, short-term time limits set? This is especially salient to those situations where the aim is to "convert" the volunteer job into a paying one, as a conflict of interest potential is created. Where volunteer work is an interim strategy, limits should be set on the order of 120 hours maximum.

The benefits of using Volunteer Work Experiences, assuming the above questions have been taken into account, are:

- 1) This approach increases the range of job (task) options for people to try, beyond the usual array of TE and SE settings. In the case of someone who has had professional level ("white collar") or skilled trade experience, volunteering may be a way to try out a similar (or slightly diminished) role, e.g., a lawyer volunteering at a public interest firm, either in that capacity or as a paralegal.
- 2) For people who lack stamina, or just wish to commit less time to work, there usually is much more flexibility in tailoring volunteer opportunities to a person's preferred schedule than would normally be available in paid work.
- 3) Many people with mental illness, to avoid the stigma associated with this label, do not wish to be part of a formal "program" (such as TE) which identifies them as consumers of psychiatric rehabilitation services. Engagement in a volunteer option, such as previously mentioned (schools, hospitals, community agencies, etc.), usually allows people to retain their anonymity in this regard.
- 4) Volunteering in a "traditional" capacity (i.e., social service, health, education), gives people who often have been "patients" and "dependents" most of their lives, a chance to nurture and take care of others. Also, people who do volunteer work, often garner gratitude and accolades for helping, which many consumers of services do not usually receive.
- 5) For people concerned about the impact of earnings on their public benefits, the unpaid nature of volunteer work may be a bonus, not a detriment.

As with all the options to be considered, there are several negatives that

this approach poses:

- 1) For people concerned with the need for more immediate income, or who equate income with their personal worth, the unpaid nature of volunteer work is a hindrance.
- 2) There is a paucity of formal structure associated with most volunteer settings. When the person needs a structured work activity, this option may not be suitable.
- 3) When volunteer work is used because the consumer does not wish to be identified as a service recipient, the capacity to provide accurate feedback to the consumer on his/her functioning in that role, or support and assistance to work supervisors or other site personnel, is greatly diminished. The program staff are almost totally dependent on client self report for evaluative data. This can obviously be problematic in instances, as often happens, where the consumer's judgment is impaired by his/her psychiatric illness.
- 4) As previously noted, the U.S. Dept. of Labor requires that workers be paid for work performed, except under very restricted conditions. There is usually no problem with volunteering in a public or non-profit organization, although the same rules govern the behavior of these organizations. However, unpaid positions in for-profit organizations are not allowable, even for purposes of short-term training prior to job placement.

### *Work Crews*

Work crews are not really a discrete service alternative, rather they are a structural technique used to deliver a variety of employment opportunities to consumers. For the purposes of this article, the term "work crew" will be used to refer to any group employment activity used by a rehabilitation program. Distinctions among options will be made in the descriptions rendered in the text.

Typical work crew methodologies are: Group TE or SE, Enclaves, Sub-Contracts in Industry, Affirmative Industries, Client-Employing Businesses, and "Handyman" work crews. There is often much overlap in the terminology. The purpose of the definitions below are to identify the terms typically used in the field. Practical short definitions of each are:

*Group TE or SE*— Any approach that meets the definition of SE and/or TE, which uses a group, as opposed to individual employment opportunities.

*Enclaves*— A formal name popularized in the SE literature, "in its

broadest application, ... a group of individuals with disabilities who are trained and supervised among non-handicapped workers in an industry or business." (Mank, Rhodes, & Bellamy, 1986, p.143.) This term describes a group of SE workers in one location who usually do one definable task on a work site, but usually in a segregated fashion- either in a separate room or in a specific, separate space in the larger work environment. However, the term has also been applied to a group of SE workers who may be disbursed throughout the work force individually, or in smaller groups.

*Sub-Contracts in Industry*—A method that a facility based program often uses to fund an "enclave," where the facility contracts for work done at the business location, pays the workers out of the contract, and includes costs of running the facility operation.

*Affirmative Industries*—A business entity set up for the purpose of employing people with disabilities, usually subsidized heavily by rehabilitation or social service monies. In the earlier SE literature, it was defined as the "Benchmark Model"—where contract work is procured by a service agency (initially, electronics,) and the disabled clientele is paid at piece rate (Mank, et al, 1986) This notion has been expanded more recently to include other, more community-based businesses, such as janitorial services, garden shops, restaurants, etc.

*Client-Employing Business*—A similar idea to "Affirmative Industries," except that the business here usually employs non-disabled workers as well and may formally embrace the profit motive, rather than providing "vocational services" to clients. Examples of this model which exist in several locations are specialty food operations (e.g., bakeries, cafes) and plant stores/greenhouses. There are many similarities to the Affirmative Industries concept, except for the mix of workers desired and the possibility of profitable endeavors. However, most programs that fit the mold of Client Employing Businesses have major difficulty in profit generation (Kirzner, 1990.)

*"Handyman Work Crews"*—A "catch-all" concept, coined here, which describes a variety of group options often used by clubhouses or other day programs, that essentially get groups together for day labor-such as house repairs, yard work, agricultural labor, etc. This may form an on-going business enterprise or may be organized on a job specific basis.

The major strengths of the Work Crew approach are as follows:

- 1) The peer group created can act as a major source of support for the worker. Since developing new relationships is often difficult for people with serious mental illness, the possibility of trying out a stressful rehabilitation event, i.e., a job, without the added stress of forming a new set of relationships can mitigate the difficulties inherent in new learning (McCrory, 1988.) Obviously, the strength of group support is derived from the existence of previously formed bonds. So the mere existence of a group is not necessarily supportive, unless it consists of people already known and liked by the new worker, e.g., other members of a clubhouse program.
- 2) The presence of a peer group can also act as an effective stimulus to improved performance, by role modeling, peer pressure, and creating a sense of "there's hope for me" in the worker.
- 3) A work crew is an ideal vehicle to give the most problematic worker a chance to succeed. The group can be used to "hide" a person who does not function at a level normally tolerated by employers in an individual placement.
- 4) The creation of a work crew on the "handyman" model enables a program to achieve a greater degree of flexibility in its response to generating economic opportunities in the community. In addition, for some consumers, the more flexible time demands and variety of tasks available can be a bonus.

The major deficits associated with Work Crews are as follows:

- 1) This form of vocational functioning is hard to replicate in the competitive labor market. Thus, as with any transitional approach, the skills learned may not be easily generalized. The nurturance provided by the peer group may be missed sorely by the worker in more traditional employment models, hence making this transition even more difficult.
- 2) Any group approach, by definition, increases dramatically the segregation of the person with mental illness from the community at large. The problem is more pronounced by options such as sub-contracts in industry, affirmative industries, and some enclaves, than it normally would be with a client-employing business or many "handyman" operations. In the latter two options, there is often more opportunity for contact with non-handicapped co-workers or the public at large. There is a real danger that by relying solely on any work crew opportunity, the capacity of both the worker, and the

- community, to interact effectively may be diminished.
- 3) Poor earnings often go hand-in-hand with many work crew operations. Because it is seen as a good way to get people with more significant disabilities working, often earnings are handled at sub- minimum wage levels, through either production rates (usually in enclaves or sub -contracts in industry) or pooled earnings ("handyman" work crews or Fairweather Community Lodge businesses).
  - 4) Particularly for the "handyman" crew and some sub-contract methods, the work offered can be erratic, seasonal, and unpredictable. To a lesser extent, this problem also occurs in the business models where activity, and income, are dependent on customers using a service. Having workers and staff available to meet market needs can be quite problematic- especially, for smaller rehabilitation programs and/or poorly marketed services.

The usual types of Work Crew job opportunities are in the areas of catering, cleaning, household help, shopping services, yard work, house repairs, horticultural, agricultural labor, bakeries/cafes/ diners, and particularly for sub-contracts in industry/enclaves- manufacturing companies. The "handyman work crews" are better suited to rural, than urban environs. As noted, the sub-contract approach works better in an industrial economy, as opposed to a service-based economy. The small business endeavors (either Affirmative Industries or Client- Employing Business) are better suited to an urban/suburban service based economy.

### *Supported Employment*

Supported Employment has come to be identified with day programming for individuals with developmental disabilities. Only after its initial phase, from 1978-1986, was this concept seen as being useful for individuals with mental illness. The reality is, however, that the clinical concepts inherent in this approach to rehabilitation service delivery: "in vivo" learning, i.e., site-based training, on- site support, zero reject policy, i.e., a presumption of suitability, and work integration (Minnesota DHS/Dept. of Jobs & Training, 1989) were not solely derived from work in the field of developmental disabilities.

These have been cornerstones of the psychiatric rehabilitation movement at least as far back as the mid-1960s (as evidenced by the Lodge models and psychosocial rehabilitation clubhouses such as Fountain House.) What Supported Employment has done, as exemplified by the passage of the Title VIC legislation in 1986, which amended the Rehabilitation Act of 1973 and the award of "Systems' Change Grants" to

39 states over the last six years, has been to transcend the concept of employment services from a strictly clinical issue- which it had been seen as, in its genesis in psychosocial rehabilitation. Rather, the proponents of SE in the developmental disabilities arena, transformed the debate to one of Civil Rights and societal inclusion, not simply one about the best ways to deliver services. Also, SE was much more of a radical departure from the norm of developmental disability day programs. These programs often were designed on a Special Education model, because day programs serving persons with developmental Disabilities were an outgrowth of school and institution based services developed by special educators. On the other hand, day programs for people with mental illness, were usually developed on a medical, not a rehabilitation model, and were usually created by adult service providers.

The core components of SE, as defined through the Federal Rehabilitation Amendments of 1986, with subsequent regulatory revisions in 1992, are that it consists of:

- 1) *Competitive Work*—done weekly, being done for pay, though not necessarily at minimum wage or above (consistent with the Fair Labor Standards Act).
- 2) *Integrated Work Setting*—ideally consisting of individual placements, but in no case forming groups of more than eight workers. Also, it must include regular contact with non-disabled people, other than caregivers.
- 3) *On-Going Support*—must include at least twice monthly support (formerly required on-site skills training, except for people with mental illness, but are more flexible in the most recent regulations).

An important adjunct to these components is the fact that for the purpose of this legislation, TE for persons with long-term mental illness is considered an acceptable SE outcome, as long as there is an organizational commitment to continue to assist the individual through a succession of TE placements and/or into competitive employment (State Supported Employment Services Program Regulations, 1992).

The major advantages and disadvantages to SE as a service strategy for people with mental illness are in most ways similar to those with TE, with the obvious exception that SE is designed for the person to remain on the job as long as [s]he wishes and is able to. So, the pro's and con's of "transition" and "time-limitedness" play out differently for each strategy.

Traditionally, SE and TE providers have assumed that since mental illness is not an intellectual deficit, there was very little need to concentrate

on systematic training methodology. However, more attention should be devoted to insuring that job training matches individual learning styles. Difficulty in skill acquisition can be a source of added stress on a client, particularly in one who lacks a history of success and self-confidence- the great majority of the consumers with major mental illness. Many times, a person who is having typical new job "problems" (e.g., forgetting co-workers' names after introductions), internalizes this adjustment problem into something much worse (e.g., "I must be having trouble concentrating. Does this mean I'm getting sick again?") Job instruction can quickly resolve many such problems.

### *Fairweather Community Lodge*

The Fairweather Lodge (now often called the Community Lodge) model grew out of research developed by George Fairweather, Ph.D. in the late 1950s in Palo Alto, California. It's fundamental premise was that "groups have a powerful influence on their members and can serve as a means to control deviancy and/or psychopathology" (Fairweather, Sanders, Cressler, Maynard, 1969, p.1). From this premise, a set of core principles evolved:

- The social system people inhabit is a better predictor of behavior than individual personality variables;
- People can learn skills needed to function in a group and reach effective group decisions by consensus;
- People in a Community Lodge need to establish a group small business enterprise as a way to maintain themselves as a cohesive group within the community,
- Residents of a Community Lodge need autonomy on group decision making.
- Mechanisms need to be established in a Lodge for continuous information feedback on performance back to the residents.(Tornatzky, et al, 1978.)

With the lack of a large, long-term in-patient hospital population, the Lodge concepts have had to be adapted to people with mental illness starting from a community reference. These principles have been embodied into a model which involves groups of 5-10 people with mental illness living together in the community, operating a group-owned business. Members write the rules for the Lodge and the business. Businesses can allow Lodge residents who have moved out of the residence to sometimes remain employed by the business, with the consensus of the group members (Fergus, et al, 1991). Even though not in the original design, many states

that use the Lodge model incorporate it into their more traditional residential continuum, such as halfway houses or Adult Foster Care.

The positive and negative features of this vocational model incorporate many of the same elements noted previously in discussing other group approaches to work. However, the unique nature of several Lodge concepts create some special characteristics which are noted below.

Some positive features, particularly associated with the vocational piece of Community Lodge implementation are:

- 1) Members have usually been formally taught group functioning and consensus building skills as part of the comprehensive Lodge program.
- 2) While all group modalities theoretically carry the advantage of peer support, the Lodge model, with its residential and formal group building component, enhances the capacity of the group to act supportively towards all its members.
- 3) There is a personal "stake" in the work piece because it flows directly from membership in the Lodge group. In some respects, the Lodge business is similar to work units in a psychosocial clubhouse, in that it is not just a job, but a way in which the participant demonstrates- commitment to the entity to which [s]he belongs.

Some negative features, particularly associated with the vocational piece of Community Lodge implementation are:

- 1) Creating a small business enterprise is a high risk venture for anyone, with the number of failures outweighing successes. This issue is especially germane in light of the fact that Lodge members rarely have a reservoir of successful community business experience on which to draw.
- 2) Since Lodge residents live and work together, the potential for conflicts and interpersonal dynamics to carry over from one environment to the other is great. The same reasons why people find it difficult to work with relatives or spouses hold true here.
- 3) Since a core part of the Lodge approach involves decision-making by consensus, the capacity for many Lodge business work groups to act quickly and decisively in response to economic necessity (either by choosing profitable business alternatives, based on market need not just job preference, or reacting to demands of the business flexibly by changing procedures or rules) is often limited.

- 4) Since the Lodge is usually tied into a human service component (most often, mental health residential services,) there are not necessarily, but often, rules and regulations which can hinder effective "for profit" business (e.g., hours of operation, staffing requirements, house meeting times, location, etc.).

#### *Liaison with Local Vocational Rehabilitation (VR) Agency*

An ideal service program would include all the components described in the preceding pages plus a direct, competitive placement component. The realities of scarce resources (financial, skills, energy, staff, etc.), differing philosophies on how to help people, and low incidence need in any specific, geographic area mitigate against this happening in all but a very few, if any, locations. Therefore, most smaller, more restricted programs need to include some liaison with the local VR system as a way of expanding the service mix available to their clientele. For smaller programs with few staff, this linkage may be the major service delivery mechanism in terms of volume of consumers served. The trade-offs for this collaborative approach are that continuity of care is regularly sacrificed and the referring organization (and its clients) are left to negotiate the "appropriate/inappropriate" referral maze.

What many programs ignore, or forget when trying to refer clients to another system, is that they are engaged in a marketing process. Any service system should be driven by responsiveness to client needs, but many variables intrude. It is up to the referring agency, which bears the responsibility for advocating for services for its clientele, to attempt to overcome these barriers. This is not to absolve the "receiving" system of responsibility of making itself more accessible to new clients, but rather is meant to acknowledge the fact of system advocacy as a key role for referrers. Marrone, et al (1984) describe the concepts of "Positive Indicators," "Negative Indicators," and "Red Flags," in examining how VR counselors make the subjective decisions early in the referral process about which clients with mental illness they will accept for service. It is important to note that these decisions are fueled, not by a strict feasibility/predictability factor, as often implied, but rather, by more human factors like comfort level, personal interest in the client or referrer, ease of record access, and perceived client interest in VR services.

First and foremost, as noted previously, the major goal of effective inter-agency referral and collaboration is not good relations among staff. It is access and effective service delivery to consumers. Therefore, a person making a referral for VR services must be willing to "take the heat" that effective advocacy entails. However, an on-going, productive collaborative relationship should reflect both mutual respect and the utilization of

marketing principles (i.e., meeting the needs of the "customer". In this case, VR is the recipient of the attention -- i.e., the customer.)

A referral agency that uses these precepts should understand not just VR agency issues, but also the core principles of rehabilitation- such as need to be productive, individual control, focus on the person and the environment, a skills/strength-based model of helping (Kiernan, et al, in press). In addition, if the goal of the relationship is to receive funding, as well as refer clients, it is most probable that the MH program would do so under the rubric of "work adjustment"- which can be a broad, "catch-all" category of service delivery. It is frequently most effective to identify VR outcomes which linking with the psychiatric rehabilitation program can help the VR counselor achieve. Examples of types of outcomes which might prove useful to identify, depending on the nuances of a particular place and time, are:

- Rehabilitation (work) potential leading to a "Status 26" or successful closure;
- Increased applicants or eligible clients;
- Increased "Rehabilitation Rate"—percentage of clients closed successfully of all closures; and
- Reduced failure rate or closed unsuccessfully—"Status 08", "Status 28" or "Status 30."

It is crucial to note here that an effective marketing approach on the part of the mental health program requires an understanding of which of these, or other outcomes, the individual VR counselor or office considers desirable in the given circumstance. Essential to this strategy is the development of a personal alliance with a specific VR staff member. People relate to other people, not to systems. In service to this idea, an effective engagement is based on greater frequency of contact, rather than larger amounts of time spent there. Spending one hour a week on a program site is a more useful engagement strategy for a VR counselor than spending one entire day a month. Increased frequency allows for much more personalized and suitably intense relationships, than larger blocks of time, spread out longer.

## Conclusion

The author has presented a wide variety of alternatives that practitioners in the community psychiatric rehabilitation field are currently using. No specific model or approach is effective enough with any group of persons with serious mental illness to be used to the exclusion of the others. What the field does know, is that the more traditional ways of treating

people with mental illness, such as purely from a clinical mental health frame of reference, does not, in and of itself, help people achieve vocational goals. Even in the vocational sphere, using either a sheltered work model or its polar opposite, "just" getting people jobs without much built in support, does not produce anywhere near acceptable results. Much needs to be done, before advocates for people with mental illness in the vocational arena can tout any one methodology in preference to another.

Each of the alternatives noted has positive features and accompanying flaws. In the practical reality in which most programs and providers operate, no perfect "technology" exists to produce enduring, positive vocational outcomes for people. Technology is an accurate term when there is the capacity to replicate positive results consistently (as when one turns on a light switch, or when a plane takes off.) That capacity does not exist currently, or in the foreseeable future in vocational services.

Any service has to be offered in the context of a caring, hopeful, supportive relationship between the helper and the client (Deegan, 1988; McCrory, 1991). In the absence of such caring and personal commitment, which flows from an emphasis on meeting client desires and needs, none of the approaches cited can be efficacious. With these qualities, in addition to the Herculean efforts clients undertake themselves even to gain access to the services described, any one of these services can be used to achieve vocational benefits on behalf of people with serious mental illness.

# Supported Employment Outcomes for People with Psychiatric Disability

## A Comparative Analysis

*Participation in paid work in competitive industry through placement in supported employment is compared and analyzed for two populations: 212 persons with a primary psychiatric disability and 1,588 persons with a nonpsychiatric primary disability. Results are organized in two areas: service patterns through an analysis of types of interventions, and outcomes from supported employment services. Results indicate differences in the types and amounts of interventions provided, with the majority of interventions for both populations studied provided at the job site. Persons with a psychiatric disability consistently earn higher wages across a variety of service models than do persons in the other group. Differences between the two populations were also found in types of jobs, job retention, and reasons for separation from employment. Results represent an expansion of the limited data base available to evaluate the design and effectiveness of supported employment services for persons with a psychiatric disability.*

## **SUPPORTED EMPLOYMENT**

Supported employment (SE) is defined as part-time or full-time competitive paid work, averaging at least 20 hours per week in integrated work settings where contact with nondisabled people regularly occurs, and with extended services provided beyond the allotted maximum of 18 months of state vocational rehabilitation sponsored services.<sup>1</sup> It is targeted specifically for persons with severe disabilities for whom competitive employment has been intermittent or has not traditionally occurred. A number of

*J Voc Rehab* 1991; 1(3):30-44  
Copyright © Andover Medical Publishers, Inc.

federal initiatives in the mid-1980s assisted states nationwide in developing SE opportunities. First, the Rehabilitation Services Administration funded 10 five-year grants in 1985, with an additional 17 grants funded in 1986, to develop state systems of SE.<sup>2</sup> The 1986 Amendments to the Rehabilitation Act implemented the Supported Employment Services Formula Grant program, making federal funds available to all state rehabilitation agencies to provide time-limited SE services.

Initially, SE program models and demonstration efforts were designed primarily to serve persons with mental retardation,<sup>3,4</sup> and later, people with other disabilities. In fiscal year 1988, 16.7% of the persons reported to be in SE positions nationwide had a primary disability classification of mental illness.<sup>5</sup> While there is a trend toward increasing the use of SE services with this population and identifying ways to tailor services for people with psychiatric disability,<sup>6-10</sup> there is little data on the effectiveness of the approach or on actual differences in provision of SE services for people with severe psychiatric disability.

Psychiatric disability is defined as a disability due to psychiatric illness of prolonged duration, which limits one's capacity to perform certain functions (e.g., obtaining a job, interacting with family, etc.) and ability to perform in certain roles (e.g., worker, student.)<sup>11</sup> This definition is drawn from elements common to three often-used definitions: the Rehabilitation Services Administration's (RSA) definition of severe disability; the National Institute of Mental Health's Community Support Program (CSP),<sup>12</sup> and Goldman's definition.<sup>13</sup>

Many people who became disabled from mental illness experience their first episode in adolescence or young adulthood. Psychiatric disability is episodic in nature; that is, people experience cycles of exacerbation and remission of the symptoms of major mental illnesses such as schizophrenia or bipolar disorder. Functional deficits associated with the impairment create workplace problems such as inconsistency in performance and interpersonal relationships.

In spite of a wide range of educational experiences, intelligence, career aspirations, and previous work history, people with severe psychiatric disability typically have unemployment rates as high as 85%-100%.<sup>11</sup> The average unemployment rates for persons with other disabilities is 50%-75%.<sup>14</sup> Literature reviews conducted by Anthony and associates consistently have demonstrated employment rates of 20%-25% for all persons with psychiatric disability discharged from hospitals, but 0-15% employment rates for those considered severely psychiatrically disabled.<sup>15-20</sup>

Vocational rehabilitation programs have demonstrated limited success for people with psychiatric disability. According to the RSA, based upon 1985 general agency data on "rehabilitations," people with mental illness make up the next-to-largest category of disability serviced at 17.8%, but they have the lowest rehabilitation rate of successful closures (employed for a minimum of 60 days) at 56% compared to all other disability groups at 66%.<sup>21,22</sup> Bond and Boyer<sup>23</sup> found that there are no conclusive studies that the psychosocial rehabilitation approach, a program using prevocational work crews and transitional employment (TE), improves competitive employment rates. However, accelerated entry into TE results in a 20% competitive employment rate after 15 months beyond the initial TE placement, especially for those with previous work experience.<sup>24</sup> There is also some data from Fountain House to suggest that the longer one progresses beyond the initial TE experience, the better are the chances of becoming competitively employed.<sup>25</sup> However, these rates are not much higher than the base employment rates for people with severe psychiatric disability.

Preliminary data on SE outcomes for people with psychiatric disability is beginning to appear, but references in the literature are scarce. Most prevalent in the literature are proposed descriptions of needed modifications of SE for people with psychiatric disability.<sup>6-10</sup> Some conclusions can be drawn from these descriptions regarding the modifications of SE for people with psychiatric disability. The following list summarizes some of these major modifications.

- Emphasis on active involvement describing personal job values for job match
- Longer preemployment phase to choose a job
- Wider variety of job types
- Opportunities for advancement
- More time educating employers and co-workers
- Larger proportion of support time offsite during nonwork hours
- Greater proportion of training time in emotional-interpersonal skills
- Intervention hours after placement peak intermittently over time

Some literature is now appearing regarding effectiveness of SE for people with psychiatric disability. In a study by Collignon, Noble, and Toms-Barker<sup>26</sup> on integrating mental health and vocational services in Marin County, California, over 50% of individuals placed sustained part-time and full-time employment with limited follow-up in the first year, usually with the same employer. However, as more severely disabled people entered the program, fewer maintained employment. The study concludes that ending support services may be feasible for only a few people. The services involved competitive employment, SE, and TE, along with other vocational and prevocational services. No information is available on the specific types of intervention, total number of hours of intervention, types of jobs represented, or reasons for separation from the job.

In a description of SE program development in Maryland, Isbister and Donaldson<sup>27</sup> reported that, of 19 individuals placed in SE by the Schapiro Training and Employment Program—S.T.E.P., Inc.—from September 1, 1986, to publication in the fall 1987, 14 remained employed, at an employment rate of 74%. Of the 5 who left their jobs, 1 was hospitalized (5%), 2 chose not to work (15%), and 2 were terminated for inappropriate sexual and aggressive behavior (15%). The types of jobs included caseworkers, gasoline attendants, maids, banking clerks, maintenance workers, secretaries, doughnut makers, and factory workers. Again, there is no information on the amount or pattern of intervention hours, time spent on specific types of intervention, or the distribution of workers across jobs.

Fabian and Wiedefeld<sup>28</sup> updated a study of S.T.E.P., Inc., which is described as an individual-placement model of SE for people with psychiatric disability. After a seven-week intake group meeting of 2 hours per week, 69 clients were placed in jobs. Intervention emphasized training in interpersonal skill development and increasing productivity, systematic fading, and ongoing support, with a weekly 2-hour job-retention group and a job site follow-along service, which is characterized by a series of peaks in intervention time. Results indicated that participants worked a mean number of 27.4 hours per week, earning an average of \$4.13 per hour. Forty-seven percent of those employed held their jobs for at least 6 months. Job coaches spent an average of 20 hours per week during the first month. Data is provided on reasons for job separation and types of jobs, but no information is available on intervention patterns or specific allotment of types of intervention hours.

People with psychiatric disability clearly have difficulty in obtaining and sustaining employment. Traditional vocational rehabilitation, psychosocial rehabilitation, and TE services have had limited success in improving competitive employment rates, especially once services end. SE has been effective with people who have other disabilities. This study was undertaken to evaluate the effectiveness of SE for people with psychiatric disabilities. It identifies patterns of SE services by analyzing the types of *interventions* provided by employment specialists, both at and away from the job site. It also analyzes key *outcomes* from SE services in areas such as wages, integration at job site, type of employment, job retention, and reasons for job separation. Service patterns and outcomes for people with psychiatric disabilities are compared to other persons with disabilities.

## METHOD

### The Employment Data Management System

The Virginia Commonwealth University Rehabilitation Research and Training Center

(VCU-RRTC) on Supported Employment operates a comprehensive management information system designed to monitor the employment outcomes of targeted workers with a severe disability from Virginia. The Supported Employment Information System (SEIS) consists of client employment outcome data generated from approximately 61 local programs throughout Virginia. As of June 1990, the data base contained information on 1,800 persons with disabilities placed in employment.

### Overview of the Data Management Process

The SEIS consist of over 200 data elements, organized into 9 data-collection forms. The system provides detailed information on target employees' demographic and functional characteristics, consumer assessment, results of job analyses, comprehensive data on the type of job performed by the employee, amounts and types of services provided by the SE program, and supervisors' evaluations of the target employee's work performance; and it provides complete information regarding employment retention and reasons for job separation. Some data elements are collected one time only; others are collected on regular three- or six-month intervals; and still others are collected on a continuous, daily basis.

Data forms are submitted on a prescribed schedule, and a data-management specialist reviews each form for completeness, accuracy, and consistency with previously submitted data. Data are entered through a remote terminal into an IBM 3081K mainframe computer for analysis. Following data entry and analysis at VCU, summary reports are then returned to state agencies and local SE service programs on a quarterly and monthly basis. All SEIS participants receive aggregated statewide reports that contain both numerical tables and graphic depictions of data. All quarterly reports contain complete information on the immediate quarter, as well as cumulative information, to allow managers to monitor the results and growth of an individual program over time.

### Nature of All Persons in Data Base

The 1,800 persons placed into SE that make up the data base have a variety of primary disabilities. The overwhelming majority of individuals (70.7%) are diagnosed as mentally retarded (MR). Of the persons with MR as either a primary or secondary disability, 9.5% are in the severe/profound MR category (IQ < 39; 32.7% are moderate MR (IQ 40-54); 46.3% are mild MR (IQ 55-69); and 11.5% are borderline MR (IQ 70-79). Of the non-MR population, 11.8% are persons identified by service providers as having a primary disability of emotional disorder/chronic mental illness (CMI). The remaining 17.5% are persons with other primary physical disabilities including but not limited to traumatic brain injury or cerebral palsy.

Persons were selected for placement into SE for a variety of reasons, including the availability of a potentially appropriate job match, the availability of transportation and family support, the prioritization of services to certain individuals by funding agencies, and the economic pressures to obtain employment. This study was not experimentally controlled, leading to the potential for subject selection bias by participating programs. Also, the cumulative patterns of data for the non-CMI population, with its dominant MR component, are more clearly established because of their longevity in the SEIS as compared to the CMI population. The data is, however, representative of a large sample of persons served through a statewide system of SE.

### Demographic Characteristics of Persons in Present Study

The study that follows is an analysis of data submitted by Virginia Supported Employment Providers on 212 persons in the SEIS data base who are identified as having a primary disability of emotional disorder/CMI. These individuals represent 11.8% of all reported SE participants in the state as of June 30, 1990. The 1,800 persons studied have been placed into work through an SE service provider. Functional and historical information is not available for this study on demographic descriptors such as

length or number of hospitalizations or severity of the mental illness for the CMI population. Persons for whom data are submitted to the SEIS in Virginia predominantly are served by the state vocational rehabilitation agency and have substantial handicaps to employment.

Primary demographic information available on the study population involved age at referral, disability classification, receipt of federal disability income benefits, and residential situation. The mean average age of referrals for employment services for the CMI population is 34.5; mean average age for the non-CMI referrals is 28.9. Of the 212 persons with CMI, 16.5% have a reported secondary disability of MR, predominantly at the borderline or mild level. At referral, federal disability income benefits are received by 42.3% of the CMI population and 70.7% of the non-CMI population. At the time of first placement, 33% of the CMI population live independently; 37.7% with family or relatives, and 29.3% in supported or supervised living arrangements. For the non-CMI population, 14.2% live independently; 58.2% with parents or relatives; and 27.6% in supported or supervised living arrangements.

### Nature of SE Model

Over 76% of the clients in this study are served in the individual-placement model of SE. This model utilizes an employment specialist as job coach to provide structured job-placement services and highly individual and intensive training at the job site with additional supports provided away from the job site as needed by the individual. The unique feature of SE is that the focus of vocational intervention (e.g., training, counseling, and support) occurs at the job site while the person is employed. Many of the persons now served in SE have previously been unsuccessful in retaining competitive-level work due to (1) their inability to generalize or retain skills and (2) the presence of major social, behavioral, and/or physical problems. An SE specialist provides intervention based on the job requirements and challenges presented by the individual. The employment specialist

gradually reduces time at the job site, based on observed work performance improvement and biweekly reports from the business supervisor. Once removed from the actual site, the employment specialist maintains ongoing follow-along with the employer and employee that will continue as long as is needed to assist in maintaining successful employment.

### Provider Outcomes

In September 1985, Virginia initiated a formal effort to develop a statewide capacity to provide SE services to persons with severe disabilities regardless of their disability. Initially, a primary population of persons with MR was served because of the availability of service providers and ongoing support funds for this population. As of June 30, 1990, a steadily increasing percentage of persons with CMI was being referred and placed into SE relative to the total population being served.

The VCU-RRTC SEIS contains information on 1,800 persons placed into SE positions in Virginia. Of these 1,800 individuals, 973 are reported working as of June 30, 1990. As indicated in Table 1, 105 (10.85%) of the 973 persons are CMI. In comparison, 15.5% of the referrals for placement and 12.0% of the placements made by Virginia's providers during the April 1, 1990-June 30, 1990 quarter are persons with CMI.

SE services involve a variety of interactions, termed *interventions*, by an employment specialist with the disabled person, the employers and coworkers, the family members, and others. Interventions can occur both on and off the job

**Table 1.** Profile of Provider Outcomes: Virginia State System as of June 30, 1990

Outcome Measure	Number of Persons with CMI	Number of Non-CMI Persons
Employed	105	868
In referral pool	117	685
Placed in job this quarter	21	150
Referral for placement for this quarter	15	82

site. These interventions are broken into eight categories in the SEIS as follows:

#### **Intervention Time Directly Related to Job-Skills Training**

1. **Active Time:** Time at job site actually spent working with consumer, including active observation. Includes anything done to actively train the consumer.
2. **Inactive Time:** Time spent on the job site between periods of active intervention. This is time during which you have removed yourself from active involvement with and/or active observation of the consumer.

#### **Intervention Time Indirectly Related to Job-Skills Training**

1. **Travel/Transport Time:** Time used in traveling to a job site, to a meeting about a consumer, or to the consumer's home or in transporting a consumer anywhere.
2. **Consumer Training Time:** Time spent training the consumer in other than directly related job skills while he/she is not at work. Examples are money handling, grooming, counseling, bus training, family matters, and so on.
3. **Consumer Program Development:** This is time spent developing appropriate instructional plans (writing task analyses and behavioral intervention programs). Consumer-specific job development is NOT included here.
4. **Direct Employment Advocacy Time:** Time spent advocating for the consumer with job-site personnel for purposes directly related to employment. These persons would include employers, supervisors, coworkers, and customers. Consumer-specific job development is also included here.
5. **Indirect Employment Advocacy Time:** Time spent advocating with persons not directly affiliated with the employment site. These persons would include bus drivers, school personnel, landlords, case managers, bank personnel, parents, and so on.
6. **Consumer Screening/Evaluation:** Time spent screening consumer referrals to determine eligibility for services or evaluating eligible consumers. Any time spent analyzing any information relevant to a consumer's employment potential is included here. The follow-

ing, when done for purposes of screening or evaluation would be included here: Reviewing consumer records; consumer interview; communication with parents or guardians or involved agencies; observation of consumer in real or simulated work settings.

## **RESULTS**

A presentation of the results comparing the CMI population to the non-CMI population will be organized in two areas. The first area is represented by data concerning interventions by the employment specialist. This area includes intervention categories, total intervention hours, and patterns of interventions. The second area to be presented involves the outcomes of SE. This area includes integration at the job site, hourly wages, type of work obtained by supported employees, job retentions in first placement, and separations from employment.

### **Intervention Hours by Category**

A comparison of the intervention-time categories as described in Table 2 for the CMI and

**Table 2.** Intervention Hours by Category

<b>Intervention Time Category</b>	<b>Percent of Total Hours: Persons with CMI</b>	<b>Percent of Total Hours: Non-CMI Persons</b>
Active time on job site	31.2%	43.7%
Inactive time on job site	8.5	10.3
Travel and transport time	15.8	15.8
Training time	10.2	3.5
Program development	4.2	5.2
Direct employment advocacy	15.9	11.9
Indirect employment advocacy	9.0	6.6
Screening and evaluation	5.3	3.4

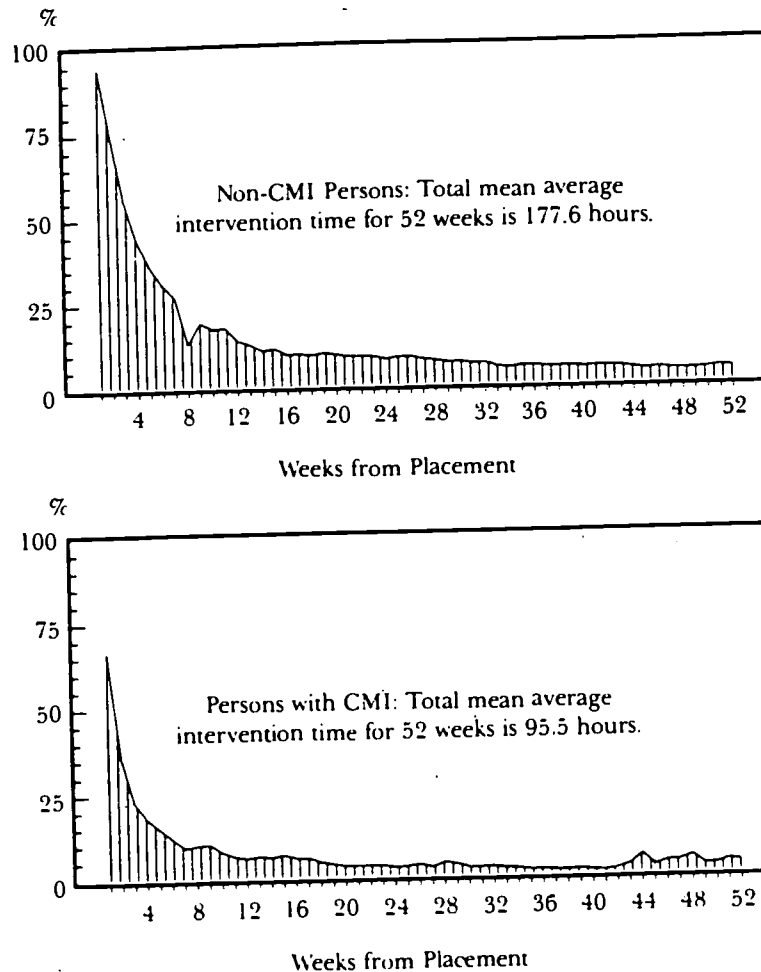

Figure 1. Weekly totals of intervention time as a percentage of consumers' work time reported by Virginia Providers

non-CMI populations indicates three primary areas of differences. Active time on the job site is 31.2% for persons with CMI as compared to 43.7% for the non-CMI population. Given the predominance of persons with MR in the non-CMI population, the 43.7% is representative of the job-skill-training needs of the MR population. In comparison, the CMI population shows a greater need for consumer training, involving training away from the job site, and for direct and indirect employment advocacy than do persons in the non-CMI population.

Figure 1 shows the intervention patterns over a 52-week period. Weekly totals of inter-

vention are represented as a percentage of work time by the supported employees. Mean average total of intervention hours over a 52-week period by employment specialists serving persons with CMI is 95.5 hours as compared to 177.6 hours for the non-CMI population. Figure 1 shows that intervention hours drop below 20% of the hours of employment by approximately the fourth week for the CMI population as compared to approximately the seventh week for the non-CMI population. The intervention hours provided during both the initial training phase and the ongoing support phase of SE are consistently less over a 52-week period for persons with

**Table 3.** Mean Hourly Wages for Placements In Various SE Programs

Employment Program	Placements of Persons with CMI (N = 253)*	Placements of Non-CMI Persons (N = 2205)*
Mobile work crew	\$2.86	\$2.75
Enclave	\$4.10	\$3.14
Supported job	\$3.78	\$3.49
Supported competitive	\$4.50	\$4.04

N for Table 3 is based on number of placements/positions reported. Some individuals in the SEIS have received multiple placements.

**Table 4.** Type of Work

Job	Person with CMI (Percent of Total)	Non-CMI Persons (Percent of Total)
Food service	25.4%	37.6%
Janitorial/custodial	22.5	26.4
Unskilled labor	1.1	2.1
Bench work/assembly	7.6	6.9
Laundry	0.7	2.8
Stock clerk/warehouse	19.6	10.4
Transportation	4.3	2.1
Clerical/office work	12.7	7.5
Groundskeeping	2.9	2.6
Human services	3.3	1.4

CMI as compared to the non-CMI population. Of note is the series of peaks in intervention hours over time for people with CMI as compared to the fairly consistent level of intervention over the year for the non-CMI population.

### SE Outcomes

**Level of integration in the workplace.** Predominantly, the degree of work-related interaction at the workplace for both populations is moderate and frequent. Eighty-eight percent of the CMI population and 82.8% of the non-CMI population are reported as having moderate-to-frequent interaction. Both populations appear to be employed in jobs with significant integration in the workplace.

**Hourly wages for persons in various employment programs.** As reported in Table 3, the CMI population has higher hourly wages in all SE program models.

The average hourly wage across all employment programs for the CMI population is \$4.39 with a 30-hour average work week (\$131.70 in earnings per week). The average hourly wage for the non-CMI population is \$3.81 with a 29-hour average work week (\$111.65 in earnings per week).

**Type of work.** Predominant job areas utilized for all persons in the SEIS are food service, janitorial/custodial, stock clerk/warehouse, and clerical/office work. As shown in Table 4, the food-service and janitorial/custodial job areas account for 47.9% of the placements for the CMI population. Persons with CMI make noticeably higher use of stock clerk/warehouse and clerical/office work job areas (32.3% combined than do persons in the non-CMI population (17.9% combined).

During the April-June 1990 quarter, 52.3% of the placements made for the CMI population are in the stock clerk/warehouse and clerical/office work categories as compared to 42.0% of the placements in the food and janitorial service industries. The non-CMI population also demonstrates an increase in the stock and office clerical areas, accounting for 23% of the quarterly placements. Quarterly statistics indicate an increased use of the stock and office clerical areas for all populations and a decrease in the percent of placements in the food- and custodial-service areas.

**Job retention in first placement.** Job retention is a critical variable in evaluating the effectiveness of SE programming. As indicated in Table 5, the CMI population has a consistently lower percentage of job retention in first placement than does the non-CMI population. Three months after first placement, 66.0% of the CMI population remained in the initial job as compared to 77.5% of the non-CMI population. Eighteen months after first placement, 25.7% of the CMI population remained in the initial job as compared to 42.6% of the non-CMI population.

**Table 5.** Job Retention in First Placement

Months of Employment in First Placement	Persons with CMI: Percent Retaining Job	Non-CMI Persons: Percent Retaining Job
3	66.0%	77.5%
6	53.0	63.4
9	42.8	55.5
12	36.3	50.6
18	25.7	42.6

SE involves a substantial investment of resources by the funding agencies, particularly during the initial stages of intensive job-site and related interventions to stabilize work performance of the supported employee at a level acceptable to the employer. Job retention and the degree to which the supported employee utilizes multiple placements are therefore significant cost-and-outcome-related issues for funding and service agencies involved in SE. Eighteen months after first placement, 40.3% of the CMI population are employed in their *first or subsequent* placement as compared to 59% of the non-CMI population. Also, 19.3% of the CMI population are discharged from services while still employed within 18 months of their first placement, usually because ongoing support services are no longer needed; for the non-CMI population, 5.6% are discharged from services while still employed within 18 months after their initial placement. Employment histories 18 months after initial placement are available within the SEIS on 109 persons with CMI as compared to 1,023 of the 1,588 individuals in the non-CMI population.

**Table 6.** Type of Separation from Employment

Separation Type	Persons with CMI		Non-CMI Persons	
	Number of Separations	Percent of Total	Number of Separations	Percent of Total
Resigned	75	58.6%	526	44.0%
Laid off	11	8.6	187	15.6
Terminated	41	32.0	466	39.0
Leave of absence	1	0.8	15	1.3

**Separations from employment.** Reasons for separation from employment fall into two general categories: employer-initiated and employee-initiated. As shown in Table 6, employer-initiated separations (laid off or terminated) occurred with noticeably less frequency for the CMI population (40.6%) than for the non-CMI population (54.6%). Conversely, the CMI population had a higher percentage of employee-initiated separations through resignations (58.6%) than did the non-CMI population (44.0%).

Table 7 shows the large number of specific primary reasons given for separations. For the CMI population, the most frequently cited reasons for separation are not wanting to work, medical health problems, and taking a better job. For the non-CMI population, the most frequently cited reasons for separation are economic situation along with taking a better job and not wanting to work. It is important to note that separations caused by work-related factors such as poor work quality, aberrant or insubordinate behavior, or poor work attitudes are not primary reasons for separations for either population.

## DISCUSSION

The results of this study indicate a number of noticeable differences in interventions for persons with CMI as compared to a predominant population of persons with MR as well as persons with severe physical disabilities receiving SE services. The first difference is the types of interventions. The SEIS contains three intervention categories involving job-site specific

**Table 7.** Primary Reason for Separation from Employment

Reason for Separation	Persons with CMI		Non-CMI Persons	
	Number of Separations	Percent of Total	Number of Separations	Percent of Total
Low-quality work	6	4.7%	64	5.4%
Poor attendance	7	5.5	71	5.9
Insubordination	7	5.5	58	4.9
Aberrant behavior	4	3.1	34	2.8
Poor work attitude	6	4.7	83	6.9
Not wanting to work	19	14.8	109	9.1
Economic situation	9	7.0	173	14.5
Medical health problem	17	13.3	56	4.7
Better job	16	12.5	134	11.2
Poor job match	9	7.0	42	3.5

activities. These categories include active and inactive time on the job site and direct employment advocacy time. Approximately 57% of the employment specialists' time is spent at the job site for the CMI population, and 67% for the non-CMI population. For the CMI population, more emphasis is placed on advocating for the supported employee with supervisors, coworkers, and customers, and less time is actively involved with the individual worker in training as compared to the non-CMI population. However, the majority of reported intervention time for the CMI population is at, and not away from, the job site. In the only other published study of actual job-coach intervention hours, Fabian and Wiedefeld<sup>29</sup> report that approximately 20 hours per week for the first month is spent by the job coach *on site* (for participants averaging 27.4 hours per week working). Although no actual data exists on the distribution of the job coach's time over various types of interventions or on the total number of service hours per year, they do note that the job coach tends to spend his or her time in modeling social interactions with coworkers and supervisors and developing strategies to increase production rate rather than in direct training in the technical skills of the job.

Persons with CMI comprise the one population exempted in the federal regulations for SE from the extended service requirement that two job-site visits per month for the purposes of skill

training be provided.<sup>1</sup> The indications in the Fabian study and in the current Virginia study are that substantial intervention time for the CMI population occurs at the job site. These findings merit attention in terms of the basis for the regulatory exemption for the CMI population from required job-site interventions and design of SE services for the psychiatrically disabled.

Several other points need to be made regarding the pattern of intervention hours. Of importance is the greater amount of time spent on-site in direct employment advocacy and off-site in consumer training and indirect employment advocacy for the CMI population, than for the non-CMI population. It seems that people with psychiatric disability generally can learn the technical skills of the job quickly but require much more assistance in coordinating services and supports outside of work area in learning skills that are not directly job-task related. Also, the employment specialist spends more time in educating and enlisting the support of coworkers and supervisors. People with psychiatric disability have complex service needs,<sup>26</sup> such as case management, residential, therapy, crisis management, education, medical, and so on, and may be involved with a variety of providers. Job coaches must coordinate efforts with these other providers to increase the support for the worker's success on the job (e.g., negotiating an evening therapy appointment time, informing the psychiatrist of

adverse medication side effects, or assisting the case manager in advocating with the Social Security Administration about financial benefits). If support service needs are not being met currently, SE providers may spend a lot of time assisting the worker in identifying and accessing services to meet those needs (e.g., getting a case manager, therapist, psychiatrist, or vocational rehabilitation counselor, or arranging transportation).

The data presented here regarding a larger proportion of time spent training the consumer in skills other than those that are directly job related seem to support the notion that people with psychiatric disability need technical skill training less and more assistance in the social-emotional areas.<sup>8,10,27</sup> Henderson and Argyle<sup>30</sup> estimate that 35%-90% of work time is spent interacting informally. Given that people with psychiatric disability may experience deficits in social skills, off-site training in these skills seems indicated.

Because of the stigma and fear of mental illness, much more time working with coworkers, supervisors, and customers may need to be spent providing accurate information and reducing fear. Employers may also need specific suggestions about how to interact with the worker with the psychiatric disability. In addition, time spent developing natural supports in the workplace may improve job retention and job satisfaction.<sup>27</sup>

The data presented here regarding the "peaks" in service hours over time is similar to observations made by Fabian and Wiedefeld<sup>29</sup> and also supports the recommendation made by others that SE services be flexible to accommodate the episodic nature of the disability.<sup>6,10</sup> Employment specialists must be vigilant in regular follow-up with both employees and employers to identify any problems arising from an exacerbation of the illness.

Also of interest is the second area of differences in intervention. The total number of intervention hours provided to persons with CMI by Virginia's providers is 53.8% of the mean average total of 177.6 intervention hours over a 52-week period for the non-CMI popula-

tion. In Fabian and Wiedefeld,<sup>29</sup> although not specifically reported, the total number of hours per year would seem to be higher than reported in this study (an average of 20 hours per week in the first month, plus a 2-hour-a-week support group, plus follow-up contacts). The findings of the Virginia study have potential implications in the determination of staff/participant ratios for staffing SE programs serving a generalized or disability-specific population and for projecting the funding requirement for persons needing SE services. For example, the mean average hourly rate in Virginia for the supported competitive employment model is \$31.81 as of June 30, 1990.<sup>32</sup> Utilizing this rate, the 52-week cost for serving the CMI population reported in this study, as represented in Figure 1, is \$3,038 as compared to \$5,472 for the non-CMI population.

Cost comparisons should be qualified for a number of reasons. First, the comparative severity of disability across the two populations in the Virginia study cannot be quantified, and the possibility of subject selection bias referenced earlier does exist. Second, multiple provider agencies were involved in this study, and the consistency of staff skills, economic conditions, and service applications in communities across the state is not known.

Information is also needed on the variety of other services, such as case coordination and counseling, provided by agencies and/or persons other than the SE provider, as this also affects costs. SE provider time spent either arranging for or providing these services (in the absence of other community resources) may significantly affect employment outcome in addition to service costs. Third, caution should be used in comparing cost-benefits and outcome.

Anthony, Cohen, and Farkas,<sup>33</sup> in reviewing the literature, could find no causal relationship between the expenditures for a rehabilitation program and the outcomes of that program. That is, proponents of SE or any rehabilitation program for this population should not cite reduced costs as a reason to provide this service. Fourth, the SEIS contains data on 273,987 hours of intervention time for the non-CMI

population as compared to 22,243 hours for the CMI population as of June 30, 1990. However, the data is based on a state-system effort to serve a varied population of persons with disabilities over a multiyear period, and to that extent, the translation of intervention hours into cost projection does have merit.

While noticeable differences in interventions were found in this study, there are also interesting points in the area of program outcomes. The two primary areas of differences between persons with psychiatric disabilities and the other populations studied are in job retention and in reasons for job separation. These issues are analyzed in greater depth in the remainder of this paper.

The job retention profile shown in Table 5 does indicate that persons with CMI separate from their initial placement at a noticeably higher rate than do persons in the non-CMI population. Poor job match was cited as a reason for separation twice as often for the CMI population than for the non-CMI population. Adjustments to the supported competitive employment model, developed initially for persons with MR, to place greater emphasis on the active participation of the CMI population in the *choice* of their job area, is viewed as a critical variable in job retention.<sup>10</sup> In addition to emphasizing interest and values in job selection, prior work skills, experience, and education might lead to identifying more compatible jobs outside the janitorial, food-service, and clerical areas. Fabian and Wiedefeld<sup>29</sup> found that 12% of those working were employed in skilled jobs. In terms of education, 34% had some college and 36% had a high school diploma. Harrison and Perelson<sup>9</sup> wrote that program participants were employed in positions such as dialysis patient assistants and laboratory assistants.

Job retention is a major issue to funding agencies investing in SE services. Substantial attention is needed for the factors potentially influencing job retention for the CMI population, including appropriateness of the initial job match; support services provided during the period of employment (both vocational and

therapeutic); extent to which the jobs utilized by the SE program provide the needed level of income and benefits; and the influence of the cyclical nature of mental illness.

It may be helpful to examine several issues related to job retention by reviewing the data compared to base rates of employment, job tenure for nondisabled entry-level workers, and vocational maturity and career development. One way to evaluate the success of SE is to compare job tenure rates to base employment rates in the literature. Anthony<sup>34</sup> reported a 30%-50% employment rate at 6 months, 20%-30% at 12 months, and 25% at 3-5 years for people discharged from the hospital. However, if the criterion for comparison is either working full-time during the entire follow-up period or employment at the time of follow-up (versus employment at some point during the follow-up period), employment rates drop to 20%-25% regardless of which follow-up time period is used. In view of this data, job retention rates in the Virginia study are better than base rates of employment up until the 18-month follow-up period, at which time rates are comparable. These rates are measurably better than the 0%-15% employment rates reported by Anthony and associates for people who have severe psychiatric disability.<sup>15,34</sup>

Job tenure and retention should also be considered in light of job-tenure rates reported for people without disabilities. Most placements in this study were in entry-level jobs. The average job tenure for nondisabled Americans in entry-level jobs is six months.<sup>35</sup> Professionals must be careful not to expect more of people with disabilities than is expected of people without disabilities. "Success" might then be defined in terms of the number of months of employment in any given follow-up period and of the number of levels of job advancement during follow-up in addition to the level of participant satisfaction with the job and the service.

This leads into a discussion of assessing SE outcome from a career-development perspective. Many people who have psychiatric disability

first experienced illness during adolescence and young adulthood, when most nondisabled people are working at summer jobs and part-time jobs, going to school, and developing a vocational identity. Successive, short-term employment experiences (in regard to job tenure) may represent a need to "catch up" in vocational development. Given that the CMI population in this study is somewhat older than the non-CMI population (34.5 years versus 28.9 years), there may be a greater sense of urgency to catch up to their similar-age, nondisabled peers. These experiences then provide the basis for a person to make sound vocational decisions and plans for the future.<sup>36,37</sup> The Fountain House report of TE indicates that employment experiences accumulate over time, producing better long-term outcomes the further away from service provision that one goes.<sup>25</sup> This would suggest the need for long-term follow-up on SE outcomes.

The issue of job selectivity and job satisfaction also needs attention. Table 4 shows that nearly one-half of the jobs utilized for the CMI population were in the food- or janitorial-service areas. Recent data in Virginia indicates a trend toward employment in office and stock clerk job areas and away from the service industries for all populations. Possibly related to the impact of job selection on job satisfaction and job retention is the finding shown in Table 6 that the CMI population studied initiates job separations at a noticeably higher rate than does the non-CMI population. It appears that greater attention is needed, during the job-selection process and during the period of employment itself, to the work-satisfaction issues experienced by the CMI population if job retention is to be improved.

Another way to improve job retention is to examine the reasons for job separation (Table 7). Of the CMI population, 14.8% left jobs because they did not want to work. In addition to examining this question prior to selecting a job, the issue should be analyzed in greater depth to identify the factors contributing to this decision (i.e., fear of high expectations once paid for working, losing benefits, loneliness, or feeling out of place). Interventions then might in-

volve modification of the SE model, advocating with Social Security, establishing natural supports in the workplace, or using a variety of other creative solutions.

Medical health played a role for three times as many persons with CMI (13.3%) as with non-CMI populations (4.7%). There may be a number of reasons for this. First, psychiatric disability is variable and episodic in nature, compared to most physical disabilities and MR. Hospital recidivism rates are 35%-50% at 1 year and 65%-75% at 3-5 years.<sup>11</sup> Community support programs and psychosocial rehabilitation programs appear to be effective in reducing recidivism rates.<sup>23,28</sup>

It also appears that the prevalence of medical illness among people with severe psychiatric disability in outpatient care is quite high. Maricle and colleagues<sup>38</sup> found that 88% of study subjects had one significant medical illness; 51% had been previously undiagnosed. This finding points to the need for service coordination addressing the health needs of people with psychiatric disability. One must interpret these results cautiously, as the average age in this study was slightly older (43 years versus 34 years). In comparing this reason for separation to nondisabled entry-level workers, one study reported that 8%-9% were terminated from employment for health reasons.<sup>39</sup>

The last major reason for job separation for the CMI population was that of taking a better job. As discussed previously, it may be a positive sign that workers are interested in career development and advancement and that shorter job tenure may not necessarily indicate poorer SE outcomes. The types of jobs may not represent the range of interests found in this population.

## CONCLUSION

This study presents preliminary data comparing people experiencing psychiatric disability and people with all other disabilities. Future research should focus on defining the target

populations more accurately, analyzing the reasons for job separation, particularly that of not wanting to work (for the CMI population), and conducting long-term follow-up studies to determine SE program effectiveness, with attention to cumulative impact of employment experiences. Outcomes should be analyzed taking a career-development perspective into account. Success should be measured in terms of the number of months of employment during follow-up rather than in terms of job tenure in a single job.

This study addressed a general population of persons with a primary disability classification of emotional disorder/CMI served by a variety of provider agencies. Limited information was available on mental health-

oriented support services provided in companion with SE services. Future research should focus on more clearly defined populations of persons with psychiatric disability in terms of length of illness, number of hospitalizations, employment history, and support services received. The Virginia study indicates that persons with a psychiatric disability can benefit from SE services and that there are noticeable differences in service patterns and outcomes for this population when compared with a predominant population of persons with MR. The further evaluation and refinement of SE services for the psychiatrically disabled will require more research-based information on well-defined populations, services, and supports.

## INDIVIDUAL PLACEMENT AND SUPPORT: A COMMUNITY MENTAL HEALTH CENTER APPROACH TO VOCATIONAL REHABILITATION

Deborah R. Becker, M.Ed.  
Robert E. Drake, M.D., Ph.D.

**ABSTRACT:** Individual Placement and Support (IPS) is a vocational rehabilitation intervention for people with severe mental disabilities. The model draws from components and philosophies of other successful programs. Employment specialists, who are part of the community mental health center team, provide services in the community. IPS emphasizes client preferences, rapid job finding, continuous assessment, competitive employment, integrated work settings, and follow-along supports. Initial research on IPS shows favorable results.

Competitive work is increasingly a goal for persons with severe mental disabilities. Like others in American society, people with psychiatric impairments want to lead normal lives and view work as one of the principal signifiers of normal adult life. In a statewide survey of people with severe and persistent mental illness, 71% of those without jobs expressed an interest in paid employment (Rogers, Walsh, Masotta & Danley, 1991). At any one time, however, less than 15% of those with severe psychiatric disabilities are employed (Anthony & Blanch, 1987).

Despite their own interests, people with severe mental disabilities have received little assistance in gaining competitive employment. Only 3% of those in a national survey had been in supported employment programs (Tashjian, Hayward, Stoddard & Kraus, 1989). Moreover, between 1977 and 1984, competitive employment for Vocational Rehabilitation (VR) clients with severe psychiatric disabilities did not improve (Andrews, Barker, Pittman, Mars, Struening & LaRocca, 1992).

Until recently, community mental health centers (CMHCs) did not emphasize vocational services (Black & Kase, 1986), in part because mental health professionals saw their role as protecting clients from stressful

situations, including employment. Independent psychosocial rehabilitation programs and nontraditional rehabilitation agencies have historically provided what little vocational services were available (Katz, 1991).

As CMHCs begin to emphasize vocational services, models that have shown successful outcomes are being considered for replication. Current vocational approaches include sheltered work, psychosocial rehabilitation (e.g., clubhouses with transitional employment), skills training, assertive community treatment, supported employment, and job clubs (Bond & Boyer, 1988). Instead of transplanting a vocational model exactly as it has been implemented elsewhere, however, several experts recommend adapting a model, or parts of several models, to fit the needs of a particular agency, clientele, and community (Bachrach, 1988; Stein & Test, 1985; Witheridge & Dincin, 1985). New models should be described with unambiguous terms, standard definitions, and clear outcome criteria (Bond and Boyer, 1988; Bond and McDonel, 1991).

The purpose of this report is to describe a vocational rehabilitation model, Individual Placement and Support (IPS), that has recently evolved in several New Hampshire CMHCs. IPS is a team-oriented, CMHC vocational service that assists persons with severe mental disabilities in obtaining and maintaining competitive employment. IPS emphasizes client choice, rapid job finding, competitive jobs, integrated work settings, and follow-along support services. Excluding clients from employment services, extensive initial assessments, and pre-vocational training are de-emphasized. Two current studies of IPS in New Hampshire are revealing positive vocational outcomes (Drake, Becker, Fox, & Lounsberry, 1992; Drake, Torrey, Wyzik, Becker, & McHugo, in preparation).

## PRINCIPLES

IPS was developed by considering the philosophies, values, and critical components of several approaches to vocational rehabilitation in relation to the particular characteristics of the New Hampshire public mental health system. It draws most heavily from the Program of Assertive Community Treatment (PACT) in Madison, Wisconsin (Russert and Frey, 1991; Test, 1991a). Other influences include the supported employment movement (Federal Register August 14, 1987; Wehman, 1986), Boston University's

Center for Psychiatric Rehabilitation (Anthony, Cohen, & Farkas, 1990), and several thoughtful reviews of the empirical literature by Bond (Bond & Boyer, 1988; Bond & McDonel, 1991). IPS incorporates the following principles.

1. *Rehabilitation is an integral component of mental health treatment.*

IPS assumes that nearly all people with severe mental disabilities can engage in some type of work and that work is good treatment. Furthermore, because symptoms and disabilities are intertwined, rehabilitation and other treatments require careful coordination. That is, work and therapy are dynamically interactive; each influences the other. While some vocational models attempt to separate rehabilitation from other treatments, IPS integrates them closely.

Rehabilitation is therapeutic in several ways. Work can lead to changes in motivation, self-confidence, structured activities, and relationships. In addition, work often impacts directly on the client's psychiatric disorder. Though work can increase stress and the need for medications, it often motivates clients to improve their self-management of symptoms and may reduce the need for medications. In a reciprocal fashion, other treatments influence rehabilitation. For example, addressing medication noncompliance and interpersonal difficulties, which are often impediments to long-term employment, can improve the effectiveness of rehabilitation.

2. *The goal of IPS is competitive employment in integrated work settings.*

Clients in a statewide survey (Rogers et al., 1991) and in our focus groups in New Hampshire indicated a preference for competitive jobs in integrated work settings (i.e., settings that contain non-disabled workers) rather than sheltered or volunteer work. Although research has not shown that integrated work settings are always more beneficial than sheltered settings, integrated work settings are more normalizing. Clients report that they feel stigmatized in enclaves of other disabled workers. IPS follows a place-train strategy (Wehman, 1986) in which clients enter competitive jobs and receive needed training and support on the job. Some clients will inevitably need to transition through volunteer jobs or other pre-vocational activities. Nevertheless, since expectations tend to provide a self-fulfilling prophecy, and low expectations (e.g., sheltered employment) may result in clients failing

to fulfill their wishes and potentials, IPS focuses consistently on competitive work as the ultimate goal.

*3. People with severe mental disabilities can obtain jobs rapidly.*

IPS emphasizes entering work as soon as possible rather than preparing for work. Newman (1970) described several advantages of rapidly obtaining employment in terms of assessing employability, reinforcing capabilities, and experiencing the worker role. Bond and Dincin (1986) found that clients were more likely to engage in competitive employment if they participated in an accelerated placement program rather than a prevocational program. Their clients expressed dissatisfaction with prevocational assessments and training, and preferred rapid placements in real jobs in the community. Focus groups in several New Hampshire CMHCs confirmed that clients prefer to seek jobs without lengthy prevocational training and assessment.

*4. Vocational assessment is continuous.*

IPS incorporates assessment as an ongoing process that continues after acquiring a job (Wehman, 1986). Each work experience provides more data about the client as a worker and helps in planning for the next job. Job endings are, therefore, always framed in positive terms. This approach contrasts with traditional programs in which clients' vocational abilities are assessed through extensive tests and evaluations conducted prior to acquiring employment.

*5. Follow-along supports are often necessary to sustain employment.*

Job retention is more difficult than job finding for many people with severe mental disabilities. Follow-along support includes any services that assist clients in keeping their jobs -- e.g., transportation, advocacy and education with the employer, and counseling about work relationships. The levels and sources of support vary depending on the clients' needs.

*6. Services are based on clients' preferences and choices.*

Services are client-centered in both planning and delivery. IPS encourages clients to participate as much as possible. The New Hampshire mental health system has been based on a collaborative philosophy for many years. Treatment planning occurs in regular client-centered conferences.

This philosophy has been applied to vocational rehabilitation at the Boston University's Center for Psychiatric Rehabilitation by conceptualizing the process from the client's perspective – i.e., choosing, getting, and keeping a job (Anthony, Howell & Danley, 1984). Those clients who are unable to express their views, make choices, and initiate activities independently can also fit easily into IPS because it is implemented in a highly individualized manner. Depending on levels of disability and verbal, cognitive, and interpersonal skills, clients need varying degrees of staff guidance and support in finding, acquiring, and maintaining a job.

*7. Services are usually provided in the community.*

Client contact and training is *in vivo*, in the client's natural environment. This approach has several advantages: Since skills learned in the CMHC do not generalize, clients learn skills in community settings where they are used. Clients feel empowered when meeting CMHC staff in a setting more neutral than the clinic, which may be perceived as stigmatizing. By observing people in their natural environment, the employment specialist can assess clients' needs, behaviors, and support networks more directly. Assertive outreach in the community is often essential. Clients sometimes disengage when they are fearful, discouraged, or pressured by network members not to work. Employment specialists can reach out at these critical times to provide necessary support and encouragement.

*8. A team approach promotes integrated services.*

A team approach with regular communication between the employment specialist and other treatment team members permits the careful integration of mental health and rehabilitative services. Symptoms, illness management, interpersonal behaviors, and activities and relationships on the job are interrelated. The employment specialist, for example, conveys pertinent job-related information such as job starts, terminations, and work problems. The employment specialist may also identify symptoms that occur at work. The case manager, the nurse, and the psychiatrist in turn inform the employment specialist of changes in the client's medicines, living arrangements, and important relationships. They describe both chronic interpersonal difficulties that are likely to arise on the job and prodromal

symptoms. The team collaborates with the client as these interactions inevitably shift with changes in vocational status.

The forum in which the employment specialist communicates with other members of the treatment team varies depending on the organizational structure of the CMHC. IPS was designed in New Hampshire to be implemented in CMHCs that have teams of clinical case managers with caseloads of approximately 20-30 clients per case manager (Kanter, 1989; Harris & Bergman, 1988). Employment specialists regularly attend case management meetings and treatment team meetings.

### *PROGRAM DESCRIPTION*

A staff of employment specialists, integrated with the CMHC treatment team, implement the IPS program and provide liaison with other agencies. The program will be described in several phases including referral, engagement, assessment, acquiring employment, and job support.

#### *Organization*

The IPS program is staffed by a vocational coordinator and two or more employment specialists. The program coordinator, who typically has a master's degree in rehabilitation, supervises the employment specialists, works with referrals, and acts as administrative liaison to other departments and programs. Employment specialists carry caseloads of 20-25 clients, varying with the level of client needs, and usually work in pairs to cover for each other. This staffing arrangement also provides a staff support system.

Employment specialists come from a variety of backgrounds, but the most successful ones are assertive, high-energy, task-oriented, and optimistic. They firmly believe that most people can work if the right situation is found. They also believe in doing the job outside of the clinic, in the community. Other qualifications include: knowledge of severe mental illness, including diagnoses, medication management, and treatment; knowledge of a broad range of occupations and jobs; ability to interact with employers; assessment and counseling skills; and ability to work as a team member with staff from other disciplines.

While the core of IPS is integrating vocational services with other CMHC services, employment specialists also link clients with outside agencies, such

as private vendors, the Department of Employment Security, and the Division of Vocational Rehabilitation (VR), as needed. For example, VR can provide additional assessments, training, job-related equipment and supplies, placement, and support. VR may also purchase IPS services. CMHC and VR offices typically develop official agreements, but the personal relationship between VR counselor and IPS employment specialist is critical.

### *Referral*

Clients can be self-referred or referred by family or CMHC staff. Those who are 18 years and older and have a major mental illness that qualifies them for services in the CMHC's community support program are eligible. The only additional requirement is expressing interest in competitive employment. IPS assumes that clients can make appropriate choices about their own rehabilitation program. After attending an educational group, clients make an informed choice about whether to participate (Drake, Becker & Anthony, in preparation). Consistent with our philosophy of attending to clients' preferences and maximizing vocational outcomes for all, clients are rarely screened out by staff. Our research indicates that a high proportion of those who select IPS are able to obtain competitive jobs.

### *Engagement*

Upon starting the IPS program, clients are linked with an employment specialist with whom they meet individually. Establishing a trusting, working relationship with the client is the *sine qua non* of vocational rehabilitation. Some clients prefer not to meet at the CMHC because of the stigma about mental illness. Getting to know clients in the community, in their world, allows the employment specialist to observe relationships, daily routine, home environment, interests, and habits -- all of which are useful for job exploration and assessment.

Readiness for work of course varies. Some clients want to go to work quickly; others express an initial desire to find a job, but then back off from any activities related to a job search. The employment specialist meets regularly with clients, even if they do not always talk specifically about work. If a client drops out at any point, the employment specialist reaches out in an assertive manner to attempt to renew the process.

### *Vocational Assessment*

The initial vocational assessment includes the client, the CMHC staff, the case record, family members, and previous employers. Key data include work background (education and work history), current adjustment (physical health, endurance, grooming, interpersonal skills, medication management, symptomatology), work skills (job-seeking skills, job skills, aptitude, interests, motivation, work habits relating to attendance, dependability, stress tolerance), and other work-related factors (transportation, family support, substance use, expectations regarding personal, financial and social benefits of working). The goal is to specify a first job. Afterward, assessment occurs continuously as the client and employment specialist learn what kinds of jobs and supports are likely to be successful and satisfying.

Job choices should be congruent with client's abilities, preferences, and style. The IPS employment specialist tries to help the client find a job that is tailored to his or her needs rather than to change the client to fit a specific job. For example, if a client has a long history of poor hygiene and grooming, despite previous efforts of others to help the client change, they find a job that accommodates this appearance. The nature of the psychiatric disorder often determines the optimal type of job, the work environment, and needed job supports. The client who has paranoid, referential thoughts around people might not do well as a food server in a fast-food restaurant, but might feel comfortable preparing food alone in the kitchen. Someone who continually feels anxious and restless might not be suited for a desk job but might excel in a delivery position. A client who shouts at hallucinatory experiences might have difficulty in a quiet office but might do well in a noisy outdoor work setting.

The goal of IPS is competitive employment in integrated settings with follow-along supports, yet some clients feel so overwhelmed that they will only consider volunteer or sheltered jobs as a first step. Clients can gain confidence and good work habits through volunteer or sheltered jobs (e.g., workshop jobs or CMHC-based sheltered jobs), but these settings can also reinforce dependency. IPS therefore emphasizes competitive work, even if only a few hours per week with supports, to gain experience.

Each IPS client has an employment plan that includes vocational goals, timelines for achieving the goals, supports needed for obtaining the goals, and people responsible for implementation. The vocational plan, modified

as needed by new information, is incorporated into the client's individual CMHC treatment plan.

### *Obtaining Employment*

When job preferences have been identified, the employment specialist and client work together to find a job in the community. In the job-seeking process, the client takes the lead as much as possible. Some clients do not want the employer to know about their mental illness or their involvement with the CMHC, so the employment specialist assists indirectly in the job search. For example, the employment specialist coaches the client about job interviews but does not attend the appointments. For some clients, however, psychiatric symptoms interfere with developing the skills to negotiate a job with an employer, so someone else must help to secure the job. Even if the client can obtain a job independently, the client often agrees to the employment specialist contacting the employer in order to assist with potential problems. The employment specialist provides education, guidance, and support to the employer as needed.

Employment specialists help with the job search in varying ways. Their approaches are creative, flexible, and imaginative. They may review newspaper want ads, but nontraditional approaches seem to be more successful. Some go unannounced to a business, to learn about its operation, needs, current job openings, and possibilities for future opportunities. They also find openings in new businesses that are hiring personnel, in businesses that are expanding, and from employers at the Chamber of Commerce. A major source of leads is through personal contacts. Employment specialists talk to as many people as possible about the types of jobs they are seeking. They talk to their own family and friends, other staff, and family members of clients. Members of the Alliance for the Mentally Ill are often helpful. Through all employer contacts, employment specialists build a network of employers to whom they can refer clients as job candidates.

Sometimes a job must be created. For example, an employment specialist whose client enjoyed landscaping went to a local fast-food restaurant for dinner and noticed the unattractive grounds around the restaurant. She asked to speak to the restaurant supervisor and told him about her client. The client was hired on a time-limited basis, and soon after, the job became a permanent part-time position.

1006

When negotiating a job, the employment specialist provides the employer with several benefits. These include knowledge of the client, ongoing supports, crisis intervention, and information about employment practices, such as the Americans with Disabilities Act and the Targeted Jobs Tax Credit. Our experience indicates that employers are interested in all of these.

### *Job Support*

When the client is working, the employment specialist provides follow-along support to the client and the employer. They discuss problems as they occur. The client may need frequent contacts initially, even daily meetings to go over what happened at the job. Although on-site job coaching is available, most people with severe mental illness need minimal assistance in this area. They benefit instead from guidance and support that is provided away from the job site to address difficulties such as interpersonal relations.

The employment specialist sometimes intervenes if a potential problem appears. For example, with the help of his employment specialist, a client acquired a job at a fast-food restaurant doing counter work for 20 hours per week. After two weeks, the restaurant manager offered to increase his weekly work hours to 40. The client expressed interest in working full-time, but the employment specialist knew that in previous jobs the client had become overwhelmed and had lost jobs when he increased his work hours. The employment specialist discussed with the client the previous work pattern and suggested that it might be best to continue with part-time employment and slowly increase to full-time work. The client asked the employment specialist to talk with the employer about the work hours, and the employer subsequently adjusted the work hours to a part-time schedule that proved to be manageable for the client.

After a client has been working, the need for the employment specialist's involvement often decreases and becomes sporadic. Clients typically do well but have periods of difficulty as symptoms of the illness or interpersonal problems arise. At these points, the employment specialist may help the client to negotiate a reduction in work hours or a leave of absence, or just increase supports. With appropriate supports, work can be a stabilizing factor during difficult times.

Along with the employment specialist, other treatment team members provide services that help the client to maintain employment. The psychiatrist adjusts medication as needed. The case manager provides support to the client on vocational concerns and other areas in his life that may affect his work performance. One client, for example, struggled with expressing sexual urges inappropriately at work. The client met with his case manager to discuss how to prevent this problem from interfering on the job.

## DISCUSSION

IPS is an eclectic approach; it represents an amalgamation of other prominent models of supported employment. Since it was developed specifically to fit in New Hampshire's CMHCs, its success may be related to the context. New Hampshire's ten community mental health centers are relatively well-supported small programs that emphasize comprehensive services for people with severe mental disabilities. They are located in small cities or towns with populations of between 60,000 and 150,000 people. In other settings, with larger populations, less coherent mental health systems, or systems with a different orientation, the IPS model may be more difficult to implement.

One unusual feature of the New Hampshire mental health system is its emphasis on mental health services research. The New Hampshire-Dartmouth Psychiatric Research Center is an integral part of the Department of Mental Health (DMH) and participates in planning, implementing, and evaluating many programs (Drake & Teague, 1990). Research data are used continuously in the process of modifying programs and shifting resources from ineffective programs to those that achieve better outcomes (Drake, Becker, & Bartels, in press). As the IPS model began to emerge in New Hampshire, DMH sponsored conferences and meetings to clarify the model and moved rapidly to evaluate the model.

Because IPS is part of an extensive research program, a detailed treatment manual (available from the authors) has been developed, clinicians have received specific training and supervision in the model, and services and outcomes are tracked carefully. Two research projects on IPS are currently underway in New Hampshire. In the first, which is sponsored entirely by DMH, one CMHC agreed to close one of its two day treatment facilities and to

convert the staff positions to IPS employment specialists. Clients in this program have been followed longitudinally and compared with those in a similar day treatment facility, which did not close, in the same CMHC. One-year outcomes indicate that both volunteer jobs and paid jobs increased in the program that converted to IPS. For example, 55% of the high utilizers of day treatment services in the converted program secured a paid job in the community within one year of the program change compared with only 8% of similar clients in the unmodified program (Drake et al., in preparation).

The second project, which is funded by the National Institute of Mental Health, compares IPS with vocational services provided by a private vendor outside of the CMHCs. Clients who are randomly assigned to IPS or the private vendor are being followed carefully for 18 months. The project includes an ethnographic component to elucidate key process issues and a cost-effectiveness component to identify the costs of providing vocational services in the two ways. This experiment is in progress, but one-year results favor IPS and are consistent with the findings of the first study. Thus, a strong empirical base for IPS is rapidly emerging.

Despite these findings, we as yet have no data on the long-term effects of IPS. Clients' vocational careers over a number of years should be studied in detail to understand their evolution and the factors that determine long-term success and the relationship to quality of life, symptoms, community tenure, and other important outcomes. Vocational adjustment should be considered in terms of a career, not just short-term success. Recent evidence indicates that the success in vocational adjustment associated with PACT treatment attenuates over time (Test, 1991b). IPS, which emphasizes rapid placement, may also have greater initial success than long-term success. While short-term success has value in its own right, studying the long-term impact of early job acquisition is critical.

Persons with severe mental disabilities, like the rest of us, are undoubtedly acculturated into their roles and self-images as workers or non-workers. Rehabilitation specialists have sometimes argued that mental health settings are stigmatizing and socialize clients into dependence and disability (Anthony et al., 1990). The IPS model explicitly directs employment specialists and clients to focus on competitive jobs in integrated work settings in the community, but places the vocational staff within teams in the CMHC to facilitate clear communication and coordination. Our research indicates

that interorganizational communication difficulties and conflicts often arise when vocational services are provided by an outside vendor.

A further unanticipated advantage of the IPS model is that organizing vocational services under the auspices of the CMHC influences how case managers and other staff regard vocational goals. Many of the same clinicians who were previously indifferent or even skeptical toward vocational rehabilitation have been positively affected by IPS and, despite their initial resistance, have become advocates for vocational services. Their conversions appear to affect the culture of the mental health centers.

### *SUMMARY AND CONCLUSIONS*

IPS offers supported employment as an integrated component of the CMHC treatment program. The treatment team collaborates in supporting clients in their vocational pursuits. Clients rapidly obtain competitive jobs that are congruent with their personal preferences and their clinical and rehabilitative needs. Vocational assessment is an ongoing process that incorporates information from each additional job experience. Ongoing supports are arranged to enable the client to keep the job, but job endings are viewed as opportunities for learning rather than as failures. The short-term success of IPS, in terms of obtaining jobs and modifying the culture of CMHCs, appears to be excellent. Because IPS is being developed in association with a mental health services research center, its outcomes and cost-effectiveness, including long-term impact, are being studied carefully.

## *ACKNOWLEDGMENTS*

The authors would like to thank the IPS teams, especially David Allen, Matthew Lavey, Marion Lounsberry, Paula Mattis, Sheila Morin, Brian O'Hare and Matt Rivero for their work in developing the IPS manual and preparing this manuscript. Special thanks go to Jana Frey and Bill Knoedler for the training they provided on the PACT program, and to Gary Bond for comments on an earlier version of this paper.

MENTAL ILLNESS AND SUBSTANCE ABUSE

1015

# 1

## Dual Diagnosis: Fact or Fiction?

Andrew E. Slaby

*Fair Oaks Hospital, Summit, New Jersey; New York University,  
and The Regent Hospital, New York, New York*

Dual diagnosis, simply defined, refers to the concurrence of two separate diagnostic entities in one person. In the area of substance abuse, this means that a substance abuse disorder such as alcoholism occurs together with a psychiatric disorder such as major depression or panic disorder. In most situations, there are actually many concurrent diagnoses. A cocaine user, for example, frequently uses alcohol or heroin to come down. If the same person has a bipolar disorder, he/she would have at least three separate disorders: cocaine abuse, heroin or alcohol abuse, and bipolar disorder. In this chapter, I will discuss how a diagnosis may be confused by the simultaneous occurrence of both a substance abuse disorder and a psychiatric disorder as well as by other substance abuse disorders or medical disorders either induced by substance abuse or occurring independently. Emphasis will be on what is known epidemiologically and clinically of dual diagnosis. Unfortunately, the instability of this patient population over time makes it difficult to follow the group for outcomes of treatment except for those who have a psychiatric disorder that they are self-medicating. The self-medicating group does quite well if the psychiatric disorder is recognized and given diagnostic-specific treatment negating need for further self-medication with recreational drugs. Research into clinical presentation and course of use of recreational drugs is further complicated even in a stable population by the fact that substance abusers often do not know the drug they have taken with

any degree of certainty and in most cases do not know the dose or contaminants.

Want of clinical acumen, as well as economically or politically motivated desire to oversimplify diagnosis and management of substance abuse, leads to untold pain for patients and families and to compromised quality of care. Cost is greatest to the young, where concomitant undiagnosed and treated Axis I and II psychiatric disorders, coupled with substance abuse, contribute to the genesis of enduring patterns of maladaptive coping styles and diminished self-esteem. Unrecognized dual-diagnosed patients drain both public and private health care systems by repeated and lengthy hospitalizations. These individuals rapidly resume substance abuse after discharge and fail to comport to treatment plans. These people do not respond to the best of self-help groups such as Alcoholics Anonymous, Narcotics Anonymous, and Cocaine Anonymous. Some join the ranks of the homeless.

As many as 74% of psychiatric inpatients reportedly have abused substances [2]. Thirteen percent consistently abuse drugs other than alcohol. Frank alcoholism occurs in 8.7-17.1% of general medical patients [2]. Psychiatric patients admitted without diagnosed substance abuse problems have been found to differ from medical/surgical controls in quantity and frequency of drug use and problems associated with the drug used [2].

One of the principal clues to differentiating drug users with major psychiatric illness from those whose symptoms are primarily a response to drug abuse is onset of symptoms [3]. Patients with a long history of deterioration prior to hospitalization, as measured by duration of psychotic symptoms, previous psychopharmacotherapy, and poor occupational adjustment, are more likely to be dual-diagnosed. Pattern of drug use and presence or absence of violence does not have as great diagnostic significance [4]. Double depression (i.e., major depressive disorder superimposed on dysthymic disorder) occurs in this population and poses special problems. The double depression group exhibits significantly greater alcohol and amphetamine use [5]. Since both forms of depression are generally antidepressant resistant, identification of this subpopulation can lead to successful treatment of all three disorders: major depression, dysthymia, and substance abuse. Psychic suffering accompanying substance abuse, coupled with psychopathology, results in interpersonal difficulties and impaired social adjustment, contributing to a misimpression of a schizophrenic rather than an affective process [6].

The majority of patients with psychiatric problems are attended by primary care providers rather than mental health professionals, contributing in part to the appalling fact that only about 19% of those affected have been provided help for psychiatric disorders in the previous six months [7]. The

1017

impression of many nonpsychiatric health care providers is that substance abuse disorders are different from psychiatric disorders and should receive differential referral. After all, why are there three separate institutes at the National Institute of Health: the National Institute of Mental Health (NIMH), the National Institute of Drug Abuse (NIDA), and the National Institute of Alcoholism and Alcohol Abuse (NIAAA). Specialist, if not subspecialist, care is required to determine the role recreational drugs, concomitant medical and surgical illness, psychosocial variables, and preexistent or precipitated Axis I and Axis II psychiatric disorders play in the development of the clinical picture. Psychiatric disorders, medical disorders, and substance abuse disorders must be independently identified and differentially treated to reduce repeated and lengthy future hospitalizations. Both a differential diagnosis and a differential treatment plan must be elaborated.

#### SEXUAL DYSFUNCTION AND OTHER CONCURRENT MEDICAL PROBLEMS

Problems in sexual drive and/or performance frequently precede or correlate with substance abuse. These merit special discussion because, unlike many other medical problems, including the changes in hormonal function with alcoholism that lead to feminization, sexual dysfunction is more frequently due to psychological reasons than organic disease. As the old adage goes, alcohol increases desire but decreases performance. Actually, a small amount of *spiritus fermenti* was once recommended in *The Merck Manual* to overcome inhibitions that entrapped Victorian desire.

There are a number of ways in which drugs and alcohol impact sexual performance:

1. Sexual dysfunction may be a direct side effect of a drug.
2. Stress may lead independently to both sexual dysfunction and substance abuse.
3. Drug abuse may result from anxiety over sexual performance or lack of it.
4. Substance abuse may represent an attempt to self-medicate the primary psychiatric disorder.
5. Poor judgment attendant upon psychiatric disorders such as schizophrenia or medical disorders such as Alzheimer's disease or AIDS dementia may result in substance abuse.
6. Guilt over sexual prowess (e.g., multiple extramarital liaisons) may engender substance abuse.
7. Substance abuse may result from a pattern of socializing required to

meet sexual partners, as in the instance of depressed married men and women seeking homosexual companionship at gay bars.

8. Impotence or decreased libido may be entirely independent of drug use and due to physical and psychological factors that represent neither a drug effect nor a major psychiatric illness.

Drug-associated impotence has been reported to be as high as 25% [8]. Chronic airflow obstruction can occur contemporaneously with psychiatric problems and drug use, particularly alcoholism and inhalant abuse. Alcohol abuse is frequently seen in older age groups and in heavy smokers. Emphysema with air hunger is common in both groups. Of 50 consecutive patients with chronic lung disease in one study assessed both medically and psychiatrically, 58% were found to suffer panic and 34% other anxiety disorders [9]. The role substance abuse and other psychiatric symptoms plays in this group, as with impotence, is complex. Substance abuse may represent a response to anxiety associated with the illness. In other instances, a person may self-medicate the anxiety that is a symptom of air hunger occurring with chronic lung disease. In both instances, inhalant use or crack smoking may have contributed to lung problems. Finally, an independent psychiatric disorder (e.g., panic disorder) may coexist with substance abuse and pulmonary disease. Occurrence of three independent diagnoses, as in the case of alcoholism, panic disorder *not due to chronic airway obstruction*, and emphysema, is an example of triple rather than dual diagnosis. The addition of yet a fourth diagnosis, such as antisocial personality on Axis II, would result in a quadruple diagnosis [10].

Substance abuse is associated with a number of medical conditions that challenge even the most seasoned diagnostician. Historically, various forms of syphilis and tuberculosis confused all psychiatric pictures. Syphilis presents as general paresis, cerebrovascular syphilis, meningovascular syphilis, gummas, and tabes dorsalis. Tuberculosis causes tuberculomas, cerebral abscesses, tubercular meningitis, and the general neurasthenia associated with pulmonary and other forms of tuberculosis. Today, AIDS complicates the picture in a myriad of ways, ranging from depression in subclinical AIDS prior to confirmation by seroassay to AIDS dementia. Hepatitis, cirrhosis, and other liver diseases are associated with mood change [1].

Cocaine causes a number of cardiovascular changes, in addition to pulmonary and upper respiratory problems [1]. Skin and systemic infections are common sequelae of intravenous drug use. Drug abusers may present with bilateral pyopneumothoraces and bacteria from jugular vein self-injection [11]. Factors impacting on the occurrence of medical and dental complications include adulterants present when a drug is taken, nonsterile needles, overdose tolerance, extant dependence and withdrawal, life-style of drug

user, and age of drug user [12]. Trauma is common with substance use. Unilateral or bilateral subdural hematomas from falls while intoxicated may present solely as depression or may be entirely overlooked because continued intoxication obfuscates recognition on exam in the absence of obvious clinical signs such as a unilateral dilated pupil. As serum alcohol level rises, the risk of any form of accident increases [13]. History of trauma may be a clue to undiagnosed alcohol abuse. Laboratory findings (e.g., elevated GGPT) appear to have a high sensitivity only with more chronic alcoholics and those who have ingested alcohol in the previous 24 hours [1,12].

Psychiatric symptoms reported as complications of AIDS and the AIDS-related complex (ARC) mimic a number of psychiatric disorders and precede seropositivity for HIV. These range from mild chronic dysphoria to acute psychosis. Early symptoms resemble those of advanced cocaine psychosis [14]. Both frequently appear in the same population, confusing the diagnostic picture. Agitation, panic attacks, anorexia, delusions, disorientation, insomnia, hallucinations, depression, impaired memory, and dysattention are reported. Seizures and tachycardia are also seen. Organicity should be suspected in all patients known to be seropositive. Intravenous drug users are the HIV-positive subpopulation that is most rapidly expanding. Heroin and cocaine are the preferred drugs for intravenous use [15]. In the population of IV drug users, acting out behavior due to central nervous system AIDS infection may be seen as sociopathy. In alcoholics, both young and old alike, the fluctuating consciousness of CNS HIV infection may be misconstrued as alcohol withdrawal delirium, and AIDS dementia as alcoholic dementia or Alzheimer's disease, depending on the age of the patient [16].

## DUAL DIAGNOSIS AND ALCOHOL ABUSE

### Alcoholism and Affective Disorders

Uncomplicated alcohol abuse is common only during the initial stages of drinking [1,12]. As desire to drink progresses, so too does frequency of dual or multiple diagnoses, complicating the picture. Therefore, it is rare to see an alcoholic who abuses only alcohol. Multiple drug use is more common [1]. In the final stages, the mental status picture represents the interaction of a number of acute and chronic factors such as delirium and intoxication superimposed on dementia and the other CNS consequences and liver failure.

Depression is usually present. The critical clinical question is not whether a depressed alcoholic suffering the psychosocial consequences of chronic substance abuse is feeling worthless and helpless but rather whether he or she has a treatable affective disorder and whether that affective illness pre-

ceded alcoholism. In the later instance, the drinking may represent self-medication of dysthymia.

The relationship between alcoholism and depression has long fomented debate. Schuckit feels this is due to confusing drinking, alcohol problems, and alcoholism on the one hand and sadness, secondary depression, and affective disorders on the other. Of the 80-90% of Americans who drink at some time during their lives, 10-30% develop alcohol-related problems. Only 8-10% of men and 3-5% of women, however, go beyond alcohol problems in their drinking to meet criteria for the diagnosis of alcoholism [17-19]. Many heavy drinkers are remorseful over the social and economic ramifications of their intemperance. Only a fraction of these have significant affective illness requiring more than detoxification and nonmedical rehabilitation. The group with both alcoholism and affective disorders requires greater deployment of medical resources for diagnostic-specific treatment in order to successfully avoid exacerbation of illness and consequences of untreated major affective illness. While one-third of alcoholic patients experience depressive symptoms, only 1-3% of alcoholic men are reported to suffer major depressive disorder [20].

The greater incidence of depressive symptoms as opposed to depressive illness found in actively drinking alcoholics is attributed to the physiological symptoms of withdrawal, the apathy of the alcoholic personality, the state of chronic intoxication, and concomitant drug use [21]. Severity of symptoms independent of affective illness is positively correlated with worse prognosis, suicide, and treatment attrition. For instance, a comparison of nondepressed and depressed alcoholics indicated that the latter have longer histories of problem drinking, more previous treatment for alcoholic misuse, more difficulty controlling alcohol consumption, more mental problems, and more physical symptoms related to alcohol abuse. They have a detached interpersonal style, distracted cognition, alienated self-image, and mixed depressed-anxious emotionality [22].

A number of clues facilitate identification of primary depression (antedating onset of alcoholism) and secondary depression. There is more impairment in patients with primary depression than in those with the secondary or concurrent type [20]. Age of onset and length of illness are two other factors discriminating primary from secondary depression; primary affective illness tends to last longer and have an earlier age of onset. Patients with depression secondary to alcoholism when compared to patients with depression secondary to nonsubstance abuse disorders, excluding schizophrenia, report less severe depression and tend to be predominately male [23].

Family history is important in identifying primary as opposed to secondary depression. Relatives of probands with subtypes of primary affective illness other than bipolar show a greater incidence of alcoholism in addition

to affective illness [24]. Data are inconclusive. Other genetic studies indicate that depressives without alcoholism do not transmit alcoholism, while those with both alcoholism and depression transmit both, suggesting that alcoholism and depression are not manifestations of the same disease process [25]. Anxiety disorders are found more frequently in relatives of probands with alcoholism, suggesting self-medication in selected cases [26]. Families with a high incidence of alcoholism exhibit more dysthymic disorder and secondary depression rather than primary major affective illness.

A dose-response relationship between level of depression and alcohol consumption in alcoholic and nonalcoholic women has not been demonstrated. Personality disorder and anxiety level appear more influential. An inverse relationship between depressive symptoms and alcohol consumption exists among healthy women. Nonalcoholic dysthymic women consume significantly more alcohol than major depressive, subclinically depressed, and psychotic nondepressive women and less than the healthy nondepressed population. There is no difference in consumption among major depressive, dysthymic, and other diagnostic groups among alcoholic women. Progression of alcoholism is related to progression of depressive symptoms and correlated with increasing dementia in older age groups [27].

Groups at highest risk for the dual diagnosis of affective illness and alcoholism are females ages 20 through 30, individuals not presently married [28], and patients of low social class [29]. Family history of alcoholism or behavior associated with alcoholism does not differentiate primary alcoholics, alcoholism with secondary affective disorder, and primary affective disorder with secondary alcoholism. The three groups do differ, however, in past personal history and family history of affective disorder and time spent in hospital for both alcoholism and affective disorder. Risk is greater with patients with anxiety disorders and antisocial personality [30,32]. Higher prevalence in the latter group may relate to concomitant factors such as young age and more familial psychopathology, drug use, and subjective anger.

Alcoholics have reason to be depressed. They experience family disintegration, poor social and work role performance, and a myriad of medical problems. Infections, pancreatitis, cirrhosis, and arthritic diseases may themselves contribute to depression [33,34].

In a study of 49 severely depressed alcoholics, 80% with an initial major depression by Research Diagnostic Criteria were no longer depressed two weeks after cessation of drinking, indicating need for at least two weeks of sobriety prior to use of antidepressant therapy [35,36]. Chronic ethanol ingestion may lead to disturbance of the diurnal rhythm of cortisol secretion or stimulation of the adrenocortical activity, raising plasma cortisol levels in chronic alcoholics that is positively correlated with manifest depression [37].

The dexamethasone suppression test (DST) may facilitate rational selection of the subpopulation of alcoholics who will benefit from antidepressant therapy, but false positive results exist with this test [38]. False positives result from hepatic enzyme induction, acute alcoholic withdrawal associated with hypercortisolism and Cushing's disease.

Prognosis of alcoholic patients with affective illness is better if diagnostic-specific treatment is provided for the mood disorder [28]. Incidence of severity of depressive symptoms is greater in alcoholics who relapse than in the general population [39-41]. Debilitating depressive symptoms may first emerge in periods of abstinence. A study of 72 alcoholics abstaining a mean of 64 months revealed a 15% incidence of depressive symptoms beginning after a mean of 35 months of sobriety [42]. Rate for relapse was higher in the symptomatic group. Lithium reduces alcoholic abuse but not depressive symptoms in this group [43]. It is hypothesized that the group that benefits most is cyclothymic, with alcohol abuse exacerbated in the hypomanic rather than depressed phase. Other studies confirm that past psychiatric history is predictive of outcome in both alcoholics and narcotic addicts [44].

Depressive symptoms, as opposed to depressive illness, decrease markedly without treatment as patients progress from active drinking to abstinence [45]. Symptomatic mood changes without affective disorder may relate to major physiologic changes attendant upon alcohol use that abate as drinking ceases, with a concomitant decrease in depressive symptoms. Regardless of what the depressive symptoms relate to, however, depression as measured by the Beck Depression Inventory and Hamilton Psychiatric Rating Scale for Depression in alcoholics directly correlates with self-reports of previous suicide attempts [46,47]. Numerous other studies document the incidence of depression and depressive symptoms among alcoholics [48].

Impact of antidepressants on depression associated with alcoholism is contingent on whether the mood change represents true affective disorder rather than psychological response to a person's feeling out of control with his or her drug use in the absence of genetic predisposition and subsequent manifestation of a DSM-III-R mood disorder. In the absence of diagnostic-specific indications, there is little evidence of efficacy [49].

Psychosocial support mollifies depression associated with perceived consequences of alcoholism [50]. Reordering the social and personal life of the alcoholic and reinforcing valued nondrinking social ties the alcoholic has developed serves to reduce the depression in those without true affective illness. Patients who have a history of drinking primarily to facilitate social aspects of their lives are most likely to have residual depressive symptoms after treatment of alcoholism, indicating need to work aggressively with these patients to develop alternate means of social interaction.

## Alcoholism and Nonaffective Psychiatric Disorders

Less attention has been afforded to concurrence of alcoholism and other psychiatric disorders except for the anxiety disorders already mentioned. Affective illness and anxiety disorders are far more prevalent, and therefore their relationship to alcoholism is easier to study than illnesses with significantly lower prevalence.

Alcoholism is a significant problem for schizophrenic patients [51] but not to the reported degree for mood-disordered patients [52]. Studies of monozygotic and dizygotic twins indicate that alcoholism and schizophrenia are more common in the monozygotic group, suggesting that individuals suffering from both schizophrenia and alcoholism have a genetic predisposition to both disorders of the same nature as that which occurs when alcoholism and schizophrenia appear alone. Schuckit points out that primary alcoholism can mimic almost any psychiatric disorder and that secondary alcoholism can exacerbate any psychiatric symptoms [19].

Diagnoses of character disorders are particularly difficult among alcoholics. This is in part due to the fact that Axis II diagnoses are not as devastating to the integrity of the personality, and therefore may be obfuscated by substance abuse. Alcohol intensifies the moroseness of a depressive and the anxiety of those with anxiety disorders. In a disorder, such as antisocial personality, drinking generally accompanies a behavior pattern that, in the absence of the personality disorder, could be attributed to the drinking alone. Rigorous criteria are required to document the existence of an antisocial personality [19] including, at a minimum, difficulty in at least four life areas, namely, problems with family, peers, school, and police, commencing before age sixteen. By these criteria, approximately 10-20% of male and 5-10% of female alcoholics suffer antisocial personality disorders. These individuals bear a more negative prognosis than those whose difficulty with the law is solely alcohol-related.

Public intoxication, belligerence, driving under the influence, and other alcohol-related crimes generally disappear upon cessation of drinking and are not part of an enduring pattern of antisocial behavior [19]. Because anxiety and insomnia may persist for three to six months following cessation of alcohol use, anxiolytics and hypnotics with any addicting properties should be avoided. This is done to avoid dependency and because anxiolytics and hypnotics seldom maintain effectiveness after two to four weeks, lending to abuse to maintain effect [19]. Nonmedical approaches such as no caffeine after 3 P.M., going to bed and arising at fixed times without any daytime napping regardless of how little sleep was achieved, and use of relaxation techniques such as meditation and self-hypnosis should be prescribed.

The distinction between alcoholic hallucinosis and paranoia and schizophrenia is particularly important. Schizophrenia has a decidedly worse outcome. Alcoholic paranoia and hallucinosis, on the other hand, frequently clears within days or months, regardless of treatment [19]. Embryopathy is greater among offspring of alcoholic than nonalcoholic mothers [53]. Many of the psychiatric disorders seen with alcohol use are the expected depression attendant upon use, which disappears upon cessation of drinking; the occurrence of specific alcohol-related psychiatric disorders such as delirium tremens and paranoia [54]; and what we perceive to be personality disorders [55,56].

Personality disorders may be partially conditioned by the need to secret alcohol as well as to deny alcoholism in order to maintain an amiable relationship at work and with family. Studies of families of alcoholics have failed to demonstrate increased risk for schizophrenia. Family members of schizophrenics are rarely alcoholic [19].

A number of provocative findings reported in the literature merit further investigation. One is that the level of an alcoholic proband's subjective anger is more closely associated with alcoholism than antisocial personality [31]. Another is the finding that while antisocial personality and substance use disorders are common psychopathologies among male alcoholics, major depression and phobias are common among female alcoholics [57-59]. In women, psychiatric disorders often appear to precede alcohol abuse or dependence. In men, however, with the exception of antisocial personality and panic disorder, psychopathology usually occurs subsequent to alcohol use. Other studies [60] indicated that phobias and non-confrontational personality disorders precede abuse of alcohol. Drinking tends to relieve the distress. For both men and women, alcoholism coupled with antisocial personality or drug abuse has a poor prognosis [61-63]. Major depression with alcoholism is associated with a better outcome.

### Alcoholism and Organic Mental Syndromes

Concurrent psychiatric disorders and alcohol abuse are only part of the diagnostic dilemma of dual diagnosis and alcoholism. Chronic and sporadic excess alcohol drinking is associated with more physical problems than other substance abuse. Falls lead to subdural hematomas with organic mental syndromes; sudden cessation of use may result in delirium tremens with seizures. Indiscriminate hetero- and homosexual behavior at times of intoxication leads to AIDs and other sexually transmitted diseases, with their attendant psychiatric syndromes (e.g., AIDS dementia and delirium). Nerve cells die with chronic abuse, leading to alcoholic dementia and peripheral neuropathies mimicking hysterical paralysis. Neglect of diet leads to

Wernicke's encephalopathy and a host of other deficiency diseases associated with changes in mental status.

Chronic alcoholism is a potentially treatable cause of dementia [1,64]. Thiamine deficiency is etiologic in development of Korsakoff's psychosis, the chronic component of the Wernicke-Korsakoff syndrome. Amnesia with relative preservation of other cognitive functions is its most striking feature. Confabulation occurs early. Alcohol dementia, a more global syndrome than Korsakoff's, occurs on autopsy in about two-thirds of patients with alcohol changes in the brain. Cortical atrophy and reduced cerebral blood fluid are found. While end-stage dementia is unremittable, abstinence produces some resolution in less chronic cases if detected early [64]. Neuropsychological impairment appearing upon cessation of drinking becomes less pronounced with continued abstinence [66]. Early remission is attributed to reversal of cerebrospinal fluid acidosis, to other ionic imbalances, and to inhibition of brain protein synthesis. Changes occurring over a longer period include increases in dendritic arborization and glial tissue. As much as two years may be required for reversal of sleep disturbances and electroencephalographic abnormalities. Short-term memory, visual motor performance, and general intellectual functioning all improve [66]. In addition to the Wernicke-Korsakoff syndrome and alcohol dementia, an undetermined number of adult alcoholics suffer the residual form of the attention deficit hyperactivity disorder (ADHD). Some feel that the diagnostic criteria for Wernicke's encephalopathy (confusion, ophthalmoplegia, and ataxia) are too rigid, thereby missing a number who have the disease at necropsy who might have been successfully treated if the disease had been identified early. One of the criteria is absence of any other cause of dementia deemed sufficient for the diagnosis [66].

Seizures are a predictable occurrence with abrupt discontinuation of alcohol intake. Alcohol also lowers the seizure threshold for those with epilepsy. Nearly half of the seizures occur 13 to 24 hours after cessation of use [67]. Therefore, seizures in an alcoholic may be due to cessation of use just as they may be due to excess use of cocaine or amphetamines and *not* represent a separate diagnostic entity.

Alcohol and drug use per se do not lead to AIDS; sharing needles and careless sexual behavior under the influence do. Alcohol and other drugs, however, are known to inhibit the immune system and, therefore, may play a contributing role by impairing initial resistance to the virus. AIDS can present with insomnia, abulia, anhedonia, psychomotor retardation, dysmnesia, anorexia, weight loss, mania, command hallucinations and persecutory delusions mimicking schizophrenia, alcoholic paranoia, and affective illness [68]. The course may be quite prolonged with only subtle changes and may be masked by alcohol use.

Changes in blood pressure and in the heart lead to hypertension and congestive heart failure, both of which can mimic a number of anxiety disorders [69-71]. The Los Angeles Heart Study revealed mean blood pressure of heavy drinkers to be significantly higher than that of light drinkers and nondrinkers. In the Framingham study, rate of hypertension was twice that of nondrinkers [70]. Alcohol-induced blood pressure increase is one of the treatable causes of hypertension [71]. Level of gamma glutamy/transference (GGPT), an enzyme particularly sensitive to ingestion of alcohol, is related to high blood pressure [72].

Alcohol-induced liver and bone diseases all produce illnesses that may compound the diagnoses of alcohol-induced mental changes [75,76]. Acute and chronic hepatic disease is associated with lethargy and depression.

#### DUAL DIAGNOSIS: DRUG USE/AFFECTIVE ILLNESS

Rates of major depressive disorder, scores on depression scales, and rates of self-reported suicide attempts increase progressively with increased use of licit (tobacco, alcohol, and psychotropics without prescription) and illicit substances [77]. A number of depressive scales have been evaluated for relative sensitivity and specificity in detecting depression in substance abusers. On the whole, sensitivity is good (65-94%). Specificity is less impressive (39-61%). Rounsaville et al. [62] have found the 13-item patient self-report the most specific and sensitive test for depression and recommend it for screening for depression in substance abusers. Substance abuse is a particular problem among young patients, particularly young adult chronic patients [78]. Persistent substance abusers have psychiatric hospitalization rates twice as high as patients who are former users or nonusers. Abuse of drugs, in fact, frequently precedes hospitalization. That these patients tend to deny use underscores need for urine and serum screens of all young adult chronic patients to identify and treat substance abuse and minimize readmission. Safer [78] reports that 45% of this subpopulation have been hospitalized three or more times; 60-73% are unemployed. More than 50% receive government assistance; 24-41% have adult criminal records; and 34-50% have documented substance abuse. The young adult chronic population is currently responsible for considerably more community problems than it was in the past. Young handicapped men as a group show more depression and alcohol- and drug-related problems than matched controls, highlighting need for particular care in assessment and treatment of this group [79].

Depression and/or substance abuse are commonly found in eating-disorder patients. Hatsukami and her group [40,41] evaluated 108 women who met DSM-III criteria for bulimia and found that 43.5% had a history of affective illness and 18.5% a history of alcohol or drug abuse. Approxi-

mately 56% of the bulimics scored within the moderate-to-severe range of depression on the Beck Depression Inventory. The relationship between affective and eating disorders is a concern of some controversy. On the one hand, it is clear that a significant number of patients with bulimia and/or anorexia respond to antidepressants. On the other hand, people who fear that they cannot achieve a body image to comport with their fantasized ideal may feel that they have reason to be depressed. That greater than one-half of patients with bulimia have been found to have positive dexamethasone suppression tests (DSTs), a rate comparable to that found in patients with major depression, along with the reported high incidence of affective illness in first-degree relatives, suggests a relationship between the two illnesses. Substance abuse in this group is not limited to alcohol and recreational drugs. Marijuana, cathartics, diuretics, and steroids are also abused. The subpopulation of bulimic patients with both substance abuse and affective disorder show a higher incidence of attempted suicide and more social problems [41].

Schizophrenics may have particularly bizarre patterns of substance abuse, given their disorganized thinking. In one study [80], it was found schizophrenics who abused drugs had an earlier age of onset than those who did not. Drugs may have been taken in response to the mounting stress of an incipient psychotic deterioration or may have precipitated it. Low intelligence and academic difficulties are also correlated with early onset and may also contribute to the apparent link between substance abuse and early onset.

Patients with borderline personality are another group at high risk for substance abuse. This group is more pathologic than nonborderline substance abusers, [81] showing more depression, poorer impulse control, impaired reality testing, and antisocial tendencies.

Medical problems compound the picture of any substance abuse disorder. This is particularly true of AIDS which, perforce, is higher in intravenous drug and other substance abusers as well as in patients who experiment with both drugs and sex. The manifestations of AIDS, both medically and psychiatrically, are as legend as those of tuberculosis and syphilis [82]. All organ systems may be impacted by drugs. Even the eyes may be a site of drug absorption or suffer neurologic or vascular damage due to specific drug effects [83-84].

While patients with major psychiatric disorders and substance abuse are in need of more intensive inpatient and outpatient treatment, they more frequently drop out of treatment [85,86]. Outpatient management for the 21-39% of patients with substance abuse disorders who have a concurrent diagnosis usually of a personality disorder, affective illness, or psychosis is particularly problematic [85]. These patients often demand irregular discharges from the hospital, present only partially committed to treatment,

and are seen in emergency rooms after failure in standard treatment programs. High symptom level for other disorders is correlated with treatment failure in both outpatient and inpatient settings [85]. These factors have contributed to a therapeutic nihilism that has limited access of dually diagnosed patients to many treatment programs, creating an untested impression that nothing is available to treat this group successfully.

It is true that the patients with more severe psychiatric disorders evince lower levels of improvement [86]. Figures substantiating this fact, however, come from nonmedical programs or treatment centers where limited attention is paid to diagnostic-specific interventions for patients with concurrent DSM-III-R disorders. Traditional nonmedical treatment centers cannot handle such patients. A patient who is accepted and not treated for the concurrent diagnosis frequently fails to improve and is seen as "not committed to treatment." When these patients are included in studies of outcome of inpatient care, it appears that neither inpatient nor outpatient treatment works. Demonstrating differential treatment impact requires a structured medical inpatient program with treatment tailored to individual patient needs. This is especially true for an adolescent population, where patterns of use are less enduring and personality development is in a sufficiently formative stage to allow greater impact. There is, in fact, some evidence to suggest that the severity of psychiatric symptoms and poor treatment outcome is less highly correlated with adolescents than it is with adults.

#### DUAL DIAGNOSIS: DRUG USE/SCHIZOPHRENIA

Unusual drug use patterns are seen in schizophrenia. Disorganized and delusional thinking in this group contributes both to bizarre patterns of use as well as to less used routes of administration (e.g., eye, penis, vagina) [1,12]. Certain drugs enhance symptoms of the primary illness or may, in fact, perfectly simulate functional psychosis. Cocaine, amphetamines, and other stimulants create a paranoid psychosis in a clear sensorium that perfectly simulates paranoid disorder and paranoid schizophrenia. Phencyclidine (PCP), in fact, not only creates a paranoid psychosis but is also associated with considerable violence, which may be incorrectly attributed to the schizophrenia, enhancing the stigma associated with the disorder. Fortunately, while there is considerable experimentation among chronic psychiatric patients with stimulants, alcohol, marijuana, and hypnotic sedatives, only a small number actually use PCP [87]. Hallucinogens, on the other hand, do not create psychoses that truly simulate schizophrenia. Drugs like LSD, psilocybin ("mushrooms"), mescaline, and peyote ("cactus buttons") evoke chemical psychoses with characteristic hallucinogenic distortions of perception such as synesthesias (a condensation of two sensations); for

instance, a person will "taste" green or "smell" gray. These symptoms suggest concurrent or sole use of a hallucinogenic drug when a patient presents psychotic. The picture in some patients remains sufficiently complex to render a number of LSD psychoses indistinguishable from acute schizophrenia. In one study of 52 LSD psychotics and 29 matched first-break schizophrenics [88], LSD patients did not differ in incidence of psychosis or suicide among the parents. Rate of parental alcoholism, among the parents of those with LSD psychosis, however, far exceeded that of controls and of the general population. While the two groups were distinguishable in some clinical parameters, they were equivalent in premorbid adjustment and by most cognitive measures when initially hospitalized or reassessed three to five years later. Both groups had the same rehospitalization rate.

Many believe that LSD alone does not produce an enduring psychosis but rather precipitates schizophrenia in predisposed personalities. There remains an uncertainty as to the relative role of monoaminergic pathways in schizophrenic illness. LSD is active in serotonergic systems, and studies indicate serotonergic aberrations in schizophrenia. Part of the confusion originates in the fact that when an already psychotic patient takes LSD, the preexistent psychosis may be misconstrued as induced. LSD use may have been an attempt either to self-medicate, to help give "insight," or to organize the external world when the internal world is chaotic. It may also simply represent poor judgment or superimposed character disorder, resulting in use of a drug that complicates the clinical picture and can lead to fatal behavior. People on LSD have assumed that they can fly, resulting in a death that may be construed as a suicide when, in fact, it is the result of the distorted thinking symptomatic of hallucinogen use. Incidence of psychiatric illness requiring hospitalization is increased in parents of patients with LSD psychosis [89]. Patients can be singularly inventive in their use of substances that induce psychosis as they seek "insight" or "psychotherapeutic progress." One patient was able to induce a schizophrenic-like psychosis by ingesting isosafrole after he failed to do so with amphetamines and LSD [90].

#### DUAL DIAGNOSIS AND COCAINE USE

Cocaine poses special problems in dual diagnosis, given the multiple routes of absorption and the various organ systems on which it impacts. Cocaine is absorbed rapidly from mucous membranes. Commonly taken nasally or via the lungs ("freebasing"), cocaine can also be absorbed through the conjunctiva of the eye, the mucous membranes of the mouth (freezing), the vagina, and the penile urethra. It also can be injected intravenously or subdermally ("skin popping"). This drug is associated with high bioavailability since

there is no hepatic first-pass effect. Cocaine blocks neuronal uptake of norepinephrine and dopamine and reduces the concentration of serotonin. Release of norepinephrine and dopamine by neurons is facilitated, and tyrosine hydroxylase is activated. Tryptophan hydroxylase activity is inhibited. Net effect: decreased serotonin, dopamine, and norepinephrine turnover [91].

The most common concurrent psychiatric illness with cocaine abuse is affective illness. Depression is found significantly more often in patients using cocaine than among opiate and depressant abusers. Remarkably, incidence of affective disorder in first-degree relatives of cocaine abusers is also increased when compared to the other groups, suggesting that, in the dual-diagnosis patients, use of cocaine or crack may represent self-medication of an affective disorder. Early euphorogenic effects are attributed to increased dopamine and norepinephrine activity due to inhibited reuptake of these transmitter substances at presynaptic terminals. This effect is similar to that of some antidepressants and to amphetamines, which cause similar mood elevation in depressed patients. The effect is not sustained. In most patients, continued and increased use of cocaine leads to a worsening of depressive symptoms [92].

The particular psychopharmacologic effects and multiple routes of administration lead to many medical complications that can result in dual, triple, and more diagnostic problems. Myocardial ischemia [73], myocardial infarction [93] and cardiomyopathy, myocarditis, and malignant ventricular arrhythmias are among the most dreaded effects [94]. Risk for myocardial infarction is greatest among those with preexistent angina. Cocaine is arrhythmogenic, causing sinus tachycardia, ventricular premature contractions, ventricular tachycardia and fibrillation, and asystole. Cocaine also produces hyperpyrexia, leading to seizures and possibly arrhythmias. Large amounts of cocaine can lead to marked increase in systemic arterial pressure and rupture of the ascending aorta [93].

Pulmonary complications include spontaneous pneumothorax when "pocket shot" is used by IV drug abusers seeking access to the internal jugular vein [95]. Freebasing has been reported to cause, or contribute to, asthma in those predisposed as a nonspecific irritant [96]. Necrosis with perforation of the nasal septum, atrophy of the nasal mucosa, loss of smell, lung damage, pulmonary edema, respiratory paralysis, and reduction in the capacity of the lungs to diffuse carbon monoxide are other respiratory complications [93].

Cerebrovascular accidents have been found temporally related to cocaine use. Subarachnoid hemorrhage has been reported within minutes of intranasal administration. Individuals with occult arteriovenous malformations are at particular risk. Cocaine users with headaches should be apprised of this

risk. A common central nervous system effect is seizures. Cocaine lowers seizure threshold, with the result that a seizure may be caused by as little as a single dose. Cocaine-induced seizures should be considered a possibility in anyone presenting for the first time with epilepsy after age ten [93].

Other complications of cocaine use that may present concurrent use include intestinal ischemia with pain or frank gangrene in individuals who take cocaine orally or serve as "mules" or "body packers" by swallowing cocaine to get it through customs; complications of pregnancy (e.g., abruptio placentae, spontaneous abortion, congenital malformations, neurobehavioral impairment, perinatal mortality); severe lactic acidosis, especially in the sprint-trained athlete [97]; precipitation of acute porphyria [98]; spontaneous pneumomediastinum; and pneumopericardium [93]. Aberrations of glucose metabolism can lead to a number of behavioral changes that resemble those of cocaine use itself (e.g., aggressive and depressive behavior) and of other major psychiatric disorders (e.g., major depression). The changes in glucose levels may be due to neglect of diet seen in drug abusers and alcoholics, noncompliance with medication prescribed, and sensitization to epinephrine, which mobilizes blood glucose. Sexual dysfunction may antedate or follow cocaine use. Concerns over lack of sexual responsivity may result in seeking out cocaine as an aphrodisiac to enhance sexual performance. Sparing use can lead to increased sexuality and delayed ejaculation and orgasm-heightening pleasure. Prolonged use is generally correlated with diminished sexual performance and interest. Cocaine becomes the mistress or lover before whom all competitors fail.

#### DUAL DIAGNOSIS AND SOLVENT USE

Recreational use of inhalants and solvents for transient highs is correlated with preexistent psychopathology and can induce a number of neuropsychiatric and physical complications, obfuscating the underlying primary pathology. Deliberate inhalation of metallic paints, for instance, leads to hemorrhagic alveolitis [99]. Despite severe and predictable harm to the body from this practice, chronic solvent abusers' response to substance abuse treatment is poor, perhaps because those who abuse solvents over protracted periods of time have behavioral patterns that militate against good social adjustment and positive treatment response. Long-term inhalation of paint thinners, aerosols, gasoline, and cleaning fluids (generally from solvent-soaked rags in plastic bags) leads to some euphoria and disinhibition. Auditory and visual hallucinations occur, coupled with ataxia and tinnitus. The effect wears off in 30-45 minutes as the patient falls asleep with impaired memory of the event [100]. Medical complications include cerebellar toxi-

city, potentially irreversible encephalopathy, renal dysfunction, cardiac irritability, generalized weakness, and abdominal pain.

Solvent abusers tend to be adolescents. Only a small fraction experiment beyond a few times. Any inhalation of solvents that may lead to permanent damage is distressing. Chronic use entails development of permanent maladaptive characteristics in the developing personality in childhood and adolescence. Solvent abusers as a group are more depressed than those who do not abuse solvents [101]. Solvent abusers also more frequently abuse alcohol. Chronic use for some is on the trajectory to heroin addiction. Shoplifting, truancy, and problems in school have been found to coexist with solvent abuse [100]. Lead tetraethyl (the antiknock agent in gasoline) creates a short-term psychosis characterized by hallucinations, mania, fear, and schizophreniform symptoms [102]. These isolated periods of psychosis resemble the micropsychotic episodes of borderline patients and may be misconstrued as such. Obviously, in some instances, the abuse may be symptomatic of a borderline or antisocial personality. One may, in fact, question whether what becomes a borderline personality is, in some cases, the outcome of a multiple substance-abusing episode at a time when the identity is evolving. The adult identity has elements of psychosis that are derived from aberrations of thought and effects of substance abuse.

#### DUAL DIAGNOSIS AND BENZODIAZEPINE USE

Benzodiazepines are used by depressed, eating-disordered, and manic patients. Abuse may be intentional to obtain relief or iatry. In the latter instance, anxiolytics and soporifics have been prescribed for anxiety or panic accompanying a depression or eating disorder or to induce sleep in insomniac depressives and hypomanic and manic patients. With progression of the mood or eating disorder, more is required to achieve the same effect because of either habituation or progressively increasing intensity of symptoms. Eventually, patients are addicted. Any reduction in dosage is fraught with discomfort. Increased doses are required for relief. Intermittent intoxication and withdrawal results in an oneiroid state mimicking schizophrenia. The primary use of benzodiazepines is the management of anxiety and panic with the exception of alprazolam, which also appears to be useful in the management of some depressions.

Despite widespread use of benzodiazepines for anxiety disorders and depression, it is remarkable that many do not become addicted [103]. Dependence occurs at remarkably low doses [104], to the surprise and dismay of patients and physicians alike. Long-term therapeutic use of even small doses can lead to remarkable dependence (so-called low-dose dependence),

requiring considerable skill in both management and withdrawal. Symptoms of withdrawal or intoxication are often confused with those of primary anxiety or mood disorder.

#### DUAL DIAGNOSIS AND PSYCHOSTIMULANTS

Psychostimulants are commonly abused by psychiatric patients. The most commonly abused, cocaine, has already been discussed. Less commonly used but equally potent in their impact are dextroamphetamine and methylphenidate. These typically cause manic-type highs, the anxiety symptoms of a racing heartbeat, and palpitations. Frank paranoia and profound depression on cessation of use ("crashing") is also seen. Concurrent use of cocaine and amphetamines often occurs. Use of stimulants contributes to relapses in schizophrenia. Short-term use alone of moderately large doses of stimulants without dormant schizophrenia can induce acute paranoid psychosis [105]. These psychoses are usually of brief duration, remitting rapidly upon cessation of stimulant use. There is some question as to whether the facility with which psychoses may be generated relates to the degree psychosis lies dormant in the user.

Stimulant psychoses, more than hallucinogenic psychoses, resemble psychogenic psychoses, particularly paranoid schizophrenia. Paranoia occurs in a clear sensorium with ideas of reference and at times auditory hallucinations. It differs in that delusions tend to be less well developed with stimulant use and stereotopics are more frequent with stimulants. Neuroleptic response is the same for both. Only the fact that the paranoid psychosis passes with cessation of stimulant use is helpful. In addition to causing paranoid psychosis, stimulants intensify or exacerbate symptoms in someone already schizophrenic or manic.

#### DUAL DIAGNOSIS AND PSYCHOTROPIC ABUSE

Psychotropic drugs such as thioridazine, doxepin, amitriptyline, and anti-Parkinson drugs, which are sold on the street, to attenuate or qualitatively impact on the character of sensory change with substance abuse. For instance, anti-Parkinson drugs are abused to achieve a euphoric state, for stimulant effect, as hallucinogenics, and for social stimulation [106]. Effect is dose-dependent. Higher doses than that required to manage extrapyramidal side effects are required. Trihexylphenidyl has particularly great abuse potential. Termination of anti-Parkinson drugs may lead to premature termination of treatment because of unpleasant symptoms independent of motor problems.

## LABORATORY STUDIES

The dexamethasone suppression test (DST) has been employed to support the diagnosis of depression. Of patients with major depression, 45–50% fail to suppress cortisol after being given a 1-mg oral dose of dexamethasone at 11 P.M. Diagnostic sensitivity varies depending on blood collection times, laboratory accuracy, dexamethasone dosages given, and diagnostic criteria. Numerous medical conditions impact on its validity and reliability, making its use particularly problematic with dually diagnosed patients. Drugs specifically influence the dexamethasone metabolism via liver enzyme alterations. Burch et al. [107] found, in a study of 336 psychotic inpatients, that 60% were taking one or more drugs that changed the DST results in either a false-positive or false-negative manner. Fluctuations in neurotransmitter production affects hypothalamic-pituitary-cortisol feedback mechanisms, altering DST outcome. False-positive results may be found with sedative hypnotics, alcohol, and narcotics. False negatives occur with benzodiazepines and stimulants such as cocaine and amphetamines [107]. Marijuana can cause both false positives and false negatives. Withdrawal phenomena and liver abnormalities altering catabolism of steroids may be responsible for abnormal DSTs during the first two weeks of abstinence. The response with continued abstinence resembles that of normal controls. Nonsuppression of cortisol secretion, coupled with clinical signs of depression, suggests need for a trial of antidepressants or electroshock [108]. Modest hepatic dysfunction does not appear to invalidate DST results [109]. Chronic alcoholism impacts the hypothalamic-pituitary-adrenal axis preventing the cortisol hypersecretion often seen with depression. That this is not always so is indicated by a number of studies showing nonsuppression in a significant number of alcoholics reporting depression [35,36].

The thyrotropin-releasing hormone (TRH) test, which also is abnormal in some patients with depression, is not specific for major depression with cocaine abuse [35,36]. There is evidence that cocaine is associated with blunted results on TRH testing in much the same way that dopamine infusions in humans cause a blunted TRH response. In alcoholics, TRH abnormalities may be due to the fact that chronic alcoholism causes both endocrine abnormalities and hepatic dysfunction.

## PSYCHOTHERAPY WITH DUALY DIAGNOSED PATIENTS

Group techniques, particularly 12-step programs such as Alcoholics Anonymous and Narcotics Anonymous, are a critical component of substance abuse treatment. For the compliant without a coexistent psychiatric disorder, it may be all that is necessary. When a primary psychiatric illness exists,

the attending psychiatrist must be aware of the philosophy of AA, NA, and CA (Cocaine Anonymous) and of the need for concurrent involvement of the patient in these groups. Family members and lovers should be encouraged to attend Nar-Con and Al-Anon. A therapeutic alliance is necessary to assure that patients continue psychopharmacotherapy as prescribed as well as abstinence and involvement in a 12-step program. Therapists should take both an active educational and confrontational role [110]. The clinician's understanding of the pharmacology and pattern of use of substances abused is necessary to achieve continued abstinence and appropriate pharmacotherapy as well as to maintain credibility and respect with users and their families.

### CONCLUSION

In conclusion, it is uncommon today to see any one drug used alone, including alcohol. Polysubstance abuse is more usual. Identification of preexistent or concurrent psychiatric disorders is complicated by the myriad of psychiatric symptoms caused by drug use and by the medical conditions it induces. While a panic attack may be due to the tachycardia and chest pain attendant on cocaine use, the correct identification of true panic disorder leading to substance abuse can lead to diagnostic-specific treatment. Treatment of nonsubstance abuse psychiatric disorder is more effective than treatment of pure substance abuse. In addition, the reported rates of suicide in untreated major depression (15%) and panic disorder (18%) [111] suggest that not only may dually diagnosed patients be self-medicating depression or panic but may also be indulging in a self-destructive behavior that predictably is a consequence of the untreated course of their illness.

# Issues in Managing an Alcoholism Caseload

L. Murdock Smith

The issues involved in managing a caseload with persons who are substance abusers are many, and can be stumbling blocks for effective work by the rehabilitation counselor. This article identifies four areas of concern (counselor issues, family issues, employment issues, and client issues) that may assist the counselor in the evaluation of personal and professional responses. Additionally, some practical suggestions are offered.

Alcoholism is a disease that crosses all social, economic, ethnic, racial, and geographical lines. Estimates on its prevalence in the United States vary from 4% of those eighteen years and older to 10% of the males and 5% of the females eighteen years and older (Gallant, 1987). A 1978 Gallup Poll asked the question, "Has liquor ever been a cause of trouble in your family?" and 24% of those queried responded positively (Apthorp, 1985). There can be little doubt that rehabilitation counselors will encounter persons who have this disease. Whether counselors have a general caseload to manage, or a specialized caseload of clients whose disability is alcoholism, there are certain issues related to alcoholism that must be addressed for effective case management.

Such issues may be divided into four general areas, as illustrated by Figure One. First, there are issues concerning a counselor's personal experience with the disease and the subsequent perceptions and reactions to persons with the disease. Second,

the disease of alcoholism affects all family members. The involvement of the client's family members in the disease process and in the rehabilitation process will be a source of issues to be evaluated. Third, alcoholism entails issues affecting the client's employment history (e.g., multiple positions, unfocused future, and lack of acceptable work habits). Finally, there are issues specifically relating to the client. These relate to the chronic,

progressive and potentially fatal nature of the disease of alcoholism.

## Counselor Issues

The first area of discussion focuses on issues arising from the counselor's personal experience with the disease. One of the realities about alcoholism is that it is characterized by highly charged emotional undercurrents—everyone has an opinion. These undercurrents may manifest themselves in both personal and social ways.

The counselor should begin by looking to his or her own experience with alcohol and alcoholism. This personal evaluation can begin with some basic questions. Did the counselor grow up in a home where one or both parents were alcoholic? Is the counselor married to an alcoholic? Does the counselor have reason to be concerned about her or his own use of alcohol? Is the counselor a recovering alcoholic? Is the counselor currently abusing alcohol? Affirmative answers to any of the above questions should be warning flags for the counselor. The counselor's effectiveness with clients with alcoholism may be determined by a personal experience with the disease. This same awareness also applies to counselors who grew up in a dysfunctional family of any description. The estimates are that one in three helping professionals are adult children of alcoholics, because helping others is an easy and natural role for adult children. These persons had family roles of care-takers from an early age, and it was an easy transition to teaching and helping professions (Anonymous, 1988).

It is possible to believe that a person should be knowledgeable about working with persons with alcoholism, because they grew up in a home where alcoholism was present. As with so many factors related to alcoholism, the obvious and logical cannot be taken for granted because of the dysfunctional thinking that grows out of the dysfunctional family system. In some ways the least effective counselor, whether an alcoholic or the adult child of an alcoholic, is the one who has not acknowledged and dealt with a personal history with alcoholism. Anonymous (1988) warned that "our early experiences in alcoholic homes may have caused us to develop attitudes and to exhibit behaviors that actually impede the work of the school [or rehabilitation agency] in substance abuse prevention and recovery (p. 22)." It is easy for the counselor to become a *professional enabler*, making it possible for clients and colleagues to avoid the consequences of their addictions (Anonymous, 1988). If a counselor is to work effectively with clients who are alcohol abusers, then that counselor must come to terms with personal and family history.

There are numerous community and learning resources available for persons with a personal or family history of alcoholism. The most well-known programs are Alcoholics Anonymous and its derivatives (e.g., Narcotics Anonymous, Al-Anon, Nar-Anon, ACOA/ACA (Adult Children of Alcoholics), CoDA (Codependents Anonymous)). Information about these Twelve Step programs and meeting times and locations are available through the local AA Hotline (the number can be found in the telephone directory).

There are a number of excellent books available about alcoholism, chemical dependency, and the many variables involved. Writings by Janet Woititz (*Adult Children of Alcoholics*,

*Home Away From Home*), Claudia Black (*It Will Never Happen To Me!*), Sharon Wegscheider-Cruse (*Choice-Making*), Melody Beattie (*Codependent No More*), Earnie Larsen (*Stage II Recovery: Life Beyond Addiction*), Vernon Johnson (*I'll Quit Tomorrow*), George Vaillant (*The Natural History of Alcoholism*), and Donald Gallant (*Alcoholism: A Guide to Diagnosis, Intervention, and Treatment*) are all excellent beginning points.

There are primary treatment programs (inpatient, outpatient, and residential) for alcohol and drugs, co-dependency, eating disorders, adult children of an alcoholic and dysfunctional family. Information about alcohol and drug treatment centers may be obtained by calling the different centers in one's area. These treatment centers, whether freestanding or connected with medical centers, will be listed in the telephone book. Again, the local AA Hotline can be a valuable resource for treatment center information.

Opinions about alcoholism are also expressed in a social setting also. It is only within the last generation that the American Medical Association has recognized alcoholism as a disease. In the collective understanding of American culture, alcoholism previously was seen as a moral weakness. This perception lingers today in more subtle ways. It is not unusual to hear statements like, "I really don't like those alcoholic people. They should do something about their drinking."

One of the perceptions of alcoholism that is common in society is that the person who is alcohol dependent is *morally weak*. Alcoholism is seen also as *willful misconduct* by some persons, institutions, and organizations. "Alcoholism, [is] a medically accepted definition that carries no moral judgments. To that end, we can be most effective if we understand alcoholism to be a primary, progressive, chronic, and fatal disease... *alcoholism is not a symptom of a more serious problem* (Apthorp, 1985, p. 57)."

The consequences of such a perception of alcoholism result in marginal treatment opportunities, limited support of the client who is in recovery, and denial of the magnitude of the disease's power over the client's life—past, present and future. It is also a pessimistic view for ultimate recovery through treatment and rehabilitation. To hold such a position is not unlike saying that the person with diabetes or cancer has developed their disease because they chose to do so. The surest cure for such a perception of the disease is continuing and continual education on alcoholism and drug addiction, both for counselor and the community.

## Family Issues

The second area of discussion includes issues related to families. Alcoholism does not exist within a vacuum, for it is a disease shared by the whole family. It is often described as a family disease. The type and extent of family members' involvement in the rehabilitation process will have definite effects on the way the counselor manages the case. Good family involvement is essential for successful rehabilitation. As with persons with other types of disabilities, the person who is an alcoholic will have family involvement across the full spectrum ranging from total rejection to overprotection and enabling manipulation.

One extreme of familial *presence* is alienation, rejection, or being disowned by one's family. The resulting sense of isolation and disconnectedness feeds the poor self-esteem that is often part

of the client's psyche. Another expression is the family member or members who encourage alcohol abuse out of their own sickness. This arises when family members are alcohol abusers themselves, from a pathological need to maintain control, or from the multiple dynamics of codependency. Gallant (1987) maintains that:

*Although there is no consistent family system or psychological pattern that develops within families of alcoholics, the therapist working with alcoholics should be aware of a number of maladaptive behavioral patterns common to such families. The alcoholic has a profound effect on family members and other individuals closely associated with the family. Psychological reactions to the alcoholic can vary considerably among family members, depending partially on the alcoholic's behavior while sober as well as drinking and partially on the family member's psychological state. (p. 199).*

The client's rehabilitation can easily be sabotaged by a family member determined to maintain a familiar family system. It even may be a wildly dysfunctional family system but it is one that is known. The operative principle is that known unhealthy behavior is better than unknown health. A family system naturally seeks the *homeostasis*, the balance, regardless of dysfunctional expression in order to reestablish a sense of peace in the family. This sense of familial peace is often false, unhealthy, and temporary, but in the dysfunctional perception of the family it is seen as *normal*.

The counselor's awareness of such actions by the client or client's family is essential. Awareness and action by the counselor may avert a situation that jeopardizes the rehabilitation plan and goals, and may lead to a loss of sobriety. In many ways, this is the most difficult area for the counselor because it is the one over which the counselor has little or no control. There are families who clearly are the greatest threat to the client's sobriety, recovery, and rehabilitation.

How does the counselor deal with such a situation? There is no easy or standard answer for this problem. The counselor may find that the client can best be served by leaving the home environment, and entering a half-way house. Referral to community mental health agencies, child and family services, private social service agencies, or private mental health providers may be the most effective path to follow. Here the counselor's developed network of community resources can come into play for the client's benefit.

## Employment Issues

The third general area of discussion concerns issues revolving around the client's employment history, such as multiple positions, unfocused vocational future, and lack of acceptable work habits. Issues in this area relate to past, present and future employment obstacles. Employment and alcohol have a symbiotic relationship. Employment is often necessary to obtain the money to purchase alcohol, and alcohol significantly affects productivity in the economy.

Employee Assistance Programs (EAPs) came about in the 1940s in response to the needs of recovering alcoholics, who "returned to past employers and said, 'If you hadn't been so nice to us, we might not have lost our jobs and families. We know there are many other alcoholics in the workplace—will you let

us start a program?'" (Watts, 1988, p. 11). EAP consultant Dale Masi found that, on average, public agency supervisors covered up for twelve years and private-sector supervisors for up to eight years for problem drinker employees. "It's much easier to close your eyes to problem employees, demote them, promote them, or put them on detail work." (Watts, 1988, p. 11). In the job development and placement portion of rehabilitation, the potential exists for finding employers who will be enablers of the client's disease by avoiding the *tough love* decisions that become part of recovery. Employers may be alcohol abusers themselves, and do not consider alcoholism a disease. This places the client in an environment that jeopardizes sobriety.

It is not unusual for a client, whose disability is alcohol abuse, to have a voluminous work history. The recovering alcoholic who has a career or a profession to return to after treatment is not often a client for public rehabilitation services. The type of client that the counselor normally encounters is an individual who has had multiple jobs in varied fields, but rarely for an extended period of time. They often have been terminated because of drinking. The typical client has a limited sense of their vocational future because little or nothing has happened to encourage forward thinking on these issues.

One of the clear strengths of rehabilitation counseling is its routine use of vocational assessment. A client with a *spotty* work history can well be served by vocational evaluation. This could include not only such factors as interest inventories, intelligent tests, and achievement tests, but also the person-to-person interview. This evaluation process should not begin until the client is well into treatment, and is drug-free.

Counselors also must face the need for adjustment in client work habits. Interwoven within the client's poor work habits are recurring events of conflict with the boss and other persons in positions of authority. Absenteeism or *laying out* are undesirable traits, that are often a typical part of a client's work history because of the physiological effects of alcohol abuse. The client's referral to a work adjustment program may be an essential ingredient of a total rehabilitation plan. The counselor will have to determine the timing of training and adjustment according to local resources. Specialists in job placement and development can be an invaluable resource at this portion of the rehabilitation process.

## Client Issues

The fourth area of discussion concerns issues that specifically revolve around the client. Once it was thought that someone was an *ex-alcoholic* or a *recovered* alcoholic as if there was a cure for the disease. However, the counselor needs to always remember that there is no known cure for the disease, and that a client will never become an *ex* but will always be *recovering*. The single most important goal for the client is to maintain sobriety by not doing things that would jeopardize recovery.

One of the important ways that the counselor may benefit the client is to understand the patterns of alcohol abuse that the client followed. Knowledge of this may provide necessary warning flags of possible relapse. The disease process and symptoms were defined by E. M. Jellinek (1942, 1960) as having three stages. Stage I is the Early Stage in which alcohol is consumed socially (use). Stage II is the Middle Stage when a person

becomes a problem drinker (misuse). Stage III is the Late Stage in which a person is dependent on alcohol (abuse). Another descriptive pattern maintains that there is a five-stage process leading to chemical dependency: (1) experimental use; (2) social use; (3) habitual use; (4) abuse; and (5) addiction.

Those reaching the final stage, the alcohol abuse client, are often children of an alcoholic home. They left a dysfunctional home and moved into or created one that was equally dysfunctional. This familial unhealthy environment has provided clients with skills to survive in *craziness* but not in health. Such clients often will have great difficulty appropriately expressing emotions and feelings. Such clients may have their feelings so tightly under control that they truly do believe that they feel okay. They have a poor self-image, and their self-esteem will need constant attention. Further, clients will often prefer to be in the *safety* of the known past or self-structured fantasy of the future. It is often less painful to avoid the realities of the present. This is particularly characterized by denial of a problem. The significance of denial in the disease process of alcoholism is such that it is seen as one of the definitive symptoms. The counselor may be one who will assist the client in staying in the present, confronting client denial, and dealing with the realities of rehabilitation.

The physical deterioration that comes from chronic alcohol abuse could present additional complications for the counselor, particularly if the client enters rehabilitation in later stages of the disease. Counselor knowledge of the significance of relapse on the physical condition of the client is essential. The client who starts to drink again will not return to a pre-drinking stage, but will begin at the point where he or she was before the period of abstinence. There may be accelerated physical and mental deterioration with death an ever-increasing possibility. The physiological processes are unrelenting in their potential for deterioration. This, if for no other reason, should merit the counselor's attention to the dangers of relapse. Relapse is an ever-present danger for a client, particularly during the first months of sobriety. But there are community programs available to support the client.

Considering the emphasis that is placed on the Twelve Steps of Alcoholics Anonymous in alcohol and drug treatment units, and the success of the program of Alcoholics Anonymous, it is appropriate for the counselor to be familiar with the Twelve Steps. The two books that contain essential information on Alcoholics Anonymous (A.A.) and on the Twelve Steps are *Alcoholics Anonymous* (1976) and *Twelve Steps and Twelve Traditions* (1981). As stated above, additional information on AA and access to its many resources are available through the AA Hotline (see the local telephone directory). Though a person cannot be forced to be involved in AA, the client would well be served by participation. The AA Twelve Step program is the one that succeeds where others have failed.

## Summary

To be effective in the management of a specialized alcohol abuse caseload, or to be effective with alcohol abuse clients in a generalized caseload, the counselor can benefit from viewing the issues in four areas.

**Counselor issues**— how the disease may have affected the client in the past or is affecting the counselor in the present.

**Family issues**— alcoholism is a family disease so the counselor needs to be attentive to familial interplay and its effect on the client.

**Employment issues**— often the client will not have a good work history, will have poor work habits, and the counselor will have to work diligently in the development of the rehabilitation program.

**Client issues**— the alcohol abuse client will come with a variety of inappropriate, immature, or unhealthy emotional patterns or responses, and the counselor will be part of the client's learning new and healthy ways to cope with daily living and in gainful employment.

## Suggestions for Successful Rehabilitation

1. Require the client to make a commitment to abstain from all non-prescribed mood-altering drugs.
2. Have the client participate in an on-going treatment and recovery program (e.g., inpatient or outpatient treatment at an alcohol and drug treatment center, AA meetings, Continuing Care/Aftercare after primary treatment).
3. Involve the client's family at all levels of the rehabilitation process.
4. Have the client develop a social system supportive of recovery (e.g., family, friends, other persons in recovery, employer, shop steward).
5. Have the client make a commitment to a daily structure that supports recovery.
6. Encourage the client to continue learning about the disease.
7. Encourage the client to look beyond self for the means and strength to continue in recovery— in the tradition of Alcoholics Anonymous, this is one's self-defined Higher Power.
8. Develop clear expectations and consequences with the client regarding renewed use. Follow through on the consequences.
9. Develop clear expectations and consequences with the client's employer regarding renewed use. Follow through on the consequences.

Working with persons with alcoholism can be exciting, rewarding, and frustrating all at the same time. There will rarely be a dull moment in dealing with the myriad of issues arising from an alcoholism caseload.

*Albany, New York 12229*

## ABSTRACT

This paper reviews the literature on patients presenting for general psychiatric treatment who are also substance abusers. Place of presentation, diagnosis, and treatment are considered. A considerable portion of patients seen in emergency rooms, as much as half in some settings, are substance abusers, and over a third of general psychiatry admissions have been found to have their presenting problems materially influenced or precipitated by substance abuse. Substance abuse is also frequently found among psychiatric inpatients. Diagnostically, the differentiation of general psychiatric and addictive syndromes can be difficult: primary and secondary affective disorder from consequences of long-term substance abuse; and self-medication patterns from primary general psychiatric syndromes. Treatment studies are often focused on concomitant psychotherapeutic management for patient being treated for addiction. Often, emphasis is placed on pharmacotherapy for enhancing outcome in the dually diagnosed. Qualitatively, new options tailored to this population still remain to be studied, however, as do the changes necessary in the treatment system to assure proper long-term management.

**INTRODUCTION**

Relatively little information is available on the proper treatment of substance abuse in patients who present with other psychiatric problems. Despite this, there is a growing recognition among clinicians that patients treated for nonaddictive psychiatric illness often have their rehabilitation compromised by alcohol or drug abuse [1]. Although treatment facilities are generally segregated into separate units for general psychiatric disorders and substance abuse, it is becoming increasingly clear that many general psychiatric patients require coordinated treatment for combined disorders.

This article addresses the problem of patients with acute psychiatric presentations who present in general psychiatric facilities, and who additionally have primary or secondary addictive illness. These patients come to the attention of treating parties as they enter the mental health "portal" of the health system, and are distinguished from the patients who come through the addiction treatment "portal," for alcohol and drug problems, and are then found also to have psychiatric disorders. The problems of patients coming through the addiction portal have been addressed elsewhere, as in reviews by Meyer [2] and Gottheil [3].

**PLACE OF PRESENTATION**

There are no data available for the prevalence in the general population of combined general psychiatric and substance abuse disorders. The most exciting and most recent assessment of the prevalence of psychiatric disorders in the population overall is the Epidemiologic Catchment Area study, carried out in three metropolitan areas in 1980-82, where the following 6-month prevalence rates were found, on average [4]. Altogether, alcohol and drug abuse were found in 6.4% of the population (5.0% for alcohol and 2.0% for drug abuse, respectively). Comparable figures for schizophrenia and for affective disorders were 1 and 5.2%, respectively. Not surprisingly, substance abusers, characterized by denial of their illness, were poor consumers of treatment services. Only 1 in 7 (13.6%) was likely to have made mental health visits during the previous 6 months, whereas almost half (46.7%) of those with schizophrenia and a third (31.4%) with affective disorder (31.4%) had been seen during the same period.

As we shall see, patients with schizophrenia and affective disorders constitute a sizable portion of all persons treated in the mental health system who have difficulties with substance abuse. In order to ascertain the magnitude of the dual diagnosis problem, the presentation of such patients, as reported in the literature, will be considered in several different settings: the emergency room, the general hospital psychiatric unit, the Veterans Hospital, the public psychiatric facility, and the private psychiatric hospital. Because patients present differently in each of these settings, each is instructive with regard to the manifestations of the syndrome of dual diagnosis.

**The Emergency Room**

Of the wide range of patients who present in the emergency rooms (ER) of general hospitals, only a minority are admitted to inpatient services for acute care. In order to ascertain the fate of alcoholics in this group, Schwartz and Fjeld [5] followed the routing of alcoholic patients who presented at an emergency room in a large public general hospital by examining clinicians' evaluations of a series of alcoholic patients (*N* = 305). Half (49%) of these alcoholics were sent home from the ER, with or without clinic referral. Of the 39% who were admitted, one-third were sent into regular psychiatric units, having presented with acute problems meriting their care in an acute psychiatric unit. These latter patients were more often Black, probably, the authors speculate, because Blacks were more likely to treat their psychoses with alcohol rather than seek traditional psychiatric care. In a similar study of consecutive emergency cases (*N* = 174), Treier and Levy [6] found, using patient self-reports, that fully 35% of their sample had alcohol-related and 15% drug-related admissions.

In a more detailed evaluation, Atkinson [7] had house officers complete a research questionnaire on 503 patients seen in a psychiatry emergency service, so that each patient was evaluated to ascertain the importance of alcohol and drug abuse in his admission. Some measure of substance abuse was found relevant to precipitating the presentation in over half of the cases, with alcohol alone in 20%, drugs alone in 21%, and both together in 12% of the admissions. When cases were reviewed by diagnosis, it was

found that alcohol or drug use played a role among 53% of transient situational disorders, 29% of schizophrenics, and 20% of affective disorders.

The studies noted here drew on either clinician assessment or patient report. None was based on data from urinalyses for drugs of abuse, although this technique has recently been found to be a valuable diagnostic tool, as will be subsequently seen. Nonetheless, even without such verification, it is amply clear from these findings that the emergency service is an important site for case-finding with regard to combined psychiatric and addictive disorders. If there were hospital-based services specifically designated for such problems, it is likely that a good number of emergency patients would be referred there.

#### The Psychiatric Acute Inpatient Service

The most severely disordered of psychiatric patients generally begin their care with admission to general hospital psychiatric units. How often is this course necessitated by circumstances related to alcohol and drug use? Crowley *et al.* [8] carefully evaluated 50 consecutive patients admitted to an adult psychiatric ward making use of clinical assessments, psychometric measures, and serum and urine analyses for drugs of abuse. By these means they found that 18% of these admissions would probably not have entered the hospital if not for a drug or alcohol problem, and an equal number had a substance abuse problem that contributed substantially to their admission. Both these groups were more likely to be diagnosed as character disorders than the balance of the patients, whose admissions were unrelated to drugs.

Urinalyses were positive for sedatives most frequently (24%), followed by alcohol (10%), narcotics (6%), and antipsychotics (3%). (It should be noted that the study was done in the early 1970s, and predated the recent rise in cocaine abuse.) Importantly, urinalyses revealed that the patients themselves often did not report the nature of their current drug use to interviewing physicians, underlining the importance of multiple sources of information.

Profiles on the Minnesota Multiphasic Personality Inventory suggested less psychosis and more sociopathy among the drug/alcohol-precipitated group of admissions. These patients apparently manifested less severe ancillary pathology than the other admissions, and were apparently hospitalized for drug-related symptoms primarily. Indeed, the authors point out

that the alcohol/drug group had originally aimed to remedy their own difficulties, such as dysphoria and marital problems through intoxication, but these intoxicants were now more the cause of such problems than a result.

The findings of this study are complemented by those of two others. Ritzler *et al.* [9] found that patients in a psychiatric inpatient service with more acutely debilitating diagnoses, such as schizophrenia and other psychoses, were less likely to be heavy drinkers than patients with diagnoses of personality disorder or neurosis. In addition, the issue of social problems associated with substance use among patients on psychiatric services were examined by Davis [10], who used standardized interview schedules after admission to study a population of psychiatric inpatients ( $N = 170$ ) and outpatients ( $N = 130$ ). He found that 63% of the males and 49% of the females had a history of heavy use of alcohol or drugs, although these findings were not generally apparent in admission histories or hospital notes. Over half of the patients who used substances heavily (65% of the males and 45% of the females) experienced deleterious social consequences from their use.

It is difficult to differentiate whether social problems are a cause of drug abuse or a sequela. For example, Westermeyer and Walzer [11] studied patients ( $N = 100$ ) between the ages of 15 and 25 who were admitted to the psychiatric unit at the University of Minnesota Hospitals, and defined 39% of them as heavy drug users. In comparison to other admissions, these patients were more often unemployed, divorced, or separated. They had experienced more problematic social events, such as felonies or truancy, and had more impaired social resources, such as family discord. The authors point out, however, that in some cases the problematic social behavior predated drug use and in others it followed it.

Altogether, these findings strongly suggest that substance abuse plays a prominent role in precipitating the admissions of a large portion of patients in acute psychiatric services, perhaps a third. Furthermore, relevant patterns of drug use are not necessarily ascertained in clinical interviews at the time of admission, and are generally not picked up in the hospital unless intoxication or withdrawal characterize patients' presentations.

#### Veterans Hospitals

Veterans Administration Hospitals house a population at considerable risk for substance abuse. Many veterans abused alcohol or drugs while in

the military service, and subsequently found that the opportunity existed for continuing substance abuse while they were hospitalized at VA facilities. McLellan *et al.* [12], for example, found that half (49%) of a sample of VA patients ( $N = 156$ ) hospitalized for psychiatric problems acknowledged that alcohol or drug use had been a "problem" for them at some points. These patients were more likely to have used *drugs* than alcohol if they had been hospitalized *during* the Vietnam era, and more likely to have had a problem with alcohol if hospitalized before. Importantly, almost a third (30%) of the overall sample indicated that they had used alcohol or drugs at least 3 times weekly during their stay in the hospital, therein reflecting the considerable access of patients to substances of abuse in this typical veterans facility.

Alterman and associates conducted a number of studies on substance use and abuse in Veterans Hospitals [13-15]. We shall consider their findings in relation to alcohol first. With the aid of nursing staff on nonsubstance abuse wards, they were able to identify 9.5% of schizophrenics among hospitalized patients (101 of 1,063) who carried a secondary diagnosis of alcoholism [13]. Of this group most (55%) were reported to be drinking during their hospitalization, and almost half of them (46% of the total) were known to become intoxicated. In addition, half were seen to have drinking-related problems interfering in their treatment (47%) and management (53%) in the hospital. Problem drinkers tended to be younger, more likely Black, and more likely paranoid than the remainder of the schizophrenic population.

In another study, Alterman *et al.* [14] evaluated general psychiatric patients in a VA psychiatric hospital ( $N = 979$ ) and excluded those on designated substance abuse units. Altogether one-quarter carried a primary (11%) alcohol-related diagnosis (ARD) or a secondary or tertiary (13%) one. Altogether, 9% of the patients were reported to be drinking in the hospital although, interestingly, most of the drinkers came from the sizable group of patients who carried neither primary, secondary, or tertiary ARD. The authors point out that patients' drinking in the hospital seriously compounded their psychiatric problems, and was likely to yield a much poorer treatment prognosis.

Alterman *et al.* [15] also examined drug problems in the VA in another study, using reports by nursing staff. Altogether 40% of patients ( $N = 533$ ) on acute and subacute psychiatric units had a history of alcohol abuse, and an additional 18% had a history of either drug or combined drug and alcohol problems. Furthermore, a majority of those patients with drug problems

(58%) were illicitly using drugs in the hospital. Compared to nonusers, drug users tended to be younger, more likely Black, and with the same incidence of schizophrenia (83%). Half of the drug users were taking drugs 3 or more times a week, with marijuana used by almost all (96%), and alcohol by half (48%) the users. As with the alcohol users, negative attitudes toward treatment were commonly found among these drug abusers, along with cliquishness, secretiveness, and the need for greater supervision.

These considerable rates of alcohol and drug use in the VA hospital bode poorly for patients if substance abuse problems go untreated while they are in the hospital. Their attitudes are poor and the likelihood for abuse upon discharge is considerable. As with patients in acute general hospitals, the need for proper attention to alcohol and drug problems among general psychiatric patients is underlined in these studies.

### Public Psychiatric Hospitals

Public psychiatric hospitals generally admit patients whose mental illnesses are acutely disruptive, severely debilitating, or life-threatening. Because of this, their populations are revealing with regard to the relationship between substance abuse and severe mental illness. One early study drew on statistical reports on internees in facilities operated by the Department of Mental Hygiene of New York State [16]. Admissions between 1951 and 1960 in 18 hospitals revealed a notable finding in relation to patients who had psychoses due to alcohol. Whereas the number of admissions overall had declined over the course of this period, the number of patients admitted for psychosis due to alcohol had increased (from 6.8 to 8.1 per 100,000). An examination of this population of alcoholic psychotics revealed that the large majority (82.5%) were from metropolitan areas and that the incidence of alcoholic psychosis among Blacks was almost 4 times that among Whites. Significantly, however, these were not the only patients whose admission may have been precipitated by alcohol use, as it was found that approximately 17% of all admissions overall were known to be "inappropriate users of alcohol."

These findings are augmented by McCourt *et al.* [17] who studied patients at Boston State Hospital. Only 30% of this sample ( $N = 115$ ) were given a diagnosis of alcoholism, but more than half (57%) had at least one trouble area due to drinking, and a quarter (24%) of the patients themselves reported that they were alcoholics. The authors conclude that although state

mental hospitals have many diagnosed alcoholics, they may indeed have many more admitted under other diagnoses.

Similar results were found in a study conducted on patients admitted to psychiatric facilities in North Carolina [8]. Two samples were evaluated, one in a state hospital ( $N = 100$ ) and the other in a veterans hospital ( $N = 320$ ), and in both the incidence of alcoholism was found to be 24%. The breakdown among alcoholics by primary diagnosis was manic depressive (33%), schizophrenic (22%), psychoneurotic (25%), and depressive (20%). The authors comment with some pessimism on the plight of the treating physician, pointing out that he often responds "with disgust" to individuals who use alcoholic excessively. On the other hand, if he were to respond with compassion, recognizing alcoholism as an illness, he may, according to the authors, experience undue optimism, referring the patient to Alcoholics Anonymous in hope of a positive outcome, and then finding that the patient responds poorly.

Admissions precipitated by drugs of abuse were also studied in a population of diagnosed drug abusers ( $N = 112$ ) who were admitted to Bellevue Psychiatric Hospital, a large acute public psychiatric facility in New York City. In this study Hekiman and Gershon [19] grouped patients by their primary drug of abuse. All were admitted in either a psychotic, toxic, or withdrawal state, and represented overall approximately 5% of admissions to the hospital. Those whose admissions were precipitated by heroin (20%) were most often diagnosed as sociopathic, and their admissions were generally related to toxic or withdrawal states. On the other hand, admissions precipitated by marijuana (7%), amphetamines (20%), or psychedelics (42%) were generally diagnosed as schizophrenic; these latter patients typically had a preexisting history of psychotic symptoms which were exacerbated by the drug of abuse, reflecting the considerable vulnerability of more seriously disturbed patients exposed to substances of abuse with psychotomimetic potential. Additional patients (12%) were admitted for use of barbiturates, cocaine, glutethimide, and other drugs.

The difference in severity of pathology among groups using different drugs was also evident in that only a small number (19%) of heroin addicts required further hospitalization after their Bellevue admission, whereas marijuana abusers required it in half the cases. The authors underline the importance that over half the patients in the marijuana, amphetamine, and psychedelic groups were considered schizophrenic or were treated for this condition before they resorted to their drug use. This underlines the puzzling but compelling interrelationship between drug abuse and psychopathology in

certain schizophrenic patients, and the need to clarify what impact the combination has on the course of these patients' illness.

### Private Psychiatric Hospitals

Drug use and attendant psychopathology are clearly affected by culture and subculture. This is seen in the case of private psychiatric hospitals, which typically cater to a more affluent and better educated population than public facilities. It is particularly evident in the patterns of drug use that emerged in the counterculture era, which peaked in the early 1970s. For example, one evaluation carried out on patients 25 or younger at the Institute of Living in Hartford, Connecticut, revealed a population ( $N = 167$ ) that was almost exclusively White, from middle- and upper middle-class socioeconomic backgrounds [20]. Most of these patients (73%) had used marijuana, and fully half (52%) had used LSD or other hallucinogens. An appreciable number had also used amphetamines (62%), barbiturates (44%), and narcotics (34%). Altogether, 74% of the patients studied had used one of these drugs. Significantly, among those who did use drugs, the frequency of use was quite high; about half of those who had used a given drug, had used it at least 30 times (45-68% for the various drugs, respectively). The use of any drug before the age of 15 was likely a predictor of more serious subsequent involvement, in particular, of the eventual use of barbiturates and narcotics. The authors observed that for these adolescents, drug use was in part a way of coping with life difficulties and intrapsychic stress, but one which in actuality only created further conflict.

These authors did not examine the relationship between drug use and the circumstances precipitating admission. It is clear, however, that during the counterculture era, considerable psychopathology was precipitated by psychotomimetics *per se*. A considerable decline in use of this category of drugs has, however, taken place since then. For example, federal surveys on high school drug use [21] show that the incidence of hallucinogen use among students within the last 12 months had declined by almost half (from 11.2% in 1975 to 6.5% in 1984). Reports are available, however, on the incidence of psychopathology precipitated by hallucinogens during the period when they were more popular [22-24].

The use of drugs among patients admitted to private facilities during the counterculture era is further evident in a study of patients ( $N = 224$ ) admitted to Hillside Hospital, a private psychiatric institution in New York City.

Chen and Klein [25] reported a sixfold increase in the incidence of illicit drug use between 1960 and 1967 (from 5 to 31%). They were able to study a sample of 70 abusers from 1967 patients, and divided them into 39 "extreme" drug users, characterized by almost habitual use of 2 or more drugs, and 31 mild to moderate abusers. Drug abusers on the whole tended to have a higher IQ than other patients at the hospital ( $X = 113$  vs 103), reflecting the culture of the time. Marijuana, amphetamine, and LSD were the most commonly abused drugs. Notably, the large majority (85%) of the extreme drug users were diagnosed as having character disorders, with only a small number (5%) of schizophrenics among them. Corresponding figures for the mild to moderate drug users showed a considerable shift toward schizophrenia (58 and 26%, respectively), and those for the patients who were not drug users showed an even greater shift (46 and 40%). Again, these findings reflect the incidence of character disorder among patients admitted with histories of drug use. Based on these findings, the authors suggest that for these young middle-class psychiatric patients, involvement in illicit drugs was part of a subculture which encouraged drug use and promiscuous sexual activity, too.

Patients at the same hospital, age 15 to 25, were subsequently studied to ascertain their use of illicit drugs *during* the hospital stay [26]. Whereas the previous study was done retrospectively by chart review, this one drew on weekly urinalyses carried out over the course of an average of 27 weeks, beginning with the time of admission. Analyses were done only for barbiturates, amphetamines, and narcotics, though, due to limitations in the technology available at the time. At the time of admission, 52% of patients had urines positive for one of these drugs, and over their course in the hospital, 60% were positive for barbiturates (53%), amphetamines (24%), or narcotics (13%) at one time or another. Since no patient was found to use narcotics more than 5 times or amphetamines more than 7, the authors speculate that the more heavily addicted patients may well have left the hospital early in their stay. They further pointed out that in order to ascertain the episodic use of drugs in the hospital, it is necessary to do multiple testing on at least 10 occasions. Because of possible interactions between psychotropic medication and drugs of abuse, they suggest that urine testing should be considered as a general policy among hospitalized patients.

### Some Observations

Given the apparent magnitude of the dual diagnosis problem, it is notable that there are so few recent studies on the epidemiology of this syndrome.

There are no published data on prevalence of dually diagnosed patients in the general population, and only a few of the studies on patients in the general psychiatric population cited here have been published since 1980. Nonetheless, there is considerable need for further empirical observations. In the first place, we know little about the relationship between the nature of dual diagnosis in the general population relative to how it presents at treatment facilities. Furthermore, more sophisticated diagnostic instruments which have been developed in recent years, such as the Diagnostic Interview Survey, have yet to be applied to dually diagnosed populations for more accurate psychiatric assessment. Because of this, little is known about the relative utilization of mental health services for this syndrome or the need for services.

Because of changes in the kinds of drugs abused by the general public, it is important that the epidemiology of specific drugs abused be examined. Such trends in drug use are illustrated by the considerable decline in psychotropic use in recent years, and the increase in cocaine use—particularly in the "crack" form. This latter agent, because it allows for rapid onset of action at high doses of free-base cocaine, generates a major onslaught on the mental health of persons who are already psychiatrically disabled.

Dually diagnosed patients are generally found to have a lower incidence of schizophrenia and major depressive disorder than other general psychiatric patients. Conversely, dually diagnosed patients have a higher incidence of character disorder. Why is this? It may be that the more severely disabled patients lack social skills which are necessary to sustain a drug-abuse habit. Alternatively, patients with less debilitating diagnoses may be vulnerable to drug-induced crises of adaptation which precipitate the need for psychiatric treatment. Furthermore, it may be that drug-seeking is one manifestation of character disorder and the complex adaptive problems which it precipitates.

Studies on chronic-stay facilities such as private psychiatric hospitals and Veterans Hospitals illustrate that psychiatric patients are prone to using drugs during their hospitalization so long as the opportunity presents. It is likely that such patients use drugs to an appreciable extent when engaged in ambulatory care, too. Little attention has been paid to this problem in order to assess its psychiatric sequelae and impact on rehabilitation, and almost none has been paid to the specialized treatment necessary to address such patterns of abuse. Given the findings reported here, however, it is reasonable to assume that an appreciable portion of morbidity and treatment failure among chronic psychiatric patients is due to their ongoing patterns of drug and alcohol abuse.

## DIAGNOSIS

We will now review those studies that address the specific diagnostic problems resulting from the combination of each psychiatric disorder and substance abuse.

### Affective Illness

The combined clinical picture of depression and substance abuse appears to be fairly common. While secondary depression ranges from 28 to 70% among alcoholics [27, 28] and from 32 to 46% among opiate addicts [27], addiction also frequently complicates primary depression. In an inpatient study [29] of male psychiatric patients ( $N = 279$ ), for example, McLellan *et al.* found that 38 (44%) of 87 depressives reported serious abuse of alcohol or other substances. Fifteen patients were alcohol dependent, 12 were addicted to barbiturates, 8 were heroin addicts, 2 patients abused amphetamines, and only 1 reported abusing hallucinogens. Depression, on the other hand, has been observed frequently among alcoholics. Schuckit [30], in a retrospective study ( $N = 577$ ) that included face-to-face interviews with male alcoholics and two relatives for each patient, found that 30% of these primary alcoholics had suffered from at least one secondary affective episode during their years of heavy drinking.

Not surprisingly, the overlap of symptoms of affective illness and substance abuse frequently lead to diagnostic confusion. Descriptive dilemmas include problems in differentiating alcoholism from drinking on one hand, and feelings of sadness from major affective illness on the other. Weissman *et al.* [27] and Schuckit [31] have argued that the symptom patterns of depressed alcoholics are similar to those of nonalcoholic depressives. Keeler *et al.* [32], for example, administered several diagnostic tests to a group of recently detoxified alcoholics ( $N = 35$ ). Sixty-six percent of the MMPIs and 43% of all Zung depression scales obtained were compatible with a diagnosis of depression. Keeler *et al.* [32] and Liskow *et al.* [33] found that most depressions identified during alcohol detoxification subsided following a period of 2 to 4 weeks of abstinence. Similarly, Pettinati *et al.* [34] in a 4-year follow-up study ( $N = 133$ ) failed to observe evidence of significant depression in the MMPIs of a group of abstinent alcoholics.

The above described studies suggest that temporary depressive symptoms can be expected during the course of alcohol abuse. There appears to be

general agreement that in 90% of heavy drinkers of either sex who display symptoms of both alcoholism and depression, the diagnosis is alcoholism and not primary affective illness [30, 35].

Disorders of affect also confound the differential diagnosis during withdrawal states from other drugs, such as amphetamines and cocaine [36], opiates [37], and barbiturates [38], and during the recovery phase of phencyclidine (PCP) intoxication [39].

Regarding bipolar illness and alcohol abuse, it seems that while the prevalence of alcoholism among bipolar patients is not higher than that of the general population [5], problem drinking complicates the clinical picture of at least 20% of acutely manic patients [40, 41]. Bipolar patients are also reported to frequently abuse other substances such as cocaine and amphetamines [42]. In an uncontrolled inpatient study ( $N = 36$ ), for example, Linstroff *et al.* [42] found evidence of at least one drug of abuse in 41% of bipolar manics, in 30% of bipolar depressed, and in 43% of bipolar mixed patients. The generalizability of these findings, however, is limited since the sample of patients studied included subjects who had been initially admitted for problems related to primary drug addiction.

### Schizophrenia

The prevalence of substance abuse among schizophrenic patients is unclear. Ambulatory schizophrenics have not been found to abuse alcohol more often than the general population. Rimmer *et al.* [43] in a controlled adoption study ( $N = 33$ ) identified alcoholism in only 3% of a sample of Danish schizophrenic adoptees. This small prevalence of alcoholism was not different from that found in the control group of nonschizophrenic adoptees. Studies on inpatient schizophrenics, however, have yielded much higher rates of alcoholism, ranging from 14% [29] and 22% [18] to 63% [44]. McLellan *et al.* [29] studied a group of hospitalized schizophrenics ( $N = 141$ ) and found that 44 (31%) had histories of alcoholism. According to this study, about half of all inpatient schizophrenic males can be expected to suffer from secondary addiction, particularly amphetamines, alcohol, and hallucinogens.

In the clinical context, two factors account for the diagnostic dilemmas arising between substance abuse and schizophrenia. Secondary alcoholism or other substance abuse can mask an underlying schizophrenic disorder [18]. For example, it has been proposed that alcohol can serve as a stabilizing

function (especially of anxiety) in schizophrenics, thereby obscuring the expression of diagnostic symptoms [45]. Alternately, although the overall prognosis is that of schizophrenia and not of alcoholism [46], the clinical picture of the severely alcoholic schizophrenic patient is likely to be dominated by frequent intoxications and overall alcoholic behavior [45]. A second source of diagnostic confusion is the group of psychotic syndromes (characterized by hallucinations, delusions, and other disorders of thought, affect, and behavior) that frequently affect substance abusers, not only during withdrawal states from alcohol, barbiturates, and other central nervous system depressives, but also during acute intoxications with hallucinogens, cocaine, amphetamines, marijuana, lysergic acid, phencyclidine, and inhalated substances.

#### Antisocial Personality Disorder

Although both alcoholism and antisocial personality disorder (ASPD) often share a variety of clinical characteristics such as problem drinking, positive family history of alcoholism, and the commission of asocial acts, current data from family and clinical studies strongly suggest that sociopathy and alcoholism constitute, in fact, two different clinical entities [46, 47].

ASPD is frequently complicated by secondary alcoholism [47] and other drug abuse [8, 48]. Lewis *et al.* [47] studied the prevalence of addiction disorders in a group of medically hospitalized patients of both sexes ( $N = 412$ ). Twenty-five percent of all males diagnosed as ASPD, and 6% of their female counterparts, were found to suffer from both alcoholism and other drug dependence.

In a 1-year follow-up outpatient study [46] of men admitted to a Veteran's Hospital because of alcohol problems ( $N = 577$ ), Schuckit found that while the differentiation between sociopaths and primary drug abusers were made difficult because of the similarity in substance abuse patterns in both disorders, sociopaths could generally be distinguished from primary alcoholics. Patients diagnosed as ASPD were found to develop problem drinking at an earlier age, suffered from more severe alcohol-related life problems, and also abused other drugs more often than primary alcoholics. Both primary drug abusers and ASPDs had a greater likelihood of drug abuse, more police and social problems, and demonstrated more adverse clinical outcomes than the group of primary alcoholics studied. The more

severe patterns of alcoholism among ASPD than among primary alcoholics reported in this and other studies [48-50] have been explained by Lewis *et al.*, who postulated that ASPD increases both the early exposure to problem drinking and the risk of alcoholism once the vulnerable individual is exposed [47].

#### Anxiety Disorders

In light of multiple reports available, secondary addiction in patients with severe anxiety disorders is not uncommon. The prevalence of alcoholism in patients suffering from panic attacks has been consistently reported to range from 10% [51, 52] to 15% [53]. Conversely, in primary alcoholics, agoraphobia has been found in 14% [54] to 16% [55]. Generally, significant symptoms of anxiety can be expected in at least 44% [56] of alcoholic patients.

Because of the frequent occurrence of anxious feelings during drug and alcohol withdrawal [51], an adequate history confirming the existence of anxiety disorder and a period of observation of at least 2 weeks [46] of abstinence are necessary in order to diagnose a primary anxiety disorder.

Quitkin *et al.* [55] reported that a large number of patients who suffer from panic attacks and/or a phobia (generally agoraphobia) attempt to mitigate their symptoms, including the anticipatory anxiety, by self-administration of alcohol and other depressant drugs such as barbiturates [51]. Additionally, alcohol abuse has been observed in individuals suffering from posttraumatic stress disorder whose frequent nightmares are apparently relieved by this drug's ability to suppress REM sleep [55]. Quitkin *et al.* suggest that the clinical presentation of this dual disorder is frequently dominated by the secondary addiction [55], and that the successful diagnosis of a primary anxiety disorder requires an active search for a history of anxiety attacks or evidence of phobias in the past [51].

#### TREATMENT CONSIDERATIONS

One single research work attempts to remedy the prevailing lack of data on the concurrent treatment of psychiatric disorders and addiction. Kofoid *et al.* [58] conducted a pilot, outpatient study ( $N = 32$ ) on a dually diagnosed population treated in an ambulatory program that incorporated techniques

from both psychiatric and substance abuse treatment. For example, although it emphasized symptom control and compliance with prescribed medication, abstinence from drug and alcohol represented its main focus of treatment. The program is described by the authors as specifically designed for those patients seriously impaired by both their primary psychiatric illness and their secondary addiction, who had derived little or no benefit from previous treatment experiences. Following an initial stabilization that included brief hospitalization in some cases, patients attended weekly groups, were routinely prescribed disulfiram, and were encouraged to attend Alcoholics Anonymous and Narcotics Anonymous. Abstinence was monitored by surprise urine screenings and breathalyzer assessments. Patients were also expected to develop ancillary support abstinence groups, usually Alcoholics Anonymous, and had a variety of adjunct treatments made available to them, such as individual and family counseling, skill training, and day treatment. DSM-III diagnoses were made and retrospective symptom scores were obtained from subscales of the Addiction Severity Index. Since strict criteria for retention in treatment were applied, the authors equated retention with treatment success.

The results of the study include a very high dropout rate of 60% within 2 months. A second group of only 11 patients (34%) remained in treatment for 3 or more months. While these two groups were demographically similar, the distribution of psychiatric diagnoses between the two groups differed, mainly due to the overrepresentation of personality disorders in the early dropout group. Finally, contrary to other reports [59, 60], symptom severity and history of previous hospitalizations did not seem to influence treatment retention. Retention, however, was enhanced in the presence of a previous experience in outpatient treatment.

With the exception of addicts with personality disorder for whom no specific treatment was conceptualized, the authors suggested that dually afflicted patients warrant treatment along the following guidelines: (1) Initial hospitalizations for detoxification (which would also facilitate both the evaluation and management of suicidal depressive and manic states) followed by open-ended outpatient treatment of both disorders by a multidisciplinary staff; (2) treatment specifically aimed at symptom relief; (3) discriminant use of legal coercion; and (4) use of disulfiram as a treatment adjunct for those stable patients involved in ongoing treatment.

The validity of these treatment recommendations is limited, however, due to the very short duration of the study, the lack of treatment technique controls, and the small patient sample. These shortcomings prevent both

comparative determinations of long-term outcome according to psychiatric diagnoses and reliable assessments of the clinical effectiveness of different treatment modalities.

We will now review the specific treatment studies regarding each of the psychiatric diagnoses complicated by substance abuse considered in the previous section.

### Affective Illness

Since very high suicide rates have been reported among addicted depressives [61], most authors recommend a period of hospitalization during the initial phase of treatment for these patients [42, 46]. Nonetheless, the vast majority of serious depressions observed during detoxification of alcohol and other drugs can be expected to remit following a few weeks of abstinence [32, 57]. Rounsaville *et al.* [62], for example, studied depressed opiate addicts ( $N = 157$ ), following them over a 6-month period to ascertain the course of their depression. He found that improvement of depressive symptoms was related to retention in treatment but was not the result of specific antidepressant pharmacotherapy and did not differ across treatment modalities.

The outcome of primary depressives with associated addiction problems may prove to be different from that of primary addicts. It has been suggested, for example, that depressives with alcoholic problems may have a better outcome and stand a better chance of attaining long-term abstinence than primary alcoholics [46]. Appropriate comparative outcome studies, however, are necessary to clarify this important question.

Another important issue in the treatment of affective patients with secondary addictions is the use of antidepressant and anitmanic medication. The effectiveness of antidepressants and lithium carbonate in treating the primary affective disorder and their contribution to drug relapse prevention, however, have not been determined. Neither has the comparative value of different treatment modalities been established for this population. The single outpatient study available [58] on dually diagnosed patients previously reviewed included only 4 patients with affective disorders (bipolar disorders). Since neither their demographic and clinical characteristics nor their comparative rates of retention in treatment are described in the study, no diagnostic-specific recommendations can be drawn regarding their treatment.

### Schizophrenia

The early identification of schizophrenic addicts in the treatment context have been strongly recommended, mainly because of the need to respond promptly to the particularly difficult management problems that these patients represent [42, 46, 63]. The addicted paranoid schizophrenic, for example, has been described as among the most difficult to treat [64]. Illustrating the difficulties in treating these patients, as already mentioned, is the finding by Alterman *et al.* [13] that more than half of the inpatient schizophrenic alcoholics included in their study were reported to drink while still in the hospital.

The diagnostic picture of addicted schizophrenics, particularly at the beginning of treatment, is frequently confusing and is often the cause of delay of appropriate treatment planning [46, 63, 65]. Additionally, the exacerbation of schizophrenic symptoms by drug abuse, the extremely high suicide potential in this population [46, 66], and the frequent difficulties in engaging schizophrenic addicts in treatment [58, 67] are all factors that seriously compound the management of these patients. Complicating matters, the staff generally lacks appropriate training in the simultaneous treatment of both psychosis and addiction [58, 63]. Ottenberg [68] reported on the ability of the psychotic addict to disrupt the entire program of a psychiatric unit. Alterman *et al.* [13, 14, 70], for example, in a study of inpatient addict schizophrenics ( $N = 101$ ), observed that at least 30% of these patients represented severe management and treatment problems for the staff. Not surprisingly, schizophrenic addicts frequently are either altogether refused admission or prematurely discharged from both psychiatric and detoxification wards [69, 70].

There is very little data on the concurrent ambulatory treatment of schizophrenic addicts and their outcome. In the outpatient pilot treatment study [58] previously described on 32 dually diagnosed individuals, only 6 out of 16 alcoholic schizophrenic patients remained in treatment for at least 3 months. Those patients in the study who remained this long in treatment were the ones most likely to have had previous mental health treatment, suggesting that even one psychotherapy experience may eventually contribute to the patient's ability to comply with treatment even in the absence of abstinence. Although the sample size in this study precludes reliable comparisons of retention rates among different psychiatric disorders, schizophrenics did not seem to drop out of treatment earlier or more often than other patients, as would be expected in view of the reported difficulties

experienced by schizophrenic addicts in establishing relationships with ambulatory oriented treatment facilities [64]. Pancipinto *et al.* [71] reported that schizophrenics, unlike patients suffering from personality disorders, consistently attended brief, symptom-oriented visits to the inpatient treatment program, but simultaneously failed to become involved in other staff members. As pointed out by Gottheit [63], this behavioral pattern suggests that schizophrenic alcoholics may be more compliant with pharmacologically oriented treatment program which encourages only minimal exploration of thoughts and feelings. While neuroleptics are indicated in the treatment of the primary schizophrenic process, there are no clinical studies available to help clarify the indications and overall contribution of neuroleptics in the treatment of secondary addiction.

An important issue in reference to pharmacotherapy in this population is the use of disulfiram. A controversy about disulfiram administration in schizophrenics exists that revolves mainly around the reported psychotic reactions it occasionally induces with consequent risk of schizophrenic relapses [72]. Kofoed *et al.* [58], however, report no complications in routine disulfiram administration to the dually diagnosed population previously described. In fact, their overall disulfiram compliance rates and individual patterns of compliance were reported to be almost identical to those reported in alcoholics without other psychiatric illness [73].

An important consideration for the ambulatory treatment of addicted schizophrenics concerns their reported failure to integrate with large groups. Because of their difficulties in tolerating and participating in highly cohesive groups without becoming passive or paranoid [64], referral of these patients to groups such as Alcoholics Anonymous and Narcotics Anonymous has not been recommended.

### Antisocial Personality Disorder (ASPD)

Not much has been reported on the concurrent treatment of sociopathy and addiction. The few reports on addicted ASPDs response to ambulatory treatment uniformly describe these patients as having the worst short- and long-term prognoses of all dually diagnosed patients [46, 55, 58]. Schuckit [46], in a 1-year follow-up study of male alcoholics ( $N = 577$ ), for example, reports that patients with antisocial personality disorder demonstrated more adverse outcomes than other groups of primary alcoholics, substance abusers, and affectively ill patients. In agreement with other reports [74],

sociopaths in this study showed a higher prevalence of police problems, using weapons while drunk, taking other drugs, and lack of stable residence than other psychiatric patients. They also dropped out of treatment earlier and had less abstinent days than primary addicts and alcoholics.

In another study ( $N = 110$ ), Woody *et al.* [75] observed that psychotherapy outcome of addicted sociopaths, although generally poor, was enhanced in the presence of associated depression. These authors speculate that depression appears to be a condition that allows the sociopathic patient to be amenable to psychotherapy.

The only information available on substance abuse by other personality disorders derives from Kofoid's outpatient pilot study [58]. Unlike all other patients suffering from a different psychiatric disorder, most patients in this study diagnosed as having borderline personality disorder (7 patients, 22% of the sample) dropped out of treatment by 4 months, earlier than all other psychiatric patients. Upon analysis of their findings, the authors declare themselves uncertain of the correct treatment approach for addicts with personality disorders.

### Anxiety Disorders

Quitkin *et al.* [51, 55] described a treatable syndrome in which the recurrence of both a panic disorder and an associated secondary addiction can be successfully prevented by proper pharmacological treatment of the primary anxiety disorder with tricyclic antidepressants. In an outpatient study [51], the clinical courses of two small groups ( $N = 10$ ) of addicted anxious patients suffering from panic attacks, phobias, and anticipatory anxiety were compared during a period of 6 months to 3 years. Only the group treated with imipramine did well and did not return to alcohol or drug abuse.

More studies are necessary to corroborate these findings. The proper treatment for other anxiety disorders complicated by addictions has not been determined.

### OBSERVATIONS

This review was undertaken because of the serious clinical problems, largely unattended, which have been posed by dually diagnosed patients. We have summarized the current literature on the place of presentation,

diagnosis, and treatment of persons presenting for general mental illness who have concomitant alcohol and drug abuse problems. What emerged as a problem of considerable dimension, one seriously compromising the operation of the mental health system, and one on which relatively few specialized studies have been carried out. A number of factors contribute to this unfortunate situation.

In the first place, teasing apart the symptoms of combined addictive and general psychiatric illness in combination is quite difficult, even though this problem is very common. Our diagnostic nomenclature has been developed for discrete, single illnesses, but the entirety of addictive and general psychiatric problems is a good deal more complex than the sum of its parts. It may be necessary to develop a nomenclature for certain concomitant illnesses; for example, a characteristic pattern of depressant abuse (such as alcohol), different from the one generally described, emerges from the dysphoria accompanying chronic mental illnesses. This pattern often remits with the treatment of the primary illnesses.

Second, patterns of drug use have changed considerably with the passage of several years. Pure opiate use has been replaced by methadone maintenance combined with polydrug abuse; phencyclidine has been replaced in many emergency rooms by freebase cocaine ("crack") as a primary precipitant of drug-induced psychosis. While the federal emergency room reporting network has been useful in tracking changes in drug abuse patterns, little has been done to examine changes systematically in pathophysiology of the dual diagnoses presenting with these drug-abuse patterns. Much more intensive studies on both symptom presentations and the effects of drugs on psychopathology are needed.

Finally, new modalities are needed in the area of treatment. We have only begun to use modalities for treating drug abuse when it occurs independent of other psychiatric illness. Not surprisingly, the few studies noted here that do address combined problems utilized established techniques. Much more remains to be done about the innovative application of psychotropic agents to subgroups of dually diagnosed patients and of newly developed psychosocial modalities which address combined cognitive, affective, and addictive symptoms in an integrated manner.

CULTURAL DIVERSITY AND PSYCHIATRIC REHABILITATION

Comas-Diaz, L. (1988). Cross-cultural mental health treatment. Clinical Guidelines in Cross-Cultural Mental Health. Lillian Comas-Diaz and Erza E.H. Griffith (Eds). New York: John Wiley and Sons. 337-361.

— CHAPTER THIRTEEN —

*Cross-Cultural Mental  
Health Treatment*

LILLIAN COMAS-DÍAZ

INTRODUCTION

This last chapter touches on some aspects of the clinical practice of cross-cultural mental health not addressed in previous chapters. Cross-cultural mental health is an emerging and growing field in the United States. Historically, this treatment approach has evolved through the influence of (1) indigenous, folk-healing practices, (2) psychoanalytic anthropology, and (3) the delivery of mental health services to ethnic minorities.

The first documented anthropological accounts of indigenous or folk healing date to the nineteenth century. These accounts mention practices such as psychic healing, but present them as ethnographical curiosities and are silent as to any behavioral change process attendant to treatment, according to Draguns (1981). However, as ethno- and transcultural psychiatry developed, adherents proclaimed the importance of the psychiatric qualities of shamans, *curanderos*, witch doctors, Yoruba priests, spiritualists, Navaho

healers, and so on (Kiev, 1972; Moffatt, 1974; Torrey, 1972). (In this volume, Ezra E.H. Griffith and John L. Young present the psychological merit of some of these practices.)

The second major influence in the development of cross-cultural mental health treatment was the advent of psychoanalytic anthropology. As its major exponent, George Devereux laid the foundation by studying cultural factors in psychoanalytic therapy and using his psychoanalysis of Plains Indians and culturally marginal White patients as the basis of his findings (Devereux, 1953). Several other therapists began to disseminate their findings using psychoanalytically oriented therapy in a cross-cultural context. For instance, Sommers (1964) studied identity disorders in patients with dual cultural memberships. More recently, Gehrie (1979), using a psychoanalytically informed, anthropological research model, has asserted that culture is an internal representation and that, as such, it ought to be an integral aspect of psychoanalytic treatment.

A third influence on the development of cross-cultural treatment has been the challenge to the mental health profession to deliver effective services to ethnic minorities, for example, Blacks, Hispanics and Latinos, Asian Americans and Pacific Islanders, and American Indians and Alaska natives. The civil rights movement and passage of the Community Mental Health Act have added impetus to this challenge. Issues such as ethnicity and social class, minority group membership, dysfunctional versus adaptive behaviors, therapist-patient match, and culturally relevant treatment are still debated.

Meanwhile, cultural pluralism is emerging as a distinct feature of American society. The United States is becoming a "nation of newcomers" (Piers & Piers, 1982); the massive influx of immigrants is currently "changing the face of America" (Immigrants, 1985). The melting pot theory is proving to be obsolete as our society is being transformed into a nation of ethnocultural diasporas. Given this context, the availability of effective cross-cultural mental health services is imperative.

### THERAPIST-CLIENT DYAD

Individuals in an alien cultural environment undergo a process of adjustment to their new settings that involves struggling with their ethnocultural identities. Erikson (1959) has theorized that individuals in crisis situations, such as cultural transition, experience a heightened awareness of their identities, undergoing what he calls a transitory, excessive identity consciousness. Cultural transition tends to move individuals along the developmental pathway at a faster rate than other external factors. Thus during acculturation or a period of sociocultural transition, their self-images may

undergo dramatic changes and lead to subsequent identity crises. According to Sluzki (1979) the effects of cultural transition are still manifest in families generations after a migration has occurred. (See Behnaz Jalali's in-depth discussion of this issue in the first chapter of this volume.)

The role of therapists in helping patients who have made cultural transitions is a complex one. Such patients are likely to have worldviews that differ from their therapists' and, at times, views that conflict with the western notion of mental health. Patients entering therapy also may experience considerable anxiety about the ethnocultural differences between themselves and their therapists (Sue, 1981). Suspicion, apprehension, anger, and preoccupation with self-image and identity are likely to surface, putting the therapist's trustworthiness and credibility to a severe test.

Research demonstrating the therapeutic benefits of therapist-patient ethnocultural similarity is inconclusive (Cortese, 1979; Jones, 1978). Nevertheless, research does show that a therapist's effectiveness tends to depend on his or her perceived credibility (Sue, 1981). Regardless of the therapeutic orientation, one of the crucial factors in successful therapy seems to be the therapist's understanding and sensitivity to the patient's ethnocultural background (Griffith, 1977). In determining what characteristics make for a therapist's successful "minority style," Smith and his colleagues (1978) say it is an understanding of the biculturalism of patients in a cross-cultural setting that is essential.

In defining pluralist psychotherapy, Padilla (1981) asserts that its goal is to help patients clarify their personal and cultural standards. In order to accomplish this, the pluralistic therapist needs to understand both the patient's ethnic group and the dominant group culture and know the points of contact between the two cultures and the process by which the cultural standards of each influence the patient. Padilla adds that pluralistic therapy is a complex task when the patient is culturally marginal, (i.e., has a bicultural background without a dual ethnocultural identification). In this case, the therapist must integrate the dual ethnocultural experience into the therapeutic process. Thus the therapist, with the patient's help, must decide how much separation from and/or how much acculturation to the dominant culture is necessary to effect a successful therapy.

Padilla's assertions acquire added relevance when patients use the therapeutic session as a forum for the expression of conflicting ethnocultural identities. For example, Gómez and his associates (1982) state that the majority of patients they studied manifested identity conflicts through an expressed preference for their original culture over the host culture. They found that patients complained when their therapist had a different ethnocultural background. Based on these findings, it can be speculated that the effective therapist may be perceived as a guide, fostering ethnocultural

identifications in the process of identity formation. Similarly, Varghese (1983) states that the fundamental task in psychotherapy is to be aware of the patient's feelings toward the therapist, sometimes by monitoring one's own feelings, reflecting back to the patient, and thus gaining an empathic understanding of the patient.

Elsewhere, we (Comas-Diaz & Jacobsen, 1987) introduce a model of the impact of cultural dislocation on the therapeutic process. We note that culturally translocated individuals often attribute ethnocultural qualities to their therapists. For example, a dark-skinned Brazilian male suffering from depression says to his Afro-American male psychiatrist: "You can understand my predicament because we Black people always have had bad luck." After a year of treatment, a first-generation Portuguese female says to her female Puerto Rican therapist: "We can conduct the treatment in Spanish. I know the language because I was once engaged to a Cuban man." A Black female says to her Asian-American male therapist: "Although I grew up as a Baptist, I am now involved in Eastern philosophies and perhaps you can help me heal my soul." Although these quotes can be interpreted in the context of diverse theoretical orientations, we believe that they demonstrate that patients who have experienced cultural dislocation may presume and then attribute to their therapists certain ethnocultural characteristics that may or may not be accurate.

As an auxiliary therapeutic tool, ethnocultural identification can help the patient manage cultural values, negotiate transitional experiences, and cope with the identity readjustment in an alien cultural environment. Within this framework the initial task of the therapist is to perform an ethnocultural assessment. This assessment involves the exploration of several stages in the formation of the patient's cultural and ethnic makeup. (In Chapter 6, Frederick Jacobsen provides a detailed description of the use of ethnocultural assessment aided by clinical methodology. Here, I will concentrate on the use of ethnocultural identification in the psychotherapeutic process.)

Should the ethnocultural assessment confirm that the patient's self-identity is indeed fragmented, the therapist actively fosters patient identification with his or her ethnocultural origin. In order to accomplish this, the therapist engages in three major therapeutic functions (Comas-Diaz & Jacobsen, 1987).

1. Reflection, whereby the therapist "mirrors" the ethnocultural pieces of the patient's fragmented self
2. Education, whereby the therapist guides the patient through a reformation of ethnocultural identity
3. Mediation, whereby the therapist helps the patient integrate his or her ethnocultural self into a consolidated sense of self

Reflection acknowledges the pervasive influence that ethnicity and culture have on the patient's life. The therapist underscores those aspects of the patient's life that reveal his or her ethnocultural identity conflict: "It is difficult for you to see yourself as \_\_\_\_\_ [ethnicity]," or "You avoid people from your community because they remind you of being \_\_\_\_\_ [ethnicity]." These statements communicate to the patient an awareness of his or her fragmented ethnocultural self.

Reflecting pieces of the fragmented ethnocultural identity conveys to the patient that the therapist understands the circumstances of biculturalism-multiculturalism. This can allow the patient to perceive the therapist as empathizing with his or her complex identity and thus facilitate the development of trust.

In executing the second therapeutic function, the therapist acts as a guide in the reconstruction of the patient's ethnocultural identity. The therapist provides a "safe" environment where the patient can examine his or her conflicted identity. By using directive approaches, the therapist helps the patient examine inconsistencies between aspects of his or her own ethnic background, and between his or her ethnocultural values and those of the second culture.

The third therapeutic function is the mediation between the ethnocultural identity and the personal identity. Here the therapist helps the patient to connect different aspects of the self to achieve a more integrated identity. According to McGoldrick (1982), restoring a sense of identity may require resolving cultural conflicts within the family, between the family and the community, and/or between the individual and the wider context in which the patient and his or her family function. During this mediation, the therapist encourages the patient to verbalize existing identity conflicts. Enunciations such as "It is confusing to you because, at times, you feel like a \_\_\_\_\_ [ethnicity] and at others you feel like an American" help the patient to "name" the identity conflict and hence initiate the reintegration process.

Ethnocultural identification follows a developmental framework, similar to Adler's (1975) model of the individual's adjustment to cross-cultural transition. Adler posits that the specific psychological and ethnocultural dynamics appear during and after the cultural transition. His model delineates progression through five stages: (1) initial contact with a second culture, where the individual is insulated by his or her culture of origin; (2) disintegration, where awareness of being different results in depression and withdrawal; (3) reintegration, where the second culture is rejected through anger and rebellion; (4) autonomy, where the person is able to negotiate different situations culturally, thus surviving new experiences; and (5) independence, where ethnocultural, social, and psychological differences are accepted and enjoyed. In this last stage, the individual is able to exercise choice

and responsibility and to discern the cultural aspects of everyday interactions and circumstances.

As a therapeutic tool, ethnocultural identification can assist patients in progressing through the five stages of Adler's model. By mirroring the fragmented self, the first, or reflective, stage heightens the patient's ethnocultural awareness so that he or she can move toward Adler's developmental stage of autonomy. Finally, the third, or mediative, stage aims to enable the patient to achieve the final developmental stage of independence.

The following is a case vignette illustrative of the use of ethnocultural identification in cross-cultural mental health treatment. (The patient's identifying data have been changed to ensure confidentiality.)

Nancy, a 25-year-old recently migrated Jamaican woman, was hospitalized because of the breakup with her lover. After discharge, she was referred to outpatient treatment with a diagnosis of brief reactive psychosis.

During the first outpatient session, Nancy asked her therapist (a female Puerto Rican) if she knew the differences between Afro-Americans and West Indians. Initially, she responded to Nancy's question at its content level, affirming the legitimacy of the patient's inquiry into her therapist's cultural understanding. Later, when Nancy continued to make comments such as "I like being American, but I am not Black," or "I am part British and do not understand the English spoken by Black Americans," the therapist decided to perform an ethnocultural assessment.

Results from the first stage of the assessment revealed that all of Nancy's relatives were Jamaican. Like Nancy's paternal grandmother, her mother had left Jamaica for another Caribbean island when she was in her thirties. At this point Nancy asked her therapist if she was Puerto Rican. When she responded affirmatively, Nancy noted that "Puerto Rico is a Caribbean island," suggesting a link between the therapist and patient.

The second and third stages of the assessment revealed that Nancy perceived her immigration as a female duty; that is, she was following the examples set by her mother and paternal grandmother. Several sessions were devoted to the completion of the ethnocultural assessment, including an exploration of religious beliefs during which Nancy stated that she was raised as a Catholic. In the last stage of an ethnocultural assessment the therapist's own ethnocultural background is examined for potential overlap with the patient's. In this case the overlapping areas identified were: Caribbean background, upbringing in the Catholic faith, and the experience of cross-cultural transition.

The results of the assessment provided the groundwork for the ethnocultural identification. During the initial stages in therapy, Nancy began

to discuss her relationship with her ex-boyfriend. She blamed herself for the breakup, stating that she had changed in the United States; that is, she was "no longer pretty." Exploration of this issue revealed that, as a light-skinned woman, Nancy was considered very attractive in Jamaica. In the United States, however, she was viewed as an attractive Black woman.

According to Brice (1982), a light-skinned Black is accorded more status than a dark-skinned Black in the British West Indies. In the United States, Whites are observed not to make the distinction: A light-skinned West Indian is "another Black." Thus Nancy's belief that she was no longer pretty was a reaction to being considered "attractive Black" as opposed to "attractive woman." Her self-identification had changed and so, too, her self-image.

In therapy, however, Nancy began to draw parallels between herself and her clinician. Enunciations such as: "You don't look White, but you don't seem to mind" or "Your hair is just like mine" were elicited as the clinician reflected back to Nancy the latent content of her self-dissatisfactions. Nancy began to identify the characteristics she shared with the therapist and to discover that, though they were devalued by herself, they were accepted by her therapist. This process continued through several sessions to help Nancy reestablish her identity as an attractive woman.

During this stage in treatment, a crisis emerged, where Nancy confessed that she had been "hanging out with some Rastafarians, smoking ganja." Assessment revealed that her cannabis smoking was sporadic and that she did it in order to "belong to the Jamaican community." The therapist then took an active and directive stance in helping Nancy reformulate her ethnocultural identity. She was helped in dealing with culture shock and the subsequent feelings of loss that she was experiencing. Therapy was the arena for mourning meaningful cultural objects, and for guiding Nancy in redefining her identity as a Jamaican woman living in the United States. This was done by encouraging Nancy to discuss how she did or did not fit into the Jamaican community in the city that she was living in, and by examining the differences between Jamaican women in Jamaica and Jamaican women living in the United States. This exploration, together with a look at the behavioral alternatives available to her and their likely consequences, provided Nancy with more self-awareness and a sense of empowerment.

At this stage in therapy, Nancy mentioned that she had the power of healing by the laying on of hands. This revelation was carefully examined within her ethnocultural context and did not appear to be pathological. The healing symbolism of the laying on of hands was perceived as Nancy's identification with the healing functions of her therapist.

Nancy began to feel more comfortable and accepting of herself as she achieved an integrated ethnocultural identity. She was capable of managing cultural inconsistencies, such as being labeled "Black" when she grew up considering herself "colored." Within this context, she used therapy to help her cope with a new cultural reality: American racism. Furthermore, she was able to maintain her job and to act on her plans to attend college.

Ethnocultural identification was used as an auxiliary to dynamic-oriented therapy to treat Nancy's DSM-III atypical personality disorder. This case vignette illustrates how the fragmented ethnocultural identity can be at the forefront of the patient's clinical presentation. The therapist's awareness and active use of the ethnocultural identification facilitated the therapeutic work with this patient.

#### GENDER ISSUES IN CROSS-CULTURAL PSYCHOTHERAPY

Early on, culture imposes upon the individual the pervasive task of becoming a psychological male or female. Similarly, the socialization process involves the development of behaviors and feelings, in addition to a sense of self, that are considered culturally appropriate for each gender. Thus the role of each gender may develop differently, depending on the cultural context.

Gender issues have received special attention in mental health treatment. The relevance of sex roles has been highlighted in terms of potential distortion due to gender differences in communication and interaction, particularly in the psychotherapeutic context (Johnson, 1981). Kaplan (1979) argues that both patients and therapists bring to therapy remnants of their upbringing within a culture that values different characteristics for males and females. According to her, this upbringing can influence both the position taken by each member of the therapeutic dyad and the ways in which each perceives and interprets the behavior of the other.

Gender issues obtain added significance in cross-cultural psychotherapy, as they are one more variable to complicate the therapeutic process. Ethnic differences intertwined with gender variables can stymie the process and outcome of psychotherapy. Wilkinson (1980) asserts that the risk for misconceptions and other obscurations is highest when the patient is a female of an ethnic minority and the therapist is an Anglo male. Thus the need to analyze the ethnocultural-gender interaction in cross-cultural therapy is critical. Yet most research on ethnicity and mental health has not been gender specific, leading Wilkinson (1980) to call for systematic studies that do take into account the clinical significance of the ethnicity and/or race and the sex of both patients and those who formulate theory and engage in clinical practice.

#### Ethnicity, Cultural Transition, and Gender Roles

According to Landau (1982), an individual or nuclear unit tends to feel extremely threatened when moving from a traditional, extended family into a new culture where nuclear independence is expected. Landau further posits that the threat leads the culturally relocated individual to place an intense emphasis on the culture of origin. Other studies reveal that ethnic values and identification with the culture of origin are retained for many generations after immigration has occurred (Greeley, 1981) and so, too, the effects of cultural transition are manifest in clinical situations generations later (Sluzki, 1979). Thus ethnicity is a major determinant of identity, playing a significant role in family life and personal development throughout the life cycle. It fulfills the basic psychological need of belonging and having historical continuity (McGoldrick, 1982). Indeed, recent immigrants as well as second-, third-, and even fourth-generation Americans differ from the dominant culture in values, behaviors, and life-styles (McGoldrick, 1982).

Gender roles tend to be affected by cultural transitions and subsequent cultural adaptation. O'Reilly (1985) states that, for women, the cultural transition is a transforming process. She believes that most immigrant men desire to return to the old country and the old ways because they had status in their homelands merely because they were males. On the contrary, women prefer to stay in the United States, even though they have to struggle with the "double day," that is, both performing the household tasks and working outside the home to help meet their families' economic needs. They prefer to stay, albeit paying a high price, because they achieve more autonomy, something hard to obtain in their homelands. For example, Puerto Rican women who migrate to the mainland tend to be actively engaged in the transculturalization process of their society, due to the availability of opportunities and the existence of more egalitarian sex roles. Puerto Rican men tend to feel more comfortable within their traditional sex roles and, therefore are less involved in the transculturalization process (Comas-Diaz, in press).

Culture shock may include confronting different sex role expectations, thus causing gender role confusion. High-level ambiguity about sex roles, dating, and sexual expression has been found among adolescent Cuban refugees, for example (Scopetta, King, & Szapocznik, 1977). The following case vignette is another example.

Antonio is a 21-year-old Salvadoran male who immigrated to the United States aided by an American Christian group. He immigrated to a northeastern state where his girlfriend, who had left El Salvador 6 months before he did, resided. Antonio had a college education and was politically active in an underground movement in his country. His girl-

friend, whom he met in college, had been supportive of his role, though not politically active herself.

Upon entering the United States, Antonio began to live with a minister and his family (wife and three small children). After a few weeks, the minister took him into a mental health clinic for Hispanics. Antonio was complaining of insomnia, anxiety, depression, and "nerves." He received chemotherapy for his depression and subsequent individual therapy to help him in his "adjustment to this country" (patient's own words). During evaluation, it was revealed that Antonio had contacted his girlfriend, but that the relationship had turned sour. He explained that she was not "the way she used to be; not listening to him and being too independent." He attributed her change to "[becoming] an American woman." Antonio was encouraged to bring his girlfriend to therapy, but he refused because "he was no longer in love with her."

Antonio continued in therapy with a Hispanic female, dealing with his feelings about "what happened and what he did in El Salvador," in addition to his adjustment difficulties. Six months into treatment, he requested to see the medical backup, a Hispanic male. Antonio confided to him that he was experiencing severe problems at home. He stated that the minister's wife was sexually available and that he wanted to have sex with her. However, Antonio was conflicted because he did not want to betray the minister's trust and face the risk of being asked to leave. Upon exploration into this conflict, Antonio revealed that as a *macho completo* (complete male) he had to respond sexually to any female who signaled her availability. He added that, although he had a good relationship with his female therapist, the medical backup could "better understand his problem."

#### *Gender-Ethnicity Interaction: Effects of Psychotherapy*

Gender roles vary according to ethnicity and need to be identified to ensure effective psychotherapy. The following examples illustrate gender issues among three ethnic groups: Blacks, with their long history of residence in the United States; immigrant Greek women; and Hispanics, with varying degrees of acculturation to the mainstream culture.

**The Patriarchy Myth: Blacks.** Black American children are more likely than Whites to reside in single-parent households headed by females (Harrison, 1977), and research suggests that Black girls tend to identify with the image of the "strong Black woman" (Ladner, 1971). Schaffer (1981) states that Blacks regard working outside the home as an appropriate female role and that Black girls are encouraged to rely on their achievements and not on

men and marriage for future security. In contrast to what had been expected of Anglo girls, educational and occupational aspirations are accepted and encouraged for Black girls. In short, it appears that the Black female is socialized to be more independent, autonomous, and stronger than her Anglo counterpart. Given that Black women have had to work in order to survive economically, relationships between Black men and women generally tend to be more egalitarian than between Anglo men and women. Furthermore, research indicates that Black men and women have very similar expectations about gender roles in marriage and child rearing, and that both sexes prefer women to achieve a balance between self-actualization and family orientation (Schaffer, 1981).

That the Black female is socialized to be strong, independent, and a breadwinner may have led to the supposition that Black American culture is matriarchal. However, research suggests that this notion of a Black matriarchy is a myth. For example, Harrison (1977) has asserted that the highest concentration of underemployment in the United States is among Black women, and thus the notion that Black culture is matriarchal is not empirically substantiated. Furthermore, in research examining gender role stereotypes among Blacks and Whites, Smith and Millham (1979) found that the images of the "shiftless" Black male and the "matriarchal" Black female are not operative within contemporary Black America.

The myth may be perpetuated by the fact that Black women may appear stronger, more independent, more resourceful, and thus less "feminine" compared to middle-class Anglo women. Myth or not, describing Black culture as matriarchal has been a way to blame Black women for the problems that can be traced to slavery's destruction of Black social and family structures, which this country's long legacy of racism has compounded. According to Staples (1971), the notion that Black America is a patriarchy is a scapegoat tactic, and Black men as well as Black women have suffered as a consequence. As family breadwinners, for example, Black women have been accused of emasculating Black men (Schaffer, 1981).

Obviously, these aspects of gender and race should be understood so that, if and when they surface in the course of therapy, their significance will not be ignored. Similarly, therapists should be aware of general patterns that studies of Blacks in therapy indicate. For one thing, these studies show a general correlation between sex and the complaint diagnosis made.

In a survey of therapists asked about their Black patients, Jones and Gray (1984) note that Black men most often were diagnosed as having affective nonpsychotic disorders. Anxiety disorder was the second most frequent diagnosis. For Black women, the diagnoses were reversed. That is, anxiety disorder was diagnosed most frequently and affective nonpsychotic disorder was second.

Depression and work-related problems were the most frequent complaints cited by Black males, while Black females cited depression and family problems most often. Therapists said that their Black male patients experienced aggression-passivity as the most frequent unconscious conflict and high-low self-esteem as the second. The order of frequency was reversed for women.

That self-esteem is a pervasive mental health issue for Black women has been well documented (Dansby, 1975). Indeed, among professional Black women, the issue of self-esteem has been tied to difficulties in relating to significant others (Bell, 1980). Finally, racism is one theme that is shared to the same degree by Black men and women throughout the therapeutic process (Jones & Gray, 1984).

The following case vignette illustrates some of the issues just described:

Ann is a 25-year-old Black woman, whose physician referred her to an outpatient clinic after she was asked to leave her job. Employed as a nurse's aide in a general hospital for a year, Ann began having anxiety attacks and overate enough to gain 15 pounds in 2 weeks.

Once in therapy, Ann vented her anger at her former supervisor, a White female, arguing that she was fired solely due to racism. She then became angry with her therapist, a Puerto Rican woman, because she did not know "what it's like to be a Black woman."

Eventually, however, the therapist "proved" herself and Ann began to trust her. In therapy, she worked at controlling her temper and was able to obtain another job as a nurse's aide. During therapy it was revealed that Ann had a drinking problem, which was assessed and treated. (It has been reported that alcoholism among Black women is a special mental health problem resulting from their historical, racial, cultural, and structural position in the society (Smith, 1985). In this volume, F.M. Baker further discusses alcoholism among Black women in her chapter on Afro-Americans.) Later, Ann began to talk about her boyfriend, outlining problems in their relationship. The therapist suggested couples treatment, to which Ann enthusiastically agreed. Ann's boyfriend, John, a 30-year-old unemployed Black man, expressed commitment to the relationship and willingness to participate in psychotherapy. The couple explored their relationship, including difficulties with their expectations of each other, and their roles within their respective families. They both completed treatment.

This case illustrates that the therapist's ethnicity and gender did not adversely affect her Black male patient's ability to engage in and benefit from therapy, denoting the egalitarian sex roles characteristic among Blacks. The

therapist's ethnicity, however, did arise as an obstacle to trust in early sessions with her Black female patient. Themes of trust, racism, and Black women's pride pervaded the individual therapy. Themes of sexuality, marital expectations, and racism were present during the couples treatment. The therapist had to pay close attention to ethnic and gender differences so as to appreciate and then deal with their impact on the therapeutic process.

*The Persephone Syndrome: Immigrant Greek Women.* According to Welts (1982), the Greeks are family oriented, and their sex roles are highly stereotyped. Men are the providers and masters of their families, who expect to be obeyed by all members. They rarely assist in child rearing or household activities. In general, Greek men are observed to be authoritarian, sensitive to public opinion, and on guard against potential threats to their honor. Women's roles are secondary to men's. In order for a Greek woman to be treated with respect, she must become the mother of a son. Only then will she achieve status or be considered trustworthy. This cultural dynamic is complemented by the Greek man's practice of worshipping his mother and taking care of her old age (Welts, 1982).

Greek wives are expected to follow tradition and, when marital conflict does arise, they rarely confront their husbands, but resist passively, often joined by their children (Welts, 1982).

Studies of Greek women emigrés to the United States show that they experience cultural traumas, one of which may be what Dunkas and Nickelly (1972) call the Persephone syndrome. In Greek mythology, the personalities of Demeter and her daughter Persephone were merged into one until Persephone married Hades and left for the Underworld. When they were separated, the mother-daughter personality split in two (Hamlyn, 1963).

In their study of 60 Greek females in long-term group psychotherapy, Dunkas and Nickelly (1972) noted symptoms of anxiety, depression, psychological problems, and gross stress reactions after immigrating to the United States. According to the authors, the women's symptoms often represented guilt at leaving their mothers behind, that is, the Persephone syndrome. The therapy revealed their strong emotional attachments to their mothers and their attempts to reestablish union with them through psychological disturbance.

In the process of psychotherapy, Dunkas and Nickelly (1972) took into consideration the women's ethnic and sex role orientations. For instance, they encouraged a perception of the male therapist as a healer, and a figure of benevolent, paternal authority. They never raised divorce as an option, given the stigma that divorced women carry in the Greek culture. On the other hand, however, they did encourage the involvement of husbands in resolving the women's problems. And, in situations where marital

reconciliation appeared impossible, the therapists did recommend separation. Eventually, the authors went so far as to challenge the stereotype of the mother in the Greek culture, even though the patients' strongest loyalty was to their mothers. This suggests that, once trust and rapport are established by recognizing and accepting the patient's native behavior and values, alternative behavior and values can be presented to the patient as options.

**Marianismo and Machismo: Hispanics.** Though most Hispanic ethnic groups have immigrated to the United States from a wide range of countries, they share a similar family structure and, in particular, clearly delineated sex roles that dictate gender behavior. Traditionally, the Hispanic family is patriarchal, with an authoritarian father, a submissive mother, and a mutual acceptance of this pattern. Throughout Latin America, San Martin (1975) found women's subordination to men's authority well accepted.

Traditional Hispanic women are expected to be sentimental, gentle, intuitive, impulsive, docile, submissive, dependent, and timid; men are expected to be cold, intellectual, rational, profound, strong, authoritarian, independent, and brave (Senour, 1977). This rigid demarcation of sex roles encourages a double moral standard for the sexes, exemplified in *marianismo*. Based on the Catholic worship of the Virgin Mary, who is both a virgin and a madonna, the concept underlying *marianismo* is that women are spiritually superior to men, and therefore capable of enduring all suffering inflicted by men (Stevens, 1973).

Taught to view the Virgin Mary as their aspiration, unmarried women are expected to be chaste and virginal and not to demonstrate interest in sex once they are married. When they become mothers, Hispanic women attain the status of *madonnas* and, accordingly, they are expected to deny themselves in favor of their children and husbands. In noting the high incidence of somatic complaints among low-income Hispanic women in psychotherapy, Espin (1985) suggests that these complaints may well be a reaction to the self-sacrifice dictum, especially since somatization is a culturally accepted mode of expressing needs and anxieties.

However, Stevens (1973) asserts that the *marianista* code rewards women who adhere to it. Because motherhood is sacred, women who bear children enjoy a certain degree of power despite the outward submissiveness of their behavior. Conversely, women who do not conform to the code risk social censorship. As a consequence, a dichotomous classification of women is reinforced, that is, the *madonna-whore* complex.

The counterpart of *marianismo* is *machismo*. This cultural sex role literally means maleness or virility, and its most salient characteristics are heterosexuality and aggressiveness (Giraldo, 1972). *Machismo* also is manifested through physical dominance of women and excessive alcohol consumption. Furthermore, *machismo* dictates that the Hispanic male must

constantly signal his sexually availability; seductive behavior is mandatory regardless of marital status (Sluzki, 1982). Paradoxically, the *macho* must protect his female relatives from the sexual advances of other men while making as many sexual conquests as possible. Though it has been argued that *machismo* is more prevalent among lower socioeconomic classes (Kinzer, 1973), it is nevertheless believed to influence behavior in all strata of the Hispanic society (Giraldo, 1972).

In the United States, Hispanic women are observed to defend and thus perpetuate *machismo* as a way of insulating the egos of their male relatives from the socioeconomic humiliations they suffer. For instance, Senour (1977) claims Chicanas reinforce *machismo* in their men to compensate for their lack of status in the Anglo culture. Similarly, Steiner (1974) cites Puerto Rican women who defend *machismo* as an understandable response to deprivation in the economic, social, and political spheres; men take their frustrations out on women because they cannot make their mark elsewhere.

All the same, traditional sex roles are undergoing change among Hispanic emigrés to the United States. For one thing, the emigrés native culture, including its *machismo-marianismo* percepts, is not reinforced by the new dominant culture, which, in fact, is predated by the impact of the women's liberation movement. Furthermore, cultural transition itself often presents Hispanic men and women with a sexual role reversal in terms of public life. In studies of recent immigrant families it has been observed that the family member who most often deals with the dominant culture assumes the instrumental role, thus becoming increasingly isolated (Sluzki, 1979). Not surprisingly, in many cases the instrumental role is filled by the male, the affective one by the female. Though this split between partners in cultural transition can result in mental health and marital problems (Canino, 1982), the division of labor, so to speak, is keeping with the traditional sex role expectations in Hispanic culture.

Instrumental-affective role taking is not always respectively male-female, however. The pressures of economic survival in the new culture, as well as the type of skills that are marketable, have caused a role reversal among Hispanics. In fact, this role reversal is by no means rare, as it is often easier for female immigrants to obtain employment in the United States than it is for males. Indeed, the woman may have no choice but to assume the instrumental role because she is able to sell her sewing and domestic skills while her husband's ability to farm does him no good in the city. Consequently, the Hispanic woman's access to and ability to come to terms with mainstream American society can be much quicker and easier than the man's. Unfortunately, however, the instrumental-affective role split between partners seems to be at least as divisive, if not more so, when the woman is on the instrumental side of the equation (Canino, 1982).

Sex roles among Hispanic women in the United States can be complicated (and confused) by the expectations imposed by the two different cultural contexts in which they live. The Anglo culture tends to apply masculine criteria to the evaluation of women, ascribing the greatest value to those who distinguish themselves occupationally or professionally. Yet this tendency is contradicted enough to send mixed messages to the female. Consequently, for example, the Chicana is far surer of her role within the traditional Mexican-American culture than she is in the mainstream, where her role is ambivalent (Senour, 1977). Apparently, this sureness of role that her native culture provides has not stopped the Chicana, nor other Hispanic women in the midst of cultural transition from exploring the behavioral alternatives available to her. This experimentation can lead to conflict within the nuclear unit as well as within the extended family.

The clinician working with this population needs to be attentive to all of these issues and to recognize that the clear-cut demarcations between the sexes in traditional Hispanic culture may affect therapist-patient relations. Padilla (1981) states, for example, that some Hispanic male patients have trouble discussing their sexual concerns with female therapists; conversely, most Hispanic women prefer to discuss their personal problems with a female (Hynes & Werbin, 1977).

The following case vignette illustrates some of the issues just discussed.

Olga is a 39-year-old Colombian woman who immigrated to the United States when she was 11 years old. She grew up with her mother and two sisters; her father stayed in Colombia. She finished high school with honors and planned to finish college when she met Rafael, a 32-year-old Puerto Rican, who migrated to the mainland when he was 21 years old. At age 21, Olga married Rafael and dropped out of college after 6 months. The couple has three children, and both work in a factory, where Rafael is an inspector. The family initiated their contact with the mental health system when their youngest child exhibited behavioral problems at school. The child began to receive psychological help and the school social worker recommended that Olga also seek treatment because she was too "nervous."

Interviewed at a community mental health clinic, Olga complained of nerves, headaches, sleeping difficulties, and lack of appetite. No previous mental health problems were acknowledged. Assessment revealed that she was suffering from a reactive depression due to the family situation, and particularly, to the state of her marriage.

Rafael, her husband, was invited into the clinic to facilitate the evaluation of Olga. A male and a female therapist team conducted the session. Rafael complained that his wife was not being a "good mother" and thus was responsible for their child's problem behavior at school. In turn, Olga

argued against what she called Rafael's rigid view of her role as mother and wife. The couple's conflict over what constitutes the appropriate role of a wife and mother originated approximately a year after Olga began working outside the home.

During this session it became apparent that Olga was more acculturated to the mainstream culture than her husband. She was fully bilingual while he was not; and she espoused more egalitarian sex roles than Rafael. The couple was advised to undergo therapy together, but Rafael declined. Olga decided to continue individual treatment.

Individual sessions focused on Olga's feelings and the symptoms experienced in reaction to her family and marital situation. As some of these symptoms abated, she reported that Rafael was becoming more irritable at home. Although she did not articulate feeling responsible for the situation, she considered the possibility of resigning her job in an attempt to neutralize the conflict. After 3 months of therapy, Olga revealed that she suspected her husband of having an affair at work. She added that they were having heated arguments at home, but that he denied having an affair. Olga asked her husband to attend therapy with her, but reported he said: "I do not have to account to anyone for my actions, especially not to women."

Olga continued therapy, but there was no progress. She considered several courses of action, including resigning her job, asking for a legal separation, and leaving for Florida, where one of her sisters lived. However, she remained undecided until, late one night, accompanied by a female coworker and under the influence of alcohol, Rafael had a car accident. The incident prompted Olga's decision to seek a separation.

One month later, Rafael contacted the male clinician, who had conducted the couple's evaluation, and asked for an appointment. Rafael told the clinician that he would like to enter into treatment with Olga, if she was still interested in doing so. Olga agreed to attend treatment, although she claimed she was pressured into it by her family as well as Rafael's.

After several sessions with the whole family, marital treatment centered on the couple's changing gender expectations and the renegotiation of their roles. The fact that Olga was coping with conflicting sex role expectations ("Hispanic at home, Anglo at work") was taken into account by the male and female team who worked with Olga and Rafael for 3 months. Unfortunately, the couple discontinued treatment once it became apparent that Rafael had a drinking problem but refused to attend an alcohol rehabilitation program.

This clinical vignette demonstrates the pervasive impact of clearly demarcated sex roles in traditional Hispanic culture. Rafael demonstrates the strength of these expectations in his dissatisfaction with any behavior of his

wife's that does not conform to his gender code. Conflict between the couple heightened after Olga began working in the factory; on the one hand, this threatened Rafael's concept of what a wife and mother should be; on the other, Olga experienced confusion in coping with the conflicts between what was expected at home (Hispanic) and at work (Anglo). Rafael's refusal to enter couples therapy and his disparagement of disclosure to a female therapist also reflect his strict separation of the sexes into certain prescribed roles. Conceivably, his alcohol problem was symptomatic of frustrated *machismo* vis-à-vis his wife as well as a reaction to the broader scope of frustrations seemingly inherent in cultural transition.

More accustomed to the United States, Olga expressed interest in adopting some of the behavioral options of her Anglo counterparts. However, this put strain on her relations not only with her husband but also with her extended family. The difficulty of meshing her Hispanic heritage with those aspects of the mainstream that attracted her was a major source of emotional distress.

Here the therapists had to act as cultural mediators between two people with differing levels of acculturation to the mainstream. The couple's cultural differences created conflicts in the expectations of themselves and each other. The therapists needed to sort out and identify these cultural differences before they could begin to address the problems that flowed from them.

#### FUTURE DIRECTIONS: TRAINING AND RESEARCH

The phenomenon of cross-cultural transition can raise a host of mental health problems. If the phenomenon goes unrecognized, these problems go untreated, and they can undermine whatever else the patient and clinician have found to bind them together in a therapeutic relationship. Fortunately, the mental health profession is beginning to recognize the need to understand cultural transition and the values of a variety of cultures as part of practitioner training. Training in cultural diversity is currently being proposed as a goal by several professional associations within the mental health field. The American Psychiatric Association, for example, has established a Task Force on Multiethnicity and Cultural Psychiatry. It is the mandate of this task force to increase awareness and understanding of the variety of cultural and ethnic backgrounds within our pluralistic society, and to advocate diagnostic and treatment techniques specifically geared to particular ethnic groups (Foulks, 1982).

In 1985, the American Psychological Association reorganized its temporary Task Force on Minority Education and Training into a permanent

Committee on Ethnic Minority Human Resources Development. Like its psychiatric counterpart, this committee advocates training in cultural diversity as a prerequisite to providing psychological services to ethnic minority populations. In order to accomplish this, the committee has presented to the association a position paper urging that multicultural awareness be added to the criteria used to define the philosophy, goals, and requirements, curricula, practica, and composition of training psychology, just as scientific rigor and clinical expertise currently are used (Committee on Ethnic Minority Human Resources Development, 1985).

Still, the precise professional qualifications necessary to work in a multicultural environment have yet to be defined (Pedersen & Marsella, 1982), though attempts to identify them have been made. As a preliminary, Ridley (1985) presents what is currently being done and what needs to be implemented for the development of psychology programs that have ethnocultural relevance.

#### Current Praxis

1. **Ethical Imperative.** Treatment of culturally different patients by professionals lacking training in cultural diversity is unethical.
2. **Cultural Context Imperative.** All mental health practice occurs in a cultural context.
3. **Legal Imperative.** Professionals who treat culturally diverse individuals without duly certified cross-cultural credentials effectively violate their patients' civil rights.

#### Needed Implementations

4. **Demographic Imperative.** The cultural diversity of mental health professionals should correspond proportionately to the cultural diversity of the society.
5. **Scholarly Imperative.** Cross-cultural mental health treatment must be recognized and legitimized by academia.

Ridley concludes that, although several training modules have emerged, a conceptual, programmatic framework is still needed to develop cross-cultural training in mental health as a discipline.

Though cross-cultural training is not yet a well-defined discipline within the context of mental health, some of the necessary training components are apparent. These components are (1) didactic, (2) clinical, and (3) empirical.

The didactic or teaching component should include incorporating into the curriculum case histories and other readings on each ethnic group studied, which illustrates migration history, demographics, cultural values, family structure (i.e., sex roles), belief systems, personality development, and relations with the dominant culture.

Once trainees have obtained this theoretical knowledge, they should begin to examine each ethnic group's definition of mental illness, health-seeking behavior, treatment expectations, and attitudes and expectations toward mental health practitioners.

The second or clinical component should be a mandatory adjunct to the intellectual foray into the culture that the students have made through readings and lectures. Leighton (1982) proposes that cultural training be built into the clinical rounds made by psychiatric residents, who would be required to treat patients from ethnocultural backgrounds different from their own. The ideal here is to enable the residents to identify their own ethnocultural bias and to become sensitized to cultural differences, presumably only read about; sensitization would be the first step in developing clinician-patient rapport.

The third or empirical component of cross-cultural mental health training differs from the clinical component in that the students' focus is turned inward. Pinderhughes and Pinderhughes (1982) advocate the participation of psychiatric residents in short-term sensitivity groups in which they explore and discuss among themselves their own ethnic backgrounds, as well as the assumptions and stereotypes they attribute to other ethnic groups.

The author's own experience in training practitioners in a cross-cultural mental health clinic was characterized by a combination of all three components. The educational component consisted of teaching a seminar on ethnic minority issues in mental health based on the specific ethnocultural backgrounds of those patients using the clinic. The cross-cultural encounter between clinician and patient was analyzed in terms of special issues, such as transference and countertransference, as well as in terms of the basic therapist-patient dyad. Finally, the clinicians in training discussed with each other their own backgrounds. This experience increased their awareness and sensitivity to cultures other than their own, and led them to call on each other as resources and consultants in the course of clinical practice.

Cross-cultural mental health training is not only useful where racial and ethnic differences exist between patient and clinician. For instance, cross-cultural treatment methods also are needed when the clinician and the patient are racially and ethnically similar but have different socioeconomic backgrounds and/or different value systems, sex role orientations, religions, and educations, and/or when there is a significant difference in their ages (Atkinson, Morien, & Sue, 1979). As a practical matter, then, virtually all

clinical practice can be said to be cross-cultural in nature, and, therefore, all clinicians stand to benefit from cross-cultural training.

Furthermore, Pedersen (1981) suggests indirect social benefits from cross-cultural psychotherapy. In his view, the culture of the future is analogous to a foreign one, requiring similar patterns of adjustment and adaptation, and in fact any new situation, such as new employment, requires us to adjust our roles as well as identities. Thus, Pedersen suggests that the knowledge we are developing to treat its impact on mental health can be applied to help us all adjust to inevitable change.

Research in cross-cultural mental health is another area that demands the highest priority. As Kagehiro, Mejia, and Garcia (1985) so eloquently argue, failure to investigate and incorporate the effects of culture and ethnicity into mental health research results in limited understanding of human behavior.

Historically, research on ethnic minority populations in the United States has been divided into three categories: (1) the inferiority model, where the groups have been identified as socially and intellectually inferior to the dominant group; (2) the deficit model, where the plight of the ethnic groups has been attributed to social conditions; and (3) the bicultural or multicultural model, where the variables of an ethnic group's culture and those of the majority group's are considered interactive and not independent (Sue, 1983; Sue, Ito, & Bradshaw, 1982).

The historical studies cited here are broad, if not sweeping, in their conclusions. What becomes evident is the need to enlarge the number of variables studied in order to obtain more detailed results. To mention just a few, the following considerations should be undertaken in cross-cultural mental health research: developmental stages of ethnocultural identity; ethnic concepts of mental health and illness, for example, attitudes and expectations about mental health care, and culture-specific syndromes and their treatment; effects of cultural transition on behavior and ethnocultural identity, for example, adaptive cultural behaviors, and resilience versus risk factors among different ethnocultural groups; effects of biculturalism and multiculturalism on mental health; analysis of the therapist-patient dyad, including ethnocultural similarity and dissimilarity; the cultural relevance of different therapeutic modalities; and psychotherapeutic process and outcome studies.

Effective cross-cultural mental health research obviously also depends on continued improvement in the development of theoretical models. According to Draguns (1981) these models need to include sensitivity to the interaction of ecology and human behavioral problems, to competence building, and to the healing and helping processes.

Sue and his colleagues (1982) have developed a research model in ethnic minority mental health that can be applicable to cross-cultural mental health as well. First, the authors propose an increase in the quality and quantity of

the research; second, an investigation of the etiology of mental health and illness; third, identification of a methodology relevant to the delivery of mental health services; and, fourth, implementation of the research findings.

Other researchers note the need to evaluate and rate the relative effectiveness of traditional research design. Much of the research in cross-cultural psychotherapy has involved survey or analogue research designs, which, as Atkinson (1985) points out, have their limitations. For example, subjects in analogue and survey studies of ethnic and racial issues usually are aware of the variables studied. Atkinson believes that greater credence should be given to the results of archival studies where participants generally do not know they are being studied.

## CONCLUSIONS

Cross-cultural mental health treatment is recognized more and more as a bona fide specialty area. As our society becomes increasingly pluralistic, mental health practitioners who can competently address multicultural contexts may well be very much in demand.

Cross-cultural mental health treatment can be used in a wide range of circumstances. The treatment techniques can be effective not only in helping the patient through the crisis of cultural transition but also in healing a chronic illness with its source in a certain culture. Sensitivity, understanding, and competence in multicultural contexts benefit not only the culturally different patient but the clinician as well. Indeed, cross-cultural mental health treatment techniques may be useful even when the patient and clinician share the same race and ethnic background. Given the inevitability of differences between patient and therapist, virtually all clinical practice can be seen as cross-cultural in nature. Therefore, a clinician competent in cross-cultural issues is indeed a competent mental health practitioner.

As clinical training, practice, and research in cross-cultural mental health continue, we can expect to see advances in our understanding of the relationship between culture and mental health. Those techniques we develop to cope with individual cultural transition and life in a multicultural setting may translate well to the general human endeavor of adjustment to constant change.

---

***Afro-Americans***

---

**F.M. BAKER**

**HISTORICAL PERSPECTIVE**

This chapter will focus on Black Americans who are Afro-Americans. Their forefathers were Africans, predominantly from nations in western Africa. They lived in tribal communities, where the values of family and the good of the community were emphasized (Pinderhughes, 1982). With the economic exploration of the North American continent, a variety of ethnic groups were used as slave labor. When Africans were found able to survive the environment and the labor of the plantations in North and South America and the Caribbean, they became the primary focus of the slave trade. Following the Civil War in the United States, the progeny of these Africans fought to obtain an equal place in American society.

As the decades passed, immigrants from Ireland, Italy, China, Hungary, Puerto Rico, Cuba, and Southeast Asia arrived in America and displaced Black Americans from jobs. Although African values remained the bedrock of the Black community, the devaluation of persons of African heritage continued to exist as a pervasive, institutionalized pattern of American culture. For many years the history of Black persons was depicted as beginning with slavery in the continental United States. When African culture was discussed, it was characterized as primitive and noncontributory to the

151

development of civilization. Africans, with a history of more than 3000 years (James, 1954), were stereotyped as childlike persons who were illiterate and without culture. This pervasive stereotyping of the "Negro" in literature and the media was directly and forcefully confronted during the Black revolution of the late 1960s and the early 1970s. Subsequently, the images of Afro-Americans portrayed by the media as well as information presented in a broad range of textbooks (Romero, 1969; Salk, 1967), presented the continuity of their culture as well as their rich heritage (Halley, 1976).

The term *Afro-American* is used here to convey the combined heritage of Black persons in America. But that cultural heritage may have a further mixture including Caribbean (West Indian), Native American, and northern European components. Working with persons who appear "Black," it is important to establish the specific heritage within the individual's family of origin. Although there are areas of similarity in perspectives and expectations across these groups, there are many areas that are dissimilar. Therefore, in order to have a context for understanding the behavior, defenses, expectations, vulnerabilities, and anger of Black patients, it is important to ask patients to describe their heritage and the cultural background of their parents and grandparents. This chapter, then, will focus on problems that arise in the psychiatric treatment of Afro-Americans.

### DEMOGRAPHIC DATA

The inaccuracy of the United States Census data on Blacks has been acknowledged to be due to the failure of Black persons to respond as well as to the enumerators' fear of urban neighborhoods. Nevertheless, certain data merit presentation here, in spite of this limitation.

In 1980, Black Americans comprised 12 percent (26.5 million individuals) of the United States population. Fifty-three percent of Blacks were female and 47 percent were male. Forty-four percent of Black women were in the childbearing years, between age 15 and 44. Although Black males outnumber Black females through age 19, the loss of Black males begins in the age 20-24 category, with a significant difference noted in the 40-49 age group. This sex difference is sustained throughout the life cycle. Some 29.9 percent of the Black population were below the poverty level compared to 9.4 percent of the White population.

The average number of persons per Black family was 3.72; per White family it was 3.9. In the Black population there were 1,568,417 female-headed households without a husband present with children under age 18. For Whites, 3,166,397 resided in female-headed households without a husband present with children under age 18. Although it is often presented as a

concern in the Black community, Whites have three times the single-parent households of Blacks.

Knowledge of these demographic data provides an important context for the therapist. The middle-aged male who grieves over the loss of his teenage "buddies" and the young adult Black female who bemoans the absence of male partners are discussing the personal reality of the census data. Although emphasized, female-headed households are *not* the majority family structure in the Black community and are related to socioeconomic level. Finally, particularly in teenagers and young adult patients, the presence of the risk of violence (suicide or homicide) as an ongoing threat to life can be a daily reality. The therapist should be aware of this chronic tension as another etiology of self-medication with drugs that are not always obtained legally.

### THE BLACK FAMILY

Several authors have debated the structure and function of Afro-American families, and Mullings (1985) provides an excellent review of their different perspectives.

Moynihan (1965) characterized Black families as a tangle of pathology due to their matriarchal structure. As noted by Bell, Bland, and Houston (1983), sociological and psychological analyses of the Black family have frequently led to the erroneous premise of a matriarchy within the Black community. Consequently, Black women have been seen as unfeminine, castrating to their men, promiscuous, and commonly on welfare. In turn, Black men have been characterized as inadequate father figures and as emasculated men unwilling to provide for their families. Other authors countered this characterization of Black families by identifying the racism within American society that restricted education (Hill, 1971; Pinderhughes, 1982), employment, and housing opportunities for Black Americans and assigned many to an underclass existence that produced aberrant behaviors.

The importance of the family within the Afro-American community has evolved as part of the African heritage. In addition to community welfare as opposed to the welfare of the individual, African cultures emphasized the importance of children; the grandchild was the fruition of the grandparents' generation. The birth of grandchildren ensured the continuity of the family (Wylie, 1971). In contrast to many northern European Americans, the Afro-American family is an extended family including nonrelated persons (adults and children) who have been adopted or absorbed into the family unit (Martin & Martin, 1978).

Although chattel slavery separated parents and children by auction and

by death, family units comprising biologically related and nonbiologically related individuals formed to provide support, care, and comfort for their members as well as survival skills and key information (Gutman, 1976). These units survived slavery and continued during the period of reconstruction (Johnson, 1982). Similar patterns are seen today in the extended family units that are found in Afro-American communities (Martin & Martin, 1978; Stack, 1974).

Hines and Boyd-Franklyn (1982) reported that the Black extended family provided important intergenerational support. ~~Elder~~ grandparents and similar-aged individuals provided the wisdom of ~~their~~ years of experience, maintained a favored role as the family historian, and were productive and useful members (Baker, 1982; Seiden, 1981). Their children continued some of the traditional foci of the prior generations and began to develop their own approach to a variety of situations.

Davis (1968) discussed the role of the family in developing an adequate identity. She emphasized the importance of the family in providing a series of networks of self-support and stressed the importance of identifying the patterns of familial interactions. Although some authors described the pathology of Black families (Moynihan, 1965), other workers (Hill, 1971; Hines & Boyd-Franklyn, 1982; Johnson, 1982) have emphasized the strengths of Black families, the extended kinship network, and the adoption mechanism that provides financial and personal resources as well as role models. Thus the therapist focusing upon the nuclear family may miss important figures of support and authority in the extended family of the Afro-American. Further, the tension in the relationship of a couple may reflect ambivalence or animosity between one partner and the adopted mother of the other partner who may not be a biological relative.

Hines and Boyd-Franklin (1982) and Lewis (1983) reported on egalitarian relationships within Black families. Since Moynihan's initial publication in 1965, the concept of the Black matriarchy has been well identified as a myth. In Lewis's sample of well-functioning, working-class Black families, the families were slightly above the poverty level. In addition to the extended family network, church and scouting were important outlets and avenues of socialization for the family members. Too often the confounding influences of racism, social status, and poverty have not been noted (Pierce, 1970, 1974). When survival becomes the focus of family life, Lewis (1983) found that Black families moved toward a more rigid role definition with the stronger partner, more usually the male, setting family policy and making decisions.

What of the single-parent families? Here, also, the extended family played a moderating role (Hill, 1971). Alternative care givers for the child, and respite for the mother, as well as emotional support and financial assistance

can be provided by extended family members. The pregnant teenager has remained within the Black family (Hill, 1971), not ostracized even when there were strong cultural taboos against out-of-wedlock pregnancies in American society.

Pinderhughes (1982) has discussed the consequences of the victim system—particularly upon the Afro-American male. Unable to find employment to support his family due to limited education in a system that fulfills its prophecy of his failure (Rosenthal & Jacobson, 1968), the Black male may become negative, irresponsible, manipulative, exploitative, violent, remote, or absent. In this situation, if the mother cannot assume a strong role, the family is in serious trouble. In a family beset with financial and personal crises, with the woman as the only available parent, her role may become exaggerated and she may become the pathway for all family interactions, with the result that the children then respond to the mother's mood and wishes rather than to their own needs; and the mother relates to the children as a fused group (Hines & Boyd-Franklin, 1982; Pinderhughes, 1982). Interactions and relationships with uncles, cousins, grandparents, or the "church mother" may refocus the mother-child interaction and provide alternative significant others for both mother and child (Martin & Martin, 1978).

The therapist must appreciate the resources within the Afro-American family and mobilize them to provide effective care for the Black patient. Both the single-parent family and the working-class Black family as well as middle-class Black families may have a network of extended family members who can provide emotional and financial support in a crisis. In some cases part of the therapeutic intervention is the remobilization of this extended kinship network. Other important supports exist within the Black community. (The role of religion and the Black church is discussed in Chapter 3 of this volume by Griffith & Young.)

## ISSUES IN CLINICAL PRACTICE

Socioeconomic status may influence the individual's access to psychiatric services. The Black patient's knowledge of available services is influenced by life experiences and family comments. The history of racism in America is presented today in the stories of Black grandparents about segregated facilities, the loss of life on the way to the "Black" hospital, and the hostility of health professionals to Black patients. As most Black persons have experienced some negative interaction based only upon their skin color, the reception that a Black patient may receive in a specific setting remains an uncertainty. This often produces an anticipatory anxiety in Afro-American patients as they approach a health care institution (community mental

health center, community clinic, or general hospital) or a private practitioner. As noted by Bell and colleagues (1983), Black patients can be defensive, hostile, and nonverbal (in an initial meeting in a new setting), thereby adapting to powerlessness. They often experience fear and distrust of the White therapist. If Black patients believe the goal of therapy is to maintain the status quo and their place in society, they may be suspicious of the motives of Black as well as White psychiatrists.

Adams (1950) discussed countertransference and transference in the context of a segregated society. He emphasized the effects of the environmental covenants (segregated facilities and housing) and the racist injury for Afro-Americans that results from prejudice. For the White therapist he commented about feelings of perplexity and uncertainty in the presence of a Black patient. Further, he warned of the danger of the White therapist and the Black patient focusing upon their differences. In 1950, the feelings of aggression and hate experienced by a Black person were concealed in an attitude of submission and subervience. Feelings of insecurity in White therapist related to (1) the physical appearance of the Black patient, (2) therapists' unfamiliarity with Afro-American culture and problems, and (3) even doubt concerning the patient's ability to pay. In an effort to conceal their insecurity and guilt feelings, therapists unwittingly may be oversympathetic and indulgent or may be patronizing or hostile. The therapist's greatest danger may be a tendency to oversimplify and ascribe all problems of Black patients to cultural and racial conflict. Such a response from the therapist signals to the Black patient the ambivalent racial attitude of the therapist, and this results in the effective thwarting of the formation of a therapeutic alliance. The Afro-American patient should be able to expect, minimally, a neutral environment in the clinical setting.

Jones, Gray, and Jospitre (1982) reported on a mail survey of psychotherapists who treated Black men. Psychiatrists treating Black male patients reported the following factors as the most important in successful treatment of Black males: empathy; patience; supportiveness; tolerance; and the ability to listen and indicate directions without leading. These therapists also noted that the racial issues must be put in perspective, that the therapist must be knowledgeable, and that the therapist must gain the patient's trust.

Although the civil rights movement and the Black revolution of the 1960s removed many overt barriers of segregation and confronted the covert barriers within institutional settings, the myths that Black Americans were welfare mothers, underachievers, and marginal persons in pathological families continue in the 1980s. A Black man or woman entering psychiatric treatment expects the therapist to have some knowledge of the implications and effects of racism upon Afro-Americans in American society. The therapist should listen with an attentive and critical ear to the issues, incidents, and

experiences that brought the Black patient into treatment. This facilitates the development of a therapeutic alliance in which the patient is accepted as a worthwhile human being, who with support and understanding can address the dysfunctional adaptive styles, destructive defenses, or the loss of contact with reality that brought him or her into treatment. If a Black patient feels rejected or devalued by the therapist, he or she is likely to discontinue the treatment.

Although it is helpful if the therapist is Black because the therapist can serve as a role model, this is not necessary to accomplish the therapeutic task. What is required for successful psychotherapy with a Black patient is empathic, sensitive, and inquiring concern. This point has been emphasized by several authors (Bell et al., 1983; Bradshaw, 1978; Brantley, 1983; Spurlack, 1982). Adebimpe (1981) cautioned that disparities in background between therapist and patient can result in errors of data collection due to differences in vocabulary, modes of communication, value systems, and expressions of distress.

The strength of the extended Black family and the institutional racism manifested by American society pressured the Black family into tolerating unusual behavior. It has been reported that Black persons did not suffer from mental illness during slavery because of the protective nature of chattel slavery (Bevis, 1921; Malzberg, 1963). Historically, Afro-Americans were excluded from the health care system and depended upon indigenous healers. Prudhomme and Musto (1973) noted that the low insanity rate for Blacks was often interpreted during the nineteenth century as a result of the comforts of slavery or the dull strength of the uncivilized.

When the tolerance threshold of the family or the community was reached, Black persons were brought to a medical facility for evaluation. As payment issues continue to be determinants in the locus of provision of care, a significant proportion of Afro-Americans were treated in state hospitals or other public facilities. The family and significant others expected the patient to be gone a long time and, if released, to be "different"—not necessarily well. Mental illness was described as someone's "going off," and there was little recognition and understanding of the range of psychiatric illness, that is, depression, psychosis, personality disorders, substance abuse, and organic brain syndromes. The geographical location of the patients also influenced their entry into treatment. Psychotic delusional behavior was tolerated less in a small apartment in a housing project than in a rural farming community. Thus the definition and identification of mental illness were narrowly focused, and treatment was the "warehousing" of the patients.

In the 1960s, civil rights leaders emphasized the positive aspects of Afro-American culture and the longitudinal history of Black Americans. Such leaders confronted the institutional racism that stereotyped Black

Americans, restricted their life options, and directed Blacks into second-rate career paths, residences, and health care systems (Wilcox, 1973). The significant improvement in self-image for Black Americans resulted in more assertive behavior and in increased expectations. With the introduction of neuroleptics and antipsychotic medication in the late 1950s, the treatment of psychotic symptoms was revolutionized (Langsley, 1985). The length of stay in treatment facilities was significantly reduced, and alternatives to the large state hospitals were explored. The initiation of federal funding to build mental health treatment facilities within local communities then centered psychiatric services in the community. The increased visibility of mental health facilities and specific outreach programs to service Black populations increased the knowledge within the Black community about psychiatric symptoms and treatment options. With community participation mandated on the boards of these facilities, community leaders became active participants in policy decisions. Although the degree of effective participation varied from center to center, the Black community through its leaders participated in discussions that defined illness, addressed the various treatment modalities, and assessed outcomes (Bragg, 1982).

With their increased expectation of institutions, Afro-Americans sought help at the CMHCs and sometimes demanded aid that psychiatry could not provide. Clarification of the "walk-in customer's" request became an important task for triage personnel (Lazare, 1972, 1975). Psychiatry could treat specific psychiatric illness, but its ability to influence social welfare legislation and housing codes was based on the individual votes of psychiatrists, not on their skills as physicians. The advisory councils of CMHCs served as a community nucleus to address these social and economic factors that are significant environmental stressors for poor Afro-Americans (Bragg, 1982).

The deinstitutionalization of state hospital patients was catalyzed by several factors, among which were the use of neuroleptics and the existence of CMHCs. A long-absent family member returned home to receive treatment locally at a CMHC, possibly with instructions to continue taking medication. It was often unclear whether the illness was cured or in remission and what the patient's significant others could do to maintain the well-being of the patient. There was significant anxiety about the potential for unusual or violent behavior and concern about the true availability of CMHC staff. Black patients without extended family and difficulty with treatment compliance joined the number of homeless persons in our cities. In the world of homeless people, it is suggested that between 25 and 50 percent have serious and chronic forms of mental illness (Arce & Vegacre, 1984).

Today, 10 years down the road, American society is discussing mental illness openly. Some private psychiatric hospitals advertise their treatment of depression and alcoholism. Political, movie, and sports personalities reveal

their personal histories of psychiatric illness and treatment. There is an increasing understanding by many Black Americans that specific behaviors are signs of mental illness and that treatment can be sought at the general hospital and CMHC as well as at the area state hospital. The family member is expected to return home improved and continue treatment locally at a CMHC. For patients with recurrent illness who are noncompliant with medication, their families complain that they are released too soon. When the family as well as the patient is involved in the treatment plan, treatment compliance and realistic expectations of care are defined effectively for all and better compliance is obtained (Jones & Seagull, 1977).

The treatment compliance of Black patients is influenced by the quality of the interaction between the therapist and the patient (Bragg, 1982). The ease of psycholinguistic communication, the mutual understanding of cultural references, and the avoidance of confounding the transference-countertransference issue with ethnocentrism (racial stereotyping) will facilitate the formation of a therapeutic alliance. Although this type of interaction is facilitated by a Black therapist and positive role modeling is possible, the therapist can be non-Black, effective, conversant with cultural themes, and knowledgeable about the historic context of Afro-Americans and psychotherapy.

### CLINICAL PRACTICE

Before discussing specific psychiatric illnesses in Black populations it is important to review the historical problem of psychiatric diagnoses in Black patients. Bell and colleagues (1983) summarized the myths and stereotypes that resulted from racism and influenced diagnoses, treatment, and research decisions. From the early notions about the biological inferiority of Blacks, the period of reconstruction saw the falsification of census figures to reflect an increased incidence of mental illness in Blacks who had "lost the benefits of slavery" (Deutsch, 1944). In the early 1900s Blacks were characterized as "too emotional, sexually promiscuous, lazy, in need of authority, criminally inclined, and unintelligent" (Bevis, 1921). During slavery there was no provision for mentally ill slaves. When mental hospitals were established in the 1800s, only a few northern facilities admitted Afro-Americans to segregated units. The majority of psychiatrically ill Black persons were admitted to almshouses or placed in jail (Prudhomme & Musto, 1973).

In the 1900s differences in diagnostic patterns between Black and Whites were noted. Cannon and Locke (1976) analyzed admissions to state and county hospitals. They found that White males were diagnosed with alcohol disorders while Black males were diagnosed as schizophrenic. When

discharged diagnoses from general hospital inpatient services were reviewed, the predominant discharge diagnosis observed in both Black males and Black females was schizophrenia, and in White males and females the discharge diagnosis was depressive disorder. The international studies of schizophrenia identified the overdiagnosis of schizophrenia by United States psychiatrists (Cooper, Kendell, & Gurland, 1972).

Owing to racial biases in diagnoses, Blacks were more likely to be diagnosed as schizophrenic (Everts, 1914; Fisher, 1969; Frumkin, 1954). Unfortunately, reports by several authors over the years emphasized that Afro-Americans either were too inferior ~~to be~~ <sup>to be</sup> included in the intrapsychic framework to become depressed (Wilson, 1957). ~~This~~ <sup>This</sup> resulted in a misdiagnosis and underdiagnosis of affective illness in Black persons. Recently, other authors have presented evidence to dispel this erroneous assertion about Afro-Americans (Bell & Mehta, 1979; Helzer, 1975; Jones, Gray, & Parson, 1981).

### *Black Suicide Attempters*

A suicide attempt has been defined as "an intentional self-inflicted injury (including ingestion), unless there is strong evidence both in circumstances and in the patient's statements that there was not even any partial ambiguous self-destructive intent" (Weissman, Paykel, French, Mark, Fox, & Prusoff, 1973). Suicide is defined as the intentional self-termination of one's life. Prudhomme (1938) provided the first discussion in the literature of suicide in Afro-Americans. Having discussed the intrapsychic conflicts existing for the Black American whose physical characteristics were labeled as "bad" by the majority groups, Prudhomme noted that the number of actual suicides among Negroes was unmistakably smaller than in Whites and the number of attempts at suicide among Negroes was proportionally as great as or even greater than in Whites. The Negro was considered a neurotic group, this neurotic state being brought about through a system of inhibition and repression (Prudhomme, 1938). He reported that the lower incidence of completed suicide was due to factors such as the restricted access to economic opportunity, rural living, and group solidarity facilitated by racism. Several decades later, Benedis (1969) studied a New York sample of attempters. He emphasized the roles of tenement living, economic exclusion, and racism in the etiology of suicidal behavior by Black young adults. In a sample of Black suicide attempters studied in Newark, New Jersey, Kiev and Anumonye (1976) found interpersonal discord in the context of alcohol abuse as a precipitating pattern. Fosseliat (1975), Christian (1977), and Davis (1979) all emphasized the usually lower suicide attempt rate in Black women. Factors that helped to explain this low incidence included the Black family, the

Black community, and the Black church. These institutions provided support to persons alienated from society with few options for activities and experiences to enhance self-esteem. Apparently, these options were not utilized by Black males or were more readily utilized by Black females.

The effect of psychosocial tension and economic stressors upon the Afro-American life cycle has been discussed by Baker (1987). Owing to the self-fulfilling prophecy of school failure (Rosenthal & Jacobson, 1968), economic options are narrowed in late adolescence, and Black teenagers and youth are thwarted in their adult development. Alternative and aberrant routes, such as street life and teenage pregnancy, result in individuation from the family home and establishment of their own residence. If young Black males are caught in the quagmire of the street, the rage of being excluded from the mainstream of American life and being powerless in the broader society may erupt in violence. If this violence is directed toward the self, a suicide attempt results. If directed toward others, Black-on-Black homicide results (Poussaint, 1975). If the Black males survive, they may be caught in an illegal act resulting in incarceration and the possibility of spending 10 to 25 years in jail (Baker, 1984, 1985).

In a recent review of Black suicide attempters in New Haven, Baker (1984) found that Black women who attempted suicide were single, stressed, had had an argument with a significant other, and their self-injury was an impulsive act. Although similar in marital status, precipitants, and impulsivity to White female attempters in this sample and in the literature (Weissman, 1974), the suicide attempt rate for Black females was 11.88 per 100,000 compared to a White female rate of 41.43 per 100,000 for the New Haven Standard Metropolitan Statistical Area. Black males in her sample were older, had a prior psychiatric history, were in ongoing treatment, and had more severe psychiatric diagnoses. Both Black male and Black female suicide attempters had an increased history of psychiatric treatment; 76 percent of males and 64 percent of females had had prior treatment. Thirty-five percent of males and 54 percent of females had made a prior attempt. This study raised specific questions regarding suicide attempters in general and Black suicide attempters specifically. In her recent review of the literature on Black suicide, Baker (1987) emphasizes the increased risk for poor Black adolescents who are only marginally involved in society due to school failure or inability to obtain employment. Specific recommendations and primary preventive strategies are included in that report.

As the locus of psychiatric care moves to the general hospital, CMHCs, and emergency rooms due to deinstitutionalization, are the patient populations in these settings changing? Is a greater percentage of patients in current treatment or are persons who have had prior psychiatric treatment attempting suicide and seeking care in these settings? Are the diagnoses of suicide

attempters becoming more severe? Is the proportion of attempters with no prior psychiatric contact or psychiatric treatment history declining? Further studies of suicide attempters, evaluated in various settings, are indicated to clarify these points. Additional replication of Baker's findings in other settings is needed before generalizations can be made. Recent studies in both Black and White attempters (Task Force on Youth Suicide, 1987) confirm an increase in attempts by persons aged 20 to 24, particularly in White males (Bogard, 1970) and Black males (Frederick, 1978).

Specific treatment strategies for Black **suicide** attempters were presented by Baker (1984). Recognizing the need to clarify the diagnoses based upon the assessment of the patients, and, if available, past symptoms from an old medical record or family member or friend, a current diagnosis should be developed. Suicide is a life-threatening behavior. It is not a psychiatric diagnosis, but rather the manifestation or result of a specific psychiatric disorder. A change in the patient's diagnosis based upon current assessment may be an important and significant intervention in view of the treatment implications for different diagnoses. As noted in Baker's sample of Black male attempters, 41 percent were schizophrenic and 18 percent were bipolar.

It is important to recognize the supportive role of the extended family for Afro-Americans and the way in which interpersonal conflict can precipitate suicide attempts. Often, the relative who accompanies the suicide attempter has been involved in the events that preceded the attempt. The initiation of couple- or family-oriented crisis intervention in the ER can clarify the stressors and their meaning to attempters and their families and allow assessment of the family dynamics. The family's willingness to enter treatment often serves to influence the decision of the attempter to accept therapy and remain in treatment (Baker, 1984). The current crisis can be reduced and everyone in the system encouraged to use a walk-in center during a future crisis to talk through the problem. This intervention can help the family to recognize more easily when something is wrong in the future. Public health education activities taking place in churches and community centers would increase the awareness of the family members of psychiatric patients by helping them to understand the implications of changing behavior(s), thoughts, and mood(s) and would enable them to identify a decompensation in the patient. Also, such educational programs could enable a family to identify a Black adolescent or youth as severely stressed without the youngster attempting suicide to convey his or her distress. Such increased sensitivity by the collective family to the impending decompensation of a member will obviate the need for dysphoric adolescent females or psychotic young males to "act out" their increasing difficulty so as to bring it to the attention of the family (Rubenstein, Moses, & Lidz, 1957).

An 18-year-old single Black female resided with her mother and younger brother. Completing high school, she was anxious about obtaining employment, but unsure about her career direction. Her mother supported the family by working as a licensed practical nurse. The patient for several years had been responsible for meal preparation, household tasks, and the care of her younger brother. A maternal aunt visited frequently to "look in on" her sister's children. Facing graduation, the increased tension between herself and her little brother, and the breakup with her first boyfriend with whom she had been sexually active, she attempted an overdose by taking three 10-mg Valium tablets prescribed for her mother's back pain. After taking the pills, she called her aunt who took her to the ER.

Initially silent and withdrawn, she was reinterviewed with her aunt who presented a picture of a conscientious, reliable, and responsible young woman who had assumed the role of surrogate mother to her younger brother. The accidental death of her father, an innocent bystander to a street fight, had created financial insecurity for the family. Her mother worked swing shifts as well as overtime to maintain a firm economic base for the family. As her younger brother became a teenager, he began to resent the restrictions and test the limits of his sister's authority. Their mother, tired from frequently working two consecutive shifts, told her children not to argue. When the therapist suggested that it must be confusing to be both a parent and a child as well as to be facing leaving school, the patient became tearful and began to verbalize her ambivalent feelings toward her mother and brother and her anger at the loss of her boyfriend because "I always have to stay home and watch the kid."

Referred for family therapy, the children, mother, maternal aunt, and uncle-in-law were seen. The therapy focused on role definition, recognition of the different needs of all family members, and establishing mechanisms for family communication. The aunt and uncle were concerned and involved, providing both emotional and financial support. The aunt and uncle assumed the role of disciplinarian in place of the patient. The aunt established a schedule of biweekly outings with the teenage son and the family developed its own list of responsibilities for each member and the consequences of failure to implement the responsibilities.

Finally, the daughter and her mother were seen separately and their problems with communication were addressed. The daughter felt unappreciated, and she was concerned about the narrowness of her own life. The family established a plan so that the mother could take a long-delayed vacation and would have her evenings out. Mother and daughter clarified the ground rules and expectations concerning dating.

### Alcohol Abuse and Alcohol Dependence

The use of alcohol by Afro-Americans has varied during their history in America. At the height of the Black temperance movement in the 1840s and 1850s, abstinence from alcohol was synonymous with freedom from slavery and moral uprightiness. This resulted in increased respect and social opportunity (Baker, 1985). Slavery and demon rum were seen as examples of moral depravity. Chronic drunkenness was rare among Blacks at that time. The 1880 U.S. mortality statistics for deaths due to alcoholism or liver disease reported a rate per 1000 deaths from **cirrhosis** of "6.6 for Irish, 2.7 for Germans, 2.5 for whites, and 0.7 for coloreds" (U.S. Census Office, 1886, p. xvii). Following the Civil War, temperance was emphasized by Afro-Americans as a means by which one could attain economic and political equality and maintain social respectability. Only in the early 1900s when the temperance movement became associated with Black disenfranchisement and White supremacy did Afro-Americans withdraw from a movement that would reverse the gains established at emancipation (Herd, 1985).

The Black migration of the 1920s and 1930s, coupled with an economic recession and unemployment, involved more Black people in the production, sale, and consumption of alcohol. Increasing use of alcohol in the Black community was associated with the employment of Black entertainers in northern clubs ("speakeasies") and their involvement in the "night life." From this period on, alcohol progressively became a public health problem in the Black community (Herd, 1985).

Today, mortality statistics are alarming. Herd (1983) reported that seven cities (Baltimore, Chicago, Detroit, Los Angeles, New York, Philadelphia, and Washington, DC) accounted for 50 percent of *all* cirrhotic deaths occurring in Blacks. The cirrhosis mortality for Black males ages 25 to 34 was 10 times the cirrhosis mortality rate for White males of the same age. When all age groupings were reviewed, the mortality rate for Afro-Americans was twice that of Whites (Herd, 1983). Gary and Gary (1985) noted that, although Black women were more likely to be abstainers, when they did drink they were more likely to be heavy drinkers and to participate in a relatively high percentage of escape drinking. Further, the age-adjusted death rate per 100,000 for females with chronic liver disease and cirrhosis of the liver was 7.0 percent for White females and 14.4 percent for Black females (DHHS, 1983). Cirrhosis was identified as one of the six causes of the observed excess deaths in Blacks between 1979 and 1981 (Task Force on Black and Minority Health, 1985). In males and females up to age 45 cirrhosis was responsible for 4.9 percent of the excess deaths observed in Blacks compared to Whites. In males and females up to age 70 cirrhosis was responsible for 3.7 percent of the excess mortality. Clearly, cirrhotic deaths were a particular issue for Blacks below the age of 45.

Leibach reported in 1975 that 15 to 25 years of heavy drinking was required for cirrhosis to emerge. Johnson (1975) noted that alcoholism in Afro-Americans was a disease of late adolescence and early adulthood. Bell, Thompson, and Lewis (1985) emphasized that a 35-year-old Black male being evaluated for hallucinations can have a drinking history of 20 to 22 years. Robin, Murphy, and Breckenridge (1984) showed that young Black men drink heavily and start at a younger age; one out of eight of their Black subjects reported having a drink before age 11. Further, Viamontes and Power (1974) reported earlier drinking among Blacks from a lower socioeconomic background in comparison to Whites. Primm and Wesley (1985) discussed the treatment of the multiply addicted Black alcoholic.

Although the studies are few, there are some data concerning Black female alcoholics. Miller, Lescault, and Heller (1980) reported on their sample of 405 females, of whom 31 percent were Black. In this sample, Black women were younger, had lower educational status, were more likely to be receiving welfare assistance, tended to be Protestant as opposed to Catholic, and were less likely to have an alcoholic nuclear family member than White women in the study. The reader is referred to the work of Gary and Gary (1985), which provides a comprehensive review of the current studies of Black female alcoholics.

The larger society's attitude toward the use of alcohol will require change. Currently, media present alcohol use as an enjoyable, sophisticated, and relaxing activity. The increasing activities of Mothers Against Drunk Driving (MADD) are presenting the negative consequences of alcohol use.

A 32-year-old single Black male (W.S.) was brought to the emergency room of a general hospital by the police. He was tearful, distraught, and reported suicidal ideation. He also reported accusatory auditory hallucinations. Alcohol had been used prior to his ER arrival. He was referred for inpatient treatment of a schizoaffective episode, depressed.

Physiologic evidence of a withdrawal was identified, after which a careful substance abuse history was obtained. The patient, W.S., began drinking at age 13 "to be like Dad." Within a year he was drinking over 2 pints of alcohol daily, had dropped out of school, and was of concern to his family. The death of his father ended all attempts by W.S. to control his drinking. A history of frequent arrests for disorderly conduct and frequent ER visits for treatment of alcohol-related injuries began. When he was age 23 his mother, brother, and other family members refused to attempt to help him anymore. He was ostracized. At age 31 he began a relationship with a 21-year-old single woman whom he met in a bar. His admission was precipitated by his celebration of the birth of his first child, a son.

Treatment began with a focus upon diagnosis. By history and from old medical records it was established that W.S. was dysphoric, distraught, and hallucinating whenever he used alcohol. In group and individual therapy he was confronted consistently about his alcoholism so as to break through his denial. Biologic and extended family members refused to participate in treatment because "we went through all of this 10 years ago . . . and he didn't change."

In individual therapy with a Black male therapist, issues of self-esteem and "proving oneself" were addressed. Maternal and paternal grandparents being deceased, his alcoholic father had been his only male role model. No extended family members lived near the family, and his mother was not involved in church. Trying to prove his manhood by "being able to drink with the guys," W.S. was unable to control his drinking.

Therapy focused upon his ability and need to take control of his life. When his feelings toward his son were explored, W.S. was adamant in wanting to be "a real father to my son," to be available, responsive, and supportive. Identifying that this was the relationship W.S. missed with his father, W.S. began a mourning process for the lost opportunity for such a relationship with his father, and the loss of 18 years of his life.

The treatment focus shifted to a definition by W.S. of the various roles involved in being a man: friend, husband, lover, father. Clarification of his lack of work skills, the lack of mastery in any role, and the lack of effective male role models was developed. Within the therapeutic alliance, the therapist moved from rejected distant father to a caring mentor, similar to a maternal uncle with whom W.S. was close until the uncle died of a heart attack (W.S. was 12). As W.S. began to feel strong enough to take a risk, he was referred to a rehabilitation day hospital program. He maintained sobriety with Antabuse and Alcoholics Anonymous for 9 months, and his girlfriend joined him in couples therapy and they began an exploration of their expectations in the relationship.

### *Misdiagnosis Versus Differential Diagnosis*

Historically, Black persons who reported auditory or visual hallucinations and paranoid ideation were diagnosed more frequently as schizophrenic (Cannon & Locke, 1976). The disparity between the prevalence of schizophrenia and manic-depressive illness in England and that in the United States (Cooper et al., 1972) further stimulated a review of American diagnostic procedures. The past 10 years have seen the beginning examination of psychiatric diagnosis by American psychiatrists (Taylor, 1978).

The presence of affective illness in Black persons has been underdiagnosed because in the past Black persons were regarded as too jovial to be depressed or too impoverished to experience object losses (Prange & Vitols, 1962). Several authors (Adebimpe, 1981; Bell & Mehta, 1979; Jones et al., 1981) studied Black patients and summarized their patterns of presenting illness.

In a multihospital, collaborative study sponsored by the National Institute of Mental Health, Black and White patients were screened for the presence of depressive symptoms by two clinicians prior to entry into the study of the diagnosis of depressive illness. Thus clinical features of depression were similar for Black and White patients in the study. Although the authors controlled for age, sex, and social class, White patients were diagnosed more often as depressed and Black patients were diagnosed more often as having some form of schizophrenia. The authors of this study (Raskin, Crook, & Herman, 1975) found it difficult to explain these diagnostic differences. Adebimpe (1981) emphasized the importance of psychiatrists' knowledge of these findings. He argued that factors that could contribute to misdiagnosis were the social and cultural distance between patient and clinician, stereotyping of Black psychopathology, false-positive symptoms, biased diagnostic instruments, and the combined effects of various sources of diagnostic error.

Jones and colleagues (1981) demonstrated that psychotic symptoms in Black persons were not pathognomonic of paranoid schizophrenia. Further, the work of Bell and Jones and their colleagues questioned the frequently taught axiom that bipolar patients were college educated, middle-class, and usually White. Poor Black patients also manifested the symptoms of bipolar illness that responded to treatment with lithium carbonate and neuroleptics. Studies by Vitols, Waters, and Keeler (1963), Liss, Weiner, Robins, and Richardson (1973), Sletten, Schuff, Altman, Ulett (1972), and Singer (1977) demonstrated that hallucinations and delusions occurred more frequently among Black persons in the populations these authors studied. These findings led Adebimpe (1981) to caution against making the diagnosis of schizophrenia in Black patients based solely upon these symptoms, which also were seen in mania, psychotic depression, chronic alcoholism, and acute organic brain syndromes. Adebimpe cautioned that if hallucinations and delusions occurred more frequently in any group of patients there was a likelihood that schizophrenia could be overdiagnosed in that patient group. Two well-designed multicenter studies demonstrated the diagnostic disparity between Black and White patients with the same psychopathology. Simon, Fleiss, Garlans, Stiller, and Sharpe (1973) compared the diagnoses of psychiatric researchers who used a structured mental status interview with the diagnoses of the hospital psychiatrists in nine New York State mental hospitals. They found that race and diagnosis were associated strongly based on

the hospital clinician's diagnosis, with Black patients diagnosed as being schizophrenic and White patients diagnosed as having affective illness.

The presence of psychotic symptoms in an Afro-American individual should stimulate a meticulous diagnostic effort. The differential diagnosis of psychosis (Slaby, 1981) should begin by obtaining all available historical data from past medical records, from immediate and extended family, and from the last place of residence (hospital, home, or halfway house). The individual may be unable to answer questions regarding past psychiatric symptoms, past hospitalizations, substance use, family history of medical and psychiatric illnesses, current medications, and toxic exposures due to occupation or environment.

The importance of ascertaining prior substance abuse is key to preventing a misdiagnosis of schizophrenia or affective illness. Further, the possibility of unsuspected drug exposure should be explored carefully for the etiology of psychotic symptoms in a previously well-functioning person who has no history of drug use. In Washington, DC, and Los Angeles, the use of phenylcycidine (PCP) was endemic in the 1970s, and its use continues in the 1980s (Ayd, 1979; Fauman, 1976). Although the presentation varies based upon the amount of PCP ingested (Aronow & Dane, 1978; NIDA, 1979), certain behavioral patterns and physical findings are suggestive. An Afro-American college student was brought to an infirmary for evaluation by her cousin for irritability, tenseness, and a complaint of numbness in her extremities of several hours' duration. Nystagmus was evident. When asked to give her birth date, the patient was unable to recall the date, and, frustrated, she battered the office telephone to fragments. Subsequent history revealed that she had inhaled a marijuana cigarette 4 hours before her evaluation that unknown to her had been saturated with PCP. A urine test was positive for PCP.

The practice of "speedballing" (using a mixture of heroin and cocaine to produce a sustained euphoria and avoid the cocaine "crash") may produce a psychosis with dysphoria. An individual complaining of paranoid ideation and Lilliputian hallucinations (visual hallucinations of little people) whose psychosis resolves without intervention within 2 hours has manifested a cocaine psychosis (Goldfrank, 1981). A complaint of formications (a sensation of ants creeping upon the body—"cocaine bugs") may facilitate the diagnosis.

Cultural practices should be explored also. An African male convinced his Afro-American wife to ingest a mixture of juices that contained 2 tablespoons of nutmeg. The wife's symptoms of visual hallucinations, time distortion, depersonalization, and paresthesias subsided in 12 hours from the time of ingestion without psychopharmacologic intervention and only supportive monitoring (Faguet & Rowland, 1978). An inappropriate diagnosis of brief reactive psychosis was avoided by a detailed history.

Caffeinism due to excessive ingestion of caffeine-containing beverages and the possibility of environmental occupational toxic exposure are other etiologies of psychotic symptoms to be explored. A stream contaminated by industrial waste may have fish contaminated with a large amount of an organometallic compound such as methyl mercury (Felton, 1972). The ongoing vigilance for alcoholic hallucinosis and alcoholic withdrawal delirium can prevent the misdiagnosis of these presentations. Finally, the manifestation of psychiatric symptoms due to medical illness such as thyroid disease (Davidoff, 1977) or endocrine disorder (Tonks, 1977) or due to medications, for example, steroids to treat sarcoidosis and systemic lupus erythematosus (SLE) in Black patients (Boston Collaborative Drug Surveillance Program, 1972), must be considered.

H.T. was a 35-year-old single Black male with a psychiatric history beginning at age 20. Diagnosed as a paranoid schizophrenic, he had been maintained on 25 mg of prolixin decanoate intramuscularly at 2-week intervals for 6 years. He had been stable and asymptomatic for 4 years. Within a 4-day period, he became increasingly agitated. Reporting auditory and visual hallucinations of God and the devil, H.T. began pacing and sleeping less than 2 hours in a 24-hour period. He was evaluated in an emergency room, and a diagnosis of acute decompensation in a chronic schizophrenic state was made. He was referred for inpatient treatment, and his mother and sister were interviewed. Two recent stressors were revealed: the return of a recently separated brother into the family household and the decision by an adopted brother to drop out of a local community college. H.T. continued to have a hostile relationship with his separated alcoholic brother, who denigrated H.T. when drinking. The family reported that H.T. episodically drank one or two cans of beer per week. With the return of his separated brother, he drank no alcohol. H.T. had had a very close and loving relationship with his adopted brother, who H.T. believed no longer visited him due to the return of the separated brother.

A review of his prior 13 hospitalizations revealed a pattern of psychotic episodes at 8- to 12-month intervals with a similar clinical presentation without a specific psychosocial stressor in many of the admissions. The fourth hospitalization at age 23 was precipitated by the loss of his girlfriend, who had drowned during a family outing that H.T. did not attend. The admission note reported that he was depressed in mood, tearful, psychomotorically retarded for 2 months before admission with positive neurovegetative signs. Auditory hallucinations began a week before admission. Other admission notes reported flight of ideas, pressured speech,

psychomotor agitation, and a driven quality to both speech and behavior. In view of the data the diagnosis was changed to bipolar disorder, manic. As H.T. gradually stabilized on lithium carbonate and neuroleptics over a 6-week period, he revealed his fear that his brother, the devil in his hallucinations, would assault him again with a knife. This assault had triggered his eleventh admission. The revelation of this family secret resulted in fuller discussion of the family history. H.T.'s father, an episodic drinker, had battered his wife on occasion in front of the children. This infrequent behavior had ceased before H.T. was age 14. He reported his fear that his mother would be seriously injured and die. At this point in therapy, H.T. was unable to articulate his feelings toward his father.

As H.T. improved, his adopted brother began to visit him on the unit. A family meeting was held involving them both. In this meeting, they reaffirmed their affection for each other and the adopted brother was encouraged to explain his "rejection" of H.T.

In a low-intervention medication maintenance program for several years, significant institutional intervention was required to enter H.T. in a group psychotherapy treatment for patients with bipolar disorder. Stabilized on lithium with household tensions significantly decreased at discharge, H.T. looked forward to continued work with his group and to beginning a job training program within 4 months.

## TREATMENT

### *Psychotherapy*

Since the Black population is a heterogeneous group, it is too complex a task to delineate specific treatment interventions here. Nevertheless, certain general constructs merit consideration. Economic resources as well as the Black patient's knowledge and appreciation of psychiatric resources will determine the patient's initial entry into treatment. An Afro-American professional may contact a physician of his or her acquaintance and request a referral. An Afro-American construction worker may walk into the local community mental health center for confirmation that the problem requires psychiatric intervention. In addition to the usual anticipatory anxiety of any new patient, the Afro-American seeking health care often cautiously wonders about the type of reactions that will come from the therapist. As noted by Adams (1950), Bell and colleagues (1983), and Spurlock (1982), the Afro-American patient brings to the initial session a well-honed ability to

"read" verbal and nonverbal behavior. The Black patient will be likely to pick up any evidence that emanates from the therapist of anxiety, discomfort, or rejection. Once he has identified a hostile and non supportive environment, the patient will probably leave and not return to treatment.

If the treatment focuses on developmental tasks and the reworking of maladaptive patterns, individual psychotherapy is probably indicated. Following the initial evaluation of two or three sessions, it is important that the therapist review his or her findings in understandable language with the patient and discuss the prescribed treatment and its length. For some patients with a specific precipitant to an adjustment disorder, a focused, brief treatment contract may be the most efficacious therapeutic intervention. Upon completion of the brief treatment with resolution of the precipitating difficulties, the Black patient may be willing to address other areas of conflict that have been identified, such as maladaptive coping mechanisms, in a longer period of individual psychotherapeutic treatment. Once a successful therapeutic alliance and attained therapeutic benefit have been further established, work will then be feasible.

When psychotic illness or affective illness is involved, the extended family should be involved in the initial evaluation and at a relevant stage of treatment. Although significant tensions may exist between the patient and a family member or close friend, the therapist with family and group psychotherapy training and experience can use therapeutic skills to get the issues out on the table, gather a firsthand assessment of the Black patient's significant connections, and inform everyone about the current understanding of the illness, its course and treatment, and the expected outcome. Although all members of the extended family may not prove to be therapeutic allies, it will be helpful to know that a period of respite for the patient at the home of a specific relative is quite feasible, whereas time spent with another given family member has the potential of precipitating a relapse.

For Afro-American patients with extended family and significant others, taking the time to inform them of the treatment process and encourage their involvement is essential. Although medical treatment facilities are no longer segregated on the basis of color, the explanation to family members of mental illness, its course, treatment, and prognosis is frequently not emphasized enough. This time invested by the therapist is preventive medicine at its best, as informed family can monitor signs of progress as well as evidence of decompensation and bring the patient in before a frank psychotic deterioration or a full-fledged drug reaction has occurred. Education of the Afro-American patient and his or her extended family should be part of the process of forming the therapeutic alliance. Although this will vary for each specific patient, it should be a basic general strategy for the therapist.

The negative associations and daily insults Black Americans address (Pierce, 1970) provide a continued assault upon their sense of self-worth and their self-esteem. For some patients, the association of assertiveness training in a group with individuals and/or couples or family therapy can be beneficial. As specific assertive techniques are learned, they can be implemented in situations in which the Black patient has been silent, withdrawn, or articulate though angry. Developing an effective mechanism for verbalizing the feelings identified in the psychotherapeutic process in a manner that conveys his or her specific concerns results in a new sense of mastery that can be incorporated into the therapy. Dual modalities of treatment should be considered, where indicated, to facilitate the maximum improvement of the patient. The use of group assertiveness training may be of specific benefit to the young Black female suicide attempter whose self-esteem and image as a woman are dependent upon a relationship. If the relationship fails, then her sense of self is fragmented.

There have been to date no large-scale outcome studies of individual therapy, group therapy, family therapy, assertiveness training, and outpatient detoxification programs in Afro-American populations. As no Black population has the same heritage, social support networks, education, and socioeconomic status, it is inappropriate for any therapist to assert there is a "best treatment" that is applicable to all Black patients. The decision for a specific therapeutic regimen should be dependent upon the assessment, the diagnosis, and the wishes of the particular patient and his or her family.

Although the extended family and its support network as well as the Black church are important resources for Afro-American patients, these resources do not exist in all communities. For patients without these resources the therapist must include within the therapeutic prescription referral to a rehabilitation program as well as a local church group or community program for recovering patients to facilitate the rebuilding of a support network.

### Drug Therapy

Unfortunately, no controlled clinical trials or prospective studies have been done to address the pharmacodynamics of the major classes of psychoactive medications (antipsychotics, antidepressants, and anti-anxiety) in Afro-American populations. Although anecdotal information and case reports are available, these have yet to develop into the indicated studies.

Shader (1982) emphasized three examples of known pharmacologic reactions that are relevant for Black populations. First, the ability to metabolize a given medication may require an acetylation step. Different groups

are rapid or slow acetylators. Approximately 45 to 55 percent of Afro-Americans are slow acetylators and more at risk to drug-induced systemic lupus erythematosus upon exposure to marker drugs. Phenelzine, a monoamine oxidase inhibitor used in the treatment of depression, is one such medication.

Second, Shader (1982) pointed out that part of the differential diagnosis of pain in an Afro-American includes sickle-cell crisis. As a sedative, hypnotic medication could decrease respiration, increase hypoxia, and worsen the crisis. The emergency room physician must be alert to this possibility before prescribing. Also, if a bipolar patient had sickle-cell anemia, it is theoretically possible that the two diseases could have an additive effect upon the kidney. Sickle cells alter the current in the medulla of the kidney and affect the reabsorption and retention of reabsorbed water. Lithium in such a patient would affect the reabsorption of water in the distal tubule, further compounding the problem of reabsorbed water.

Third, there is research evidence in animals that exposure to lead when the animal is immature, with subsequent absorption of lithium as an adult, tends to cause irreversible central nervous system disease (Mailman et al., 1978). As poor Afro-Americans have a greater exposure to lead-based paint during childhood because of restricted housing options, there may be an increased risk for such Black patients on lithium who have a history of elevated lead levels. Obviously, further research is needed.

In the emergency room setting where a hallucinating Black male patient may be feared by the staff who is expecting him to become violent and assaultive, too often "knocking him out" or putting him in a "Haldol strait-jacket" becomes a reflex response. Although the sedation of a psychotically disorganized patient is highly effective (Simpson & May, 1985), the dose estimated to achieve sedation in a Black patient may be very different from that required to sedate a White patient. A retrospective review of emergency room and inpatient records comparing age, sex, diagnosis, symptoms, and weight-matched samples of Black and White patients may provide an interesting contrast in the psychopharmacologic management of the same diagnosis and comparable symptomatology in two racial groups.

In treating the Afro-American inpatient, it is important to remember that titration of a dose of medication requires 4 to 5 half-lives of the prescribed dose to reach a steady state (Mayer, Melmon, & Gilman, 1980). Therefore, the steady-state serum levels will lag behind the actual dose being administered. Finally, the Black patient who appears to be refractory to high-dose neuroleptics may reflect the fact that one has achieved a "toxic" serum level of antipsychotic medication. *Dose reduction* and environmental management over a period of 5 to 7 days can effect the clinical improvement that increasing the dose of antipsychotic medication has not.

### Special Population Considerations

Psychiatric disorders occur throughout the life cycle in the young, the middle-aged, and the elderly. The onset of many psychiatric disorders occurs in the teenage years and the twenties. While adolescents and young adults are frequently involved in suicidal behavior, homicide, and sexual assaults, the mental disorders of affective illness (unipolar and bipolar), adjustment disorders, and some variants of schizophrenia occur from youth through ages 30 to 50. Substance abuse, particularly alcohol, remains a concern throughout the Afro-American life cycle (Baker, 1985). In older cohorts (age 60 and over) disorders of cognitive impairment have been recently a major research focus (Folstein, Anthony, Parhad, Duffy, & Gruenberg, 1985; Mortimer, Schuman, & French, 1981).

There has been little focus upon the psychiatric illnesses of older Afro-Americans (Baker, 1982, 1987). Specific data about the Black elderly are sparse. Two previous studies have included data on the Black elderly. Folstein and colleagues (1985) reported on an elderly eastern Baltimore sample that was part of the Epidemiologic Catchment Area survey. Although the numbers were small, the Black participants showed a trend to an increased incidence of multi-infarct dementia. Schoenberg, Anderson, and Harer (1985) completed a prevalence study of dementia in rural Copiah County, Mississippi, and in this sample, which was 39 percent Black, the prevalence of severe dementia was higher in Blacks than in Whites. With the early onset of drinking and heavier drinking at a younger age in Black Americans (Robins et al., 1968), the prevalence of cognitive impairment due to alcohol (alcoholic dementia) may be higher in Afro-Americans (Baker, 1987). Research into mental health problems in older Black Americans as well as specific studies of dementia is needed. As both multifactor dementia and alcoholic dementia are preventable, irreversible diseases through regulation of hypertension and abstinence from alcohol, the public health implications of these initial studies are of clear importance in public health planning as well as in the implementation of a research strategy for Black Americans (Baker, 1987). Although the 1981 White House Conference on Aging emphasized the importance of implementing studies in minority elderly populations (White House Conference on Aging Report, 1981), definitive studies have not been published to date. Other studies of mental disorders in non-Black or mixed populations suggest that 25 to 35 percent of persons over age 65 are depressed (Weissman & Myers, 1979), have adjustment disorder (Straker, 1982), and exhibit paranoid disorders (Post, 1980). Comparable data in Black populations do not exist. The Epidemiologic Catchment Areas Survey (Rieger, Myers, Kramer, Robins, & Blazer, 1985) was designed to provide both prevalence and incidence data on mental disorders in probab-

ity samples at five sites. In both the eastern Baltimore site and the Durham, North Carolina, site, there was a significant population of Afro-Americans. As the data are analyzed, perhaps additional information about the Black elderly participants will provide some of the missing information. The National Black Survey completed by Jackson's group in Detroit may provide important data on the perception by Black people of their circumstances and their physical and mental health (Jackson, Chatters, & Neighbors, 1982). Research into mental health problems in older Black Americans as well as specific studies of dementia is needed (National Institute on Aging, 1987).

### SUMMARY

This chapter has focused upon the psychiatric disorders in Afro-Americans and their treatment. A historical context has been provided to clarify the past history of psychiatric diagnosis and treatment for Black Americans and the problems in diagnosis that resulted from conscious and unconscious biases in clinicians and researchers. Factors facilitating and negating the formation of therapeutic alliance were discussed. Case histories were presented to illustrate diagnostic issues and treatment strategies. Areas of future research including clinical trials of therapeutic blood levels as well as psychiatric illness in older persons were presented. The importance of an empathic, sensitive, and culturally informed therapist was emphasized as the effective psychotherapist for Black Americans, exclusive of racial or cultural background.

# The Interaction Between Disability Status and the African American Experience: Implications for Rehabilitation Counseling

By Reginald J. Alston  
Simphiwe Mngadi

Date of Acceptance: January 27, 1992

---

*This article provides information that is useful to rehabilitation counselors and human service professionals providing services to African Americans with disabilities. The potential double bias of being African American and disabled is examined in the article. Special focus is on the similarities in stigmas experienced by persons with disabilities and members of the African American community and how the interaction between minority race status and disability status effects the delivery of rehabilitation services to African Americans. The client-centered approach is described and suggested as a theoretical orientation to be adopted by rehabilitation counselors to lessen the impact of a double stigma on this population.*

---

Counseling ethnic minorities with disabilities is a topic deserving scholarly debate and discussion in the counseling literature. If quality counseling services are to be provided to ethnic minorities with disabilities, rehabilitation counselors and human service professionals must examine the issues involved in interacting with this client group. As suggested by Herbert and Cheatham (1988) and Kunce and Vales (1984), the success of rehabilitation counseling services to ethnic minorities is dependent upon the counselor's understanding of the life factors unique to clients whose sociocultural experiences are different. For example, the rehabilitation challenges facing African Americans with disabilities are varied and complex and require counseling approaches that are sensitive to the idiosyncracies of the African American community. African Americans comprise about 12% (30 million) of the total United States population and are the largest racial minority group in the nation. Though African Americans have made remarkable strides in many spheres of life in the past few decades, discrepancies still exist in many other areas. Atkinson, Morten, and Sue (1989) reported that African Americans as a group still suffer the most

severe underemployment, unemployment, undereducation, and miseducation compared to any other group.

The impact of economic and educational disparities on the African American community is particularly felt by its members with disabilities. According to Rogers (1987), there are nearly 22 million adults with disabilities in the United States. Walker (1988) noted that the 1980 census reported that 14.1% (approximately 2,280,000) of working age African Americans had one or more disabilities. On the other hand, 8% of Caucasian Americans had disabilities. According to Bowe (1983), an African American with a disability is more likely to be female (53.9% are female), to be 42 years of age, to have less than a high school education, and to be unemployed. Only 16.4% of African Americans with disabilities were employed in 1980, and they earned less than \$3,000 a year on the average. The general unemployment rate of individuals with disabilities in the total population is 33% (Frieden, 1988).

The statistics cited above would suggest that being African American and disabled increases one's chances for economic poverty. Also, individuals who are African American and disabled cope with stigmas specific to both statuses (Atkins, 1986; Wright, 1998). Therefore, African Americans with disabilities pose a unique challenge for rehabilitation professionals. Sampson, McMahon, and Burkhead (1985) defined the primary function of rehabilitation as assisting individuals with disabilities to achieve their highest level of functioning in order to facilitate entry or re-entry into the workforce. Such a definition is based on the assumption that vocational placement will generate a domino effect that will have a positive influence on the other aspects of an individual's life. For instance, being employed enables one to care for oneself and one's family. Self-sufficiency is a great self-esteem booster, and a healthy self-esteem is one precondition for healthy relations with others. Healthy relations with others can contribute to one's general satisfaction with life.

There is a need in the counseling literature to address the issues relevant to the rehabilitation of African Americans with disabilities. Wright (1988) and Atkins (1986) indicated that human service professionals need to be cognizant of the cultural issues involved in serving African Americans with disabilities. The purposes of this article are to examine the similarities in stigmas between the statuses of African American and disability; to explore the interaction effects of

minority race status and disability on the delivery of rehabilitation services to African Americans; and to propose the client-centered approach for lessening the combined effects of a double stigma on this population.

### Relationship Between Disability and Minority Status

The similarities in stigmas and inequities experienced by African Americans and persons with disabilities are numerous. Historically, both groups have been excluded from the mainstream of American life and share an underprivileged status. Walker (1988) gave a brief historical account of societal perceptions of people with disabilities. Though some societies looked upon individuals with disabilities with "awe and reverence", in most societies disability has traditionally been associated with tremendous negativism. In the most recent past, as indicated by Walker, persons with disabilities have been "tolerated but not allowed to participate fully in society" and have been "consistently relegated ... to economic deprivation and dependency" (p. 184). It is safe to say that the stigmas associated with the African American minority status reflect these experiences. As noted by Wright (1983), racial minority-group members have always dealt with non-minority individuals who insist that they "not only know their place but also to keep their place--that is, to feel and act less fortunate than others." Wright (1983) suggested that the oppression of minorities stems from an ethnocentric attitude by non-minorities toward out-group members in general. Intrinsic to this attitude is the belief that one's race, culture, or nation is superior to all others. Wright (1983) developed a similar concept called "requirement of mourning" to describe the oppression of persons with disabilities. This concept explains the need of nondisabled individuals to preserve their values and elevate their own status by either (1) insisting to themselves that the person with the disability is suffering, or (2) devaluing the person for not suffering in the face of his or her misfortune. This process protects the nondisabled person's beliefs about self and enables them to rationalize the harsh realities of disability. When the person with the disability appears neither to suffer nor to comply with a devalued status, the nondisabled person often is disconcerted and shocked because their sense of safety is threatened. In comparison, Wright (1983) stated "Aren't some people disconcerted and even shocked when ethnic and religious minority-group members advocate equality or show in other ways that they deserve as much respect and opportunity for development as anyone else?"

In the area of education, Walker (1988) asserted that students with disabilities, similar to African American students, are less likely to receive encouragement and recognition for their efforts and to be recommended for participation in enrichment programs. Obviously, both persons with handicapping conditions and persons of African descent share a history of disempowerment which has stood in the way of them achieving their optimal potential. As Wright (1983) pointed out, both groups are not expected to perform well at school, and as a result suffer exclusion from opportunities for self-development solely as a function of their membership in the respective groups and regardless of their true capabilities. Funk (1987) asserted that the relegation of persons with disabilities to "inferior economic

and social status" is viewed by most people as a direct and inevitable result of their physical or mental deficits. Likewise, there have been suggestions that the lower educational performance of the average African American is due to the inherently poorer intellectual endowment of the African American as compared to other ethnic groups (Jensen, 1969).

Herbert and Cheatham (1988) noted that either having a disability or being a minority can present stigmas that pose barriers to full participation in education, employment, and social opportunities. As asserted by Wright (1983), an individual is appraised according to the presumed characteristics of the group in which he or she is placed. For example, persons with disabilities are often stereotyped as having suffered a great misfortune and whose lives are consequently disturbed and damaged (Wright, 1983). Stereotypes also exist for minorities in the larger society. For example, African Americans are perceived as low achieving, promiscuous, and untrustworthy (Atkins, 1988). Wright (1983) asserted that the stigma associated with disability or minority status can be so intense and pervasive that it can overpower any other positive personal characteristics of the individual which may run counter to it. These observations by Herbert and Cheatham (1988), Wright (1983), and Atkins (1988) are significant because they suggest that African Americans with disabilities must learn to cope with what Marshall (1987) called the "double whammy"--racial discrimination and physical impairment. The double bias of being a member of both status groups can manifest itself through extreme prejudice on the part of nondisabled, non-minority individuals who lack awareness and sensitivity to the potential combined effect of being a minority and having a disability.

### Implications for Rehabilitation Service Delivery

Herbert and Cheatham (1988) conducted a review of research pertaining to rehabilitation service delivery to African Americans with disabilities. Their review revealed that African Americans were less likely to be accepted for services compared to Caucasian Americans. If accepted, their cases were more likely to be closed without job placement, and if job placement occurred, then they received lower weekly incomes. Walker et al. (1986) conducted a study involving eight state and nineteen private rehabilitation agencies around the United States. They found that though there was a larger number of African Americans with disabilities, the percentage of Caucasian Americans receiving services was twice and sometimes three times that of African Americans.

There are numerous reasons why African Americans are underserved and fare worst in rehabilitation. Brewington, Daren, Arella, and Randell (1990) described three classes of obstacles to successful vocational rehabilitation. These were the client, nature of the rehabilitation program, and finally, society. Client variables may include temperament (motivation), interests, work experience, educational level attained, skills possessed, and so forth. Program factors include availability of resources (both manpower and monetary) and quality of staff. Finally, societal factors include attitudes prevalent in society that affect the success or failure of service delivery. Granted, the interplay between these variables is an intricate one. As Atkins (1986) indicated, clients enter a rehabilitation process with a

set of beliefs, attitudes, values, and goals, and they encounter rehabilitation counselors with their own set of beliefs, attitudes, values, and goals. Undeniably, the interaction between client and counselor attributes could be critical in determining whether clients are accepted into a rehabilitation program and whether they leave the program "rehabilitated". As it is indicated in the preceding paragraph, the client's race appears to be a significant attribute.

Another important variable of rehabilitation service delivery is the client's previous life experiences. Being an American of African descent exposes one to a unique set of life experiences. It is these experiences which serve to shape one's view of the world. For instance, African Americans with disabilities are aware of stereotypes and negative attitudes held by the majority American society against African Americans in general. They know, for example, that the slow economic progress of African Americans is often attributed to laziness and low motivation to work hard (Atkins, 1988). This could stand in the way of African Americans with disabilities seeking out rehabilitation services. Even those that do seek out such services may do so with low success expectancy levels if their prior experiences with majority American institutions have been tainted by discrimination.

Rotter, Chance, and Phares (1972) postulated that previous experiences have a great influence on expectancy. Rotter (1954) had defined expectancy as "The probability held by an individual that a particular reinforcement will occur as a function of a specific behavior on his part in a particular situation" (p. 107). According to Weiner (1980), intensity and persistence of behavior are mediated by both expectancies of success and anticipated emotional responses to these outcomes. If these theoretical formulations are accurate, then as a result of prior experiences of exclusion, African Americans with disabilities are likely to enter a rehabilitation process with low expectancies for success. Therefore, African American clients with disabilities may not exert as much effort in working with rehabilitation counselors, especially if they sense an adherence to negative stereotypes.

Some of the other client variables that affect the rehabilitation process such as educational attainment, skills possessed, and work experience are to a large extent determined by the client's race. The statistics provided previously substantiate this claim. The "second generation discrimination" in the schools described by England et al, (1990) ensures that most African American children drop out before they have acquired any marketable skills. According to England et al, those who stay in school are often trapped in vocational classes that further ensure that they end up in menial and low income occupations. Therefore if disability occurs, it finds African Americans poorly prepared to compete in the world of work. Skill deficiencies resulting from life experiences prior to their need for rehabilitation services lessen their chances of benefitting from such services.

#### Client-Centered Approach

A rehabilitation counselor can neither alter experiences that have shaped the characteristics that a client brings into a rehabilitation situation nor convert society and cleanse it of at-

titudes that pose barriers to the full rehabilitation of African Americans with disabilities. However, a rehabilitation counselor may, by first adopting a client-centered approach to counseling, make a difference. The client-centered approach, developed by Carl Rogers, dictates that every human being deserves acceptance and unconditional positive regard--respect for the mere reason that one is human. Therefore, an adoption of this philosophy would be reflected in the rehabilitation counselor's understanding and acceptance of the African American client with a disability from the client's own perspective; understanding and accepting the client's background, culture, and personality even though these might be different from those of the counselor (Corsini, 1979; Herbert & Cheatham, 1989).

Adoption of the client-centered approach would also require rehabilitation counselors to engage in a careful introspection in order to examine their own biases, attitudes, and values for the purpose of self-awareness and personal growth (Corsini, 1979). This approach would encourage rehabilitation counselors to purge themselves of those attitudes and behaviors that might impede the overall optimum growth of their clients. Working with African Americans, in particular, requires that a rehabilitation counselor avoid being driven by derogatory stereotypes in dealing with clients, and not only to appreciate the strengths these clients bring into the situation but also to build on them.

Carl Rogers espoused the importance of recognizing the client's positive attributes when using client-centered counseling (Corsini, 1974). The significance of building on the assets and positive elements (e.g., desire to be self-reliant, desire to be in control of one's own destiny, etc.) of African Americans was emphasized by scholars on the rehabilitation of African Americans (Atkins, 1986; Atkins, 1988; & Cheatham, 1990). Respect for and valuing of the African American client's positive elements can be reflected in the rehabilitation counselor's willingness to involve the client as much as possible in examining possibilities and setting rehabilitation goals (Atkins, 1986). Obviously, if clients are allowed to participate in decision making, they will more likely commit to goals and take responsibility for the choices they make.

Sensitivity to the basic (immediate) needs of the individual is also paramount in the client-centered approach. It was indicated in an earlier discussion that despite an increase in the number of African Americans who have achieved middle class socioeconomic status, a large number is still trapped in poverty. Therefore, if immediate problems such as not having transportation or enough resources to live from day to day are not addressed first, long term positive outcomes of rehabilitation may not materialize. As Atkins (1986) noted, another function of rehabilitation should be advocacy - linking the clients with available resources or, better still, teaching them self-advocacy skills.

#### Conclusion

According to Kirchner (1987), the functions of rehabilitation include personal adjustment counseling, vocational counseling, job training, and assistance with job placement. Fulfillment of these functions depends partly on client variables such as race,

work history, and educational level. However, counselor variables such as cultural biases and prejudices are equally important in influencing rehabilitation outcome. Despite client conditions such as those cited that make it harder for rehabilitation to fulfill these functions, genuine commitment on the part of rehabilitation counselors to make a meaningful difference in the lives of their clients, regardless of race, would go a long way toward offsetting the effects of these conditions. As the information in this article indicates, African Americans with disabilities are a complex client population with unique conditions that warrant special attention. Lack of awareness of the issues confronting African Americans with disabilities can result in rehabilitation case management problems.

Rehabilitation counselor education programs need to equip their trainees with minority-oriented counseling strategies. This does not mean that there is a "cookbook" method for working with African Americans or other minorities. However, as Wright (1988) aptly put it, each minority group has experiences that bring forth a unique set of problems. It is imperative that rehabilitation counselors understand the collective experiences of the minority group members they are working with while at the same time being sensitive to the needs of individual clients. Preservice rehabilitation counselors need opportunities to work with minority clients. Workshops and seminars should be organized for both preservice and practicing rehabilitation counselors (Crystal & Alston, in press; Atkins, 1988). Seminars present a forum through which rehabilitation counselors can develop the necessary sensitivity needed to serve African Americans with disabilities. Also, workshops foster an atmosphere in which rehabilitation counselors can be challenged to confront their own attitudes and seriously reflect on how these might impact service delivery to African Americans and other minorities with disabilities.

# Problems in Diagnosing Schizophrenia and Affective Disorders Among Blacks

Billy E. Jones, M.D.  
Beverly A. Gray, M.A.

*In this country schizophrenia has been consistently overdiagnosed and affective disorders underdiagnosed, particularly among blacks and lower socioeconomic groups. The general causes of such misdiagnoses include overreliance on the classic thought disorder symptoms as pathognomonic of schizophrenia and, for affective disorders, lack of clearly defined boundaries between normal and abnormal mood and failure to realize that patients with affective illness can manifest cognitive symptoms. In addition to the above factors, misdiagnosis*

*among blacks results from such factors as cultural differences in language and mannerisms, difficulties in relating between black patients and white therapists, and the myth that blacks rarely suffer from affective disorders. Clinicians and researchers must pay more attention to the effects of cultural differences on diagnosis, and baseline behaviors and symptomatology for blacks must be established.*

Over the years major efforts have been made to address some of the problem areas in psychiatric diagnosis. *DSM-III*, the third edition of the *Diagnostic and Statistical Manual of Mental Disorders* (1), has

been a significant development in psychiatry partly because it provides standard diagnostic criteria that have been tested for reliability and are operationally defined. In general, however, little attention has been given to diagnostic issues as they relate to blacks.

Several studies have shown that earlier diagnostic methods resulted in a consistent overdiagnosis of schizophrenia and an underdiagnosis of affective disorders (2-4). Blacks and lower socioeconomic groups have been particularly affected.

In other fields of medicine, diagnosis is arrived at by determining the etiological agent or malfunction involved in the illness and weighing it in conjunction with the accompanying symptoms. In psychiatry the etiological agents and malfunctions are generally unknown, and psychiatry lacks measurements, tests, and methods to establish their presence. Hence diagnosis has relied almost entirely on signs, symptoms, and behaviors—a major drawback because different illnesses may have the same or similar signs, symptoms.

Dr. Jones is director of the department of psychiatry and Ms. Gray is coordinator of research in the department of psychiatry at the Lincoln Medical and Mental Health Center, 234 East 149th Street, Bronx, New York 10451. Dr. Jones is also professor of clinical psychiatry and Ms. Gray is an instructor in psychia-

try at the New York Medical College in Valhalla. This paper is based on a presentation at the annual Transcultural Seminar of the Black Psychiatrists of America held November 8-12, 1984, in Jamaica, West Indies. It is part of a special section in this issue on important issues in black psychiatry.

and behaviors. In addition, symptoms and behaviors may be culturally related and thus differ from one ethnic group to another.

The problems involved in psychiatric diagnosis have been particularly evident for schizophrenia and major affective disorders. Our review of the literature indicates that the misinterpretation and misunderstanding of three areas involved in symptom presentation have contributed to problems in the diagnosis of these conditions in blacks. These areas are disorder of thought content (hallucinations and delusions); disorder of thought process (looseness of association, incomplete thoughts, and flight of ideas); and the cultural distance between patient and therapist (as in language, behavioral mannerisms, and style of relating) when it hinders patient-therapist rapport.

This paper will review general problems in diagnosing schizophrenia and major affective disorders and specific problems related to the diagnosis of these conditions in blacks. Because it is impossible to address these two broad spectrums of disorder with any completeness in one article, we can present only an overview.

### Schizophrenia: general diagnostic problems

Three major problem areas will be discussed, two of them reflecting current trends in the field.

*The role of classic symptoms.* The past emphasis on classic schizophrenic symptoms such as hallucinations and delusions as diagnostic criteria has contributed to the use of "schizophrenia" as an overinclusive label. The present decrease in emphasis on such symptoms is narrowing the diagnosis. There is an increased reliance on mood and other affective symptoms as more diagnostically useful, and a shift toward classifying schizophrenia as more similar to affective disorders in that affective disorders may include thought disorder. There is no longer a clear demarcation between symptomatology of schizophrenia and affective disorders (5). The use of clas-

sic symptoms has also given way to increased use of explicitly defined operational criteria, as in *DSM-III*, derived with an emphasis on reliability.

Schizophrenia has long been considered a disorder of thinking, and thus any symptom indicative of thought disorder, such as hallucinations, delusions, and looseness of association, has been considered pathognomonic for the illness. This view has also contributed to the overdiagnosing of schizophrenia.

Research in schizophrenia diagnosis has supported a symptom cluster approach over a pathognomonic approach (6). The past, almost relentless search for classic pathognomonic symptoms has proven futile. While Bleuler's four A's (7)—loosened associations, flattened affect, ambivalence, and autism—and Schneider's first-rank symptoms (8) have aided diagnosis, they have not assured accuracy. Pope and Lipinski (9) reported that several key symptoms of schizophrenia, such as delusions and hallucinations, are found in 20 to 50 percent of documented cases of manic-depressive illness.

*Schizophrenia as a unitary disease.* Walters (6), like many others, raised the issue of whether schizophrenia is a single disorder or a collection of separate but related disorders. Kinney and Jacobsen (10) indicated there may be several subtypes of schizophrenia based on etiology. One type may be associated with a strong family background of schizophrenia, a second type with perinatal cortical damage, and a third with social and environmental factors. The existence of the last subtype could have special significance for blacks and others in lower socioeconomic groups.

Others have noted that the manifestations of schizophrenia might be general symptoms of numerous illnesses, much as chills and fever are, rather than specific symptoms of a particular illness. This view also suggests that schizophrenia may be a host of different disorders. The concept that schizophre-

nia is a unitary disease is currently fading (5).

*Overdiagnosis and misdiagnosis.* Obviously, both the problems noted above affect overdiagnosis. Another problem that has led to the overdiagnosis of schizophrenia is misdiagnosis. The curse of being familiar or common is that a familiar entity, such as schizophrenia, inherits what is marginal or unclear. The tendency to diagnose unclear and confused clinical pictures as schizophrenia persists.

Some researchers, such as Pope and Lipinski (9), state that American psychiatry has indeed overdiagnosed schizophrenia and underdiagnosed manic-depressive illness. They report that the "classic" symptoms of schizophrenia are ineffective in differentiating between schizophrenia and manic-depressive illness. They feel the diagnostician must supplement the presenting symptoms with additional information, such as a family history and course of illness, before reaching a diagnosis.

### Schizophrenia: specific problems for blacks

Studies have indicated that just as schizophrenia is overdiagnosed in the general population, it is overdiagnosed in blacks, and that in this country blacks are more likely to be overdiagnosed than whites (11-18). Being black and requiring psychiatric treatment carries a significant risk of being labeled schizophrenic.

Adebimpe and associates (14) reported that "the higher incidence of schizophrenia usually reported in blacks as compared to whites is not found when strict diagnostic criteria are used in making the diagnosis." They suggested that "clinicians overdiagnose this disease in blacks because they are unduly impressed by symptoms such as hallucinations and delusions which are characteristic but by no means pathognomonic of schizophrenic illness." They believe that some blacks experience a variety of nonschizophrenic hallucinations.

Mukherjee and colleagues (11)

compared the misdiagnosis of schizophrenia in bipolar patients who are black, Hispanic, and white. In their study black and Hispanic bipolar patients were "at a higher risk than whites for misdiagnosis as schizophrenic, particularly if they are young and experience auditory hallucinations during affective episodes."

Simon and others (16) compared research diagnoses with hospital diagnoses of black and white patients in nine New York State mental institutions. The hospital clinicians more often gave blacks the diagnosis of schizophrenia than of affective disorder; race and diagnosis were significantly related. However, the research psychiatrists' diagnoses were quite different, and race and diagnosis were not related. In a cross-cultural study of diagnosis in New York and London, Cooper and coworkers (19) reported similarly that blacks were overdiagnosed as schizophrenic and underdiagnosed for affective disorders.

Mukherjee and colleagues (11) noted further that "the misdiagnosis of bipolar patients as schizophrenic is also related to the lack of awareness that some delusions and hallucinations may commonly be seen in acutely ill patients. This is particularly important to bear in mind when evaluating black and Hispanic patients, since they may more frequently exhibit these symptoms during affective episodes [than white patients do]. Until these factors are better understood, the use of structured interviews, a clearer knowledge of phenomenology, strict adherence to operationally defined diagnostic criteria such as provided in *DSM-III*, and most importantly, explicit exclusion of manic or depressive syndromes before arriving at a diagnosis of schizophrenia should minimize misdiagnosis regardless of the ethnicity of the patient or the psychiatrist."

Some of the specific cultural problems affecting the diagnosis of schizophrenia in blacks include cultural differences between the black patient and white clinician,

lack of understanding of the black norm, and stereotypic thinking.

Black patients' use of language, behavioral mannerisms, and style of relating, as well as the type of life experiences they have had, often are not understood by non-black therapists. As a result such behaviors may be considered symptoms of psychopathology, most often schizophrenia. Language not understood is often considered evidence of thought disorder; styles of relating are sometimes misinterpreted as disturbance of affect; and unfamiliar mannerisms are considered bizarre. These mistakes are avoidable.

Haimo and Holzman (20) examined thought disorder in schizophrenics and normal controls. They stated that "the usual indications of schizophrenic thought disorder are not specific to a particular social class or race such as the white middle class, and therefore patterns of thought expressed in language used by lower-class blacks and whites are distinguishable from examples of thought disorder, although higher-social-class patients tend to manifest higher levels of thought disorder than do lower-social-class patients."

Grier and Cobbs (21), in their book *Black Rage*, wrote about the "black norm," a body of adaptive character traits developed by blacks in response to a particular environment. They stress that this complement of psychological devices is essential to life for black men in America. For instance, they submit, "It is necessary for a black man in America to develop a profound distrust of his white fellow citizens and of the nation. He must be on guard to protect himself against . . . hurt. . . . For his own survival, then, he must develop a cultural paranoia in which every white man is a potential enemy . . . and every social system is set against him." This normal (for blacks) protective wariness is often mistaken as paranoia, symptomatic of schizophrenia.

A compounding issue is the reluctance and hesitancy that some

blacks have in relating to a white therapist, which is born out of dislike and hostility. Such reluctance is most often manifested by strict control over affective response and a resistance to establishing rapport and communication. These behaviors are often misinterpreted as flat or blunted affect and problems relating to others and may be mistaken as further evidence of schizophrenia. According to Grier and Cobbs, other character traits of the black norm are cultural depression, cultural masochism, and cultural antisocialism.

Stereotypic thinking that may affect the diagnosis are the views that schizophrenia is more common than other illnesses in lower socioeconomic groups, especially among blacks, and that schizophrenia more frequently occurs among blacks than among whites. These myths are self-perpetuating.

#### **Affective disorders: general diagnostic problems**

Although there are many general problems in the diagnosis of affective disorders, we shall address only two of the most fundamental concerns: the broad range of affective disorders and the mix of affective and thought-disorder symptomatology they can manifest.

*Range of affective disorders.* The lack of a clear demarcation between normal and abnormal mood creates special difficulties. Klerman (22) has pointed out that "because clinicians and investigators do not fully agree as to the complete range of affective disorders to be diagnosed as psychopathological, the boundary between normal mood and abnormal depressions remains undefined." The lack of clear demarcation also exists between normal mood and mania. At what point does more activity, more energy, greater functioning, and feeling good become abnormal?

A related concern is the number and type of illnesses that constitute affective disorders. Because mood illnesses are distributed across a wide spectrum from mild depression to life-threatening mania, it is

often difficult to determine which disorder is present, particularly without knowledge of the patient's past history and previous course of illness. *DSM-III* groups all affective disorders together regardless of whether they have psychotic features or are associated with precipitating life events.

**Symptomatology.** Because affective disorders have always been defined as disorders of mood, the symptomatology has been considered to relate primarily to mood and activity, such as depression and psychomotor retardation or elation and hyperactivity. However, it is clear that affective conditions can incorporate symptoms of thought disorder.

Roukema and associates (23) found that 95 percent of their manic patients, as diagnosed by Research Diagnostic Criteria, clearly showed moderate to severe thought disorder that was characterized by bizarre idiosyncratic thinking. "Thus, if allowed to continue without treatment, the behavior, affect, and thinking of the manic state reach a combination that is difficult to distinguish from schizophrenia," they concluded. Delusions and hallucinations may also be part of the symptomatology of involuntal, bipolar, and unipolar depression, all now termed major depression, whether single episode or recurrent.

#### **Affective disorders:**

##### **specific problems for blacks**

As noted above, most earlier studies have found lower rates of affective disorders and higher rates of schizophrenia among blacks as compared with whites. These findings have always been controversial. The reports were often statistically biased and were based on stereotypes that blacks rarely suffered from depression or manic-depression (24-26) and that such disorders were upper- and middle-class illnesses (24,27,28).

More recent studies have demonstrated a higher incidence of major affective disorders among blacks than previously believed. For instance, Keisling (29) found no evidence that blacks had manic-

depressive illness less frequently than whites. Dovenmuehle and associates (30) and Tonks and associates (31) have reported higher rates of manic-depressive illness among blacks and low-income groups than among whites and higher income groups. In addition, Tonks and associates and Warheit and others (32) found higher depression scores among women, blacks, young persons, and those in low socioeconomic groups.

In a study examining clinical symptoms of manic-depressive illness in black patients diagnosed as manic-depressive by *DSM-III* criteria, Jones and coworkers (33) found the clinical symptoms of manic-depression, manic type, to be similar to the clinical symptoms reported for white patients. They stated, "The precise expression of a particular symptom may assume any of a potential number of allomorphic forms with the exact selection possibly being influenced by a number of factors." They believed the variance in symptom presentation to be one of the factors contributing to misdiagnosis in general. In other words, the same symptoms may be expressed through a variety of behavioral actions that are determined by other factors, such as culture.

Further confirmation of the incidence of manic-depressive illness among blacks comes from the retrospective study by Jones and associates (34) of a random sample of lower income urban blacks; 15 percent were diagnosed as manic-depressive according to *DSM-III* criteria.

Thus it appears that misdiagnosis of affective disorders among blacks has been a primary problem. The causes arise both from the general problems of diagnosing affective disorders described above and from factors specifically affecting blacks, and thus the causes are closely intertwined.

For instance, the general lack of a clear demarcation between normal and abnormal mood may become more confusing if what is normal for blacks is not well understood. The erroneous beliefs that blacks are generally happy

people who seldom suffer from depression makes the distinction between a normal state and depression less clear. Mild and even moderate depression is more likely to be considered in the realm of normal. Likewise, if manic-depression is believed to occur rarely in blacks, hyperactive behavior is more likely to be seen as normal.

The general issue of symptomatology in affective illness clearly affects blacks specifically. As stated, blacks and Hispanics with affective disorders may exhibit delusions and hallucinations more frequently than whites (11). Blacks are at higher risk of being misdiagnosed if thought disorder is not considered symptomatic of affective illness. In case studies demonstrating bipolar illness in a low-socioeconomic black population, Roukema and associates (23) found that diagnostic errors were made on the basis of symptoms resembling schizophrenia. Patients with these symptoms were not schizophrenic but in fact were in the later stages of the manic phase of manic-depressive illness.

Social and cultural differences between black patients and white clinicians are more of a problem in the diagnosis of schizophrenia, but they can also be operative in affective disorder. Language, mannerisms, and style of relating may be misinterpreted as depression or hypomania if the clinician is not familiar with the patient's culture and social customs. A black patient's unwillingness to relate to a white clinician may be seen as depression instead of resistance.

Adebimpe (13) comprehensively reviewed several possible causes of misdiagnosis of black patients: social and cultural distance between patient and clinician, stereotypes of black psychopathology, false-positive symptoms, biased diagnostic instruments, and the combined effects of various sources of diagnostic error. Each of these factors has also been cited in other reports.

Bell and Mehta (35) provided three case histories demonstrating the misdiagnosis of manic-depressive illness in blacks as the result of

institutional dynamics and clinical error. In a second study they found a rate of manic-depressive illness among their black patients similar to rates reported in surveys of white patients (36). However, the black patients had been more frequently misdiagnosed than white patients and had received inappropriate treatment.

### Conclusions

The state of the art in psychiatric diagnosis has enabled the field of psychiatry to determine the existence of hallucinations in schizophrenia and in major affective disorders, but there are no studies differentiating the nature of the hallucinations in the two illnesses. The inclusion in *DSM-III* of non-symptom criteria, such as duration of symptoms and age of onset, in addition to symptom criteria may help resolve some of the problems incurred when diagnosis is based solely or primarily on symptoms. However, it is clear that more than *DSM-III* will be required to resolve these and other problems in diagnosis. The development of biological markers and other diagnostic methods will greatly assist the field of psychiatric diagnosis. However, all such diagnostic instruments, tests, and markers must be validated for use with blacks before they are employed.

Research to investigate more closely how the general diagnostic problems in psychiatry affect blacks is needed. More attention must be paid, both in research and in clinical settings, to cultural and racial differences of black patients as they may affect the diagnosis. Finally, baseline behaviors and symptomatology for blacks must be established.

# The Chinese perception of mental illness in the Canadian mosaic

by Ruth N.F. Lee, R.N., BScN., Sunnybrook Medical Centre, University of Toronto Bayview Avenue, Toronto, Ontario M4N 3M5.

## Abstract

The author examines Chinese philosophical and religious teachings, their effect on the Chinese perception of mental illness, and the help-seeking behaviours of mentally ill individuals and their families within the Chinese community in Canada.

On October 8, 1971, in the House of Commons, Prime Minister Pierre Elliott Trudeau announced his Government's multiculturalism policy. He described it as follows: "A policy of multiculturalism within a bilingual framework commends itself to the government as the most suitable means of assuring the cultural freedom of Canadians. Such a policy should help to break down discriminatory attitudes and cultural jealousies. National unity, if it is to mean anything in the deeply personal sense, must be founded on confidence in one's own individual identity; out of this can grow respect for that of others and a willingness to share ideas, attitudes and assumptions (Trudeau, 1978, p. 45).

More than 4,000,000 immigrants have entered Canada since the end of the Second World War (Leacy, 1983, p. 8), and it is estimated that during the next 15 to 25 years, 150,000 immigrants will be admitted into Canada each year (Statistics Canada, 1980). We are now living in a multicultural society, among men and women with different skin colours and languages, different standards and traditions in dress, habits, diet, different religions and, more importantly for health care professionals, different health beliefs and practices. A sound knowledge of cultural values and practices is especially important for health care professionals who work with psychiatric patients, since a variety of mental health problems are largely related to cultural contact and sudden cultural changes which leave the individual confused and helpless (Leininger, 1978, p. 105).

Although Chinese people began to emigrate to Canada more than a century ago, their traditional philosophical and religious teachings continue to have a great impact on the values, attitudes, and behaviour of the average Chinese Canadian (Ontario Ministry of Culture and Recreation, 1974, p. 1). It is important to realize, however, that the Chinese, like all other ethnic groups, are by no means homogeneous. They differ significantly according to their duration of stay in Canada, their

geographical origin, their social class, and even their political affiliations.

The second- or third-generation Chinese Canadians, who are fluent in English and well integrated into the major culture, do not usually pose special problems for the health professional. It is the individuals who have a language barrier and whose cultural values differ from the dominant Canadian culture who require special sensitivity.

## Chinese philosophical and religious teachings

Confucianism, Taoism and Buddhism are the three major philosophical and religious teachings that have guided Chinese moral and ethical considerations for centuries.

Confucianism sets the rules and regulations for social interaction; therefore, it has traditionally been the most pervasive influence on Chinese behaviour. Confucian teachings on social interaction stress reciprocity and loyalty, benevolence and righteousness, self-respect, self-reliance, self-control, and face-saving. Reciprocity means that one treats others as one would like to be treated. Loyalty is unquestioning allegiance and total subordination to one's superior and elders. Reciprocity and loyalty lay the foundation of authoritarianism, filial piety and the closely-knit family structure of the Chinese (Yang, 1967, p. 269). Benevolence is an awareness of others; that is, one should treat others in a kindhearted manner. Righteousness is doing what is appropriate according to benevolence. In the building of one's character, one should always demonstrate self-respect and self-reliance by exerting restraint over one's emotions, and by avoiding extremes. Face-saving, keeping an honourable family name, is a behavioural duty expected by both the family and the community, and the only way to accomplish it is by following Confucian teachings closely.

Taoism advocates non-action, detachment from the world, and a harmonious personal life in relation to cosmological natural and social environments (Lin, K.M., 1981, p. 95). Taoist views of nature emphasize cyclical changes; e.g. the cycle of birth and death, and belief in reincarnation and spirits.

Buddhism, which originated in India, stresses the temporariness and emptiness of life. Reincarnation and the cause and effect of one's deeds are central beliefs; therefore, it is very important to accumulate good deeds in order to reach a higher state of being in one's next life (Cher. Louie, 1983, p. 200).

There is a lot of overlapping in these three major philosophical teachings, and most Chinese are not able to articulate the concepts involved. These teachings are internalized during the process of their upbringing.

## Chinese perception of mental illness

The Chinese view of the etiology of mental illness is largely influenced by Chinese philosophical teachings and physical health beliefs. The multifaceted perception of mental illness includes moral, religious, physiological, psychosocial and genetic factors.

### • Moral factors

Rules set by Confucian teachings are regarded as the proper way of conducting one's life; therefore, any misconduct or deviation from socially prescribed behaviour, especially in neglecting the respect due to ancestors, can result in mental illness for the person responsible or his descendants.

dants (Lin, K.M., 1981, p. 95). Usually, the male head of the family will draw upon Confucian teaching concerning the virtue of good conduct in the hope of correcting the mentally ill person's "misbehaviour."

### • *Religious factors*

Mental illness is traditionally believed to be caused by the wrath of gods and ancestors, incurred by the patient or his family members, in either present or former lives. For the Buddhist, prayers and offerings will be given at temples in the hope that good deeds will be accumulated to please the gods. As for the Taoist, priests will be hired to engage in magical healing through expulsion of evil spirits which are believed to have possessed the patient (Lin, T.Y. and Lin, M.C., 1981, p. 387).

### • *Physiological factors*

Due to their philosophical teachings, it is very difficult for Chinese to express their emotions and feelings. Studies (Tseng, 1975; Leong, 1976; Kleinman, et al., 1978) have shown that the practice of somatizing emotional feelings is prevalent among Chinese Canadians today. The physiological explanation of health and illness rooted in the Yin-Yang theory was first defined in the "Yellow Emperor's Classic of Internal Medicine" more than 5,000 years ago (Spector, 1979, p. 214). Yin represents the female principle, the negative energy that produces darkness, cold and emptiness. Yang is male, the positive energy that produces light, warmth and fullness. Yin-Yang exert power not only over the universe but also on human beings; therefore, all illness is caused by an imbalance of nature's two opposing forces. According to the Yellow Emperor's Classic of Internal Medicine, a person is rendered mentally ill or more susceptible to mental illness by five harmful emanations of Yin-Yang (Veith, 1967). The five disturbances are numbness, wildness, insanity, disturbance of speech, and anger. Excess or deficiency of physiological functions, such as breathing, eating, bowel movement, sexual activities, and physical exhaustion are the causes of the disturbances. With the influence from Western medicine, hormonal imbalance, vitamin deficiency and brain dysfunction have become the modern additions to the somatic orientation of the Chinese to mental illness (Lin, T.Y. and Lin, M.C., 1981, p. 387). Consequently, one will often hear the mentally ill patient complain of malaise and lack of vitality caused by his weak kidneys, rather than about feeling depressed. In order to replenish vitality and restore the balance of Yin-Yang forces, remedies are sought by the family, usually in consultation with traditional herbal doctors and respected elders in the kinship; acupuncture is also a popular alternative treatment for the patient (Spec-

tor, 1979, p. 219). Such physical treatments often render psychological relief to the family for their shame or guilt over the patient's mental illness, which they believe may have been caused by their misconduct.

### • *Psychological factors*

Crisis situations, extreme psychosocial stress such as breakdown of family relationships, failure in career and finance, death and mourning of a loved one, are all viewed as potential causes of mental illness. However, the Chinese believe that, if one follows Confucian teachings closely, and avoids excessive and incongruent emotions, mental disturbances should not occur. Confucianism also teaches that maintaining harmony in familial and social relationships requires inhibition and avoidance of emotional expression. Thus, the logical suppression of emotions and the taboo against discussing one's feelings can be seen as psychocultural coping mechanisms (Yeh, 1972, p. 132).

### • *Genetic factors*

Belief in the cyclic phases of birth, death and reincarnation influences the Chinese to consider both physical and mental illness as genetically transmittable. This belief is often demonstrated by the common practice of searching back three generations into the family history of a potential son or daughter-in-law by the potential parents-in-law, in order to rule out any "bad seeds" in the family (Li, 1984).

## Current help-seeking behaviour

In a Vancouver study, Dr. T.Y. Lin identified five phases of the help-seeking pattern of mentally ill Chinese and their families in Canada (Lin et al., 1978, p. 3). These five phases, extending from the onset of the illness to eventual hospitalization, are:

- 1) Exclusively intrafamilial coping;
- 2) Inclusion of certain trusted outsiders in the intrafamilial attempt at coping;
- 3) Consultation with outside helping agencies, physicians and finally a psychiatrist while keeping the patient at home;
- 4) Labelling the problem as a form of mental illness, and a subsequent series of hospitalizations;
- 5) Scapegoating and rejection.

Different factors contribute to such a help-seeking pattern. Traditional cultural negativism regarding mental illness is one of the major factors. Because of traditional perceptions of mental illness, mentally ill patients are seen as a disgrace, and thus become family secrets. Exposure would negatively affect the prestige of the family. The face-saving factor results in the con-

cealment of the patient, and the illness is denied proper care. Minor mental disorders are often viewed as being caused by one's deviation from the major philosophical teachings or from physiological homeostasis. Only those suffering from the major mental illnesses, i.e. psychoses, are accepted as mentally ill (Li, 1984). The head of the family is usually the one who assumes the responsibility for the treatment modality and its implementation. His choice of treatment modality depends on his philosophical and religious beliefs, but herbal medicine is almost always used. It is only when the family members have exhausted their resources and their treatment modality has proven ineffective that they turn to the professionals. Studies (Lin and Lin, 1978; Wong, 1978) have indicated that an extended delay in seeking help from psychiatric institutions is universal for Chinese psychiatric patients, and such practices have led to numerous chronic psychotic cases in this patient group. For new Chinese immigrants, the language barrier and the relative lack of information about public services are also obstacles that delay proper care at an early stage (Li, 1984).

## Recommendations and conclusion

Cultural values are most important in determining the health beliefs and practices of an individual. Cultural values act as the blueprints for human health behaviours. They determine what cultural groups will do to maintain their health status and the quality of care that those who become ill will receive (Leininger, 1978, p. 39).

Practitioners must take into consideration the values, beliefs, and customs of patients and their significant others. When working with mentally ill patients of another ethnic origin, the practitioner should maintain a broad, objective attitude and not be misled into assuming that the colour of their skin determines their culture (Leininger, 1978, p. 87). While there are common features and cultural characteristics, it is important for the practitioner to give individualized patient care rather than making the assumption that everyone is similar. A cultural assessment tool, such as the one developed by Davies and Yoshida (Figure 1) can assist the practitioner in accomplishing this goal.

For the practitioner who understands the cultural perception of mental illness, it is not difficult to recognize that stigma is a major problem that the mentally ill Chinese Canadian and his/her family must face every day. Reassurance of confidentiality can be psychologically soothing for the patient and the family. Furthermore, better utilization of community resources, such as the Greater Vancouver Mental Health Service in Vancouver, B.C. and the Hong Fook Mental Health Association in

Toronto, might prevent or reduce the need for hospitalizations. This would ease the family's stress of having a "crazy" family member being "locked" in a mental institution.

Genetic counselling can be helpful for patients who firmly believe that mental illness is transmitted from generation to generation. Practitioners must be sensitive to the shame and guilt feelings of the older family members of the patient, because they may have the belief that their behaviour in the past has caused the illness. Involvement of the family, especially the male head of the household, should be encouraged.

A thorough assessment of the patient's previous treatment modality should be carried out before any medication is prescribed, for most Chinese families would use Chinese herbal medicine on the patient despite other treatment plans designed by the professionals.

Due to their philosophical teachings, Chinese patients and their families usually have difficulty discussing their problems or expressing themselves emotionally, especially in an alien tongue. Practitioners should not consider such behaviour as depression or as a sign of uncooperativeness. We should respect their practices and rituals; however, alternatives should be offered at the same time. Health teaching of topics such as the etiology of mental illness, medication, nutrition and effective communication are particularly helpful. Trust can be gained when the family is convinced that the practitioner understands their psychological suffering and their cultural heritage. An interpreter who is knowledgeable in the Chinese culture and fluent in the patient's mother tongue would be invaluable in the treatment of this group of patients.

Incorporating instruction about social structures, cultural systems and transcultural human services into mental health education and in-service programs can be the beginning of our attempt to assist mentally ill persons from different ethnic backgrounds.

We cannot guarantee a thorough understanding of each ethnic group within our multicultural mosaic, but we can take steps to guarantee our sensitivity to their needs and to demonstrate our sincerity in helping them on the road to recovery.

# Asian Americans and Rehabilitation: Some Important Variables

By Paul Leung, and  
Robert Sakata

---

*Rehabilitation counselors will come increasingly into contact with Asian Americans as part of their workload. This article describes and discusses the Asian Americans with the purpose of setting aside myths and stereotypes as well as providing some information helpful to understanding the Asian Americans within the rehabilitation process.*

---

In his landmark work on rehabilitation, Wright (1980) pointed out the importance of cultural variables in the rehabilitation process. Especially underscored was the need for rehabilitation counselors to recognize the negative effects of stereotyping and culture bound attitudes (Wright, 1980).

Rehabilitation practitioners will increasingly encounter Asian Americans who are in need of rehabilitation services, as well as those who will, as fellow professionals, work side-by-side with them in providing rehabilitation services. It should be noted from the outset that there are counselors practicing in major metropolitan areas, such as Los Angeles, Seattle, Honolulu, and New York City who have already encountered and provided services to Asian Americans and who are quite familiar with the rehabilitative needs of this segment of the American population. This paper is intended more for those counselors who have yet to have extensive experience with serving the Asian American.

The reader might speculate why the need for this paper given the awareness of the multiethnic and multicultural nature of American society. However, there seems to be no lessening of racism, prejudice and discrimination despite the extended presence of Asian Americans in the United States since the 1800s. The stereotyping and expectations of Asian Americans by the larger majority in the United States is particularly significant because of the relatively small numerical size of the Asian American population in relationship to the majority population. The vast majority of the American population has had very little contact with Americans of Asian descent and many times what contact occurs is only through the popular media. Even now television, movies and advertising continue

to portray Asians with heavy accents and pigtailed, or as Charlie Chan, mysterious and inscrutable, or as Suzie Wong, an exotic sex object. At the other extreme, Asian Americans have been pitted against other minority groups and held up by the majority to be the "model" minority able to succeed and to achieve.

The purpose of this article is to introduce the reader to the current status of the Asian American population. It is hoped that the result will be an understanding by rehabilitation practitioners of Asian Americans and a sensitivity in serving them. Just as increasing numbers have made Asian Americans more visible in the political arena (*Wall Street Journal*, 1988), Asian Americans are becoming more visible in rehabilitation programs. Some of the variables that have impact on perceptions of Asian Americans as well as those variables that have had influences on Asian Americans today are discussed.

## Fast Growing Minority

Americans of Asian descent are the fastest growing minority group in the United States both from births by residents and through continued immigration. One and a half million or .8% of the population were of Asian or Pacific Island descent as identified by the 1970 census. By 1980, the census count was 3.7 million and 1.6% of the total population. During the past year, in California, Asians surpassed the number of blacks making up 9.3% of California's population (*Asian Week*, 1988). Another significant factor in the growth of the number of Asians is the admission of large numbers of refugees from Southeast Asia. One estimate has this number at about 4,000 per month (U.S. Commission on Civil Rights, 1986). The distribution of Asian Americans in the United States is uneven. The 1980 census shows that 60% reside in three states: California, Hawaii, and New York. The majority of the Asian American population is concentrated in the West where they make up 5% of the total population and in the Northeast where they constitute 1.2% of the total.

## Diversity

It is significant that Asian Americans are not a homogeneous group even though it is often said that one cannot "tell them apart." This is even more evident when Pacific Island people are included. It has been suggested that the category Asian American and Pacific American includes at least 32 distinct ethnic or cultural groups. In alphabetical order they are Bangladesh, Belauan (formerly Palauan), Bhutanese, Burmese, Chamorro (Guamanian), Chinese, Fijian, Hawaiian

H'mong, Indian (Asian or East Indian), Indonesian, Japanese, Kampuchean (formerly Cambodian), Korean, Laotian, Malaysian, Marshallese (of the Marshall Islands, which include Majuro, Ebeye, and the U.S. Missile Range, Kwajalein), Micronesian (of Federated States of Micronesia, which include Kosrae, Ponape, Truk and Yap), Nepalese, Okinawan, Pakistani, Filipino, Saipan Carolinian (or Carolinian from the Commonwealth of the Northern Marianas), Samoan, Singaporean, Sri Lanka (formerly Ceylonese), Tahitian, Taiwanese, Tibetan, Tongan, Thai, and Vietnamese (Wong, 1982).

The ethnic and cultural differences are complex and great between these groups. Not only are there vast geographical distances between the many countries cited earlier, but language and an ancient cultural heritage rich in unique customs and traditions separate these various populations as well. It would be misleading to lump them together as one homogeneous group.

### Historical Experience

Asians have been in the United States since the early 1800s. Some would argue that their presence would predate that to the much earlier time when a land bridge connected the two continents. Regardless, Asians have faced persistent racial discrimination since their arrival, with restrictions on their entrance not lifted until 1965. For example, the Chinese Exclusion Act was passed by Congress in 1872 and reinstated in subsequent years which prevented the immigration of the Chinese. And in 1924, wives of Chinese males already in the United States were specifically barred from entry.

Other discriminatory events included the humiliation and incarceration of the American citizens of Japanese descent during the Second World War. Then President Franklin Roosevelt signed an executive order authorizing the detention of Japanese Americans in relocation camps. No other minority group which manifested peaceful coexistence has experienced similar treatment in U.S. history.

### Current Discrimination

The third and fourth generations of Asian Americans still carry the onerous hyphenated label of Asian-American. Present day immigrants from Europe or Great Britain are not categorized in the same manner. More recent immigration by the South Koreans to the United States has again perpetuated the "need" to provide them with a hyphenated label, Korean-American. In another curious twist of cultural logic, the Tongans, Samoans, and Fijians do not suffer the same hyphenated labeling; but nevertheless, suffer similar exclusionary, outgroup status. Social psychological theory of cognitive consistency seems to provide some basis for understanding the need for labeling (Kitano, 1973).

There have been a number of incidents in the past few years indicating that overt discrimination continues against Americans of Asian descent. The beating death of Vincent Chin, a Chinese American, in Detroit in 1982, was the result of two laid-off automobile workers believing Chin to be Japanese and blaming Chin for what has happened with the automobile industry. Other incidents of a more current nature include problems between Vietnamese fishers and other fishers in the G  
tensions between Korean businesses and other resi-

dents in the Los Angeles and New York areas, and the death of a Chinese American woman pushed into a subway train in New York by a man who said he had a "phobia about Asians." Though often touted as a minority group that has achieved, these events clearly indicate that discrimination against Asian Americans is not a thing of the past.

Noting that racism persists, the most benign form seems to be racial tolerance and passive discrimination. Kitano (1973) theorizes that discriminatory behavior by a "normal" group can be understood by its relationship to a cohesive, identifiable subculture and the resultant restrictions (real or assumed) of their outgroup interactions. He contends that the insulation of subgroups in our pluralistic society provides a perhaps unwanted, but nevertheless powerful structure that fosters discriminatory behavior against outgroups. The person who is fully integrated into a subculture is the person most likely to discriminate. The person less fully integrated into the subculture is less likely to discriminate.

### Model Minority?

Perhaps the most prevalent view of Asian Americans is that they have made it. An initial look at the statistics would seem to bear this out. The mean earnings for workers of Asian descent between the ages of 25 and 54 are essentially at parity with whites. The mean income for Japanese American males in 1979 was about 10% higher than for white males. Korean, Chinese, and Filipino males of Asian descent had incomes of 96%, 90%, and 86% of whites. The one group with lower earnings is the Vietnamese with an income level averaging 57% of the white majority. With regard to occupational level, Asian Americans would also seem to have done well. Almost 13% of Chinese and Japanese Americans were executives or managers compared with 11% of whites. However, the figures for Korean Americans were 9.9%, for Filipinos it was 7.7%, and only 4.5% of Vietnamese.

But another real and contrasting view of the Asian American provides a different and distressing picture. The poverty rates for Chinese, Korean, and Vietnamese are considerably higher than for the white majority. Ten and a half percent of Chinese, 13.1% of Korean, and 35% of Vietnamese families are in poverty compared with 6.6% of the white population. Poverty status of the Vietnamese is the lowest nationally (Fujii, 1980).

With the often assumed strong motivation toward high educational achievement by all Asian Americans, the reality of differential achievement is sobering. In spite of high math and science achievement, Sue (1981) cited a study in which 50% of entering students of Asian descent to the University of California at Berkeley did not pass the "bonehead" English examination. Asian American students were twice as likely as whites to fail the English examination. A study in New York City (*Insight*, 1988) found that 17,500 students of Asian descent fell below the cut-off for adequate English language proficiency. This number was about 30% of the overall school population of 57,631 Asians. In the same *Insight* (1988) article, Shirley Hune, an associate professor in educational foundations at City University of New York was quoted as saying, "The stereotype is that all Asian students are excelling. The result is that

teachers and society fail to pay attention to them. Those in need are passed over because we are led to assume all is well."

Another problem area of concern in contemporary American society is drug use. What little data are available regarding Asian Americans seem to indicate drug abuse to be problematic. A report released by the Seattle King Country Drug Commission stated:

The evidence presented . . . suggests that drug use within the Asian youth community is much more serious than what is recorded by law enforcement agencies or indicated by the policies of drug treatment programs . . . Asian youth appear to use drugs at a level equal to if not higher than the national average . . . known users tend to begin the use of drugs earlier and continue in a manner and extent far above the national average. (Washington State Commission, 1983, p. 115)

Finally, a recent article appearing in *Asian Week* (1988) highlighted the problems of Southeast Asian immigrants and refugees. These include the severe disintegration of the family structure which forces many Southeast Asians to adopt lifestyles in conflict with their traditional life experience. The results include high divorce rates, family problems especially of the young who have little supervision from parents preoccupied with survival, and incidence of domestic violence.

The idea that Asian Americans are a model minority is a myth. Believing that Americans of Asian descent have made it and do not need help can interfere with providing the necessary support and services to which all Americans are entitled.

### Generational Status and Recent Immigration

Ethnic and cultural diversity among the numerous Asian American groups stretches beyond categorization. Each subgroup possesses a number of unique characteristics which should be considered if one is to have understanding of and sensitivity toward that group. More generally, however, there are characteristics, in addition to some of the historical experiences alluded to earlier, which may be useful in understanding a member from any of the subgroups.

Generational status is an important variable to consider in working with a particular individual or family. This refers to the time which the person or family has been in the United States. A fourth generation Asian American has obviously different perspectives of self, culture, etc. than a new immigrant or refugee. This is true for perspectives on family structure as well as the reliance upon support systems.

As with immigrants from Europe, the first generation Asian Americans show greater affinities for ethnic traditions, customs, and methods for dealing with sickness and adversity. The next generation, those born in the United States, show greater acculturation and attenuation towards white, middle-class standards and expectations. The third generation show a further attenuation, but one which appears more ready to confront issues of inequality.

The older generations, i.e., those who immigrated in the late 1800s to early 1900s, represent a small and diminishing group of individuals who are rural in background and not well educated. These elderly are more likely to rely on the traditional ethnic community as the primary resource. More recent im-

migrants are likely to be middle class and more demanding of services from the greater community.

Recent immigrants, such as the Hmong from Southeast Asia, experience more keenly stressors such as a breakdown of the car, homesickness, lack of information on medical services, loss of job and communication problems at work, and unpleasant work experiences. It seems the more recent the immigration and the smaller the supporting ethnic community, the greater the stress reaction.

The more recent the immigration to the United States, the greater the anxiety about dealing with unknown governmental procedures and the resultant reluctance in requesting needed public services. It appears that many of the Asian Americans with disabilities do not identify themselves out of fear of dealing with governmental agencies.

Though acculturation or more specifically, Westernization, is often cited as an important element in understanding where a person is and how they would describe their values, etc., it is not always linked to generational status. An illustration of this would be a person born in the United States, but due to whatever circumstance lives in a traditional ethnic community insulated from outside contact.

Within any given group, there may be additional differences important to understanding individual and family attitudes and perceptions (Lee, 1982; Smith, 1985). Although Chinese by descent, a person or his forebearers might have come from many different areas not only in China but also from other Asian countries.

Variations in the use of one's "native" language and one's competence and comfortableness in doing so may be an important factor in fostering communication and successful rehabilitation. The difficulty of translated concepts between languages has often been cited as problematic in health care settings. Rehabilitation would be no different. Fluency in English and skills in communication are not exclusively tied to American-born Asians, it is often the case that apparent limitations can be found among the second generation, i.e., those born in the United States.

While educational achievement would appear to be a clear cut prediction of social competence, it is critical to know not only the level of education attained but also where that education was obtained. Whether or not the education was obtained in the United States or in Asia may be vital to understanding and being sensitive to particular styles of thinking and problem solving.

### Attitudinal Differences

The differences between white and Asian American students are important to our understanding of the unique help-seeking process of Asian Americans. However, previous comparison studies (Tracey, Leong, & Glidden, 1986) seem to imply that all Asian Americans are alike, that is, that Chinese Americans are similar to Japanese Americans, both of whom are similar to Filipino Americans. This uniformity myth may have some value when whites are the standard of comparison, but each of the Asian American cultures is quite distinct. Asian Americans are often not only not collective, but are subgroups of Chinese Americans or Japanese Americans. Analyzing all Asian

Americans together neglects important self-identified differences among the various Asian cultures (Sue & Kirk, 1973; Kuo, 1984) as resources to better understand Asian cultural differences.

Potentially negative social and political attributions have an impact on accessibility and service delivery that is often overlooked. That some Chinese Americans have an affiliation with the anticommunist movement or to have current ties with the Taiwan government versus any identification with mainland China can affect our understanding of them.

### Use of Health Resources

Local community networks, whether formal or informal, are important. For first generation immigrants, traditional family associations often wield considerable power in choice and access to health and rehabilitation resources. The organized formal churches where ethnic groups congregate are important for information exchange and knowledge about resources. Informal networks such as "majong" groups that congregate daily or weekly may be useful in education, etc. Ethnic media, newspapers, radio, or television also affect perceptions and attitudes.

The search for relevant health or mental health services first takes place within the local ethnic community, based upon kinship and local associations, it is only when these resources within the ethnic community are exhausted that the older Asian is forced to seek outside public services, interaction with the outside, greater community limits access or utilization of available services.

Within any particular Asian group in the United States, there are a considerable number of factors that influence its members in seeking rehabilitation services. Even among new arrivals, their particular status as either immigrants or refugees may be important. As Liu (1987) has indicated, there are subtle or sometimes not so subtle influences. Refugees may experience an "acute flight" situation where there was little preplanning and they may have entered the country with little knowledge of the destination. On the other hand, immigrants may have spent some time learning about their destination and learning skills that will be needed for successful adaptation.

Age may be another factor of importance. For example, in working with older persons, the professional must be cognizant of the client's frame of reference. Traditions, customs, etc. need to be explored with the client and the support person(s). Diet preferences, mode of hospital dress, propriety of interview techniques, perception of the sick role, are subtleties in variables which need to be integrated as part of the rehabilitation process. The rehabilitation practitioner might do well to seek the assistance of someone the client trusts and who can facilitate communication. Many elderly are confused by self-directed decision making and choice selection and rely heavily on medical authority. Clients often view health professionals as ineffective if the client is left with the decision making. Authority by role and professional status are relied upon for decision making.

Rehabilitation professionals need to understand that Asian American clients and their families in fact have many differences among them. These differences are not easy to recognize,

to even catalog or inventory, but knowing that they are there may be equally as important in successfully working with this particular population as the treatment itself. That basic psychological tenet of not generalizing and working with the individual becomes that much more important. The rehabilitation professionals may need to understand their own attitudes and feelings along with their expectations and perceptions of Asians.

In summary, rehabilitation counselors and rehabilitation practitioners who work or plan to work with Asian Americans with disabilities need to understand the diversity of Americans of Asian descent and not attempt to treat them all in the same manner. It is helpful for rehabilitation counselors to be aware of the historical experiences of Asians in the United States and the discrimination they continue to face if rehabilitation counselors are to be sensitive to their Asian American clients' needs. Finally, in spite of the progress that Asian Americans have made, this progress is not reflected equally either in all the Asian American populations or often within each group and rehabilitation counselors would do well not to dismiss Asian Americans as having the capability of solving their own problems. Given a single Asian American ethnic group, its within-group differences in response to severe disability will vary according to status as recent refugees, elderly naturalized citizens and U.S. born citizens all will show differences in the effects of acculturation or Westernization, assimilation, and ethnic identity. Much more research regarding the impact of disability on Asian Americans and ways to work effectively with them is needed. The contemporary Asian American, in contrast to the traditional, stereotyped image, is not well known and difficult to describe. However, rehabilitation practitioners will be increasingly called to provide rehabilitation to Asian Americans. Recognition of Asian American traditions, the individual and family forces impacting on them, their world view and their use of human services will bring about a more effective practitioner.

# HISPANIC WOMEN AND MENTAL HEALTH

## *An Overview of Contemporary Issues in Research and Practice*

Hortensia Amaro  
Boston University School of Medicine

Nancy Felipe Russo  
Arizona State University

In 1985, there were 8.5 million Hispanic women in the United States — 1 of every 17 women. It is estimated that by the end of the 20th century, Hispanics will be the largest U.S. minority group (Bureau of the Census, 1981a). The rapid growth rate of the Hispanic population reflects a combination of its younger age (so that a larger proportion of women are in

We would like to thank Patricia Arredondo, Manuel Barrera, Deborah Belle, Martha Bernal, Sanford Braver, Laura Brown, Glorisa Canino, Lillian Comas-Diaz, Oliva Espin, Irene Frieze, Angela Ginorio, Sara Gutierrez, Christine Iijima Hall, Jean Hamilton, Nancy Henley, Alexandra Kaplan, Rita Mae Kelly, Brenda Major, Vivian Makosy, Angela McBride, D. Allen Meyer, Carol Nadelson, Anne Petersen, Kathleen Pottick, Lenore Radloff, R. E. Roberts, Gloria Romero, Banisa Saint-Damian, Elaine Soto, Cynthia Telles, Carol Valentine, Meiba Vasquez, Ena Vasquez-Nuttall, and Maxine Baca Zinn, who provided extensive comments on the manuscripts that were submitted. Every manuscript that was included received an outside review and underwent an extensive revision process. In addition to the manuscripts published here, several are in the process of revision for later publication in *Psychology of Women Quarterly*. We are pleased that our goal of serving as a catalyst for the publication of research on the psychology of Hispanic women is being met, and want to express our appreciation to Editor Janet Shibley Hyde for her support and patience in the process. A special acknowledgment goes to Beth Roberts, of Cambridge University Press, for expediting the publication process. We would also like to thank Karen Applegate, Beth Walker-Corkery, Ria Hermann, and Lynn Virdin for assembling background materials for the issue, and Jan Lamoreaux for her secretarial assistance in processing the manuscript submissions. This work was partially supported by Amaro's Research Fellowship from the Hispanic Health Research Consortium funded by the National Coalition of Hispanic Health and Human Services Organizations, and the Migrant Program of the College of Liberal Arts and Sciences of Arizona State University. This project was a joint venture, with order of authorship for this overview determined alphabetically.

childbearing years), its higher fertility rate, and continuous migration from Mexico, Puerto Rico, and other Latin American countries.

Mental health policymakers have begun to recognize the importance of developing culturally sensitive mental health services for the rapidly growing Hispanic population (Subpanel on the Mental Health of Hispanic Americans, 1978; Task Force on Black and Minority Health, 1986). However, the gender bias that pervades mental health theory, research, and practice (cf. Russo, in press, for a review) is mirrored in mental health services designed to reach Hispanic populations. Furthermore, arguments that therapeutic activities and structures should reflect Hispanic culture have been used to reinforce stereotypical sex roles (Rogler, Malgady, Costantino, & Blumenthal, 1987), and have failed to recognize the realities of contemporary Hispanic women's lives.

A new scholarship on the psychology of Hispanic women is emerging — a scholarship that recognizes the reality and diversity of Hispanic women's attitudes, behaviors, roles, and circumstances. Researchers have begun to challenge the stereotype that all Hispanic women and men hold rigid conceptions of sex roles (Andrade, 1982; Hawkes & Taylor, 1975). As Vazquez-Nuttall, Romero-Garcia, and De Leon (1987) point out in their review of the literature, education and urban background have long been recognized as important influences on the sex roles of Puerto Rican women within the family (Stycos, 1955). These authors note that more recent work on other Hispanic populations has examined the effects of acculturation, education, and labor force participation on Hispanic women's attitudes, roles, and status. They conclude that the changes in roles of Hispanic women cannot be attributed primarily to acculturation. They also found that Hispanic women's increased education and labor force participation do not have homogeneous effects in changing sex roles and the distribution of power in Hispanic families. Their work documents the need to explore the relationships among attitudes towards gender and sex roles and personality traits and behaviors. Clearly, much needs to be learned if we are to understand the mental health consequences of the changes in Hispanic women's lives and circumstances (Andrade, 1982; Hawkes & Taylor, 1975; Russo, Amaro, & Winter, 1987).

While Hispanics as a group share some common cultural and linguistic characteristics, the umbrella term "Hispanic" is applied to groups with distinct historical, political, economic, and racial differences. The immigration and migration processes of these groups are distinctly different and have direct bearing on the economic, social, and political characteristics of each Hispanic group. While a complete review of the multiple factors affecting the status of various Hispanic groups in the United States is beyond our scope, the reader is referred to the excellent book by Moore and Pachon (1985) entitled *Hispanics in the United States* for an introduction to these issues.

The grouping of Mexican-Americans, Puerto Ricans, Cubans, and individuals from other Latin American countries and Spain in the gathering

and reporting of data can produce misleading findings and lead to erroneous conclusions. For example, policymakers interested in increasing Hispanic access to health care might develop very different strategies if they had access to more research that examines differences among Hispanic groups. Some findings suggest that Cuban Americans and Puerto Ricans make more physician visits than either Whites or Blacks, while Mexican-Americans make fewer visits than any group (Trevino, 1986). Obtaining an accurate picture of Hispanic women's physical and mental health in the various Hispanic ethnic groups will require substantial changes in both data collection and dissemination methods on federal and state levels.

In addition to scientific concerns about the generic category "Hispanic," there are political concerns about the use of the label as well (for a review of the scientific and political arguments on terminology referring to Hispanic populations, see Hayes-Bautista, 1980; Hayes-Bautista & Chapa, 1987; Trevino, 1986, 1987).

Unfortunately, most instruments use the term "Hispanic" to gather data on the use of mental health facilities, as do mental health policy analyses that examine ethnicity (e.g., Rosenstein, 1980). We have also used the term here, as it is most generic and most widely in use currently, but do so only with recognition of its limitations (Hayes-Bautista, 1980; Hayes-Bautista & Chapa, 1987; Trevino, 1986, 1987).

### Why Focus on Mental Health?

We have chosen to focus this special issue on Hispanic women's mental health for several reasons. The first is professional responsibility. Gender and sex role biases in psychological research and practice have enabled psychology to be used to support the status quo — which means a disadvantaged status for women (Russo & Denmark, 1984). Lack of knowledge about the psychology of Hispanic women means that stereotypes rather than realities have influenced the design of mental health policies, research, and services.

A second reason for focusing on mental health is the critical need to provide information to supplement recent policy documents focusing on minority and women's mental health. Two recent publications, *Report of the Secretary's Task Force on Black and Minority Health* (Task Force on Black & Minority Health, 1986) and *Women's Mental Health: Agenda for Research* (Eichler & Parron, 1987), have established a favorable policy context for research on the mental health of minority women. Both reports lack specific coverage of Hispanic women's issues. Thus visibility for such issues assumes greater importance. We hope that this work on the mental health of Hispanic women will serve as a catalyst for policy initiatives that will stimulate new research as well as new models of mental health treatment and service delivery.

The third reason for a mental health focus is the current tension between

academic researchers and clinical practitioners in the field of psychology. We believe that the combination of research and clinical articles presented here demonstrates the benefit of mutual cross-fertilization of research and practice. The articles in this issue approach their subject matter from different perspectives and include epidemiological data as well as clinical insights. Contributors include clinical, developmental, and social psychologists; psychiatrists, sociologists, epidemiologists, and statisticians. Since understanding women's mental health requires examination of the interaction of biological, psychological, social, and cultural variables, divisiveness among subfields of psychology and competition across disciplines can detract from the advancement of knowledge, the application of research findings, and the development of services based on empirical study rather than personal impressions.

Finally, it is hoped that a focus on mental health will be a step toward remedying the lack of information on the psychology of Hispanic women in the education and training of psychologists. Although the accreditation criteria of the American Psychological Association require responsiveness to issues of gender, ethnic, and cultural diversity in clinical, counseling, and school psychology doctoral programs, there has been little attempt to incorporate scholarship on Hispanic women into graduate and undergraduate programs in psychology. Greater accessibility to new scholarship on Hispanic women is needed to facilitate curriculum integration efforts. We have developed a selected bibliography of the social science literature that should prove useful in this regard (Amaro, Russo, & Pares-Avila, 1987).

### HISPANIC WOMEN: THEIR SOCIAL AND ECONOMIC CONTEXT

To understand mental health issues for Hispanic women, it is necessary to appreciate the social and economic contexts that shape the realities of Hispanic women's lives. The demographic picture for Hispanic women differs depending on Hispanic ethnic group in psychologically significant ways that merit attention by mental health scientists, professionals, and policymakers. According to the March 1985 Current Population Survey (Bureau of the Census, 1985b), Hispanics living on the U.S. mainland have the following backgrounds: Mexican (61%), Puerto Rican (15%), Cuban (6%), and other Central and South American countries and Spain (18%). The latter group is comprised of a growing number of individuals from the Dominican Republic, El Salvador, Honduras, and Guatemala, many of whom have emigrated for political reasons. Unfortunately, demographic data are not consistently available on the various groups that comprise this group of Hispanics. There has been little work on the differences and similarities among Hispanic groups in general, let alone specific study of variables related to gender and sex roles (Vazquez-Nuttall et al., 1987).

Special difficulties are found in the collection and reporting of informa-

tion on Puerto Ricans. Census information and health statistics typically focus on the U.S. resident population, which includes only residents of the 50 states and the District of Columbia. The over 3 million individuals who reside in the U.S. Commonwealth of Puerto Rico are thus not included in the decennial census reports. Psychological research involving island Puerto Ricans is also scarce, so that little information about this specific Hispanic group is available. The work by Canino and her colleagues with this population (1987) is a notable exception.

As Salgado de Snyder (1987) and Espin (1987) point out, the experiences of migration and immigration have significant mental health implications. While migration/immigration and cultural adaptation issues are important for all Hispanic groups, the proportion of individuals not born in the continental U.S. varies among them. The majority of Mexican-Americans (75%) are born on the U.S. mainland. In contrast, most Puerto Ricans (55%), Cubans (75%), and Central or South Americans (64%) are born elsewhere (Moore & Pachon, 1985).

Regional issues must be taken into account, particularly when discussing service delivery issues. Hispanics live in every state, but are concentrated in the Southwest (Mexican Americans), Northeast (Puerto Ricans), and Southeast (Cubans) (Bureau of the Census, 1981c). Urban issues affect a larger proportion of the Hispanic population than the Anglo population. Puerto Ricans (97%), Cubans (97%), and Mexican-Americans (85%) are more likely to live in metropolitan areas than Anglos (74%) (Bureau of the Census, 1985b), and urban residence has also been found to be associated with higher rates of symptomatology (Canino et al., 1987).

Espin (1987) points out the critical role that the ability to switch back and forth between English and Spanish can play in therapy. While not all Hispanics speak Spanish, it is estimated that over 11.5 million people in the U.S. (5% of the nation's population) speak Spanish in the home (Moore & Pachon, 1985).

As Russo, Amaro, and Winter (1987) point out, age is significantly related to the etiology and diagnosis of mental disorder, as well as to the utilization of mental health services — and its effects vary with gender and diagnosis (Lewine, 1980, 1981; Rosenstein & Milazzo-Sayre, 1981; Russo & Olmedo, 1983; Russo & Sobel, 1981). As a group, Hispanic women are younger (median age = 26 years) than females in the general U.S. population (median age = 32 years). However, there are large differences in age distribution among Hispanic groups. Mexican-American women are the youngest (median age = 24), followed by Puerto Rican women (median age = 26), and Central/South American women (median age = 28). Cuban women (median age = 41) are older than all other Hispanic groups, and are even older than Anglo women (median age = 33) (Bureau of the Census, 1985c). Given the differences in rates of utilization of mental health services over the life cycle, the marked age differences among ethnic groups have important implications for the design of mental health services.

of Hispanic women were government and salary workers, the majority (13%) in state and local government (Bureau of the Census, 1983).

The association between income and psychological disorder is well established (Amaro et al., 1987; Belle, 1984; Cleary & Mechanic, 1983; Ross & Huber, 1985). Hispanic women earn lower wages than Anglo women. In 1984, Hispanic women earned an annual income of \$5,830 compared with \$6,949 for women overall. Puerto Rican women have the lowest annual income (\$4,985), followed by Mexican-American women (\$5,781) and Central/South American women (\$6,212). Cuban (\$6,861) and "other Spanish" (\$6,932) women earned about the same as U.S. women overall (Escutia & Prieto, 1986).

In addition to having low individual incomes, Hispanic women frequently live in poor families. In 1984, Hispanic families had a median income of \$18,833, compared to \$27,686 for Anglo families (Bureau of the Census, 1985a). Puerto Rican families are the poorest, earning 46% of nonHispanics, followed by Mexican-American (71%) and Cuban (85%) families (Bureau of the Census, 1985b).

Since Hispanics have larger families, their mean income per family member is lower than that for all families. In 1981, Hispanics earned \$4,981 per family member, compared with \$7,941 for all families (Bureau of the Census, 1983).

Poverty has been found to be so destructive to women's mental health that it has been identified as one of the priority areas for the Women's Research Agenda of the National Institute of Mental Health (Eichler & Parron, 1987). In 1984, 25.2% of Hispanic families lived below the poverty level, compared with 9.1% of Anglo families. Puerto Rican families are the poorest, with 42% of families below the poverty line, compared with 24% of Mexican-American or Central/South American families, and 13% of Cuban families (Bureau of the Census, 1985b).

Women who are single heads of households, particularly divorced and separated women, have been identified as at high risk for stress (Miller, 1987; Thoits, 1987). In 1984, 23% of Hispanic families were headed by women, compared with 12.5% of Anglo families. Puerto Ricans had the highest proportion of families headed by women (44%), followed by Central/South Americans (21.9%), Mexican-Americans (18.6%), and Cubans (16%). Furthermore, Hispanic families headed by women are more likely (53.4%) to fall below the poverty level than Anglo families (27.1%) (Bureau of the Census, 1985a, 1985b).

1153

### Family Size and Composition

Two significant demographic developments in the 1970s were the increases in the proportions of never-married and divorced (Bureau of the Census, 1981b). In 1981, 22.5% of women and 29.4% of men 15 years and older were never married; for Hispanic women and men, the figures were 26%

and 34%, respectively. For women and men ages 30-34, 10.4% and 16.4% were never married; for comparable Hispanic women and men, the figures were 10.5% and 13.5%.

Also in 1981, 9.8% of women and 7.2% of men were separated or divorced; for Hispanics, the figures were 14.1% and 6.5%. That year only 52.6% of Hispanic women 15 years of age or older were in families with a husband present. It is unfortunate that the stereotype of the traditional Hispanic woman, married and devoted to home and family, has led to a lack of knowledge about the large numbers of Hispanic women who do not conform to the traditional family model. Given that one in seven Hispanic women over age 15 is separated or divorced, and thus at high risk for psychological distress if not disorder, the lack of research on the mental health effects of marital dissolution on Hispanic women is of particular concern.

Having children at home has been found to contribute to depressive symptomatology (Cleary & Mechanic, 1983), particularly under conditions of economic hardship (Ross & Huber, 1985), and stress related to parenting has significant mental health implications (Eichler & Parron, 1987). Hispanic fertility is higher than nonHispanic fertility. In 1984, the fertility rate (number of births for every 1,000 women aged 15-44 years) for nonHispanic women was 64.3; for Hispanic women it was 91.5. "Other Hispanics" (Central and South American, and other and unknown Hispanic origin) had the highest rate (109.6), followed by Mexican-Americans (95.8), Puerto Ricans (65.6), and Cubans (44.7) (Ventura, 1987).

Teenage childbearing has been linked to a variety of psychological, social, and economic problems (Hayes, 1987; Russo, 1986). Hispanic women are more likely to begin childbearing in their teenage years compared with nonHispanic women. Teenage births accounted for 18% of births to Mexican-American mothers and 21% of births to Puerto Rican mothers in 1984. The comparable figure for nonHispanics was 12%. Cuban mothers are the exception—only 8% of Cuban births were to teenagers, which reflects the tendency of Cuban women to be older than other Hispanic groups.

In 1984, an estimated 28% of Hispanic births were to unmarried mothers. The proportion varies widely by ethnic group: 51% of Puerto Rican, 34% of Central and South American, 24% of Mexican-American, and 16% of Cuban births were to unmarried women. In contrast, 11 percent of white nonHispanic births were to unmarried women (Ventura, 1987). Births to unmarried mothers, particularly teenagers, are likely to be unplanned and unwanted (Hayes, 1987; Russo, 1986). The prevention of unwanted childbearing has been suggested to be a critical strategy for primary prevention of psychological distress and mental health problems (Russo, 1985).

In summary, the economic and social circumstances of Hispanic women vary among Hispanic groups, and differ from Anglo women. Hispanic

women as a whole, however, are overrepresented among lower socioeconomic classes and younger ages. Thus it is important to control for economic, social class, and age differences before attributing Hispanic/Anglo differences in attitudes and behaviors to differences in cultural values. All too often, acculturation and "Hispanic cultural values" are invoked to explain behaviors without consideration of more proximal economic, social, and life cycle variables that could be influencing the behaviors as well.

## BASIC ISSUES IN MENTAL HEALTH RESEARCH AND SERVICES

### Service Access

Reports on Hispanic mental health have underscored access to services as a basic issue (Subpanel on the Mental Health of Hispanic Americans, 1978; Task Force on Black & Minority Health, 1986). Epidemiological analyses of utilization statistics have suggested that Hispanics are admitted to mental health facilities at lower rates than Whites or Blacks (Rosenstein, 1980). Russo et al.'s (1987) description of Hispanics' use of inpatient mental health facilities emphasizes the importance of examining gender differences in utilization patterns. They point out that when the currently available survey data on utilization of inpatient mental health facilities are examined by ethnicity and gender, Hispanic women appear to account in large part for the underrepresentation of Hispanics in these facilities. While the extent to which underrepresentation of Hispanics is due to unreliability of measurement, difference in prevalence, differential marriage and divorce rates in response to mental disorder, differential help-seeking, or other factors is not known, the findings are suggestive and underscore the great need for research on mental health issues for Hispanic women.

### Cultural Sensitivity of Services

Feminist criticism of psychotherapy as a form of social control has been well established in the psychological literature (cf. Carmen, Russo, & Miller, 1981; Subpanel on the Mental Health of Women, 1978). The use of psychotherapy to promote social control of Hispanic women deserves similar criticism. It was not until feminist Hispanic psychologists began to redefine the issues and develop therapeutic alternatives that the preservation of *traditional* cultural elements in the design of mental health services began to be questioned (Boulette, 1976; Canino, 1982). Cultural sensitivity should incorporate a recognition of the changes in Hispanic women's roles and circumstances (Vazquez-Nuttall et al., 1987), and should not reinforce a disadvantaged social and economic status for such women. The

articles by Espin (1987) and Comas-Diaz (1987) are particularly helpful in this regard.

### Gender Roles and Depression

Canino and her colleagues (1987) point out that both clinical and community studies of Anglos and Hispanics have consistently reported a higher rate of depressive symptoms and depressive disorders in women compared with men, and the rate of depressive symptoms is higher in women regardless of acculturation level. They review the literature on sex differences in depression, and report results from their survey of the prevalence of depressive disorders and symptomatology in a probability sample of the adult Puerto Rican island population. Their finding that gender differences in depressive symptomatology are greater for island Puerto Ricans than for U.S. mainland populations is interpreted as reflecting the more patriarchal social context of Puerto Rican society.

Comas-Diaz (1987) focuses on feminist therapy with mainland Puerto Rican women, examining the experience of cross-cultural translocation, the colonial background of Puerto Rico, and the complexity of identity development for contemporary mainland Puertorriqueñas. She points out that there has been an increase in feminist awareness and questioning of gender roles among women in Latin America. Feminism, with its political and social values that support the equalization of power between the sexes, is seen as relevant to all women, although acquiring a different form in the specific Hispanic reality, and depending on the social and cultural context. She expands Canino's description of the patriarchal nature of Puerto Rican society, discussing implications of concepts such as *espiritismo*, *marianismo* and *hembrismo* for empowerment of Puerto Rican women. She discusses the implications of the process of transculturation for the self-identity of mainland Puerto Rican women, and discusses the application of feminist therapy to this population. Her approach complements and enriches the epidemiological analysis of Canino and her colleagues.

### Acculturation and Migration/Immigration

Acculturation, the process by which the immigrant's attitudes and behaviors change toward those of the dominant cultural group as a result of exposure to the new cultural system (Rogler et al., 1987), has been identified both as a source of stress as well as a factor affecting access and appropriateness of treatment in Hispanic populations (Canino, 1982; Rogler et al., 1987). Like the Puerto Rican women discussed by Canino et al. (1987) and Comas-Diaz (1987), Mexican-American women report more depressive symptoms than Mexican-American men, even after controlling for effects of age, education, and income (Roberts & Roberts,

### Overview

1982). Salgado de Snyder examines factors associated with acculturative stress and depressive symptomatology among married Mexican immigrant women, finding them at risk for psychological problems due to discrimination, sex role conflicts, and concern about starting a family in the U.S. She underscores the need to study patterns of psychosocial adjustment among immigrant Hispanic women.

Espin's clinical approach complements the survey research conducted by Salgado de Snyder (1987). She examines the psychological implications of the immigration process, addressing issues that immigrant Hispanic women frequently present in therapy related to gender roles, acculturation, language, and loss and grief. Her clinical observations point to the need for research on therapy with bilingual patients. She suggests that the combined use of English and Spanish in therapy can facilitate the emergence and discussion of taboo topics, and can be an important tool for reclaiming parts of the self lost in the process of acculturation. Most importantly, she points out that these reactions to migration are *normal* consequences of a disturbing process and not signs of individual pathology. After reading her article, it is clear that all therapists working with immigrant Latinas need to understand the effects of the migration process.

### Employment and Mental Health

Most discussions of mental health of Hispanic populations have been based on a picture of a "... person pressured and harassed by problems of poverty, slum life, and lack of acculturation into American society" (Rogler et al., 1987, p. 567). While we have described how Hispanic women, with the exception of Cubans, are likely to have lower incomes, less education, and higher fertility than Anglo women, 13% of Hispanic women have a professional or managerial status (Bureau of the Census, 1985b). Amaro et al. (1987) examine family and work predictors of psychological well-being among this select group. Their findings emphasize the need to conduct separate analyses for Hispanic women of diverse ethnic groups. They underscore the importance of examining characteristics of both home and work environments if a complete picture of factors influencing employed women's mental health is to be attained. Further research is needed to examine how employment and family conditions affect the mental health of Hispanic women in professional and nonprofessional occupations. Since a disproportionate number of Hispanic women are employed in services, clerical, and operative occupational categories, research on women in those occupations is particularly important.

The picture of the active, effective, professional Hispanic women that emerges from their research rebuts the cultural stereotypes that depict Hispanic women as solely deriving their identity and personal life satisfaction from the roles of mother and wife, and communicates instead the

reality of the multiple sources of personal and life satisfaction for these women.

It is noteworthy that experience of discrimination was associated with psychological distress symptomatology in work by Salgado de Snyder with immigrant women, as well as by Amaro, Russo, and Johnson with high income, highly-educated professional women. It appears that addressing issues of discrimination has potential mental health benefits for a diverse group of Hispanic women.

### A LOOK TO THE FUTURE

As Amaro et al. (1987) observe, there is a growing body of research on Hispanic women, but most previous studies have focused on Hispanic women's functioning in traditional roles. Even the work on the mental health of Hispanic women has focused on conflicts engendered by traditional Hispanic culture. It is our goal that the work presented here will help to stimulate research that will empower Hispanic women, change the nature of treatment and service delivery, and transform education and training programs so that they will truly encompass human diversity. The selected bibliography by Amaro, Russo, and Pares-Avila (1987) is designed to facilitate such research in addition to enhancing efforts to integrate scholarship on women into the curriculum.

In conclusion, it is increasingly recognized that gender plays a critical role in the etiology, diagnosis, treatment, and prevention of mental disorder and in the promotion of mental health and well-being. If the nature of that role is to be understood for all women, research design and analysis must advance beyond the use of sex as a correlated or predictor variable. As Vazquez-Nuttall et al. (1987) demonstrate, the concepts of masculinity and femininity may take on different meanings in different cultural traditions. Thus, gender must be conceptualized as a dynamic construct that *itself varies across ethnic groups and social classes* and works in complex interaction with other psychological and social factors (Russo, 1987). We believe that work in the psychology of Hispanic women thus can inform all gender research.

#### NOTE

1. The term "Hispanic" refers to persons of Spanish origin, including Mexican, Puerto Rican, Cuban, Central or South American, and Spanish. Hispanics may be of any race. The term "Anglo" refers to Whites not of Hispanic origin.

## — CHAPTER TEN

# Cubans

---

GUILLERMO BERNAL AND MANUEL GUTIERREZ

### INTRODUCTION

The role of ethnicity or culture is a central consideration in providing health and mental health treatment to minority populations. Clinicians need to be equipped with basic information about the group in question, as it is critical to define what may be general and what may be specific to a particular ethnic group.

Three questions are important to consider when examining the role of ethnicity and culture in clinical work:

1. What are the effects of culture on individuals and families?
2. How does one learn about and use culture in a therapeutic way?
3. How do the effects of culture and social class interact?

A problem in defining any cultural group is that, by necessity, any description freezes the culture in time. While culture may be defined as the social transmission of ideas, attitudes, and traits that condition social

The authors are grateful to Braulio Montalvo and A. Michael Rossi for their careful review and helpful comments on this manuscript.

behavior (Bernal & Alvarez, 1983), it is difficult to describe the fluid and dynamic nature of the transmission of these ideas and behaviors. Indeed, the risk involved in static descriptions is of supporting cultural stereotypes and prejudicial views. Culture must be understood as a *process* linked to time, conditioned by the evolving social and economic context of the ethnic group in question.

However, even when these caveats are taken into consideration, there is no guarantee that the knowledge of culture would enable a therapist to become more effective in dealing with an individual or a family (Montalvo & Gutierrez, 1983). For example, within a family systems model, therapists who overstress the role of culture can be creatively assimilated by their clients. Montalvo and Gutierrez (1983) point out that a therapist should focus on fundamentals—what is basic to families—rather than on idiosyncratic cultural dimensions that may tend to make the family alien to the therapist. A helpful dimension is to look at the interinstitutional relationship between the family and the host culture, and to look at how successful or unsuccessful the family is in traversing these often complex relationships. Often, failure in these interinstitutional relations gives rise to dysfunctional patterns or pathology.

The notion that a bicultural socialization occurs when there is some successful integration from a minority to a majority culture was supported by de Anda (1984), who emphasized the bicultural socialization role of social welfare workers. In searching for a model that would be helpful for therapists working with the family, de Hoyos, de Hoyos, and Anderson (1986) identify two traditional approaches to the understanding of minority problems in social work: cultural dissonance and institutional racism. The cultural dissonance approach focuses on the problems that emerge because of cultural differences, while the institutional racism approach views problems as the result of discrimination in social structures. The authors describe a three-stage model that goes beyond cultural dissonance and institutional racism explanations, progressing from individual intervention to interactional intervention to sociocultural intervention. The sociocultural approach looks at the interaction of the individual with "the impersonal institutions of society—the economy, the government, religion, and education" (p. 62), allowing for more comprehensive interventions.

The purpose of this chapter is to describe a minority population—Cubans—by pointing out some characteristics that may be more predominant among this minority than among other minority groups in the United States. Specifically, we are referring to demographic, political, and migratory differences. Later on we will discuss some of the mental health problems that this group faces, though it is important to note that, when dealing with clinical syndromes, we do not consider that there are any typically Cuban

syndromes. In fact, we believe that any individual or family from any other minority group could present the same clinical pictures found among Cubans-Americans. The notion of culture-specific syndromes is not a particularly helpful one for clinicians. Rather, we prefer to examine the dynamics and areas of friction between two cultures, and to study interfaces that provide valuable diagnostic clues as to what is going on with a particular individual or family.

## CUBANS IN THE UNITED STATES

Cubans represent the third largest Hispanic group in the United States. The U.S. Census Bureau reported the Cuban population to be 803,226 in 1980. However, this figure did not include the almost 125,000 Cubans who immigrated to the United States from the port of Mariel during the later part of 1980. Thus the Cuban population in the United States rapidly increased by 15 percent in a matter of months and exceeded the figure of over 1 million inhabitants (Santistevan & Associates, 1984).

Cubans have established themselves throughout major metropolitan areas in North America. Miami is clearly the central geographic location, with a high concentration of Cubans. Seventy percent of all Hispanics (580,995) in Dade County, Florida, are Cuban or of Cuban descent. The other key geographical areas with a significant Cuban presence are New Jersey and New York. A sizable though smaller proportion of Cubans are also found in Los Angeles, Chicago, and other major American cities.

In comparison to other Latinos in the United States, Cubans have been considered a model minority group as measured by indices such as income and educational level. Bernal (1982) has noted that the so-called "success" story of Cubans must be tempered by the unusual demographic characteristics of its migratory waves and the response these groups received from the United States.

Briefly, first-wave Cubans migrated between 1959 and 1965. Pooling census data with registries at the Miami Cuban Refugee Center, Jorge and Moncarz (1980) estimated that 183,426 Cubans arrived during this wave. This group was disproportionately composed of Whites, upper-class, upper-middle-class, and middle-class Cubans who had educational, business, and financial resources and shared a set of values and beliefs in common with the dominant U.S. culture. First-wave Cuban immigrants received massive financial, educational, and training support from the federal government (Bernal & Estrada, 1985; Cortes, 1980a; Cortes, 1980b; Pedraza-Bailey, 1985; Prohías & Casal, 1980). The Cuban Refugee Program, the Cuban Student Loan Program, and the Small Business Administration Program are

but a few of the resources and opportunities that the federal government made available to Cubans. It is no small wonder that Cubans fare comparatively better than Mexican-Americans, Puerto Ricans, and other Hispanics (of Central and South American origin) in population indices of education, income, and occupational levels (Santistevan & Associates, 1984).

The second major wave of Cubans began in 1965 and ended in 1973. About 264,300 persons entered the United States at this time (Jorge & Moncarz, 1980). The opening of the port of Camarioca to all who wished to leave Cuba was an interesting historical precedent to the Mariel incident. About 5000 Cubans left in boats to Miami prior to the immigration agreement that resulted in the airlift from Havana to Miami. Cubans leaving at this time were composed of middle-class, lower-middle-class, and working-class persons. This group resembled more the traditional immigrant to the United States but again was not representative of the Cuban population as a whole, since this wave was heavily represented by Whites, adults, and women.

During the summer of 1980, a third wave of Cuban immigration began. By 1982, the influx of Cubans from Mariel was reduced to a trickle but the Cuban-American population had grown by 15 percent. In contrast to the first two waves, the wave of Mariel immigrants reflected the Cuban population as a whole in terms of race, occupational levels, and education. This wave was mostly composed of working-class persons who looked to the United States for economic opportunities. A second, smaller group was composed of "antisocial" persons who lived on the fringes of Cuban society (Bernal, 1982).

Understanding the nature of the Cuban migration is critical in order to appreciate the differences between Cuban-Americans, Mexican-Americans, Puerto Ricans, and other Latinos as well as the differences in the socioeconomic structures of these groups. The Cuban migration as a whole is a "political" phenomenon, not solely because the motivating factor to migrate was either economic or political (Fagen, Brody, & O'Leary, 1968). As already described, the different immigration waves from Cuba were made up of persons wishing to leave Cuba for multiple reasons (economic, political, or both). What is important in understanding the differences between Latino minority groups is the sociopolitical relationship between the two countries and the response to the migration of the host culture. For example, the social and political relationship between the United States and either Puerto Rico or Mexico has been such that neither group warranted a "political" response by the host country. By comparison, the Cuban immigration served a variety of U.S. political interests (e.g., destabilizing Cuba, pointing to the dangers of socialism, etc.).

The view of the Cuban immigration as a political phenomenon is further supported by the socioeconomic structure of the Cuban-American society

that developed in the United States. We shall now turn our attention to describing further the demographic profile and examining differences among Cuban-Americans as a means to appreciate the sociocultural heterogeneity of this group. As will become clear, these distinctions are necessary as it is impossible to speak of one single Cuban-American culture. When examining culture and ethnicity, it is necessary to frame the discussion in terms of the subculture of specific socioeconomic groups.

### *Social and Economic Differences Among Cuban-Americans*

One of the unique aspects of the Cuban experience is a politically linked migration. This meant that substantial sectors of upper-class, upper-middle-class, and middle-class Cubans left, bringing with them educational and occupational resources; some already had financial resources in the United States. While many Cubans, as with most other immigrants to the United States, experienced a significant downward socioeconomic move as a result of the migration (Jorge & Moncarz, 1980), substantial sectors of the Cuban community developed retail and manufacturing enterprises. Indeed, as early as 1967, Jorge and Moncarz (1980) found 919 Cuban-owned enterprises in Miami. This number had almost doubled by 1969 and had increased to 8000 by 1976. Thus in a relatively brief period of time the beginning of an economic enclave in the Cuban community was developed, and with it emerged a social structure resembling that of pre-1959 Cuba. (Because of the limits of space, we have restricted our discussion to Cubans in the United States. It should be noted that there are large Cuban communities in Puerto Rico and other parts of Latin America. For a discussion of Cubans in Puerto Rico, the reader may refer to the work conducted by Perez-Cruz [1984] and Esteve [1984].)

While the migration weakened some of the class barriers of pre-1959 Cuba, what is evident in the Miami Cuban enclave is a reproduction of that very same class structure, the exception being the *nouveau riche*, who rapidly rose in the socioeconomic ladder during the social vacuum of the early 1960s. The resettled Cuban aristocracy together with the *nouveau riche* make up the Cuban elite. Efforts to preserve the status system and values of prerevolutionary Cuba are pervasive. For example, the aristocratic clubs that were prevalent in Cuba before the revolution are now also prevalent in Miami. The five main society clubs have joined under one umbrella organization, now called the Big Five Club. Membership in the club is virtually restricted to people who used to belong to similar clubs in Cuba or their family members; this is one way to re-create the previous social life in Cuba where these families can maintain a myth of aristocracy and high society.

The social structure of the Cuban community has been examined by a number of authors (Jorge & Moncarz, 1980; Portes & Bach, 1985; Prohías & Casal, 1980; Santistevan and Associates, 1984; Valdez-Paz & Hernandez, 1984). Here we will attempt to integrate the work of Valdez-Paz and Hernandez (1984), based on a study of the U.S. Census, with other analyses of the Cuban community.

Five socioeconomic groups may be identified in the Cuban community (Valdez-Paz & Hernandez, 1984). First is a Cuban-American elite that originated during the first wave of immigration. This group consists of the Cuban aristocracy and the displaced bourgeoisie, who had links to U.S. capital and contacts to U.S. business prior to 1959. Together with the nouveau riche they make up about 1 percent of the economic force, consisting of large- and medium-sized business entrepreneurs, and may number as many as 25,000 families.

The second is an upper-middle-class sector composed of professionals, owners of small businesses, retail and service shops, and so on (Valdez-Paz & Hernandez, 1984). This group is similar to the petit bourgeoisie who left Cuba but incorporates a number of individuals who established small businesses aimed at providing services to the Cuban-American community that have grown substantially since the late 1960s and early 1970s (Jorge & Moncarz, 1980). This upper-middle-class group represents about 18 percent of the total work force.

The middle class is the third socioeconomic group. This is a heterogeneous sector of the population made up of salaried individuals such as professionals, technicians, administrators, managers, and so on, who are not owners of capital. This group includes persons from the first and second wave of immigration that were largely from the middle and working classes. Also, second-generation Cuban-Americans, Cubans who migrated with their parents when they were approximately 5 to 15 years of age, and persons from the displaced Cuban elite are found among this third group. According to Valdez-Paz and Hernandez (1984), the middle class is about 21 percent of the work force.

The fourth and largest sector in the Cuban community is the working class. This is a more homogeneous group, made up of salaried workers not connected to the means of production who work in the production of materials and the provision of services. Salaried office workers are also part of this group. Valdez-Paz and Hernandez (1984) estimate that this group represents about 60 percent of the work force.

The last group to consider is an antisocial sector of society. Two subgroups are identified in this category. One is from the first wave of immigration and represents elements of the Cuban population who had links to organized crime in the United States. Arguelles (1982) has noted that the

economic roots of Cuban Miami are found in the endeavors of U.S. organized crime syndicates that prior to 1959 (the forties and fifties) developed a network of tourism, gambling, and drug trafficking. The other antisocial subgroup is a subset of the most recent immigration wave. A portion of the Mariel entrants were marginal to Cuba's social, political, and economic process; some had been incarcerated and left Cuba either voluntarily or with the encouragement of the government.

The sociocultural implications of this stratification are significant in that at one level the economic enclaves that developed in Miami and Union City, New Jersey, have facilitated the assimilation of Cubans (Portes & Bach, 1985). Also, in cities where there is an economic enclave, Cubans have been able to develop some degree of political power.

While Cubans have identified with other Hispanics on some issues (e.g., on bilingual education), for the most part they have become a highly conservative group. For example, while a majority of Puerto Ricans and Mexican-Americans voted for the Democratic Party candidates, in the 1976 and 1980 presidential elections a majority of Cubans voted for the Republican Party candidates (Santistevan & Associates, 1984). Similar voting patterns were evident in the 1984 election. The attraction to the Republican Party reflects their conservatism in international affairs.

These social processes are important to consider because the Cuban cultural experience is significantly influenced by socioeconomic status. The clinician will need to understand the Cuban experience as it exists for the Cuban elite, the upper middle class, the middle class, the working class, and the antisocial classes. Now we shall turn our attention to some of the psychological aspects of the Cuban experience in the United States.

### *The Cuban Experience in the United States*

Rumbaut and Rumbaut (1976) were among the first mental health clinicians to write about the Cuban experience. These authors, writing about the first two waves of immigrants, note that the ordeal of expatriation has produced anguish, conflicts about the uprootedness, and traumatic loss. The buffers to these losses and conflicts are the relatively high occupational and educational levels coupled with informal grass-roots social and community supports, as well as organized support from local, state, and federal government.

The psychological aspects of the Cuban exile experience can present mental health conflicts related to loyalty binds (between country of origin and host country), culture shock, initial anxiety, and depression, particularly during the early stages of the migration (Rumbaut & Rumbaut, 1976). The image of Janus—the Roman god of beginnings able to look in opposite

directions simultaneously with his two faces—captures part of the struggle facing the Cuban arrivals. Facing the past can be a painful experience as issues of cultural, familial, and economic loss, abandonment, and death must be dealt with. Facing the future means building a new life, looking to meet new challenges, and struggling in a new and different cultural context (Rumbaut & Rumbaut, 1976). The dialectical resolution between these two sides captures part of the struggle that either may be constructively resolved or may persist for years, affecting the next generation of Cuban-Americans.

For a major subgroup of Cubans—the elite and part of the nouveau riche—Cuban culture in the United States is the image of Cuba as it existed in 1959. This is a subgroup that has not progressed much beyond these values, has not assimilated much from the U.S. norms, and rejects changes that have taken place in Cuban society and Cuban culture in the island. Gozalez-Reigosa (1984) refers to these individuals as representatives of the frozen culture.

A second and larger group developed what may be termed the Little Havana culture as part of the Miami Cuban experience. This is a Cuban-American group not frozen in time, molded by the life experiences in Cuba and in the United States but not accepting the cultural manifestations from the island. Their primary point of reference is Miami.

The third group is mostly composed of young people who were born in the United States or have had most of their life experiences in the United States and have for the most part totally acculturated to mainstream North American society while rejecting traditional Cuban values.

A fourth and smaller group has demonstrated an interest in reestablishing links with their Cuban roots and with the cultural manifestations of present-day Cuba. The dialogue that started in 1978 between Cuba and the Cuban community in the United States resulted in opening up travel to Cuba for the first time in many years. Families were allowed visits, and many Cubans were able to reconnect with their country and culture or origin. The dialogue was a key event for the Cuban exile community.

Azicri (1982) has described the experience of the Cuban community in the United States as a social and political process involving two phases. The first phase extends from 1959 to 1978. This period of adaptation and assimilation was described as de-Cubanization, given the disconnectedness to the culture of origin, the attempts to reconstruct a pre-1959 Cuba in the United States, and the uncritical acceptance of U.S. values and norms. With the dialogue of 1978 and the Mariel immigration of 1980, the Cuban community went through a process of re-Cubanization. Cubans in exile were revitalized by the contact with Cuba, as well as by the energy and vigor of a new immigrant group. De-Cubanization was halted, and with it a new opportunity emerged for Cubans in the United States, that is, establishing links with their cultural roots and contemporary Cuba.

## ETHNOSOCIOCULTURAL ISSUES

A number of clinicians and researchers have written about the cultural values that may facilitate the clinical work with Cubans (Bernal, 1982; Queralt, 1984; Rumbaut & Rumbaut, 1976; Szapocznik, Kurtines, & Hanna, 1978). Like a number of other Hispanics in the United States, Cubans share many Latino and African cultural patterns (Bustamante & Santa Cruz, 1975; Ortiz, 1973) found among Caribbean and Central and South American peoples. Principally, these areas of commonality are traditional values toward the family, community and other social supports, religion, and language. Below, we provide a thumbnail sketch of Cuban cultural traits. We begin with characteristics Cubans share with other Latinos, and we will attempt to point out some of the factors that distinguish Cubans from other Latinos. Clearly, the cultural heterogeneity among Cubans is extensive, and variations are found within different socioeconomic groups.

### *La Familia*

The importance and central role of the family is pervasive among Cubans in the United States. *Familismo*, the cultural attitudes and values toward the family as central in the life of the individual, is the basis of the Cuban family structure (Bernal, 1982; Queralt, 1984). In general, the Cuban family may be characterized by powerful bonds of loyalty, commitment, and unity that include both nuclear and extended family members.

The traditional view of the family is based on a hierarchy where publicly the male is at the top and expected to be the provider. *Respeto* is a means of enforcing authority from the wife and children. Marital conflicts may arise when the wife works, thus tilting the balance of power in the marriage. As the children begin to adopt U.S. norms and values, intergenerational conflicts may also develop. In a study of Cuban family relations, Richmond (1980) found that egalitarian as compared to traditional family values were related to length of residence in the United States and greater association with North Americans. Cuban women working outside the home also insisted on egalitarian values and ideals.

Acculturation is a significant factor affecting family life. Intergenerational and marital conflicts have been documented (Bernal, 1982; Szapocznik & Truss, 1978). These conflicts often arise from the collision between the values of one generation and those of another. While the nature of Cuban marriages and family life largely depends on social class, degree of acculturation, and migration stage, the legacy of Hispanic cultural family values remain strong. For example, notions of *machismo*, female marital fidelity, and virginity are apparent in modern-day Cuban relationships. Similarly, child-rearing patterns emphasize the protection of girls to ensure their innocence.

1171

The use of *chaperonas* in courtship is still common with many families as a means of protecting their adolescent girls (Bernal, 1982).

### Language and Cuban Values

Language is probably one of the most important aspects of Cuban family life (Bernal, 1982). Language is the carrier of the culture. The cutoff from the culture of origin and the negative political connotations of reconnecting with Cuba have pushed a younger generation of Cubans into a position of over-assimilation. As a result, "Spanglish" is probably spoken most in Cuban-American homes (Queralt, 1984). The older generation speaks Spanish and the younger generation speaks a hybrid of English and Spanish or only English. Nevertheless, a recent study (Diaz, 1980) of the Cuban community found that most Cubans surveyed report speaking Spanish at home. Clearly, a Spanish-speaking capability plays a major role in the delivery of health and social services. This is particularly the case if the clinician is to work with the elderly. As Bernal (1982) has noted, an important aspect of therapy may be to facilitate a recapturing of the language if it has been lost by the younger generation.

Cuban values have been examined by a number of clinicians and investigators (Bernal, 1982; Queralt, 1984; Marin, VanOss-Marin, Sabogal, Otero-Sabogal, & Perez-Stable, 1986; Szapocznik, Scopetta, De los Angeles, & Kurtines, 1978). In general, there is agreement that Cubans are oriented more toward persons and people than to ideas or abstractions in relationships. *Personalismo* represents a dignified personal approach to social situations and a distaste for impersonal aspects of situations (Queralt, 1984).

A recent large scale study (Marin et al., 1986) of acculturation and sub-cultural differences among Hispanics found more similarities than differences between Cubans, Mexicans, and Central Americans in the United States. However, Cuban-Americans scored closer to the non-Hispanic direction than Mexican-Americans and Central Americans on the value of collectivism. Cubans tended to endorse individualistic responses in problem-solving situations significantly more often than the other two Hispanic groups.

Bernal (1982) has noted that *choteo*, a form of humor aimed at ridiculing everyone, including oneself, is common to interpersonal relations among Cubans. Ortíz (1973) considers *choteo* a typical Cuban phenomenon that often involves exaggerating things out of proportion. *Choteo* is an important mechanism to reduce tension in difficult situations and to reduce interpersonal distance. When *choteo* is combined with *ruleo*—the informal use of *usted* (you), familiarity is established in interpersonal relations and distance is diminished further.

Cubans are oriented toward lineality and hierarchy in family relations. Values of action, doing, and present orientations are preferred (Bernal, 1982; Szapocznik, Scopetta, De los Angeles, & Kurtines, 1978). Thus treatment models that focus on the present are active, aim to solve problems, and involve the family are more likely to be successful.

### Support Systems

Through religious, social, health, and political organizations, systems of support were quickly established within the Cuban community. One of the first organized systems of support was the Cuban Refugee Center. Initially, the center provided basic support in terms of food, clothing, and shelter. Additionally, financial aid, health care, and later assistance in finding work and relocating outside South Florida and housing were made available. A complete discussion of the Cuban Refugee Center and its role and functions may be found in Prohías and Casal (1980).

The church is another instrument of social support. While Catholicism is the religious preference of most Cubans, the number of Cuban Catholics appears to have decreased in the United States (Rogg & Cooney, 1980), perhaps as a reflection of their becoming more integrated into mainstream North American life. Nevertheless, the church remains a powerful base of support for families. The religious community may be an important resource in the therapeutic enterprise, particularly for the elderly Cuban populations.

Folk-healing traditions that integrate African beliefs with Catholicism are common within some sectors of the Cuban community. Indeed, *botánicas* are becoming increasingly visible in most Latino neighborhoods. A *botánica* is a store where special herbs, potions, and candles may be purchased. Some of the *botánicas* are operated by *santeros* or *espiritistas* (mediums). *Santeros* are individuals who initiate others in the religion or faith-healing system of *santería*, an Afro-Cuban religion that combines the beliefs of the African (Yoruba) *Orichas* with the Catholic saints. According to Sandoval (1977) a *santero* is a priest dedicated to the cult of the *Orichas* who also functions as a healer, diviner, and director of rituals. *Santeros* believe that diseases are due to natural and supernatural causes. While a survey of the health and mental health needs (Diaz, 1980) among Cubans found that the majority of those surveyed do not use *santeros* as a primary service of health care, one out of every four respondents indicated he or she would use *santeros*, if needed. In contrast to *santería*, *espiritismo* is a faith-healing system that predominates in Puerto Rico but is found in the Oriente region of Cuba. Spiritist practice is based on a medium as a healer who exorcises the spirits causing the illness (Bernal, 1982). With some individuals, mobilizing the

BEST COPY AVAILABLE

1173

1172

folk-healing system of support can be an important leverage in therapeutic change.

Health, social, and political organizations constitute another important source of support. For example, private clinics are preferred in Miami by low- and moderate-income Cubans (Diaz, 1980). These clinics follow a tradition established in Cuba during the forties and fifties where individuals and families became members of private clinics and were thus entitled to received a variety of health services. With the trend toward privatization in the United States, these *clínicas* are becoming increasingly popular in Miami. Social and political organizations, while diverse and heterogeneous, provide another source of support and cohesion for the community.

## CLINICAL ISSUES

### *Attitudes Toward Mental Health*

Prior to the Cuban revolution in 1959, most Cubans perceived mental health services as the treatment of "crazy" people. A strong social stigma prevented seeking psychotherapy. Psychology was an emerging profession with few qualified clinical psychologists, most of whom had trained in the United States (Bernal, 1985; Garcia-Averasturi, 1980). Psychiatry was associated with the infamous *Mazorra* hospital in La Habana, a custodial institution for chronic mental patients lacking the most basic standards of hygiene and nutrition (Camayd-Freixas & Uriarte, 1980). Thus changes in attitudes toward mental health—for the pre-Maríel Cuban immigrants—reflect the influence of prevailing attitudes and behaviors in the host culture. Two survey studies to be described provide the most detailed information on this specific issue.

In a survey of 300 Cuban adults in West New York, New Jersey, Rogg and Cooney (1980) explored attitudes and behaviors related to mental health. When asked to whom they would turn for help if they or someone in their families developed serious nervous or emotional problems, 46 percent would go to their family doctor as a first choice, with another 28 percent seeking help from friends or relatives, and 13 percent from a therapist in private practice. Interestingly, only 2 percent of the sample stated that they would go to a mental health clinic as a first choice. When asked, more specifically, whether they would consider consulting a mental health professional if they had a problem, 84 percent indicated that they would definitely consider it and another 12 percent would probably consider it. When asked the kind of mental health professional they would prefer to use, 35 percent would go to a psychiatrist in private practice, 31 percent to whomever the

family doctor recommended, and 13 percent to a psychologist in private practice. Only 11 percent would seek help from a professional in an agency or clinic. These findings show a definite preference for professionals in private practice over those found in a clinic. Since West New York does not have the developed clinic network that Miami has (Diaz, 1980), these findings cannot be generalized to the whole Cuban population in the United States. Nevertheless, it is important to note that the respondents in the sample showed a strong preference for medically trained professionals—family doctors and psychiatrists—for dealing with mental health problems. In addition, psychiatrists were perceived as being better trained than either psychologists or social workers.

Most of the respondents in this study, 71 percent did not feel that people seeking mental health treatment were different from themselves, and 74 percent felt that people with nervous or emotional problems can get well. However, when asked if people who are "crazy" can get well, only 20 percent responded unequivocally that they could, with another 58 percent responding that "some can, some can't." In terms of actual experiences with mental health problems, 21 percent of the respondents indicated that they had experienced nervous or emotional problems since coming to live in West New York. Of these, 97 percent had sought help. Most of those seeking help had gone to a family doctor (66 percent), while a sizable group had been to a psychiatrist in private practice (27 percent). These results validate attitudes found in the entire sample. The study, unfortunately, did not report on the social characteristics of the subsample that sought treatment or the symptoms or complaints exhibited by this group.

A second study, conducted in Miami during 1980 and 1981, examined the attitudes of a nonclinical sample of 240 Cubans toward seeking psychotherapy (Casero, 1982). In this sample, 16.7 percent reported having seen a psychiatrist or a psychologist for mental health problems. While this rate is lower than in the West New York study (21 percent), it does not include respondents who may have sought help from a family doctor—a significant majority in the West New York study. Results of this study showed that sex, age, prior therapeutic experience, and Cuban ethnic identity were the best predictors of attitude toward seeking psychotherapy. Respondents who exhibited more positive attitudes toward psychotherapy were more likely to be female, young, to have had a prior therapeutic experience, and to have a higher level of acculturation.

These findings, along with the authors' clinical experiences, point to general tendencies that would, of course, vary from case to case. First, there appears to be a preference for a formal therapist-patient relationship on the part of the patient. Educational level, knowledge, and reputation of the therapist are greatly valued. As previously noted, there is a strong tendency

to seek help from medical doctors and psychiatrists, though this may not be as pronounced in communities where other mental health professionals become known as effective practitioners.

Similarly, attitudes toward medications vary a great deal. To our knowledge little if any research has been conducted on the attitudes of Cuban-Americans toward receiving and complying with medical treatments for psychosocial disorders. Clinical experience shows that these attitudes range widely and seem to be a function of social class, level of education, and acculturation.

Cuban and other Hispanic therapists are likely to be sought because of language and cultural considerations. Not surprisingly, women exhibit less reliance than men in entering psychotherapy. This reflects traditional family values shared by other Hispanic and non-Hispanic groups whereby men would perceive their authority in the home undermined if they were to acknowledge personal difficulties requiring treatment. These traditional values also extend to child-centered problems, which may be seen by fathers as the responsibility of their wives and not requiring their involvement in therapy. These attitudes would be less likely to be found among younger, more acculturated Cubans.

As previously noted, Szapocznik, Scopetta, De los Angeles, and Kurtines (1978) have pointed to the prevailing present-time orientation among Cubans, which would suggest an expectation for the quick resolution of problems. However, since time orientation may be affected by, among other variables, social class status, education, and degree of acculturation, it is not helpful to assume specific treatment expectations on the part of the patient. It may be far more helpful to inquire as to the patient's expectations at the outset.

## CLINICAL PRACTICE

### *Assessment: Symptomatic and Adaptive Behavior*

Several authors have noted that, as a group, Cubans have experienced a loss of occupational status after migration (Casal & Hernandez, 1975; Hernandez, 1974; Rogg, 1974). While some working-class Cubans have been able to improve their socioeconomic conditions in the United States, it has been far more common for the elite, upper-middle-class, and middle-class Cubans to have experienced a downward occupational mobility at the time of arrival. Reports on occupational gains over time are mixed. In West New York, Rogg and Cooney (1980) found that Cubans had experienced notable upward mobility between 1968 and 1979. However, in a longitudinal study

of Miami-based Cubans, Portes and Bach (1985) report that in a 6-year period, between 1973 and 1979, Cuban refugees "still had not reached the level of their original occupations in Cuba or their aspirations for life in the United States" (p. 196).

Another factor to consider is acculturation stress, typical of any migration group. Intergenerational conflicts are often the result of a faster acculturation rate among second-generation Cubans than among their parents (Rogg, 1974; Szapocznik & Kurtines, 1980; Szapocznik, Scopetta, & King, 1978; Szapocznik & Truss, 1978). Closely tied in to this source of stress are the changes that have occurred in the family structure, as a very high proportion of Cuban women have been incorporated into the U.S. labor force (Casal & Hernandez, 1975; Prieto, 1984), thereby influencing traditional male-female roles.

While many stresses and disruptions are inevitable as a result of a migration, this is often a time of great adaptation and supportive behavior. In the 1968 study of the Cuban community in West New York, Rogg (1974) found no severe adjustment problems. The author emphasized the strong manifestations of ethnic identity and family and social supports in that community, which mitigated against problems such as dropping out of school, juvenile delinquency, or family disorganization. In a subsequent study of 300 adult Cubans in West New York, Rogg and Cooney (1980) found that reporting nervous or emotional problems was not associated with social characteristics such as education, age at arrival, years in the United States, or sex; it was only associated with low frequency of church attendance. The authors interpreted this finding as reflecting a low index of community integration for those individuals, as measured by the lack of organizational (church) involvement.

### *Special Mental Health Problems*

As the early Cuban immigrants of the sixties and seventies have become more settled and assimilated into the North American mainstream, problems affecting the population at large also appear to be affecting the Cuban population. A large survey (Diaz, 1980) conducted by the Cuban National Planning Council in five cities (Miami, Union City-West New York, New Jersey, New York City, Chicago, Los Angeles) just prior to the Mariel exodus in 1980 identified the following special problems: a recent increase in dropout rate in Miami public schools; a high incidence of hypertension among adolescents in Miami public schools; a large number of elderly individuals who underutilize nursing homes; and an increased divorce rate. While these were not directly surveyed, the author also comments on the rising incidence of drug addiction and alcoholism, as well as the indication

that "mental health problems are salient among the general health concerns of the Cuban population in the U.S." (p. 29).

Ladner, Page, and Lee (1975) have reported on the epidemic abuse of sedatives and tranquilizers, and frequent overdose of these drugs by Cuban middle-aged women. In a study of 286 patients at the Spanish Family Guidance Clinic, Ladner (1976) found that the population at risk for drug abuse consisted of divorced males and widowed females; there were no significant sex or age differences in drug abuse pathology scores. Alcoholism pathology scores were significantly related to age (older patients) and sex (males). Married males and widowed females were more at risk for alcoholism than other groups. The drug of choice for women in this clinic population was tranquilizers, while the drugs of choice for men were illicit sedatives, narcotics, and marijuana. Page (1980), in a study of drug use among Cuban youth in Miami, pointed to the disavowal of traditional Cuban values and adoption of the youth subculture of the United States as an important factor associated with drug use. Another factor was the desire for a positive experience or a recreational high.

The Mariel migration has presented special problems due to a multiplicity of factors. First of all, the composition of this migration was very different than that of earlier waves. The 125,000 Cubans who came via Mariel were mostly male, young, and working class (Bienia, Van Der Decker, & Bienia, 1982). Second, they arrived in the United States at a time of high unemployment and uncertain economic conditions. The U.S. government did not provide the special programs for this wave of migration that were provided for earlier waves. Thus this group faced harsher economic and social conditions upon arrival. Resentment from the earlier immigrants became widespread initially, as the Mariel immigrants were labeled criminals and mental patients by politically motivated media reports. The controversy raged as to whether the Mariel migration was the result of Castro's emptying Cuba's prisons and psychiatric institutions. In fact, Bienia and colleagues (1982) report that, of the total 125,000 refugees, only "about 3% were recognized as having serious psychological, social, or criminal problems," although there may have been others "whose problems were not detected in the screening centers" (p. 596). Third, placement in relocation centers, awaiting processing, was often a very traumatic experience for the immigrants, who had expected to be received with "open heart and open arms"—as President Carter asserted (*Time*, 1980)—and instead were confined to military installations. While as of yet there are no available statistics on the incidence of mental health problems among the Mariel immigrants, consideration of the factors just mentioned would suggest that this group is likely to experience more stresses and adjustment problems than earlier waves of Cuban immigrants.

### Treatment

Although diverse treatment modalities have been used with Cubans (e.g., Bernal, 1982; Franklin & Kaufman, 1982; Hynes & Werbin, 1977; Klovekorn, Madera, & Nardone, 1974; Lefley, 1975; Normand, Iglesias, & Payn, 1974; Rubinstein, 1976; Tylm, 1982), little systematic treatment outcome research exists with Cuban-Americans. To date no clinical trials have been conducted that examine the differential rates of effectiveness for either different treatment modalities (psychosocial vs. pharmacotherapy, or individual vs. family or group) or theoretical approaches (behavioral, psychodynamic, etc.) for specific syndromes with this population. Indeed, treatment outcome studies are extremely difficult to conduct.

The Spanish Family Guidance Clinic in Miami deserves recognition for carrying out the only existing treatment outcome research with Cuban-Americans. Szapocznik and his associates conducted several studies to identify the drug abuse and mental health needs of Latinos and to demonstrate the effectiveness of culturally appropriate treatments. In a preliminary study, reported earlier, the structure of Cuban values was examined (Szapocznik, Scopetta, De los Angeles, & Kurtines, 1978). Based on these early findings, they developed an ecological, structural family therapy treatment model in an effort to match treatment methods to client characteristics (Szapocznik, Scopetta, & King, 1978). A variation of this modality, one-person family therapy, was seen as a more effective treatment for families with an adolescent drug-abusing member (Szapocznik, Foote, Perez-Vidal, Hervis, & Kurtines, 1978). This short-term modality involved a maximum of 12 sessions, with no more than 2 family sessions allowed.

Few studies have been published addressing issues related to inpatient treatment and pharmacotherapy with Cubans. Rubinstein (1976) has noted some clinical peculiarities, particularly the predominance of magic and religious mystic phenomena in the manifestation of emotional problems. He indicates that, despite the frequent appearance of hallucinations and delusions, such disorders tend to be depressive rather than schizophrenic. He reports on the successful use of antidepressants to treat the pseudoperceptions in two clinical cases.

### Clinical Examples

We shall now present two cases that illustrate some of the treatment issues with Cuban-Americans. (Identifying information has been changed to protect the privacy of these clients.) The first example is an illustration of a therapy conducted as part of an outpatient private practice. The second example illustrates a treatment that occurred at an inpatient psychiatric

1179

facility within a public county hospital. Sensitivity to changing cultural beliefs is a central part of the engagement and treatment in both cases. The therapist's attention to culture and socioeconomic issues in the first case produced important intergenerational accommodation and changes. In the second case, knowledge of these issues proved vital in the diagnosis and hospital treatment.

#### Outpatient Treatment: The Gomez Family

The Gomez family was seen by the second chapter author because the 16-year-old daughter, Lisa, was exhibiting signs of depression and unhappiness at home. Mrs. Gomez indicated at the time of the initial call that Lisa had been reared Cuban style but that she was not a "prisoner" in the home. Mrs. Gomez reported that she and Lisa had ongoing conflicts regarding the social behaviors that Lisa was not permitted (i.e., dating, going out by herself), but that recently these conflicts had intensified and Lisa had become extremely moody, irritable, and depressed. Mrs. Gomez also indicated that she realized it was a serious matter when she found Lisa's diary and read that Lisa had tried to commit suicide by taking antibiotic pills. Fortunately, Lisa only became mildly sick the day she took the pills. Mrs. Gomez did not tell Lisa that she had read her diary, but she became sufficiently concerned to schedule an appointment with a psychotherapist. Mrs. Gomez explained that her experience with a South American therapist had not been good at all. The therapist had been seen only once. Mrs. Gomez had been insulted when told by the therapist that in the United States a girl's virginity was not "such an important matter" and she should allow Lisa more freedom. Mrs. Gomez indicated that she was calling because she felt that as a Cuban the new therapist would better understand the situation.

At the outset of the initial session, the therapist met privately with both parents. Mr. and Mrs. Gomez turned out to have atypical Cuban migration characteristics, though common value structures and family backgrounds. Mr. Gomez, 64 years old, had migrated to the United States in 1944, when he was in his early twenties. He had been raised in Oriente province, had a working-class background, and came to the United States looking for better economic opportunities. He had been previously married and had two sons from his first wife. He had settled on the East Coast and owned a small grocery store in the *barrio*. Mrs. Gomez, 52 years old, came to the United States in 1956 with her family, in search of better economic opportunities but also abandoning a deteriorating political situation during the Batista regime. Her family was also from Oriente. She

met Mr. Gomez in the United States and they were married in 1960. They had four children, two older boys and two younger girls. Lisa was the oldest of the two girls. Thus their previous experiences with male children had not prepared them for the value conflicts they were to encounter with the girls. Mrs. Gomez still cherished the way of raising children in Cuba, with the family getting together in the house in the country, adolescent girls being chaperoned at parties, and girls retaining their virtue until marriage.

The therapist initially joined with Mr. and Mrs. Gomez by reminiscing about the "good old times" in Cuba, stating that he remembered well how things used to be and how his parents had similarly raised his sister. He praised them for preserving their values in a relatively hostile environment. The therapist reassured them that he had dealt with this problem before and that he would be able to help the family even though they were dealing with a very real, very complex problem with no easy solutions. Lisa was then seen individually.

She was an attractive youngster who attended a Catholic high school. Lisa was an excellent student who had already been inducted into the National Honor Society. She was in much distress, but not suicidal. She spoke at length about her efforts to be like her friends and how she wished she had different parents. She felt embarrassed to tell boys who would ask her out that she could not go out with them because her parents would not let her. Instead, she would tell them that she could not go out with them because she was already busy that weekend. Of course, every weekend Lisa would despair at home, knowing that she had turned down invitations to go out because her parents would not allow her to do so. Further exploration with Lisa revealed that she spoke Spanish well and enjoyed certain aspects of the culture (i.e., Cuban food, family gatherings, and social events). Thus she was not totally rejecting of the family values. She was reassured that the therapist understood her plight and that he would try to help her, though she should not expect her parents to change very much or very quickly. Lisa was told that her problems were common among Hispanic families in general and that she was being unhelpful by telling boys who asked her out that she was "busy."

The format used in the initial session—parents and daughter seen separately—was continued in subsequent sessions. The family was not seen together until the last session, when it was time to sum up the accomplishments made in therapy. A total of eight sessions were held with the family. During subsequent sessions, work with the parents was oriented toward helping them reach some compromises that they could live with. The therapist emphasized that they should not try to change their most basic and cherished values, but that they should try to find some

minor matters that they could accommodate to, taking into consideration the difficult demands of raising adolescent daughters in a very different social and cultural context. The therapist resisted giving them specific suggestions as to what they should or should not do, but exhorted them to work fast as Lisa's emotional status could deteriorate if the existing social and family pressures were to continue. The Gomezes were reminded that Lisa was an honor student who showed responsibility and motivation in her studies. He confided in them that often girls in Lisa's predicament became totally rebellious and reacted by losing their interest in school. In extreme cases, these other girls would start cutting classes and get involved with undesirable elements. In the end, involvement with drugs and teenage pregnancy were unstoppable consequences of this cycle. The Gomezes, duly alarmed, indicated that they had always been open to certain concessions—such as having a boy visit Lisa at home—but that Lisa had not gone along as she wanted to be able to go out with the boy. The Gomezes were praised for their flexibility and foresight, and the therapist remarked that it was always better for the parents to be able to meet the boys going out with Lisa, so that they would get to know them. He added that this sounded like a solid first step in seeking an accommodation with Lisa and that other steps might come later, when they felt that Lisa was ready for a little more responsibility. Lisa, separately, was told what her parents were willing to do. She resisted the idea initially, but was reminded by the therapist that it was not uncommon among Hispanic families to insist on this "dating arrangement" in the beginning, and that perhaps other concessions would follow. Again, she was counseled to warn the boy that her parents were "old-fashioned Cubans" and that they would want to meet him and talk to him for a while if he came to visit. With some hesitancy, she allowed that she might perhaps agree to have a boy come to visit over the weekend. During the next session it was learned that the boy had indeed come to visit. Both parents and Lisa discovered that their worst fears had been unfounded; the boy—who was not Cuban—related to the parents with formality and respect and did not make Lisa feel that visiting a girl at home was such a horrible thing.

Treatment proceeded along the lines described above, helping each side in the conflict understand the other side a little better and make "small" changes that in the end proved to be major concessions. Subsequent sessions dealt with other dating issues such as going to the junior prom (compromise: Father drove Lisa and her date to the prom, but they were allowed to return with another couple), double-dating, and curfew time. Upon termination, in a joint session, the Gomezes were praised for learning how to adapt to a situation that had resulted in untold grief to other

Hispanic families who proved too rigid to deal with the demands of a different culture. Lisa was praised for understanding her parents and their values better, and for "educating" her boyfriend about Cuban culture.

In examining what made treatment with the Gomez family successful, the therapist was aided by the insensitive, if well-meaning, intervention of the first therapist. That therapist challenged the parental value structure head to head at the outset of therapy and lost decisively. That intervention had been of critical diagnostic importance. It revealed the lack of parental acculturation in a rigid and traditional family structure, which, interestingly, manifested itself as a problem only when they were faced with a daughter reaching midadolescence. There was no evidence from the family history that the Gomezes' lack of acculturation had presented significant problems when their sons were growing up. Apparently, they were able to traverse that road without experiencing the pressures from the social context that they experienced with Lisa. Of course, Lisa required more vigilance and stricter enforcement because of the traditional differential child-rearing practices. The therapist's role was to help the Gomezes be more accepting of the social realities of an adolescent growing up in the United States while supporting their basic "old-fashioned" values.

Structurally, the therapist sought to dilute the mother-daughter relationship by supporting the daughter's individuation efforts and reinforcing the husband-wife relationship. Once the initial logjam was broken between Lisa and her parents, other issues were easier to deal with, in a less tense atmosphere. As Lisa experienced more freedom, her depression lifted and her disposition became more positive at home. Her parents were relieved that she ceased to be emotionally distressed and felt largely comfortable (if not 100 percent) with the decisions they had made. In the process, they found out that both of them really liked the North American boy who had first visited Lisa at home and then taken her to the prom. The Gomezes were taught, in effect, that by changing some of their practices they were being flexible and realistic, but that they would still be "good Cuban parents." The therapist created a bridge across the generational gap that would help assuage the sense of discontinuity between Lisa and her parents. The outcome was the lessening of pressure between the two cultures.

While we believe that it is not necessary to have a client-therapist ethnic match to effect change, it turned out to be helpful in this case. The family, recoiling from a previous disaster with a non-Cuban (albeit Hispanic) therapist, sought a Cuban therapist who would "really" understand their family values. The ability to speak Spanish was also critical in this case, as the parents had limited English fluency. The therapist's knowledge of Cuban family life appeared to facilitate their engagement in therapy.

1183

In our clinical experience, we have seen many instances of effective cross-cultural treatment involving therapist and clients of mixed ethnicity, race, and culture. The key to successful clinical work is excellent clinical skills coupled with an appreciation for differences. Culture and ethnicity have many manifestations, some functional, some dysfunctional. What may be functional at one point in time may be dysfunctional at another. Ethnicity and culture are important diagnostic and treatment considerations, especially when they hinder the family in its interfaces with other social institutions.

#### Inpatient Treatment: The Case of Roberto

The clinical work with Roberto was supervised by the first chapter author. The actual evaluation and treatment were conducted by a fourth-year Mexican-American medical student during a psychiatry clerkship. Roberto was a 29-year-old Black Cuban male who migrated to the United States alone in 1980. He had worked as a waiter in Oregon 2 weeks prior to his psychiatric admission in California in 1982.

Roberto was brought to a psychiatric clinic by police on a legal hold for danger to self after being found wandering into traffic. He spoke Spanish at the scene, but was mute and exhibited Christlike posturing at the clinic. He did not respond to Spanish or English instructions. No past occupational, medical, nor family history could be obtained.

The initial mental status exam revealed an adequately dressed, slightly unkempt male appearing his stated age on an identification card. The patient remained mute with his head turned laterally in apparent defiance and assuming a Christlike posture. That is, he lay in bed with eyes closed and with arms extended in the form of a cross. Any attempt to move an appendage resulted in active resistance from the patient; the intention to remain in the formation he had chosen was clear. Affect, thought disorder, and cognitive functioning could not be evaluated. A preliminary medical examination revealed a healthy, well-nourished person. However, he would not cooperate with a neurological examination. Laboratory tests and the physical exam that could be conducted were within normal limits.

The initial admission diagnosis was atypical psychosis. However, it was not possible to rule out a drug-induced psychosis or a depressive episode with psychotic features. DSM-III axes II-V could not be evaluated. The patient remained mute and uncooperative with rigid posturing during his transfer to a psychiatric unit. Rapid tranquilization with small doses of a neuroleptic medication was initiated for the first 2 days of hospitalization. The patient remained in bed for 3 days. Occasionally, he said in Spanish,

"Leave me alone, don't look at me." He refused to eat or drink, requiring constant nursing supervision for adequate water and food intake. By the fourth hospital day he would leave his room for meals only.

By the fifth day of hospitalization, the patient could be interviewed. He claimed he had never seen a psychiatrist in his life and there was no family history of psychiatric disorder. He had migrated from Cuba to the United States during the Mariel exodus. A friend mentioned going to the United States and he went along. However, he had regretted this decision since he arrived. The patient had been at Fort Chaffee for a year and then was placed in Oregon, where he obtained work as a waiter. His coworkers and friends were also recent Cuban refugees. About 2 weeks prior to the hospitalization, he moved to California to visit a friend and change jobs.

The patient could not remember the incident that resulted in his legal hold and subsequent hospitalization, stating he felt "very confused" and that he was "becoming crazy." He denied any drug abuse. He wanted to return to Cuba to his family and 5-year-old daughter. He felt that life in the United States was too hard and he had too much difficulty learning English. He felt sad and drained of energy. His appetite had been decreasing for the last 9 months, during which time he had lost 35 pounds. Also, he reported trouble falling asleep, and during waking hours he felt as if he were moving in slow motion.

Mental status examination on the fifth hospital day revealed a patient appropriately clothed, but unkempt. His feet were bare. His hand covered his eyes throughout the interview as he looked at the floor. He was cooperative, passive, speaking softly and mumbling his words. Moderate psychomotor retardation was evident. He displayed a depressed affect with a dysphoric mood. Thought processes were within normal limits. Thought content was depressed with feelings of helplessness and hopelessness, with no suicidal ideation. He denied auditory or visual hallucinations and showed no delusions. The patient was oriented to person, place, and time, with clear consciousness and fair concentration. Recent and remote memory were intact. Judgment was good and insight fair. In summary he appeared to be a depressed man with no eye contact and depressed ideation.

Antidepressive medications were initiated 2 days later. During this time, the change in the patient's behavior was remarkable. He showed an interest in grooming, his affect was brighter, and he was socializing with other patients. When he saw his therapist, he smiled and shook hands. With her encouragement, he began a letter to his mother. This enabled Roberto to begin talking about feelings of loss about his family and country.

On the fourteenth hospital day, he was discharged to a halfway house. He left the hospital in good spirits, saying he knew he wasn't crazy, and that something confusing had happened, but he did not know what. Follow-up individual therapy and antidepressant medications for 6 months were arranged.

For Roberto, the crisis at hand was the migration and the stressors involved with adapting to a new environment. The alienation from his family, homeland, and culture, coupled with a change in culture and language, was a powerful stressor. He had been experiencing signs and symptoms of depression since his move away from Cuba, but these were held in check at Fort Chaffee. His evaluation and treatment were unusual because of the limited information available on him. In this case, pharmacological and psychosocial therapies were integrated to produce a successful outcome. Pharmacotherapy targeted psychotic and depressive symptoms. The psychosocial treatment was aimed at facing the loss and facilitating his adaptation to a new environment by connecting with support groups and schools and supporting his interest in working. Treatment enabled Roberto to get in touch with his culture in a supportive social milieu. Cognitive reintegration was aided by cultural elements (e.g., use of Spanish in therapy, discussion of his family in Cuba, reviewing events of leaving Cuba and life in the United States) reinforced by his therapist.

The context of the treatment deserves mention. The patient was hospitalized in a psychiatric unit that specializes in the treatment of Latino patients. A psychiatric team composed of bilingual and bicultural professional staff sensitive to the special needs of Latinos is an integral part of this program. The patient participated with other monolingual and bilingual Spanish-speaking patients in groups, occupational therapy activities, and so on. Bilingual nursing staff were also available.

#### Nontraditional Treatment

There appears to be a large discrepancy, possibly due to a social desirability response bias, between survey reports and anthropological findings regarding the use of *santerros* for mental health problems. In Diaz's (1980) study, only 1 percent of the respondents in Miami and Union City-West New York admitted to utilizing a *santero*. However, 7 percent of the Miami respondents and 24 percent of the Union City-West New York respondents indicated they would go to a *santero* if needed, demonstrating a wider acceptance of *santeria* than was initially suggested by utilization patterns. In the Rogg and Cooney (1980) study in West New York, only 5 percent of the respondents who admitted to having had nervous or emotional problems

1186

1187

indicated that they had sought the services of a *santero* or *espiritista*. Yet Sandoval (1977) asserts that *santeria* is flourishing, especially among the socially mobile, middle-class-aspiring Cubans, who in pre-Castro times were "in the lower-middle and lower strata" (p. 61). Sandoval (1979) points out how *santeria* provides an externally oriented treatment model for a variety of complaints to persons who exhibit denial as a prominent defense mechanism. As with the use of *espiritistas* among Puerto Ricans and *curanderos* among Mexican-Americans, it is not uncommon to find Cubans who visit family physicians and *santerros* at the same time in order to "cover all the bases."

#### CONCLUSIONS

Cubans in the United States are a heterogeneous group reflecting a diversity of socioeconomic, educational, and occupational conditions as well as varied migration characteristics. While we have striven to present a global picture of this group of immigrants, clinicians working with Cubans—or with any other ethnic minority—should refrain from making a priori judgments about the specific individual or family they are about to see for the first time. What may be "characteristic" of the group may not necessarily apply to the individual. The descriptions of the culture and the group offered in this chapter should serve as a broad spectrum of colors on a canvas still in need of individual brush strokes to flesh out relevant dimensions for assessment and treatment.

Whereas a recent focus has been on acculturation as the basis of disruption in the Cuban family, this explanation is not consistent with the incidence of drug abuse and adolescent conflicts in other more acculturated groups in the United States. More cross-cultural research needs to be done in order to assess the relative importance of acculturation variables in causing mental health problems. The relative importance of acculturation may also need to be revised, given the social and economic characteristics of Cubans in Miami. Portes and Bach (1985) have pointed out that—in Miami—"the average immigrant does not need to go beyond the physical and social limits of the enclave to carry out many routine activities" (p. 199). It may well be that many Cubans in Miami who speak and understand little or no English and who otherwise exhibit no strong signs of acculturation to the host culture are well adjusted and happy with their lives. Inasmuch as they are able to transact effectively in Spanish with other significant institutions in their environment (i.e., school, health clinic, hospital, work center, recreation sources, etc.), they may not be subject to acute acculturation stress. While the lack of acculturation may play a role in intergenerational family

conflicts (as with the Gomez family), other family dimensions should not be ignored or downplayed.

In conclusion, Cubans show a moderately good adaptation to life in the United States. Cubans remain a close-knit group. Family and social ties remain strong. After stabilizing from the disruptive crisis of the migration, the problems to be encountered are likely to be similar to the problems and stresses encountered by the mainstream North American society (drug and alcohol abuse, divorce, etc.). Our knowledge base concerning the epidemiology, evaluation, and treatment of health and mental health disorders remains limited, despite the large number of studies conducted with Cuban-Americans. The challenge ahead is developing a solid empirical base upon which to build effective cross-cultural prevention and treatment programs.

# 13 Counseling Puerto Ricans

## Some Cultural Considerations

Christensen, Edward W.

D. Atkinson, G. Morten, D.W. Sue (Eds.), *Counseling American Minorities: A Cross-Cultural Perspective*. Dubuque, IA: William C. Brown, 1979.

Puerto Ricans comprise a significant percentage of potential clients for many counselors. The migration of Puerto Ricans to the mainland over the years has created cultural differences between Puerto Ricans raised in Puerto Rico and those raised in the U.S., but both groups are at a disadvantage in the dominant American culture. Migration back to the island in recent years is creating some problems for Puerto Rico, so Puerto Ricans often find prejudice both here and there. In this article the author, who married into a Puerto Rican family, discusses some values and traits that characterize Puerto Ricans and the behaviors that emerge from these traits. He offers practical suggestions for those counselors who have Puerto Rican clients.

In recent years the educational world has become increasingly concerned with students whose cultural backgrounds are different from those of the dominant culture in the U.S. This concern, though belated and still insufficient, has prompted other helping professions to follow the lead. Thus there has recently been increased publication on counseling members of minority groups, writers advocating giving more attention to the needs of clients who are culturally and ethnically different.

One of the outcomes of the increased attention given minority groups has been a tendency on the part of many to lump all minority individuals together. Thus, although early legislation and educational endeavors were designed to help blacks, American Indians, Mexican-Americans, and Puerto Ricans, they often served only to identify them all as having the same needs and disadvantages. Each group has protested this treatment, and all have insisted that their uniqueness be recognized and preserved. This need to understand the uniqueness of clients from specific cultural and ethnic backgrounds motivated the preparation of this article about counseling Puerto Ricans.

### Some Facts about Puerto Rico

There is a great deal of ignorance among mainland Americans with regard to Puerto Rico. A few years ago, when I was in the U.S. on sabbatical leave from the University of Puerto Rico, I brought my automobile, which had Puerto Rican license plates. A number of people asked if the car had been

driven from Puerto Rico! Other typical questions reveal a lack of knowledge concerning this significant group in our society. Mainland Americans have asked: "Aren't all Puerto Ricans dark-skinned?" "Does one need a passport to go there?" "You won't serve me that hot and spicy food, will you?"

Puerto Rico is an island in the Caribbean, about 1,050 miles from Miami and 1,650 miles from New York. The island is about 35 miles by 100 miles and has a population of over 2.8 million. Its population density is greater than that of China, Japan, or India. Puerto Ricans are all American citizens, proclaimed so by the Jones Act of 1917. The population is a mixture of Taino Indians, Africans, and Spaniards, although the Indian influence is much more cultural than biological, as conflicts with the Spaniards practically decimated that group. Skin colors range from as white as any Scandinavian to as black as the darkest African, with all shades and mixtures in between.

It is impossible in this article to clear up all the myths and misunderstandings about Puerto Rico and Puerto Ricans. Indeed, there is currently much study, debate, and conflict regarding many issues of Puerto Rico's culture, identity, and political future. (Readers will find relevant material cited in the list of suggested readings at the end of this article.) These larger issues will not be easily resolved, but the present reality concerning Puerto Ricans is crucial for today's educators and counselors. In order to perform in a helpful and ethical way in assisting clients to grow and make viable decisions, a counselor must recognize personal prejudices and erroneous assumptions.

The problem of understanding Puerto Ricans is confounded by the fact that today there are ~~really two groups of Puerto Ricans~~. From a crowded island not overly endowed with natural resources beyond its people and its climate, thousands of Puerto Ricans have come to the mainland, especially in the period since World War II. Many have stayed. Scarcely a state is without any Puerto Ricans, and some places, such as New York City, Boston, Hartford (Connecticut), and several areas in New Jersey, have large numbers of Puerto Ricans. Many have raised families on the mainland, and these second- and third-generation Puerto Ricans are different in many significant ways from those who were raised on the island.

The mainland-raised Puerto Rican, sometimes called Neo-Rican, is generally English-dominant with respect to language. This Puerto Rican has adapted, as one might expect, to the unique environment of the urban setting but has retained a strong influence from and linkage to a primarily Latin American setting. Thus, having been brought up in another climate, with another language, with different fears and aspirations, and perhaps often with a different reference group, the mainland Puerto Rican is understandably different from the island Puerto Rican. Yet the culturally dominant group in the U.S. defines all Puerto Ricans in the same way, and the Neo-Rican often suffers from the same prejudices inflicted on the recent arrival from San Juan, Ponce, or Ciales.

In many ways, however, Puerto Ricans from the mainland and those from the island do share common cultural characteristics. As dangerous as generalizations can be, it is important for counselors to consider some of the qualities a Puerto Rican client might possess.

### Cultural Characteristics

There are certain values and traits that are generally agreed on as being linked to the Puerto Rican ethos. Chief among these are *fatalismo*, *respeto*, *dignidad*, *machismo*, and *humanismo* (Hidalgo undated; Wagenheim 1970). Wells (1972) has added *afecto* to this list. (See the glossary at the end of this article for definitions of Spanish words used.) These cultural attributes are important to any group, and a wise counselor should have some understanding of them. The reader who has difficulty conceptualizing these terms may find it helpful to empathize with what the Puerto Rican experiences on entering an alien culture. The following explanations may help.

There is a certain amount of overlap in the words used above. *Dignidad* and *respeto*, which have to do with the dignity of an individual and respect for those deserving of it, are interrelated concepts. *Machismo*, generally connoting male superiority, is also part and parcel of the other cultural traits. Because these concepts are so central to the Puerto Rican as an individual and as a representative of a culture that is—at least politically—bound to this country, it is very important that the counselor understand how some of these attributes are translated into behaviors. The behaviors discussed apply in some degree to most Puerto Ricans, but in some instances they may be less typical of second-generation Puerto Ricans on the mainland.

Typically the Puerto Rican is highly individualistic, a person who is not used to working in concert with others, following in single file, and, in general, organizing in ways that Anglos would call "efficient." Whether in a traffic jam or a line of patrons in a bank, a Puerto Rican may break line and take a position ahead of others. But the Puerto Rican will also offer another person the same privilege, being much more tolerant than Anglos of this demonstration of individuality.

Another characteristic of Puerto Ricans is their demonstration of love and tolerance for children. It is rare that a baby or tot, taken down any street in Puerto Rico, is not exclaimed over, chucked under the chin, and generally complimented. This love for children is stronger than its stateside equivalent; generally speaking, in fact, the family unit is stronger among Puerto Ricans. Perhaps because of the love for children, illegitimacy is not frowned on or punished among Puerto Ricans. It is not unusual for families to add to their broods with nephews, nieces, godchildren, and even the children of husbands' alliances with mistresses. It is therefore difficult for the Puerto Rican arriving at a mainland school to understand all the fuss about different last names and shades of skin color and all the confusion about birth certificates among siblings.

The characteristic of gregariousness, a trait common to nearly all Puerto Ricans, often dismays many Americans, who view it as excessive when compared with their own culture. The existence of large families and extended families, the *compadrazgo* (godparent) relationship, and life on a crowded island are probably causes as well as effects of this gregariousness. Puerto Ricans love to talk, discuss, gossip, speculate, and relate. No one needs an excuse to have a fiesta. Music, food, and drink appear instantly if someone comes to visit. Group meetings, even those of the most serious nature, often take on some aspect of a social activity. I remember more than one dull and pedantic committee meeting at the University of Puerto Rico that was saved from being a total loss because refreshments and chatting were an inseparable part of the meetings. A colleague used to reinforce attendance at meetings in her office by furnishing lemon pie and coffee.

---

"Puerto Ricans are seldom found in professional or managerial jobs; they are usually working in low-paying, menial occupations, to an even greater degree than blacks."

---

Puerto Ricans' hospitality is related to their gregariousness. In the poorest home in a San Juan slum or in a remote mountain shack, a visitor will be offered what there is or what can be sent out for on the spot. And it is not good manners to refuse this hospitality; it is offered from the heart, and refusal is rejection. The visitor in this situation will give more by partaking of the hospitality than by bringing a gift.

As might be deduced from the preceding comments, Puerto Ricans are sensitive. Social intercourse has significant meaning, and Puerto Ricans typically are quite alert to responses they evoke in others and to others' behavior, even behavior of a casual nature. Often Puerto Ricans avoid a direct confrontation, and they do not like to give a straight-out no to anyone. Marqués (1967) is among those who have described Puerto Ricans as passively docile, and indeed docility is a noticeable Puerto Rican characteristic. Silén (1971), however, has interpreted this characteristic as actually having aggressive overtones, pointing out that historically this docility was simply a refusal to engage in battles that were impractical. Silén has also reminded us of some of the past and present revolutionary stirrings of the "docile" Puerto Rican. Whichever interpretation is accepted, there is evidence that there has been some change in this behavior, especially among younger Puerto Ricans on the island and those Puerto Ricans who have been raised on the mainland.

### Puerto Ricans on the Mainland

For most readers of this article, the Puerto Rican living on the mainland is likely to be of greatest interest and relevance. There are approximately two

million Puerto Ricans living in the U.S. They come to the mainland primarily for jobs. They generally do not intend to remain here and, as economic conditions for the family improve, increasingly return to the island. In recent years Puerto Rico has made some economic progress and some advances in creating jobs, and thus Puerto Ricans, who typically aspire to live in Puerto Rico, find it increasingly attractive to go back.

This return migration has created some economic, social, and educational problems for Puerto Rico. For example, when younger Puerto Ricans who have been raised in New York City or other areas return to the island, they face certain cultural assimilation problems not at all unlike those their parents faced when they came to the mainland. English-dominant young people must master Spanish for school, work, social life, and participation in family and civic affairs. These youngsters' modes of behavior are often in conflict with the attitudes and values of grandparents, uncles, and the general society. Some efforts are being made to deal with these conflicts, including the establishment of special classes given in English and even the employment of a bilingual counselor or two, but the island's resources are too limited to permit extensive help in this regard. It is fair to say, however, that the Puerto Rican returning to Puerto Rico is treated considerably better than the islander who comes to the U.S. mainland.

Puerto Ricans coming to the mainland often encounter prejudice. Part of this seems to be due to the fact that they are "foreign"; most Americans—even those whose parents were born in another country—are inclined to be cool, to say the least, toward people different from themselves.

---

"A person's name is that person, and a counselor's mispronouncing it—whether through carelessness or laziness—can easily be construed as the counselor's lack of interest in the client."

---

Certainly racism is another significant element in the prejudice against Puerto Ricans. Senior (1965) has reported:

Census figures show that fewer non-white Puerto Ricans come to the States than whites, in comparison with their proportion of the population, and a special study indicates that a larger percentage of the non-whites return to their original homes after a sojourn on the mainland. (p. 46)

But problems for the Puerto Rican are not limited to prejudice. For those young people newly arrived in the States or born here of Puerto Rican parentage, the generation gap becomes compounded by what Senior has called "second-generationitis." These youngsters must contend not only with the expectancies and pressures of a different and dominant culture but also with conflicts of values representing two different cultures. Mainland Puerto Ricans may not be able to identify completely with the Puerto Rican culture, but neither are they a part of the dominant mainland culture. Social scientists

often refer to this situation as the "identity crisis" of the Puerto Rican in the States.

As has been shown in the tragic treatment of blacks in the U.S., social and personal prejudice against a group is generally accompanied by a lack of economic opportunities for that group. Puerto Ricans are seldom found in professional or managerial jobs; they are usually working in low-paying, menial occupations, to an even greater degree than blacks. There are many causes for this. The low educational levels of Puerto Ricans on the mainland is undoubtedly a significant factor. Prejudice, suspicion, language difficulties, and the familiar self-fulfilling prophecy of low aspirations leading to lowly positions also play heavy roles in maintaining the Puerto Rican on the bottom rung of the economic and vocational ladder.

### **Practical Considerations for the Counselor**

The following suggestions offered for counseling Puerto Ricans are based on my eleven years of experience as a counselor in Puerto Rico and on those human relations tenets to which all counselors presumably subscribe. The suggestions may seem simple and obvious to the reader; they are purposely so. They are intended as exhortations for those who are thoughtless, as reminders for those who forget, and as reinforcements for those who truly attempt to accept and understand their clients.

*Examine your own prejudices.* Counselors should consider their attitudes toward poor, rural, Spanish-speaking, racially mixed, culturally different clients. Knowledge alone cannot overcome prejudice, and an intellectual understanding expressed with emotional distaste will only serve to exacerbate the situation. If a counselor has negative stereotyped feelings about Puerto Ricans, it is not likely that his or her counseling relationships with them will be open and warm.

*Call students by their right names.* In Spanish, people are given two last names. The first last name is from the father's side of the family, the second from the mother's. The American custom is to look for the last word, and this becomes the last name. If this logic is followed with Latins, a student named Angel Rodríguez López gets called Angel López, thus dropping his father's family name. Not only might the father and son be understandably insulted by such cavalier treatment, but the boy's identity—in a real as well as a cultural sense—is in question. For those who fervently desire to maintain their cultural and personal identities without being antagonistic to the larger society, acknowledgment of the correct name can be critical.

Another element in this linguistic area is simply pronouncing names in reasonably accurate ways. Even though other students and staff may pronounce names inaccurately, it would seem that a counselor who espouses the establishment of good relationships might make a special effort in this area. A person's name is that person, and a counselor's mispronouncing it—whether through carelessness or laziness—can easily be construed as the

counselor's lack of interest in the client. Counselors can check with a client about pronunciation. (Spanish, incidentally, is much more consistent in pronunciation than English, because each vowel is pronounced the same way in all words.)

*Work with the family.* For the Puerto Rican, the family is much more important than it is for the typical American. If possible, the counselor should deal not only with the young person but also with the family, getting to know them as well as the youngster. If this is not possible, the counselor can at least talk with the client about his or her family. Among Puerto Ricans, the family and extended family are often sought out for help more readily than is a counselor; research, in fact, indicates that the family is the source of greatest help (Christensen 1973). The counselor should realize that others are helping and should work with them, understanding that each person has something to offer. Ignoring this fact is equivalent to refusing to recognize that a client is also receiving help from another professional.

*Refrain from using the child as an interpreter.* In cases where a parent knows little English and the child is reasonably bilingual, it is a temptation to rely on the son or daughter to carry a message to the parent. This should be avoided whenever possible. Even though it might be a source of pride for the child, it might place the parent in a dependent position, preventing the parent from entering into the counseling relationship as a full partner. There is an additional concern: the possibility that the child might twist others' statements. Puerto Rican families are close, but a situation in which a parent continually communicates only through the child can alter relationships and create family strains.

*Understand that to the Puerto Rican you are the foreigner.* One cannot jump into instant relationships. The counselor must give the client time to know and trust him or her. To facilitate this, the counselor may need to meet the client outside of the school or the counselor's office. The counselor should share and be somewhat self-disclosing, revealing some things about his or her family, ideas, home, and so on, in order to give the client a chance to know the counselor as a person. Counselor self-disclosure can be a sign of trust for any client, but it is even more crucial where some feeling of "foreignness" is present in both counselor and client.

*Understand the concept of "hijo de crianza."* This term refers to someone other than the child's parents raising the child—either family members (such as an aunt or a grandmother), extended family members (such as a godparent), or even a friend or neighbor. It also may refer to a family's raising the father's children from another marriage or even from outside a legal union. Counselors must not apply their moral values in such situations. The child is the parents' child through love and acceptance, and exact relationships are not that important.

*Be patient.* This should be a given for all counselors with all clients, but it is especially true when counselors desire to establish any kind of relationship with clients from a different culture. Puerto Ricans have many

obstacles to overcome, some of which are not of their own making. In the counseling relationship, counselors have to overcome some of these same hurdles. Counselors must demonstrate their credibility, honesty, and reliability, just as their Puerto Rican clients must do almost daily in an alien society. The difference is that the counselor is in a more advantageous position, and therefore the counselor's initiative is crucial. The Puerto Rican client may expect the counselor to be prejudiced, arrogant, and lacking in knowledge about Puerto Ricans. The burden is on the counselor to demonstrate that these expectations will not be fulfilled.

### The Fruits of Labor

The counselor who works with Puerto Ricans of any age and in any setting may find some difficulty in doing so. But counselors who are willing to learn will find the effort rewarding. Puerto Rican clients need counselors as much as—or more than—other clients do. Moreover, in the final analysis, we Americans need them also. For they, along with all people of differing ethnic and cultural backgrounds, offer all of us a richness that even a wealthy country cannot afford to be without.

### Glossary of Spanish Terms

- afecto** literally means "affect." Refers to the affective side of life—warmth and demonstrativeness.
- compadrazgo** refers to the relationship entered into when a person becomes a godfather (*padrino*) or godmother (*madrina*). This person then becomes a *compadre* or *comadre* with the parents of the child and traditionally not only takes on certain responsibilities for the child but also is closely related to the entire family of the other person. In some cases this may also involve even other *compadres*, and then the total relationships derived from this system of *compadrazgo* are complex and far-reaching and form the basis for what sociologists term the extended family, which is so characteristic of many societies.
- dignidad** dignity, but of special importance in Puerto Rico and closely related to *respeto*. One can oppose another person, but taking away a person's respect or dignity in front of others is about the worst thing one can do.
- fatalismo** fatalism.
- humanismo** humanism, especially as contrasted with the more pragmatic set of the typical Anglo.
- machismo** related to male superiority and, in its original form, implying the innate and biological inferiority of women. Characterized as an overcompensatory reaction to the dependence-aggression conflict, *machismo* is acted out through fighting and sexual conquest.
- respeto** signifies respect, especially respect for authority, family, and tradition.

# Vocational Rehabilitation of People of Hispanic Origin

Anlta Leal-Ildrogo, PhD  
California State University  
Fresno, California

*This study presents exploratory, descriptive data from the Rehabilitation Services Administration for fiscal year 1989 for the purpose of identifying and exploring the experience of people of Hispanic origin with disabilities in state-federal vocational rehabilitation service delivery systems in the United States and its territories. Included is a demographic description of the Hispanic population, a review of the rehabilitation literature on racial/ethnic groups with emphasis on Hispanics, and information on estimates of disability prevalence among people of Hispanic origin. This study identifies and describes selected characteristics of Hispanics who applied for and/or participated in the vocational rehabilitation system. A "Hispanic origin" region was identified that accounted for 89% of the rehabilitation data on Hispanics. This region consisted of nine states (i.e., California, Texas, New York, New Jersey, Illinois, Arizona, New Mexico, Florida, and Colorado) and the island of Puerto Rico. It was estimated that there could conceivably be over two million Hispanic-origin people with disabilities in the United States. However, in fiscal year 1989, the state-federal rehabilitation system rehabilitated only 17,454 Hispanic-origin people. This study raises the following questions: How can the system reach the potential pool of Hispanic-origin people with disabilities who require services? What services will they require? What factors predict successful or unsuccessful*

*ful rehabilitation of those Hispanic-origin people with disabilities who do reach the system? The need for further research is emphasized and recommended.*

The Hispanic population presents a provocative challenge to human services delivery systems attempting to assess and meet the needs of this diverse population. The challenge is especially difficult in the areas of health, disability, and vocational rehabilitation. In the field of rehabilitation, subgroups of people with disabilities are referred to as double minorities. Virtually nothing is known of the interaction effects of multiple group membership, especially dual membership in disability and racial/ethnic groups. This is due, in part, to a lack of systematic exploration and research of minority group involvement in health/disability/rehabilitation delivery systems. This is particularly true for people of Hispanic origin.

State-federal agency personnel, if they aren't already, will become more aware of Hispanics' participation in their programs as the population grows. It is anticipated that the Hispanic population will be the largest minority group in the nation by the year 2000. Unless more is learned about the disability and rehabilitation experience of people of Hispanic origin, it will be very difficult, if not impossible, to assess the impact of the Americans with Disabilities Act on this group.

We can surmise that with the increasing Hispanic population, there should be an accompanying increase in demand for vocational rehabilitation services. But we have yet to examine the Hispanic experience in state-federal vocational rehabilitation agencies. The urgency of the need for such research is indeed notable when we examine

---

The author gratefully acknowledges Larry Mars, Senior Statistician, Rehabilitation Services Administration, for his assistance in providing the data used in the study and shown in the tables presented in this article.

the potential and existent prevalence of disability among Hispanic-origin people in the United States.

The purpose of this article is to present preliminary data on the experience of people of Hispanic origin in state-federal vocational rehabilitation programs across the nation. This study begins with a description of Hispanics as a sociological group. This is followed by a discussion of the factors that contribute to the designation of this group as an at-risk population. Next is an examination of disability prevalence among Hispanics, followed by a review of rehabilitation literature on Hispanics. Finally, a presentation is made of descriptive data of Hispanics' experience in vocational rehabilitation state-federal agencies based on Rehabilitative Services Administration data for fiscal year 1989.

### THE HISPANIC POPULATION: A SOCIOLOGICAL ENTITY

Because 90% of the Hispanic population typically is categorized as white in racial classifications, it is difficult to document prevalence or incidence of this group's experience in social systems. Furthermore, the intraethnic diversity and complexity of the Hispanic population frequently belies the fact that they constitute a sociological group. The diversity includes differences in acculturation, socioeconomic level, educational attainment, country of origin, generation, etc. While there are within- and between-group differences regarding self-identification and other characteristics, to a greater or lesser degree, the Hispanic population shares a common language, i.e., Spanish, and a common history, i.e., discrimination and economic exploitation.

The term "Hispanic" is now widely used by the state and federal system in identification and data gathering. But this was not always the case. The category "Hispanic" is a confusing and controversial term both to consumers, practitioners, and researchers. Yet, rehabilitation counselors are faced with uncertainty as to how to identify or refer to Hispanic clients when interacting. Hispanics themselves differ in the meaning that identifying labels have and may identify themselves in a vari-

ety of ways, e.g., Mexican, Chicano, Mexican American, and Latino. This confusion about the meaning of the various labels is filled with scientific and political limitations and controversy (Leal, 1990).

The diversity of the Hispanic population presents unique conceptual and methodological considerations to researchers and policy planners. When research results are interpreted, there is a methodological ambiguity as to whether the results can be generalized, and, if so, to which Hispanic subgroups. Some academic scholars propose the term "Latino" as a more appropriate and empowering term because it is self-imposed rather than externally imposed and thus more reflective of the collective identity (Padilla, 1985).

In March, 1991, this population made up 8.6% of the total U.S. population, totaling 21.4 million (U.S. Bureau of the Census, 1991). This was an increase from 20.1 million in 1989 (U.S. Bureau of the Census, 1989). Almost 63% of the Hispanic population was of Mexican origin, while 13.8% was of Central and South American origin, compared to 12.7% in 1989; 11.1% was of Puerto Rican origin, a decrease from 11.8% in 1989; 4.9% was of Cuban origin, a decrease from 5.3% in 1989; and 7.6% was of "other Hispanic" origin, a decrease from 7.8% in 1989. "Other Hispanic" origin referred to individuals who identified themselves generally as Hispanic, Spanish, Spanish-American, Hispano, etc., or whose origins are in Spain. Most Mexican-origin people lived in the southwest United States, Cuban-origin people in Florida, and Puerto Rican-origin people in New York and New Jersey. However, it is also true that all Hispanic subgroups resided throughout all areas of the United States.

### SOCIAL DEMOGRAPHICS OF HISPANIC-ORIGIN PEOPLE

From the 1986 *Report of the Secretary's Task Force on Black and Minority Health* and the U.S. Bureau of the Census March, 1990, *Statistical Brief*, we know that compared with the United States population as a whole:

1. Hispanics show dramatic subgroup differences in age, education, and economic status ranging, for example, from a younger Mexican-origin population to an older Cuban-origin population.
2. Hispanics are generally much younger and have high fertility rates.
3. Hispanics tend to have high unemployment rates and concomitant social ills that accompany poverty. In 1988, 27% were living in poverty compared to 12% for non-Hispanics. In 1989, they were twice as likely to receive public assistance.
4. Hispanics have significantly less education, adversely affecting vocational alternatives, with resultant employment that is physically demanding and dangerous.
5. Hispanics are subjected to discrimination in education, employment, and housing.
6. Hispanics are predominantly urban (88%) and live in every state of the union. There is a notable concentration of Hispanics in the southwestern United States (i.e., California, Texas, Arizona, New Mexico, Colorado). In the east and south, they are concentrated in New Jersey, New York, and Florida. Additionally, over 3,000,000 Hispanics live on the island of Puerto Rico.
7. Hispanics share, to a greater or lesser degree, Spanish as their first language. Yet while 80% of all Hispanics identify Spanish as their first language, only 10% speak Spanish. This presents linguistic obstacles in assessment and delivery of human services.
8. Substance abuse is a social problem within high-risk segments of the Hispanic population (Leal, 1990).
9. There is evidence of under-utilization of mental health services. (Arnold and Orozco, 1989; U.S. Department of Health and Human Services, 1986; Fierro and Leal, 1988; Leal, 1990).
10. Contrary to general belief, migrant health issues are not the major health problem of Hispanics. Migrants represent only 1% of the total Hispanic population.

Because of these characteristics, Hispanics, along with other minority groups, have been labeled "disadvantaged." The problem with this term is its pejorative and causal connotation. The culture mistakenly is seen as the underlying cause of the problem rather than as, in part, a result of institutionalized practices that maintain inequities in service delivery. Instead, the effects of culture must be set apart from the effects of socioeconomic status (Rivera and Cespedes, 1983).

### REVIEW OF REHABILITATION LITERATURE ON RACIAL/ETHNIC GROUPS

Information on prevalence and incidence rates of disability among racial/ethnic groups is limited. Part of the problem are the various definitions of disability. This problem is intensified by severe methodological limitations of using race as a variable or analytical tool. Wright (1988) estimates that the proportion of people with disabilities will increase by 20-50 million in the next several decades.

As sociological entities, racial/ethnic groups have been largely ignored in the field of disability and rehabilitation. Of the information that does exist, the bulk of attention has been on blacks (i.e., African Americans). However, a review of the literature also revealed a focus in several publications on the "culturally handicapped" (Johnson, 1970; Raphael, 1972; Katz, Reagles, and Wright, 1973; Cook, 1975; Rosow, 1976). This mirrored the policy emphasis in the sixties on the "culturally disadvantaged." This was followed by a shift in population emphasis in the 1973 Rehabilitation Act from the "culturally disadvantaged" to the physically handicapped (Berkowitz, 1987).

The only systematic research found on utilization of rehabilitation systems by minority groups was by Atkins and Wright (1980). In their controversial study, they examined the participation of blacks in the public vocational rehabilitation system by analyzing national closure data for fiscal year 1976. They compared blacks with disabilities to whites with disabilities on the following dimensions of the state-federal vocational rehabilitation

process: 1) education at referral, 2) primary source of support at referral, 3) weekly earnings at referral, 4) reasons for nonacceptance referred, 5) patterns of service, 6) funds spent for case services, and 7) weekly earnings at closure. Their study led to the following conclusions:

1. A larger percentage of black than white applicants were not accepted for service or were closed without being rehabilitated.
2. Blacks had lower levels of education, were poorer, and were more likely to be on public assistance.
3. Blacks were more likely to be at lower income levels even when "successfully rehabilitated."
4. Blacks were more likely to not be accepted for service because of failure to cooperate.

Bolton and Cooper (1980) were critical of this study primarily on methodological grounds. They supported "... service provision to an identifiable group of disadvantaged clients" yet pointed out that "... the goal of [vocational rehabilitation] services is to equalize opportunities to disabled persons regardless of race or ethnic origin" (p. 49).

#### Literature on Hispanics with Disabilities

The following five rehabilitation journals were surveyed beginning with the year 1970 for articles on Hispanics: *The Rehabilitation Counseling Bulletin*, *The Journal of Rehabilitation*, *Rehabilitation Literature*, *Journal of Applied Rehabilitation Counseling*, and *American Rehabilitation*. Only ten articles were found. Of those, six were published after 1987 and half of those were published in a 1988 special issue of the *Journal of Applied Rehabilitation Counseling* devoted to multicultural issues in rehabilitation. The latter was the first special issue of its kind in the rehabilitation counseling literature. The thrust of the earlier publications was on the culture and its affect on the rehabilitation process. Later publications began to look at how the system and its services could meet the needs of minority groups.

In what appears to be the earliest publication concerning Hispanics with disabilities, Roberta Church (1970) published "Migrants: The Last Human Frontier." This article described vocational rehabilitation services targeted at migratory

workers as authorized under Section 304 (c) of the 1973 Rehabilitation Act. Special needs were identified, including the need for outreach services to recruit clients and for bilingual health services.

Rivera and Cespedes (1983) described how family, language use, and health problems of Hispanic migrant and seasonal farm workers affected rehabilitation counseling interventions. They acknowledged the degree to which traditional Hispanic culture was manifested as a function of acculturation, socioeconomic class, and the general diversity within the Hispanic culture. They emphasized the need for training on cultural specifics of the Hispanic culture so that rehabilitation counselors might have specific knowledge of the Hispanic culture in order to provide culturally sensitive rehabilitation services.

Arnold (1983) noted the lack of research regarding Hispanic attitudes toward handicapping conditions. He discussed the importance of taking into account the cultural distinctions between Hispanic subgroups, including intragroup variation based on region, socioeconomic status, and educational level. He cited the need for research on rehabilitation resource utilization. He recommended the study of cultural characteristics of the population to assess their unique impact on the effective delivery of services.

Pape, Walker, and Quinn (1983) reported a study that concluded that Hispanics were underrepresented in vocational rehabilitation caseloads in New York City. Kunce and Vales (1988) focused on Mexican-origin Hispanics "and how their heritage may adversely influence the ways in which they adjust to rehabilitation services in the United States" (p. 97). Using descriptions of rehabilitation programs in Mexico as a baseline, they concluded that Mexican Americans may have unrealistic expectations of rehabilitation services in the United States.

Cuellar and Arnold (1988) discussed the importance of acculturation of Mexican Americans to rehabilitation programming. The role of the family as necessary to rehabilitation success was highlighted. Four human services delivery models were identified. These models emphasized various levels of Spanish language facility necessary in interacting with Hispanic clients as well as varying

levels of culturally sensitive services. It was hypothesized that these models probably exist in the vocational rehabilitation service delivery system, but no specific programs were identified. Medina et al. (1988) cited personal correspondence from a supervisor in the Colorado Rehabilitation Services advising that a higher proportion of Hispanics were closed in 08 status (ineligible for services) than Anglos.

In a special issue devoted to multicultural issues in rehabilitation counseling mentioned earlier, the coeditors focused on four U.S. minority groups (blacks, Asians, Native Americans, and Hispanics) (Leal et al., 1988). It was pointed out that these minority groups share a struggle with structural and institutional barriers in American society.

Santiago's (1988) study of the provision of vocational rehabilitation services to blind and visually impaired Hispanics in New Jersey revealed that Hispanic clients had limited participation in vocational rehabilitation programs. Hispanics were more likely to be involved in counseling, with less than 1% involved in programs such as college counseling, career development, and business enterprises. Regarding rehabilitation outcomes, she reported that the number of closures for whites was 10 times higher than for Hispanics. She concluded that only a small fraction of Hispanics, about 10% of the active cases, had been successfully rehabilitated. Fierro and Leal (1988) studied industrially injured Mexican-origin workers in California and found there was more depression, lower self-esteem, and increased dependency the greater the elapsed time between work injury and referral for vocational services.

The importance of understanding substance abuse as a primary or secondary disability was the focus of Leal's 1990 publication. Alcohol abuse has become a major health problem among a high-risk segment of the Mexican-origin Hispanic population. The most recent addition to the literature on Hispanics with disabilities is Trevino's (1991) article which emphasized the cultural characteristics of Mexican Americans with a focus on the importance of the family to rehabilitation planning.

As the review of the literature reveals, published information about Hispanics' utilization of vocational rehabilitation services is very limited. There is a scarcity of research on the topic and the scope of the information that does exist is limited. The studies that do exist are primarily descriptive and, though informative, they are neither explanatory nor research based. No studies were found that provided information from a national perspective. However, the studies mentioned do provide preliminary evidence that people of Hispanic origin with disabilities may have limited acceptance to and success in vocational rehabilitation delivery systems.

### **Disability Prevalence Among People of Hispanic Origin**

Disability prevalence is one source of data from which potential demand for vocational rehabilitation services can be estimated (Berkowitz, 1967). Though data is scant, there is evidence that Hispanics have a higher rate of physical, mental, and emotional disabilities compared to the general population (National Institute on Disability and Rehabilitation Research, 1989; Bowe 1981a, 1984). Approximately 8.4% of working-age Hispanic adults, or 1 in 12, reported having a health condition that prevented or limited them from working. The percentage was higher (8.6%) for Hispanic women compared to Hispanic men (8.2%). The only profile available of the typical person of Hispanic origin with a disability has been generated by Bowe (1981b) as follows: female, 40 years old, married, has a ninth-grade education, is not working part or full time, and had more than \$3,500 in income from all sources in 1980.

More recent data reveals an increase in disability prevalence among Hispanics. LaPlante (1988) conducted a statistical analysis of the National Health Interview Surveys 1983-1985 and found that 9.8% of Hispanics reported limited work activity or inability to work due to chronic medical conditions. These conditions included tuberculosis, neoplasms, diabetes, psychoses, multiple sclerosis, all heart conditions, and arthritis, among several other conditions. Using LaPlante's data, by interpolation, it is conceivable that in 1989 more than two million Hispanics had a disability

that prevented them from working and could have benefited from vocational rehabilitation services.

### National Data

The purpose of this section is to present national data from the Rehabilitation Services Administration (RSA) for fiscal year (FY) 1989 on rehabilitation applicants of Hispanic origin. This information was obtained from RSA in July, 1991, as FY 1989 totals were nearing completion, thus comprising preliminary final tabulations. These data were based on reports from all RSA regions including each state and U.S. territories. The figures include data on all individuals of Hispanic origin accepted by these agencies, as well as data on those people of Hispanic origin who were successful and unsuccessful in the rehabilitation process for the year. The baseline number for each item varies because of variation of state reporting on individual items.

Information on how Hispanics fared in vocational rehabilitation programs from application to closure across the nation and in Puerto Rico has not been systematically analyzed, although the data are collected by RSA. The *Annual Report to the Congress for Fiscal Year (FY) 1989* (Thayer, 1990) (required by the 1973 Rehabilitation Act) noted that 20% of all people rehabilitated were members of a racial minority group. This has been a fairly consistent proportion for several years. The *Annual Report* does not present specific caseload highlights on minority groups but noted that the percentage of Hispanics rehabilitated, regardless of racial origin, rose from 6.4% in FY 1984 to 7.2% in FY 1988. Based on FY 1989 preliminary data obtained for the present study, the percentage of Hispanics rehabilitated was 8.2%.

Among several required data, two items relate directly to race and ethnicity. One item asks for classification information into the following categories: black, Native American, Asian, and white. The other item asks for classification of potential rehabilitants into the categories Hispanic and non-Hispanic origin. These two items are not mutually exclusive; a Hispanic-origin rehabilitation applicant can be of any race.

According to the RSA data, the total number of people of Hispanic origin who applied for ser-

vices in FY 1989 was approximately 49,630, or approximately 2% of the total Hispanic-origin population of 23.6 million for the mainland United States and the island of Puerto Rico combined. Sixty-two percent (30,909) men and 38% (18,721) women of Hispanic origin applied for vocational rehabilitational services. This is an interesting statistic considering that Bowe (1981) reported that 53% of working-age Hispanic women compared with 47% of men had a disability that prevented them from working. Of the 49,630 Hispanic-origin applications, 22,927, or 46%, were not accepted for services. Of the 26,703 (54%) who were accepted for services, 17,453 were rehabilitated. The remaining 9,250 were closed and not rehabilitated (Codes 28 and 30).

Almost 47% of Hispanic-origin rehabilitation applicants were never married; 32% were married, 12% were divorced, approximately 7% were separated, and 2% were widowed. Sources of referral of Hispanic-origin applicants included the following: educational institutions, 6,871, or 13.9% (66% of these were from elementary or high school); hospital and sanatoriums, 2,833, or 5.7% (49% of these were from general hospitals or rehabilitation facilities); health organizations, 4,902, or 9.9%; welfare agencies, 1,982, or 4%; other public organizations, 9,266, or 18.7% (33% of this total came from correctional institutions); other private organizations, 1,466, or 3%; self-referrals, 11,698, or 23.6%; physicians, 3,781, or 7.6%; and other individuals, 6,788, or 13.7%.

The primary source of support was reported for only 26,620 Hispanic-origin applicants. Of this total, 3,515, or 13.2%, were supported by current earnings; 12,998, or 48.8%, by family and friends; 4,455, or 16.7%, by public assistance; 140, or 0.5%, from private relief agencies; 1,011, or 3.8%, SSDI benefits; 798, or 3%, by worker's compensation; 388, or 1.5%, by public institutions; 1,929, or 7.2%, from other public sources; and 1,386, or 5.2%, from all other sources.

Table 1 reports race of rehabilitated persons in FY 1989 by Hispanic origin. The majority of Hispanics (16,146) are reported as white. Note that 20% of the Hispanic-origin RSA statistics on Hispanics come from Puerto Rico, where 99.9%

Table 1. Race of Rehabilitated Persons in FY 1989 by Hispanic Origin

Race	Total	Hispanic Non-Hispanic	
		Origin	Origin
White	172,292	16,146	156,146
Black	37,561	661	36,900
American Indian/ Alaskan Native	1,208	60	1,148
Asian American/ Pacific Islander	2,781	562	2,219
Total	213,842	17,429	196,413

of the Hispanic-origin population is reported as white.

Table 2 summarizes disabilities reported for Hispanic-origin applicants. While 24.3% of Hispanic-origin applicants had orthopedic impairments, it is notable that a combined total of 29% were in the categories of mental illness and substance abuse.

Nearly two thirds of the rehabilitation statistics for people of Hispanic origin were data reported from Puerto Rico, Texas, and California. Furthermore, 89% of the Hispanics in the United States live in the nine states shown in Table 3.

Table 2. Major Disability Summary by Hispanic Origin for FY 1989

Disability	Hispanic Origin Applicants	
	n	%
Orthopedic impairments	10,982	24.3
Mental illness	7,203	15.9
Substance abuse	5,756	12.7
Visual impairments	4,947	10.9
Mental retardation	3,825	8.5
Learning disabilities	2,690	6.0
Hearing impairments	2,586	5.7
Heart/circulatory	1,025	2.3
Absence of limbs	703	1.5
Digestive disorders	659	1.5
Genito-urinary	537	1.2
Respiratory conditions	217	0.5
All other disabilities	4,052	9.0
Total	45,182	100.0

(Puerto Rico, a U.S. territory is shown for comparison.)

Table 3 shows data for those states with the greatest concentration of Hispanics on the mainland United States and Puerto Rico. These states reported 300 or more rehabilitations of people of Hispanic origin in FY 1989. This table shows the distribution of applications in this region. The table shows nonacceptances, rehabilitations, and closures for those state agencies. Note that Texas blind rehabilitations were greater than the rehabilitations reported for seven of the selected agencies. Furthermore, rehabilitations in Puerto Rico accounted for 22% of the "Hispanic Origin" region depicted in this table and for 20% of all Hispanic-origin rehabilitations for FY 1989.

Table 4 shows the proportion of Hispanic compared to non-Hispanic-origin people found ineligible for vocational rehabilitation services (i.e., code 08). "Unable to locate" and "failure to cooperate" were cited as reasons for closure of proportionately more Hispanic-origin compared to non-Hispanic-origin cases. However, non-Hispanic-origin applicants were more likely to refuse services (19.8% and 27.9%, respectively). Non-Hispanic origin in this comparison includes all other racial and ethnic groups as well as whites.

Table 5 shows the distribution of mean case service costs for Hispanic-origin clients and the mean time in vocational rehabilitation for the "Hispanic Origin" region identified in Table 2. Most notable is the range both of case cost and time in vocational rehabilitation. California has the lowest case cost and least time in vocational rehabilitation, \$927.10 and 14.4 months, respectively. This contrasts dramatically with Puerto Rico's case cost and time in vocational rehabilitation, which was \$3,188.90 and 50.3 months, respectively. Clearly, there are regional differences even within the designated "Hispanic Origin" region.

Table 6 shows the work status at closure of rehabilitated Hispanic-origin clients compared to whites. No statistical comparisons were conducted, but clearly the proportion of whites in sheltered workshops was greater than for Hispanic-origin rehabilitants (6.2% and 3.6%, respectively). Furthermore, a larger proportion of His-

**Table 3.** Distribution of Hispanic-Origin Applications, Nonacceptance, Rehabilitation and Closures for Selected\* State Agencies and Puerto Rico for FY 1989

State	Total Hispanic Population (Percent of State Population)†	Number of Hispanic-Origin Applications	Nonacceptance (Codes 02, 06 Combined)	Rehabilitations	Not Rehabilitated (Codes 28, 30 Combined)
California	6,672,000 (24.3)	12,009	5,438	4,107	2,464

panic-origin rehabilitants were working in the homemaker category compared to whites (10% and 9.3%, respectively). A greater proportion of Hispanics were self-employed compared to whites (6.7% and 2.2%, respectively).

## CONCLUSION

There is much to learn about the disability experience of people of Hispanic origin. Information is scarce, but one available source of information is that which is gathered by state-federal vocational rehabilitation service delivery systems in the United States and its territories and sent on to RSA. The

need to know is critical given the phenomenal growth of this population which has large segments at risk, especially in health-related areas.

The primary issues are as follows:

1. Who is vocational rehabilitation serving? (i.e. racial/ethnic minority groups.)
2. How can this system reach the potential pool of Hispanic-origin people with disabilities who require services?
3. How can the state-federal system meet the needs of this diverse, rapidly growing population?
4. What factors predict successful or unsuccessful

Total	22,763		224,631	

rehabilitation of those Hispanic-origin people with disabilities who do reach the system?  
 5. What are the implications for policy planning?

This exploratory study set out to identify and describe selected characteristics of Hispanics who have applied for and/or participated in the state-federal vocational rehabilitation system. We were able to estimate a population of 225,400 people

of Hispanic origin with disabilities with potential need for services. We learned that almost 17,500 Hispanics were rehabilitated in FY 1989, 20% of whom were rehabilitated in the Puerto Rico agency. In other words, there is a substantial group of Hispanics with disabilities that the state-federal system has not reached. Access is an issue.

Results of the present study indicate that Hispanic-origin rehabilitants had relatively high levels of education in contrast to the data cited, which shows the lowest educational attainment of all minority groups is held by Hispanics. How, then, can the rehabilitation system access the underedu-

cated Hispanic person with a disability? What part does language play in access to services? Recall that 90% of Hispanics in this country are probably bilingual, speaking both English and Spanish. We also learned that substance abuse and mental illness, along with orthopedic disabilities, rank high among the disabilities reported for Hispanics who applied for services. Are rehabilitation counselors appropriately trained or prepared, either in culture-specific knowledge about Hispanics or about substance abuse (Leal, 1990)? Cultural sensitivity training has been strongly recommended for rehabilitation practitioners working with Hispanics (Rivera and Cespedes, 1983; Arnold, 1983). Yet before such training can be optimally effective and well informed, we need more information on Hispanics' patterns of utilization of vocational rehabilitation services.

Efforts to synthesize and integrate cultural sensitivity into meaningful service delivery requires more awareness and knowledge of the access to and participation in vocational rehabilitation services by people of Hispanic origin. However, Hispanics remain invisible in terms of vocational rehabilitation research, especially in the area of service delivery (Fierro and Leal, 1988). There is a need for research from a national perspective

to guide policy planning, needs assessment, and intervention strategy planning. Research should be conducted to identify the predictors of successful rehabilitation for people of Hispanic origin that takes into consideration intragroup and regional heterogeneity. Explanatory analysis is needed to deal with the variation in the range of data from the various regions, in particular, Puerto Rico. There may be special interrelated factors unique to people of Hispanic origin that account for successful outcomes in vocational rehabilitation programs.

Well-planned vocational rehabilitation programs encourage maximum numbers of applications for services. Planning for the vocational rehabilitation of Hispanics for the next decade means planning for a steadily increasing population. Demographically, Hispanics present a profile of social characteristics that have implications for the provision of vocational rehabilitation services both now and in the future. Hispanics are a sociological entity within the state-federal rehabilitation system. The challenge is to identify the extent and nature of their participation in vocational rehabilitation services from a national perspective, while at the same time appreciating and taking into consideration the regional and cultural diversity of this group.

# PSYCHIATRIC REHABILITATION AND ASSESSMENT SERVICES

## Policy and Procedure

### I. POLICY

It is the policy of Western Psychiatric Institute and Clinic of Presbyterian University Hospital (WPIC), through the Department of Psychiatric Rehabilitation and Assessment Services (PRAS), to offer specialized assessments and vocationally-oriented psychiatric rehabilitation services to adolescent and adult patients who are receiving primary psychiatric treatment at Western Psychiatric Institute and Clinic.

In the context of career/or employment concerns, assessment services provided by the department may include: psychoeducational and intellectual evaluation, vocational and career interest, aptitude, and values measurement, and personality and psychopathology measurement. In addition, comprehensive career and vocational rehabilitation services are offered to patients referred to the department. These services may include career and educational counseling, liaison with the Office of Vocational Rehabilitation and community educational and training facilities, job readiness and job seeking skills training, and work adjustment and supportive services.

### II. PROCEDURES

#### A. Referral Process

Patients are referred to the department through formal consultation requests from the various WPIC treatment modules. The written request for services is generally preceded by a phone call from the referring clinician to the Program Coordinator. In the case of outpatients, a telephone call will be made or correspondence sent to establish a first appointment. A letter of confirmation is then sent specifying the date, time, place, name of PRAS clinician and clinic phone number. Upon receipt of the referral, in the case of either inpatients or outpatients, a disposition form is sent to the referral source, indicating the status of the referral.

#### B. Referral Criteria

The following guidelines are followed for patient referral:

1. Patients who are unemployed and wish to work.
2. Patients who are undesirably employed and wish to upgrade their marketable job skills, change their career or occupational field, or improve their employment status.

3. Patients who have been unable to secure satisfactory employment despite the possession of marketable job skills.
4. Patients who are experiencing difficulty in adjusting to or maintaining employment for desired periods of time.
5. Patients who are uncertain regarding career, employment, or educational/training direction and who desire counseling and assistance with these issues.
6. Patients who have or are currently experiencing significant difficulty in their academic or training program(s).
7. Patients who could benefit from referral and liaison services to the Office of Vocational Rehabilitation and other community rehabilitation, educational/training, or employment agencies.
8. It is required that patients who are referred for and who receive services through PRAS have a WPIC primary clinician for primary psychiatric treatment and care.

C. Assessment Process

A wide variety of standardized psychometric instruments, informal measures, and situational, in-vivo experiences are utilized in psychiatric rehabilitation. The selection of particular instruments and experiences is dependent upon the nature of the patient's problems, goals, and the kind of data needed in order to thoroughly assess needs, deficits, and strengths for any particular patient. When feasible, a comprehensive test battery is used, supplemented by additional testing as indicated by the particular patient performance, referral request, or rehabilitation goal.

Once the evaluation is completed, a consultation report containing a summary of assessment data and recommendations is submitted to the referring party and entered into the patient's medical record.

D. Range of Vocational Rehabilitation Services

A range of services is required in order to facilitate the career development and rehabilitation processes with persons having psychiatric disabilities. Although patients' individual rehabilitation needs are diverse, they tend to cluster around several central themes. Psychiatric Rehabilitation and Assessment Services provides comprehensive services which are organized around these prominent need areas.

1. Assessment: A comprehensive vocational assessment enables both the patient and the clinician to better understand the patient's interests, aptitudes, cognitive capabilities, academic skill levels, and environmental and interpersonal preferences as related to various career/ educational options. Vocational assessment provides an objective method for identifying a profile of characteristics relevant to career choice. Measurement instruments are tailored according to the kinds of information needed to help a particular individual make realistic choices about career or vocational endeavors. Assessment experiences utilized in the clinic go well beyond that of standardized formal psychoeducational and vocational assessment, however. Functional assessment is critical and may include volunteer experiences, site and informational interviews, credit and leisure-learning courses, and in-house situational assessments on an individual basis.
  
2. Career counseling and supportive services: Many patients referred for services have had significant difficulty in identifying and implementing or completing realistic vocational/ educational plans. Counseling services are geared toward interests, abilities, preferences, tolerance for specific stressors and available resources and supports. Significant attention is given to the patient's concerns and anxieties about adjusting to school/training or employment and the prospect of increasingly independent functioning. The use of the Service's Employment, Education and Career Resource Library provides a data base which enables clinicians and patients to have access to current information regarding employment trends, detailed descriptions of careers and requisite abilities, as well as courses of study available at local colleges, vocational schools, and rehabilitation facilities.
  
3. Job seeking skills training, job development, placement, and supportive services: Many patients have been unable to acquire employment despite the possession of marketable skills. Job seeking skills training, conducted on an individual or group basis, prepares individuals to be able to thoroughly complete employment applications, generate and follow-up on job leads, prepare resumes, organize employment searches, and present themselves well in employment interviews. Attention is specifically paid to handling interview questions regarding disrupted work histories, frequent job changes and employment accommodations. Extensive linkages and case management services are provided in utilizing various community agencies and resources which provide related employment and job preparedness services. Individualized job development, placement, and advocacy with employers are offered as appropriate.

4. Work adjustment counseling and long-term supportive services:  
Inability to maintain employment, in many cases, is related to impaired interpersonal skills, inability to cope with specific and/or more generalized work-related stressors, and difficulty adjusting to the impact of earned income on various consumer benefits. Work adjustment counseling includes training in social and coping skills with an emphasis upon adapting to stressors in the work environment, job analysis and modification, employer advocacy and intervention, and assistance in managing leisure time and finances. Flexible and long-term supportive counseling is provided for all patients for as long as it is beneficial and indicated.

## MEMORANDUM

**TO:** All WPIC Clinicians

**FROM:** Lynda J. Katz, Ph.D., Program Director *LJK*  
Michelle Geckle, M.Ed., Program Coordinator *MG*

**DATE:** 8-3-93

**RE:** Psychiatric Rehabilitation and Assessment Services Department

We are pleased to announce the opening on September 1, 1993 of the Psychiatric Rehabilitation and Assessment Services (PRAS). The Department under the direction of Lynda J. Katz, Ph.D., PRAS, will offer specialized assessments and comprehensive psychiatric-vocational rehabilitation services to WPIC patients under the care of a WPIC primary clinician and physician of record.

Psychiatric Rehabilitation services offered will include the following:

1. Vocational, intellectual, and psychoeducational assessments, including personality assessment if indicated.
2. Career and educational exploration, counseling, and planning, including individual, group, and career resource library services.
3. Referral and liaison services with community educational, rehabilitation, employment, and benefits agencies/service providers, including the Office of Vocational Rehabilitation, colleges, trade and technical schools, the Social Security Administration, and the Department of Public Welfare.
4. Pre-Employment services, including individualized resume, interview, and job search preparation, employer advocacy, and job development and placement services.
5. Post-Employment/Supportive Employment services, including work adjustment and maintenance counseling, crisis intervention, benefits analysis and management, job analysis and modification, employer intervention assistance.

1220

3811 O'HARA STREET, PITTSBURGH, PA 15213-2593

The following referral guidelines are offered for use by WPIC primary clinicians and physicians:

1. Individuals who are unemployed and wish to work.
2. Individuals who are undesirably employed and wish to upgrade their marketable job skills, change their career or occupational field, or improve their employment status.
3. Individuals who are uncertain regarding career, employment, or educational/training direction and who desire counseling and assistance with these issues.
4. Individuals who could benefit from referral and liaison services to the Office of Vocational Rehabilitation and other community rehabilitation, educational/training, or employment agencies.
5. Individuals who have been unable to secure employment despite the possession of marketable job skills.
6. Individuals who are experiencing difficulty in adjusting to or maintaining employment for desired periods of time.

The PRAS Department will be located in Suite 204 in the Iroquois Building at the corner of Forbes and Meyran Avenues. Referrals may be made by consultation with the Program Coordinator, Ms. Michelle Geckle, M.Ed, CRC at 624-2842, or in writing utilizing the Consultation Request Forms of the former Neuropsychological Assessment and Rehabilitation Services Department of WPIC, supplies of which are available in the PRAS Department. Please feel free to direct any questions or requests for further information to Ms. Geckle.

## PATIENT'S RIGHTS: CONFIDENTIALITY

### Policy and Procedure

- A. Regulations pursuant to the Mental Health Procedures Act provide that (See section 5100.31).

Persons seeking or receiving services from a mental health facility are entitled to do so with the expectation that information about them will be treated with respect and confidentiality by those providing services. Confidentiality between providers of services and their clients is necessary to develop the trust and confidence important for therapeutic intervention. While full confidentiality cannot be guaranteed to everyone as a result of Federal and State statutes which require disclosure of information for specific purposes, it remains incumbent upon service providers to inform each current client/patient of the specific limits upon confidentiality which affect his or her treatment when these limits become applicable. When facilities are required by Federal or State statute or by order of a court to release information regarding a discharged patient, a good faith effort shall be made to notify the person by certified mail to the last known address.

- B. The regulations also provide that confidentiality is a patient right.

- C. Thus, confidentiality is a manifestation of professionalism in the delivery of mental health care. Physicians, psychologists, nurses, social service personnel, psychiatric assistants, clerical personnel, and indeed, any and all persons who work at WPIC are bound, by virtue of their being employed here and by virtue of the type of job that they do, to insure that information learned about patients remains confidential. This means that the information that the patient relates to the hospital about his/her problems, or information about the patient that is gathered from his/her friends and family members, is necessary for good patient care. It is the patient's rightful expectation that the material he/she relates will not become available to persons who are not responsible for his/her care. Information that is important to good patient care may be embarrassing or of a very personal nature which the patient does not want others to know. Confidentiality as a general principle applies to the type of information the patients may relate about themselves by word of mouth, other communications that patients may write, and also the patients' records. The issue of whether or not a person even is or is not a psychiatric patient at the Hospital is itself "confidential."

- D. Patients, in the type of treatment milieu present at WPIC, may attempt to swear a staff member or an employee to confidentiality about their personal feelings of life history. Patients may sometimes say to staff that they want to relate some piece of information which they want shared with no one else. To make such an agreement with a patient, however appealing or flattering to an individual staff member or employee, is however often not in the best interests of patient care. For example, the staff member or employee is in a difficult bind if the patient talks about feelings of suicide only to that staff member. It is not an abuse of confidentiality for information given by patients to be shared with other staff members if this information is relevant to their care. As a general rule then, if a hospitalized patient asks not to have information discussed with other staff, try to indicate that this type of contract or agreement is impossible, that such information must be disclosed to other staff responsible for their care, but no one else.

E. Please consult WPIC Legal Counsel (647-8480), or Law and Psychiatry (624-2161) if you have any questions or desire assistance.

# SUICIDE PREVENTION

## Policy and Procedure

### I. POLICY

It is the policy of Western Psychiatric Institute and Clinic to take reasonable precautions to minimize the risk of suicide or other self-destructive behavior. The guidelines outlined below are based on the recognition that suicidal behavior is not pathognomonic of any specific psychiatric syndrome. It is seen most frequently in persons exhibiting depressive symptoms, regardless of whether such symptoms occur in the context of "primary" affective disorder, or, as is often the case, are "secondary" in the sense that they occur in association with some other psychiatric illness.

### II. PROCEDURE

#### A. Evaluation of Suicide Risk

Clinicians interviewing patients in the Diagnostic & Evaluation Center should specifically inquire about past and current history of suicide attempts, preoccupations about suicide, availability of weapons, drug abuse, changes in current sleep and activity patterns, family history of depression and suicide, and mental status examination. Each patient is then seen by a psychiatrist, who, together with the clinician, evaluates the patient's suicidal risk, makes a preliminary diagnosis and disposition regarding the treatment recommendations made for the patient as well as the setting (inpatient or outpatient). Whenever possible, collateral information is obtained from the family or significant others, to further assess the risk of suicide.

The following factors, culled from the literature, may be helpful in evaluating suicidal risk.

1. Marital Status
2. Physical Illness
3. Depressive Disorder
4. Insomnia
5. Gender
6. Schizophrenia
7. Alcohol and Drug Abuse
8. Previous Suicide Attempts
9. Lethality of Previous Suicide Attempts

10. Living Arrangements
11. Age
12. Religion
13. Race
14. Family History of Suicide
15. Recent Loss
16. Employment Status

Evaluation of suicidal risk continues throughout the hospitalization. Clinical information relevant to suicide which was not obtained in the Diagnostic & Evaluation Center will be obtained as soon as possible upon admission to an inpatient service. Each patient's suicide risk is carefully monitored; every effort is made on inpatient services to establish individual contact with each new patient as quickly as possible.

Patients who are referred from the Evaluation Center to an outpatient clinic receive an initial clinic evaluation and ongoing evaluation which includes a reassessment of the patient's suicidal risk. Any patient receiving care in an outpatient clinic who becomes an unacceptable suicidal risk should be considered for inpatient admission.

#### **B. Therapeutic Approaches to Suicide Prevention**

1. Listen carefully to what the patient says about his suicidal attempt or thoughts. An understanding of the patient's view of the situation, style of coping with immediate and chronic life along with his complete medical and psychiatric history is necessary before a relevant treatment plan can be formulated.
2. Provide the patient with a sense of external controls and an atmosphere of safety. Contributing to this sense of control, is that staff communicate among themselves about the patient's suicidal ideation and plans, the patient is informed of the lack of absolute confidentiality regarding this issue.

3. Search - The patient, his belongings, and the inpatient unit must be free from harmful objects. The patient is searched immediately upon admission to the unit and thereafter as needed. Razor blades, medications, glass objects, scissors, knives, etc., are removed from patient access. Objects such as razor blades will be used only under staff supervision. Belts, neckties, necklaces, jewelry, keys and shoelaces are routinely removed from the patient who would not be considered safe having these items. Safety measures are carried out in a respectful, informative style so that the staff minimizes making the patient feel more incompetent and inadequate, feelings with which he may already be struggling. It may be necessary for the patient to have a private room to maintain these precautions.

The patient's visitors are greeted by the staff and assessed so that potentially harmful gifts are not given to the patient (glass, scissors, certain foods for patients on a Parnate diet, etc.).

4. Observation

A patient who is thought to be a high risk for suicide is not alone on an inpatient unit and is on one of the following types of protective intervention.

CO connotes "Constant or Continuous Observation" by staff. The patient is within the view of a staff member at all times. The patient cannot lock himself in his room, the bathroom, or sit off from all human contact. The patient may be involved in a group, sitting alone in the patient lounge or involved any other activity where a staff member can continuously observe him.

SCO connotes "Special Constant Observation." A staff member constantly observes and interacts individually with the patient within arm's distance. SCO should only be ordered in rare or exceptional circumstances. If this level of observation is needed, a physician's order with supporting documentation is required.

Either of the above levels of observation may be ordered by a physician or initiated by the nursing staff. Should the nursing staff initiate either level of observation, rationale for this decision is recorded in the medical record and reviewed by the patient's physician as soon as possible, and always within a period of two hours. When a physician orders any of the above, the patient may only be removed from level of observation ordered by a written order by the physician changing the patient's status. Should nursing staff indicate the observation status, a physician still must assess the patient and write an order when the status can be reduced.

The patient's behavior on the unit is carefully observed and always recorded in the medical record (e.g., how the patient interacts with others, including family and friends, what the patient talks about, how he eats, sleeps and his motor activity).

C. Management

1. Patients who are high risk for suicide should eat their meals on the unit or be accompanied by a staff member to the patients' dining room. These patients should not leave the unit for any reason without staff accompaniment (example: meals, diagnostic studies, etc.).
2. If patients remain on CO or SCO longer than 24 hours, a reevaluation should be done by both the physician of record and unit staff to determine if this status should be continued.
3. Suicidal patients who elope from the hospital under the 201, 302, 303 admission status and are still considered a serious suicidal risk will be returned to the hospital as soon as possible. Patients on a voluntary (201) who need to be forcibly returned to the hospital should be converted to a 302 status if they fit the commitment criteria. The police will be notified; an initial investigation report completed and the appropriate Program Director and Hospital Administrator called (See Elopement Policy and Procedure).

# RIGHTS AND RESPONSIBILITIES OF AMBULATORY CARE PATIENTS

## Policy and Procedures

### I. POLICY

It is the policy of Western Psychiatric Institute and Clinic to recognize the basic rights and responsibilities of patients in the ambulatory care setting and to set forth these rights and responsibilities for staff and patient information and implementation. The following statements pertain to the Rights and Responsibilities of outpatients.

#### A. Patient Rights

1. Patients shall be accorded impartial access to treatment or accommodations that are available or medically indicated, regardless of race, color, religious creed, handicap, ancestry, national origin, age, sex, or sources of payment for care.
2. Patients have the right to considerate, respectful care at all times and under all circumstances, with recognition of their personal dignity.
3. Patients have the right to be interviewed and examined in surroundings designed to assure reasonable visual and auditory privacy.
4. Patients have the right to expect communications and other records pertaining to their care, including the source of payment for treatment, to be treated as confidential in accordance with the guidelines established in applicable Pennsylvania Law.
5. Patients have the right to expect reasonable safety insofar as the hospital practices and environment are concerned.
6. Patients have the right to know the identity and professional status of individuals providing service to them and to know which physician or other practitioner is primarily responsible for their individual care.
7. Patients have the right to obtain, from the practitioners responsible for coordinating their care, complete and current information concerning diagnosis (to the degree known), treatment, and any known prognosis.
8. When patients do not speak or understand the predominant language of the community, they will have access to an interpreter when possible.

9. Patients have the right to reasonably informed participation in decisions involving their health care. To the degree possible, this should be based on a clear, concise explanation of their condition. The patient will not be subjected to any procedure without his/her voluntary, competent, and informed consent or that of his/her legally authorized representative. Where medically significant alternatives for care or treatment exist, the patient shall be so informed.
10. Patients shall have the right to refuse treatment to the extent permitted by law. When refusal of treatment by the patient or his legally authorized representative prevents the provision of appropriate care in accordance with professional standards, the relationship with the patient may be terminated upon reasonable notice.
11. Regardless of the source of payment for their care, the patients have the right to request and receive an itemized and detailed explanation of their total bill for services rendered in the hospital. The patients have the right to timely notice prior to termination of their eligibility for reimbursement by any third-party payer for the cost of their care.
12. Patients have the right to be informed of the hospital rules and regulations applicable to their conduct as patients. Patients are entitled to information about the hospital's mechanism for the initiation, review, and resolution of patient complaints.

Pennsylvania Department of Public Welfare Regulations require that each facility have a grievance and appeal system in effect to insure that the patient rights enunciated in the regulations are safeguarded and disputes resulting therefrom are resolved promptly and fairly. At WPIC this process is assured by the Patient Rights Coordinator. The following individual can be contacted:

Katharine Luther, M.P.M.  
5th Floor-ERC  
Phone: 624-1993

13. Because WPIC is a teaching hospital, some patients are involved in clinical research projects and their treatment is monitored in special ways. Thus, it is possible that assessment material and intake information relating to their care will be reviewed by approved researchers for purposes of identifying them as potential subjects in a WPIC research program. Whether or not they decide to participate in a research project is, of course, voluntary.

**B. Patient Responsibilities**

1. Patients have the responsibility to provide, to the best of their knowledge, accurate and complete information about present complaints, past illnesses, hospitalizations, medications, and other matters relating to their health. They have the responsibility to report unexpected changes in their condition to the responsible practitioner. Patients are responsible for verbalizing whether they clearly comprehend a contemplated course of action and what is expected of them.
2. Patients are responsible for following their treatment plan as recommended by the practitioner primarily responsible for their care. Patients are responsible for keeping appointments and, when they are unable to do so for any reason, for notifying the responsible practitioner or the hospital.
3. Patients are responsible for their actions if they refuse treatment or do not follow the practitioner's instructions.
4. Patients are responsible for assuring that the financial obligations of their health care are fulfilled as promptly as possible.
5. Patients are responsible for being considerate of the rights of other patients and hospital personnel, and for being respectful of the property of other persons and of the hospital.
6. Patients are responsible for complying with hospital policies and directives of appropriate hospital personnel.

**II. PROCEDURES**

A copy of the Rights and Responsibilities of Ambulatory Care Patients Bill of Rights (Attachment) is available in each ambulatory care setting within WPIC. In addition, ambulatory care patients will be given a copy of the Bill of Rights at the time of the review and will sign the initial treatment plan.

**PATIENT'S RIGHTS:  
GRIEVANCE AND APPEAL PROCEDURES**

**Policy & Procedure**

**I. POLICY**

Pennsylvania Department of Public Welfare Regulations 7100.1 et seq (pursuant to the authority of 112 of the Mental Health Procedures Act) require that each facility have a grievance and appeal system in effect. The purpose of the system is to insure that the patient rights enunciated in the regulations are safeguarded and disputes resulting therefrom are resolved promptly and fairly. Patients and family members or, where appropriate, legal guardian are to be informed of the system and they are to be encouraged to utilize it when individual informal methods of resolving complaints are unsuccessful. The following procedures comprise the grievance and appeal system at Western Psychiatric Institute and Clinic.

**A. The Patient Rights Coordinator**

1. The Executive Committee shall appoint a Patient Rights Coordinator.
2. The Patient Rights Coordinator shall be a member of the Quality Assurance and Risk Management Committee.
3. Duties of the Patient Rights Coordinator
  - (1) The Patient Rights Coordinator shall develop and implement procedures which assure that each patient, or family, or legal guardian of Western Psychiatric Institute and Clinic is advised about the Patient Grievance and Appeal Procedures.
  - (2) The Patient Rights Coordinator shall communicate, when indicated, with a patient, family, legal guardian, BSU, or representative to discuss problems concerning patient rights or the quality of services and treatment provided to the patient or family. When a problem exists, the Patient Rights Coordinator shall work with the patient, family or legal guardian, and Western Psychiatric Institute and Clinic in trying to reach a solution which is acceptable to the patient, family, or legal guardian and Western Psychiatric Institute and Clinic.
  - (3) In accordance with the requirements of the Federal Patient Self Determination Act and WPIC Policy and Procedure concerning Advance Directives, upon referral by the patient's attending physician, the WPIC Patient Rights Coordinator shall provide consultation and, where appropriate, related patient information materials pursuant to advance directives and/or refusal of life sustaining treatments to patients and/or family members/concerned others/legal guardian(s).

## II. PROCEDURE

### A. Informal Complaint Procedure

The Patient Rights Coordinator shall initially respond to patient/family/legal guardian complaints by utilizing informal methods of attempting to resolve them.

### B. Formal Complaint Procedure\*

1. When the Patient Rights Coordinator is unable to informally resolve a complaint, then the Patient Rights Coordinator shall assist the patient, family, or legal guardian in presenting the complaint as soon as possible to the treatment team leader or other appropriate person. The patient, family, or legal guardian shall have the right to the assistance of an independent person and witnesses in presenting his or her complaint.
2. The treatment team leader, administrative supervisor or their designees receiving the complaint shall investigate the complaint and make every effort to resolve it. Based upon this investigation, a decision shall be rendered in writing as soon as possible but within 48 hours after the filing of the complaint. Complaints shall be decided by persons not directly involved in the circumstances leading to the grievance.
3. The patient, family, or legal guardian shall be given a copy of the complaint and final decision and a copy shall be filed.

### C. Appeal Process\*

1. Any patient, family, or legal guardian or those helping him or her, may appeal the grievance decision within 10 working days of the decision. The appeal will be filed with the Patient Rights Coordinator who shall notify the Hospital Administrator and the Chief of Clinical Services/Director of the Law and Psychiatry Program.
2. The Patient Rights Coordinator shall coordinate the establishment and meeting of a committee to fairly hear the complaint. The committee shall be composed of the Associate Director or designee, the Program Chief of Clinical Services or physician designee.
3. The patient, family, or legal guardian shall be given prompt notice of the date set for the appeal and shall be informed of his or her right to be represented by counsel.

\*In the case of a grievance/appeal made by a patient who is 14 to 18 years of age, consideration should be given to discussing the complaint with the patient's family or legal guardian. This policy shall be in conformity with WPIC policy and state law regarding confidentiality of patient information. If the patient and family or legal guardian disagree with the filing of a grievance or appeal, WPIC Legal Counsel and Law and Psychiatry should be consulted.

4. Hearings shall be informal without strict adherence to the rules of evidence. Sufficient records of the hearing shall be made.
5. The opinion of the appeal committee shall be given to the facility Director who shall make the final decision, a copy of which shall be provided to the patient, family, or legal guardian.

**D. Additional Appeal - Outside Agencies**

1. If the patient, family, or legal guardian is not satisfied with the decision of the Appeals Committee, or elects to utilize an agency external to WPIC for purposes of presenting the grievance, then the Patient Rights Coordinator shall refer the patient to the following sources in writing.
  - a. Allegheny County MH/MR/DNA Program  
Wood Street Commons  
304 Wood Street  
Pittsburgh, PA 15222
  - b. Bureau of Civil Rights Compliance  
Department of Public Welfare  
Room 412, Health and Welfare Building  
P.O. Box 2675  
Harrisburg, PA 17105
  - c. Office for Civil Rights  
U.S. Department of Health and Human Services  
Region III, P.O. Box 13716  
Philadelphia, PA 19107
  - d. Pennsylvania Human Relations Commission  
101 South Second Street  
Suite 300  
Harrisburg, PA 17105
  - e. Bureau of Civil Rights Compliance  
Department of Public Welfare - Western Field Office  
702 State Office Building  
300 Liberty Avenue  
Pittsburgh, PA 15222

Patient complaints of discrimination may also be filed with any other Human Rights Agency having jurisdiction.

## VIOLENT PATIENTS: MANAGEMENT AND CONTROL VIOLENCE PREVENTION POLICY

### I. POLICY

It is the policy of Western Psychiatric Institute and Clinic to take all possible precautions to minimize the chance of violence or other behavior resulting in harm to others.

The therapeutic control of violence is an occupational hazard among all mental health workers. For purposes of this policy statement "violence" is defined as hitting or striking behavior accomplished by a patient towards another patient or towards staff, or accomplished destruction of property. Included here is a wide spectrum of behavior ranging from the temper tantrum in the child to the barroom brawl in the adult.

Not all patients who threaten violence accomplish it. The "potentially violent" patient is defined as the patient who makes verbal threats to harm, who appears or acts in an angry manner, who speaks loudly and in an accusatory or threatening manner, the patient who by his demeanor and his actions causes staff and other patients to fear him. Most potentially violent or threatening patients do not become violent. Such potentially violent patients must be handled in a manner, however, so as to minimize the chance of actual violence.

The Institute's policies on violence can be more specifically described by conceptualizing types of violent patients:

- A) Criminal Violence plus Psychiatric Illness - If a patient is determined to have charges pending, or to be liable to charges if not admitted, the decision whether to admit or to send the patient to the mental health unit of the County Jail must be made. If the patient remains in the hospital for more than 48 hours, this is a tacit statement that staff considers this patient's behavior to be consistent with behavior found in a psychiatric setting. Priority must be given to evaluation of this type of patient because of the potential effect of this patient in the safety of both other patients and staff.
- B) Characterologic Violence plus Psychiatric Illness - There are some patients who will exhibit violent behavior whether or not they are acutely ill. The clue here is a significant Axis I and Axis II diagnosis (as per D.S.M. III-R). Institute policy regarding this type of patient is that hospitalization will be for a short-term treatment of the Axis I diagnosis after which time the patient will be discharged. Since violence is part of baseline behavior in these individuals, it is not considered to be reason for admission, or extended hospitalization (although this behavior does present clinical management issues).
- C) Violence associated with Mental Retardation plus Psychiatric Illness - Like those patients with characterologic type violence, these patients are admitted only for treatment of their psychiatric illness. If a patient is already hospitalized at a long-term treatment facility, preference would be for treating the person there with consultation with WPIC faculty and staff.

- D) Violent Behavior as a Symptom of Psychiatric Illness - Those patients whose violence appears as a symptom of an acute psychiatric illness (e.g., psychotic patient responding to command auditory hallucinations) present no conflict as to the appropriateness for hospitalization and/or other treatment at WPIC.
- E) Criminal Violence with no Psychiatric Illness Evident - The individual who is under arrest for criminal activity of a violent nature is considered to be more appropriate for evaluation in a penal setting.

In short, WPIC policies vary according to the category of violence into which a particular patient falls. This indicates that assessment is a critical variable in the decision to hospitalize, to predict violence, and to help strive towards more realistic treatment and discharge planning.

## II. ASSESSMENT OF RISK OF VIOLENCE

Psychiatric clinicians make daily decisions concerning the assessment, prevention, and management of violent behavior. The relevant literature reveals a number of correlations between violence and clinically related variables. However, most of the studies on outcomes of predictions have shown the accuracy to be about the same as a "flip-of-a-coin." It's important to note that most of the prediction studies have addressed long-term decisions usually concerning courtroom findings of dangerousness. Recent research on the prediction of dangerousness, on a short-term basis, offers tentative data toward supporting the notion that clinicians can, with greater accuracy, predict dangerousness when the time period of prediction is reduced. For example, in emergency civil commitments, the time period between point of prediction and validation period of the specific behavior is short (3-5 days). Basically, this research lends more validity to the clinical variables that have been correlated with violence.

Prediction of who will be violent or "dangerous" remains a difficult business. Persons who are in the midst of being violent; i.e., striking other persons or actually breaking up property, are therefore the only patients who are properly labelled as violent.

The most reliable predictors of future violence are:

- A. Recent history of already accomplished violence; i.e., the patient has already been violent in the previous hours to days.
- B. There is a history of previous violence prior to the immediate time period of management.
- C. The patient is a young male, for example, between the ages of 15 and 35.
- D. Drug and Alcohol Abuse or Dependence

- E. If the patient's prior history is well known, other "predictors" may be at least considered. For example, it may be useful to know that the patient has struck out in the past against others when taunted, when challenged as to his masculinity, when he has recently experienced a loss, when his reality testing has been quite disturbed; i.e., he has been psychotic or has been experiencing imperative auditory hallucinations when he has been intoxicated with alcohol or other substances. The present circumstances should be compared with the past regarding their similarity in provoking violence.

The following clinical variables have been correlated with violent behavior and should be viewed as contributing factors; i.e., with each variable evident, the risk of violence may increase. Also, these variables should be thought of as "cutting across" diagnostic categories.

A. **Assessment of the Patient**

1. **Personality Factors**

- a. General hostility
- b. Chronic anger
- c. Motivation for aggression
- d. Poor impulse control
- e. Individual beliefs and/or lack of "taboos" against engaging in violent behavior

2. **Substance Abuse**

The APA Task Force #8 (1974) described alcohol as a common contributing factor to violence. Amphetamines, PCP, and cocaine also frequently contribute to violence.

3. **History of Suicide Attempts and Current Homicidal/Suicidal Ideation or Intentions**

Some studies have demonstrated a strong correlation between suicidal and violent behavior.

4. **History of Violent Behavior**

Here it is essential to know the circumstances preceding past violent behavior. For example, has a patient struck out when he perceived a challenge to his masculinity, when he has been hearing voices, has experienced a loss, when using or abusing alcohol and/or drugs, etc.

5. **Previous History of Verbally Abusive Behavior, Temper Tantrums, Impulsivity and Other Repetitive Antisocial Behavior**

A large number of violent patients have histories of emotional deprivation, demonstrate impulsiveness and have poor control of aggressive urges. Violent patients are frightened of their own hostile urges and seek help in preventing a loss of control. The patient's use of aggressive behavior can be the patient's way of dealing with an unbearable sense of fragility and helplessness. Adding to helplessness and deprivation is intense fears and hurt feelings.

6. **History of Criminal Arrests**

Legal histories have been thought of as an important variable in predicting dangerousness.

7. - Delusions (Paranoid especially)  
Patients who are frightened that someone else is out to hurt them in some way may assault a person who becomes part of their delusional material and who they perceive is going to hurt, poison, or otherwise attack them. Such assaultive behavior would be viewed by the patient as self-protective. A patient who has delusional ideas, that, if true, would lead a "normal" person to behave destructively, requires close observation.
8. Imperative Auditory Hallucinations  
Patients who hear voices telling them to hurt someone are in danger of following the instructions of such voices which may include assaults.
9. Projective Thinking and Feeling of Self as a Pivotal Point of Events
10. Suspiciousness and Viewing World as a Hostile Place  
Hypervigilance is a clinical sign.
11. Grandiosity
12. Fear of Loss of Autonomy and Control  
A core dynamic theme seen in violent patients is helplessness. Patients may also defend against passivity, helplessness and underlying homosexual stirrings (Homosexual Panic) by adopting a hypermasculine stance whereby they become aggressive as a way of preserving their masculinity.
13. Sleep Deprivation  
Significant loss of sleep lowers the patient's level of consciousness, increases the patient's capacity to distort perception and increases irritability and limits control of impulses.
14. Cerebral Dysfunction  
Certain types of brain dysfunction appear to contribute to assaultive behavior. Examples include temporal lobe epilepsy, minimal brain damage and retardation. Although a past history of violent behavior, with associated electroencephalographic abnormalities, may involve the temporal lobe, violence as a direct seizure manifestation is very rare. Also, EEG recordings may confirm a diagnosis or reveal nothing. In those patients who are violent and demonstrated to show some form of epilepsy, attention should be paid to environmental and social factors which may play a role in the genesis of the aggressive behavior.
15. Medical and Other Organic Factors  
Violence originating from some of these factors is frequently of a primitive sort; e.g. reports of biting or scratching. The following factors should be entertained especially in patients demonstrating behavior quite out of character with pre-morbid functioning.
  - a. Tumors of the limbic system
  - b. Certain encephalitic disorders
  - c. Metabolic condition such as hypoglycemia

- d. Normal pressure hydrocephalus with dementia
- e. Pre-menstrual tension in women has been noted to be a contributing factor in criminal and aggressive behaviors.

B. Provocative Situations - Particularly on the Inpatient Unit

1. The Composition of the Nursing Staff

A study by Levy and Hartocollis comparing two inpatient units, one staffed with female nurses and aides and one unit with a more traditional nurse and male aide staffing pattern.

The unit comprised of female staff had no incidents of other-directed violence, but the traditionally staffed unit had 13 violent incidents. The authors state that when male aides are used to control violence, the probability of violence is increased because the "male aide's formal or informal role as masculine authority is based on the intent to do violence." "This intent is potentiated by female nursing personnel who expect the male aide to confront troublesome patients for them." The use of professional nurses and some female aides may keep the unit's focus on interpersonal ways of handling aggression and keep the incidence of assaultive behavior in a psychiatric unit to a minimum.

2. The Use of Physical Activities to Help Patients Express Aggressive Urges

Such cathartic aggressive behavior may seem therapeutic but in a permissive setting may maintain the behavior at its original level or increase it. The use of physical activities (basketball, etc.) must be subordinate to the therapeutic focus of having patients develop cognitive abilities to understand the causes and events that precede violent behavior. Verbal work takes precedence over physical actions.

3. Patient Experiencing Verbal Insults or Humiliation from Staff in the Form of Verbal Threats or Attempts through Bantering or Ridicule to Disapprove of the Patient's Behavior

Insults or embarrassing situations provoke aggression in patients who are prone to be aggressive and in normally non-aggressive persons.

4. Staff Fear of the Patient will Exacerbate the Patient's Potential for Violence

Patients who are frightened of losing control of themselves and who are depending on staff to assist with controls will not be reassured by a frightened staff. Staff need to spend time understanding their own feelings and getting mastery over themselves before they can be helpful to the patient. Staff need to understand what the patient is experiencing, and their own responses to the patient; working together, the staff need to develop more comfortable and reassuring ways to respond to each violent patient.

### C. Interstaff Communications

Interstaff issues and dynamics can influence the occurrence of various behaviors on the inpatient psychiatric unit. The "Therapeutic Community" and "Hospital Milieu" literature contains many descriptions of how certain staff conflicts are acted out by inpatients.

Violent behavior can many times be prevented or lessened by staff identification of problematic staff-to-staff and patient-to-staff communications. Some patients are more sensitive than others to acting out staff conflict. For example, strained communications between staff due to a split in leadership, on the floor between Medical Director and Nurse Clinical Manager, may make a tense environment among staff due to resulting splitting down through the ranks. This may lead to a tense and bitter emotional milieu. The anxieties of individual patients then increases. Furthermore, the anxieties that arise in such situations are notably more evident on a closed or intermittently closed unit, since patients feel that staff are unaware of potential danger. The patient who is a higher risk for violence (based on the factors we discussed earlier) may be the "scapegoat" who is "sacrificed" by the patient/staff group and acts out violently.

There are many ways in which staff communications may become distorted and/or problematic. Splits between senior-junior staff, between disciplines, between male-female, and between black-white are types that have been frequently observed. Inpatient group therapy sessions and community meetings can be rich sources of data on these distorted behavior patterns among staff and patients.

Staff sensitivity sessions, educational inservices, and community discussion of perceived problems are all possible ways of identifying conflicts, and then taking the appropriate action to help with the prevention of violence.

### III. CLINICAL MANAGEMENT

- A. The guiding principle is to help the patient talk out feelings rather than act them out physically. Helping the patient change from a physical style of responding to his feelings to a more cognitive and verbal style pervades all treatment with such patients.
- B. When the patient is clearly angry or verbally abusive, staff must acknowledge the patient's angry feelings and behavior. Focusing on the process of the interaction rather than only the content is an important shift in emphasis during such situations.
- C. The patient's anger may be diluted before physical aggression takes place. At times the one-to-one verbal interaction with staff is the intervention of choice; at other times using a structured, well run patient-staff group meeting can be effective in diluting anger and reassuring the patient that he will not be allowed to lose control. Well timed use of humor by those staff gifted with a tasteful sense of humor is quite effective in diluting anger. If the patient is prevented from losing control, his self-respect and dignity will have been maintained.

- D. Individual or group work with such patients acknowledges their feelings and helps them to express anger in more socially acceptable and controlled ways; this style of limit setting is experienced as reassuring to most patients.
- E. The verbal and cognitive work with such patients involves helping the patient to learn to understand and to predict in advance their own violent impulses. Only then does the patient have mastery over when to get help to prevent loss of control.
- F. When the patient is about to be violent or has a violent outburst:
1. Don't walk away from the patient.
  2. Acknowledge the patient's feelings and behavior. The staff member should use silence during a verbal outburst until it is over to avoid escalating the behavior. Here the use of "underwhelming force" is useful. Talking alone with one mental health professional about what the patient is feeling and about what has happened may be calming. The staff member and patient should be able to perceive the safety of the interaction because other staff are available at a distance.
  3. If medication is indicated for the patient, then give the medication with the message that the medication will help him control himself. Violent or suspicious patients may be fearful that you are trying to "snow" them and may refuse medication. The use of medication is to be carefully explained. If the patient refuses medication, give the patient some "elbow room." A dignified 10 minute time period for the patient to take medication on his own is preferable. If medication must be given against the patient's will, then prepare IM medication with staff prepared to use "overwhelming force," if necessary. In general, if a patient is violent as a consequence of delusions or hallucinations, an antipsychotic is used.
  4. "Overwhelming force" may be used to give medication. Walking a patient to a quiet room or to seclusion may be needed. Patients who are violent are often reacting to feelings of helplessness and loss of control. It is provocative rather than reassuring to the patient if, from his perspective, he perceives there is going to be a battle to control his behavior. It is not necessary that the patient be physically restrained or overpowered; sometimes merely approaching the patient with a clear show of force, plus making a statement by one of the group that his behavior must cease, is sufficient to cause the behavior to cease. The patient must not be touched unless there is sufficient staff available to control the patient.
  5. The use of a quiet room may be used as a temporary and nonpunitive way of helping the patient regain control of himself before discussing his violent feelings and behaviors. It is important to understand that isolation by use of a quiet room or seclusion is temporary. Placing the patient in isolation will not help the patient learn about his experience during the critical time when learning is important. Isolation should be as brief as possible and be followed by the psychological work

necessary for the patient (also see Seclusion Policy and Procedures).  
Leather restraints or wet packs may be indicated when the patient cannot be adequately protected from self injury in seclusion. (See Leather Restraint Policy and Procedure and Cold Wet Pack, Dry Sheet Pack Policy and Procedure.

6. The staff member most appropriate to be with the patient during this time of fear and violence is the one who has the best rapport with the patient--not necessarily the one with the most authority, rank, etc. Interpersonal understanding and intervention with such patients requires rapport and cannot be legislated by a person in authority who has no rapport with the patient in question.
7. Other patients should be accompanied away from the area where the violent patient is being controlled.
8. Post-violence analysis conferences can and should be called by anyone involved in the incident to determine how and what was well done, what could have been better handled, and how can future incidents be predicted and more important, prevented.

#### IV. INVOLUNTARY TREATMENT OF THE VIOLENT PATIENT

The patient on a 201 voluntary or 302 emergency detention, 303 commitment or 304 commitment status who has been recently violent, who is "dangerous" to others, may be treated with psychotropic medications, either orally or intramuscularly, even against his will and over his objection. Accompanying the treatment of such patients must be adequate documentation in the chart describing in some detail, the nature of the patient's previous violence and the rationale for his involuntary treatment, and that lesser steps have previously been tried or considered, and have been found unsuccessful or not indicated.

#### V. PREVENTION OF VIOLENCE

There is a wide range of management techniques available to prevent violence. These are referred to in the WPIC Seclusion Policy and Procedures. These include:

- A. Assessment and clinical management of the patient as previously described.
- B. Review of psychopharmacological management.
- C. Use of the patient's hospital room as a "quiet room."
- D. Assigning staff to spend time individually with patient (CO or SCO).
- E. Use of cold wet packs.
- F. Use of leather restraints (See Leather Restraints policy).

**G. Any or all of these techniques may be useful in preventing violence:**

- 1. Among patients who have not been violent but where violence is feared;**
- 2. Inpatients who have already been violent but where there is felt to be no need for seclusion. Some helpful pointers are:**
  - a) All patients should be searched for weapons before they arrive on the floor.**
  - b) Adequate histories should be taken from patients regarding any past violence, whether or not they carry weapons; what, if any, are the "explanations" for their past violent behavior.**
  - c) Some patients, though chronically threatening, hostile, and frightening to others, seldom, if ever, strike out. It is important that such persons not be provoked to violence. Neither, however, can such patients be permitted to intimidate staff or other patients, or to "have the run of the ward." A firm but empathetic style, with clear-cut limit-setting, is needed when dealing with such patients. The clinician should clearly indicate that violence will not be tolerated on the ward, that the patient will be prevented from becoming violent.**
  - d) Potentially violent patients should be informed by those caring for them that their behavior is "frightening" to other people. The reasons why it is frightening should be explained to them. Potentially violent patients are not always aware of the extent to which their behavior disturbs others. Potentially violent patients should be informed that the staff is willing to offer them more medication, more interpersonal contact with other staff, wet packs, leather restraints, use of seclusion, or other maneuvers which the patient can request to prevent their becoming violent.**
  - e) Staff should recognize their own feelings of anxiety, their concern for their own safety in managing violent patients; while managing a potentially violent patient, if staff become overly anxious, the potential for that patient's violence increases. Staff are to be taught to monitor their own feelings, when to learn to ask for help, when to terminate an interview (i.e., when they feel that the patient is losing control and that they also strive towards an understanding of their own usual defense mechanisms and how they may influence a patient's potential for behaving destructively (DiBella, 1979).**

## VI. STAFF TRAINING, ORGANIZATION AND EDUCATION

- A. A Crisis Prevention Committee has been organized to train WPIC Clinical Staff in the use of appropriate physical intervention techniques and educate staff in prediction and assessment. A unit-based program is utilized to certify nursing staff (and others) in a minimally accepted foundation of knowledge and physical performance. The certification must be renewed on an annual basis.
  
- B. There is a crisis prevention committee that is responsible for providing instruction to clinical staff. Responsibilities include:
  - 1. Meet regularly to plan, teach and evaluate crisis prevention classes and update information and techniques as necessary.
  - 2. Conduct regular inservices for clinical staff and recertification.

Commission on Rehabilitation Counselor Certification  
A division of the Board for Rehabilitation Certification  
Accredited by the National Commission For Health Certifying Agencies

Volume 6

February, 1989

## CERTIFICATION UPDATE

The Commission on Rehabilitation Counselor Certification (CRCC) is pleased to announce that a revised Code of Professional Ethics for Rehabilitation Counselors has been completed and printed here for your use.

CRCC has worked closely with the American Rehabilitation Counseling Association and the National Rehabilitation Counseling Association in the revision of this Code. Both professional associations have adopted the Code, as well as the National Council on Rehabilitation Education. We anticipate that other professional associations will adopt or endorse the Code for their rehabilitation counselors.

You may recall that in your initial application to take the CRC Examination, you signed a statement of understanding that said you would ascribe to the Code of Ethics printed on the application. The revised Code of Professional Ethics for Rehabilitation Counselors applies to all Certified Rehabilitation Counselors. Disciplinary Procedures are outlined and all CRCs are encouraged to carefully read both the Code and Disciplinary Procedures. As stated in the Preamble to the Code, CRCs are encouraged to request in writing an advisory opinion from CRCC when they require assistance in interpreting the Code. At a later date, a Guidebook will also be developed to assist CRCs in interpreting the Canons and Rules of the Code.

### CODE OF PROFESSIONAL ETHICS FOR REHABILITATION COUNSELORS

The Commission on Rehabilitation Counselor Certification has adopted the Code of Professional Ethics for Certified Rehabilitation Counselors; and the following professional organizations have adopted the Code for their memberships; American Rehabilitation Counseling Association, National Rehabilitation Counseling Association, and National Council on Rehabilitation Education.

#### Preamble

Rehabilitation counselors are committed to facilitating personal, social, and economic independence of individuals with disabilities. In fulfilling this commitment, rehabilitation counselors work with people, programs, institutions, and service delivery systems. Rehabilitation counselors recognize that both action and inaction can be facilitating or debilitating. Rehabilitation counselors may be called upon to provide counseling; vocational exploration; psychological and vocational assessment; evaluation of social, medical, vocational, and psychiatric information; job placement and job development services; and other rehabilitation services, and so in a manner that is consistent with their education and experience. Moreover, rehabilitation counselors also must demonstrate adherence to ethical standards and must ensure that the standards are enforced vigorously. The Code of Professional Ethics, henceforth referred to as the Code, is designed to facilitate the accomplishment of these goals.

The primary obligation of rehabilitation counselors is to their clients, defined in this Code as people with disabilities who are receiving services from rehabilitation counselors. The basic objective of the Code is to promote the public welfare by specifying and enforcing ethical behavior expected of rehabilitation counselors. Accordingly, the Code consists of two kinds of standards, Canons and Rules of Professional Conduct.

The Canons are general standards of an aspirational and inspirational nature reflecting the fundamental spirit of caring and respect which professionals share. They are maxims which serve as models of exemplary professional conduct. The Canons also express general concepts and principles from which more specific Rules are derived. Unlike the Canons, The Rules are more exacting standards that provide guidance in specific circumstances.

Rehabilitation counselors who violate the Code are subject to disciplinary action. A Rule violation is interpreted as a violation of the applicable Canon and the general principles embodied thereof. Since the use of the Certified Rehabilitation Counselor (CRC) designation is a privilege granted by the Commission on Rehabilitation Counselor Certification (CRCC), the CRCC reserves unto itself the power to suspend or to revoke the privilege or to approve other penalties for a Rule violation. Disciplinary penalties are imposed as warranted by the severity of the offense and its attendant circumstances. All disciplinary actions are undertaken in accordance with published procedures and penalties designed to assure the proper enforcement of the Code within the framework of due process and equal protection of the laws.

When there is reason to question the ethical propriety of specific behaviors, persons are encouraged to refrain from engaging in such behaviors until the matter has been clarified. Certified Rehabilitation Counselors who need assistance in interpreting the Code should request in writing an advisory opinion from the Commission on Rehabilitation Counselor Certification. Rehabilitation counselors who are not certified and require assistance in interpreting the Code should request in writing an advisory opinion from their appropriate professional organization.

#### Rehabilitation Counselor Code of Ethics

##### Canon 1 - MORAL AND LEGAL STANDARDS

Rehabilitation counselors shall behave in a legal, ethical, and moral manner in the conduct of their profession, maintaining the integrity of the Code and avoiding any behavior which would cause harm to others.

##### Rules of Professional Conduct

- RI.1 Rehabilitation counselors will obey the laws and statutes in the legal jurisdiction in which they practice and are subject to disciplinary action for any violation, to the extent that such violation suggests the likelihood of professional misconduct.
- RI.2 Rehabilitation counselors will be thoroughly familiar with, will observe, and will discuss with their clients the legal limitations of their services, or benefits offered to clients so as to facilitate honest and open communication and realistic expectations.
- RI.3 Rehabilitation counselors will be alert to legal parameters relevant to their practices and to disparities between legally mandated ethical and professional standards and the Code. Where such disparities exist, rehabilitation counselors will follow the legal mandates and will formally communicate any disparities to the appropriate committee on professional ethics. In the absence of legal guidelines, the Code is ethically binding.

- R1.4 Rehabilitation counselors will not engage in any act or omission of a dishonest, deceitful, or fraudulent nature in the conduct of their professional activities. They will not allow the pursuit of financial gain or other personal benefit to interfere with the exercise of sound professional judgment and skills, nor will rehabilitation counselors abuse their relationships with clients to promote personal or financial gain or the financial gain of their employing agencies.
- R1.5 Rehabilitation counselors will understand and abide by the Canons and Rules of Professional Conduct which are prescribed in the Code.
- R1.6 Rehabilitation counselors will not advocate, sanction, participate in, cause to be accomplished, otherwise carry out through another, or condone any act which rehabilitation counselors are prohibited from performing by the Code.
- R1.7 Rehabilitation counselors' moral and ethical standards of behavior are a personal matter to the same degree as they are for any other citizen, except as these may compromise the fulfillment of their professional responsibilities or reduce the public trust in rehabilitation counselors. To protect public confidence, rehabilitation counselors will avoid public behavior that clearly is in violation of accepted moral and ethical standards.
- R1.8 Rehabilitation counselors will respect the rights and reputation of any institution, organization, or firm with which they are associated when making oral or written statements. In those instances where they are critical of policies, they attempt to effect change by constructive action within organizations.
- R1.9 Rehabilitation counselors will refuse to participate in employment practices which are inconsistent with the moral or legal standards regarding the treatment of employees or the public. Rehabilitation counselors will not condone practices which result in illegal or otherwise unjustifiable discrimination on any basis in hiring, promotion, or training.

## Canon 2 - COUNSELOR-CLIENT RELATIONSHIP

Rehabilitation counselors shall respect the integrity and protect the welfare of people and groups with whom they work. The primary obligation of rehabilitation counselors is to their clients, defined as people with disabilities who are receiving services from rehabilitation counselors. Rehabilitation counselors shall endeavor at all times to place their clients' interests above their own.

### Rules of Professional Conduct

- R2.1 Rehabilitation counselors will make clear to clients, the purposes, goals, and limitations that may affect the counseling relationship.
- R2.2 Rehabilitation counselors will not misrepresent their role or competence to clients. Rehabilitation counselors will provide information about their credentials, if requested, and will refer clients to other specialists as the needs of clients dictate.
- R2.3 Rehabilitation counselors will be continually cognizant of their own needs, values, and of their potentially influential position, vis-a-vis clients, students, and subordinates. They avoid exploiting the trust and dependency of such persons. Rehabilitation counselors make every effort to avoid dual relationships that could impair their professional judgments or increase the risk of exploitation. Examples of dual relationships include, but are not limited to, research with and treatment of employees, students, supervisors, close friends, or relatives. Sexual intimacies with clients are unethical.
- R2.4 Rehabilitation counselors who provide services at the request of a third party will clarify the nature of their relationships to all involved parties. They will inform all parties of their ethical responsibilities and take appropriate action. Rehabilitation counselors employed by third parties as case consultants or expert witnesses, where there is no pretense or intent to provide rehabilitation counseling services directly to clients, beyond file review, initial interview and/or assessment, will clearly define, through written or oral means, the limits of their relationship, particularly in the areas of informed consent and legally privileged communications, to involved individuals. As case consultants or expert witnesses, rehabilitation counselors have an obligation to provide unbiased, objective opinions.
- R2.5 Rehabilitation counselors will honor the right of clients to consent to participate in rehabilitation services. Rehabilitation counselors will inform clients or the clients' legal guardians of factors that may affect clients' decisions to participate in rehabilitation services, and they will obtain written consent after clients or their legal guardians are fully informed of such factors. Rehabilitation counselors who work with minors or other persons who are unable to give voluntary, informed consent, will take special care to protect the best interests of clients.
- R2.6 Rehabilitation counselors will avoid initiating or continuing consulting or counseling relationships if it is expected that the relationships can be of no benefit to clients, in which case rehabilitation counselors will suggest to clients appropriate alternatives.
- R2.7 Rehabilitation counselors will recognize that families are usually an important factor in client's rehabilitation and will strive to enlist family understanding and involvement as a positive resource in promoting rehabilitation. The permission of clients will be secured prior to family involvement.
- R2.8 Rehabilitation counselors and their clients will work jointly in devising an integrated, individualized rehabilitation plan which offers reasonable promise of success and is consistent with the abilities and circumstances of clients. Rehabilitation counselors will persistently monitor rehabilitation plans to ensure their continued viability and effectiveness, remembering that clients have the right to make choices.
- R2.9 Rehabilitation counselors will work with their clients in considering employment for clients in only jobs and circumstances that are consistent with the clients' overall abilities, vocational limitations, physical restrictions, general temperament, interest and aptitude patterns, social skills, education, general qualifications and other relevant characteristics and needs. Rehabilitation counselors will neither place nor participate in placing clients in positions that will result in damaging the interest and welfare of either clients or employers.

## Canon 3 - CLIENT ADVOCACY

Rehabilitation counselors shall serve as advocates for people with disabilities.

### Rules of Professional Conduct

- R3.1 Rehabilitation counselors will be obligated at all times to promote access for people with disabilities in programs, facilities, transportation, and communication, so that clients will not be excluded from opportunities to participate fully in rehabilitation, education, and society.
- R3.2 Rehabilitation counselors will assure, prior to referring clients to programs, facilities, or employment settings, that they are appropriately accessible.
- R3.3 Rehabilitation counselors will strive to understand accessibility problems of people with cognitive, hearing, mobility, visual and/or other disabilities and demonstrate such understanding in the practice of their profession.
- R3.4 Rehabilitation counselors will strive to eliminate attitudinal barriers, including stereotyping and discrimination, toward people with disabilities and will enhance their own sensitivity and awareness toward people with disabilities.
- R3.5 Rehabilitation counselors will remain aware of the actions taken by cooperating agencies on behalf of their clients and will act as advocates of clients to ensure effective service delivery.

#### **Canon 4 - PROFESSIONAL RELATIONSHIPS**

Rehabilitation counselors shall act with integrity in their relationships with colleagues, other organizations, agencies, institutions, referral sources, and other professions so as to facilitate the contribution of all specialists toward achieving optimum benefit for clients.

##### **Rules of Professional Conduct**

- R4.1 Rehabilitation counselors will ensure that there is fair mutual understanding of the rehabilitation plan by all agencies cooperating in the rehabilitation of clients and that any rehabilitation plan is developed with such mutual understanding.
- R4.2 Rehabilitation counselors will abide by and help to implement "team" decisions in formulating rehabilitation plans and procedures, even when not personally agreeing with such decisions, unless these decisions breach the ethical Rules.
- R4.3 Rehabilitation counselors will not commit receiving counselors to any prescribed courses of action in relation to clients, when transferring clients to other colleagues or agencies.
- R4.4 Rehabilitation counselors, as referring counselors, will promptly supply all information necessary for a cooperating agency or counselor to begin serving clients.
- R4.5 Rehabilitation counselors will not offer on-going professional counseling/case management services to clients receiving such services from other rehabilitation counselors without first notifying the other counselor. File review and second opinion services are not included in the concept of professional counseling/case management services.
- R4.6 Rehabilitation counselors will secure from other specialists appropriate reports and evaluations, when such reports are essential for rehabilitation planning and/or service delivery.
- R4.7 Rehabilitation counselors will not discuss in a disparaging way with clients the competency of other counselors or agencies, or the judgments made, the methods used, or the quality of rehabilitation plans.
- R4.8 Rehabilitation counselors will not exploit their professional relationships with supervisors, colleagues, students, or employees sexually or otherwise. Rehabilitation counselors will not condone or engage in sexual harassment, defined as deliberate or repeated comments, gestures, or physical contacts of a sexual nature unwanted by recipients.
- R4.9 Rehabilitation counselors who know of an ethical violation by another rehabilitation counselor will informally attempt to resolve the issue with the counselor, when the misconduct is of a minor nature and/or appears to be due to lack of sensitivity, knowledge, or experience. If the violation does not seem amenable to an informal solution, or is of a more serious nature, rehabilitation counselors will bring it to the attention of the appropriate committee on professional ethics.
- R4.10 Rehabilitation counselors possessing information concerning an alleged violation of this Code, will, upon request, reveal such information to the Commission on Rehabilitation Counselor Certification or other authority empowered to investigate or act upon the alleged violation, unless the information is protected by law.
- R4.11 Rehabilitation counselors who employ or supervise other professionals or students will facilitate professional development of such individuals. They provide appropriate working conditions, timely evaluations, constructive consultation, and experience opportunities.

#### **Canon 5 - PUBLIC STATEMENTS/FEEES**

Rehabilitation counselors shall adhere to professional standards in establishing fees and promoting their services.

##### **Rules of Professional Conduct**

- R5.1 Rehabilitation counselors will consider carefully the value of their services and the ability of clients to meet the financial burden in establishing reasonable fees for professional services.
- R5.2 Rehabilitation counselors will not accept for professional work a fee or any other form of remuneration from clients who are entitled to their services through an institution or agency or other benefits structure, unless clients have been fully informed of the availability of services from other such sources.
- R5.3 Rehabilitation counselors will neither give nor receive a commission or rebate or any other form of remuneration for referral of clients for professional services.
- R5.4 Rehabilitation counselors who describe rehabilitation counseling or the services of rehabilitation counselors to the general public will fairly and accurately present the material, avoiding misrepresentation through sensationalism, exaggeration, or superficiality. Rehabilitation counselors are guided by the primary obligation to aid the public in developing informed judgments, opinions, and choices.

#### **Canon 6 - CONFIDENTIALITY**

Rehabilitation counselors shall respect the confidentiality of information obtained from clients in the course of their work.

##### **Rules of Professional Conduct**

- R6.1 Rehabilitation counselors will inform clients at the onset of the counseling relationship of the limits of confidentiality.
- R6.2 Rehabilitation counselors will take reasonable personal action, or inform responsible authorities, or inform those persons at risk, when the conditions or actions of clients indicate that there is clear and imminent danger to clients or others after advising clients that this must be done. Consultation with other professionals may be used where appropriate. The assumption of responsibility for clients must be taken only after careful deliberation and clients must be involved in the resumption of responsibility as quickly as possible.
- R6.3 Rehabilitation counselors will not forward to another person, agency, or potential employer, any confidential information without the written permission of clients or their legal guardians.
- R6.4 Rehabilitation counselors will ensure that there are defined policies and practices in other agencies cooperatively serving rehabilitation clients which effectively protect information confidentiality.
- R6.5 Rehabilitation counselors will safeguard the maintenance, storage, and disposal of the records of clients so that unauthorized persons shall not have access to these records. All non-professional persons who must have access to these records will be thoroughly briefed concerning the confidential standards to be observed.
- R6.6 Rehabilitation counselors, in the preparation of written and oral reports, will present only germane data and will make every effort to avoid undue invasion of privacy.
- R6.7 Rehabilitation counselors will obtain written permission from clients or their legal guardians prior to taping or otherwise recording counseling sessions. Even with guardians' written consent, rehabilitation counselors will not record sessions against the expressed wishes of clients.
- R6.8 Rehabilitation counselors will persist in claiming the privileged status of confidential information obtained from clients, where communications are privileged by statute for rehabilitation counselors.
- R6.9 Rehabilitation counselors will provide prospective employers with only job relevant information about clients and will secure the permission of clients or their legal guardians for the release of any information which might be considered confidential.

## Canon 7 - ASSESSMENT

Rehabilitation counselors shall promote the welfare of clients in the selection, utilization, and interpretation of assessment measures.

### Rules of Professional Conduct

- R7.1 Rehabilitation counselors will recognize that different tests demand different levels of competence for administration, scoring, and interpretation, and will recognize the limits of their competence and perform only those functions for which they are trained.
- R7.2 Rehabilitation counselors will consider carefully the specific validity, reliability, and appropriateness of tests, when selecting them for use in a given situation or with particular clients. Rehabilitation counselors will proceed with caution when attempting to evaluate and interpret the performance of people with disabilities, minority group members, or other persons who are not represented in the standardized norm groups. Rehabilitation counselors will recognize the effects of socioeconomic, ethnic, disability, and cultural factors on test scores.
- R7.3 Rehabilitation counselors will administer tests under the same conditions that were established in their standardization. When tests are not administered under standard conditions, as may be necessary to accommodate modifications for clients with disabilities or when unusual behavior or irregularities occur during the testing session, those conditions will be noted and taken into account at the time of interpretation.
- R7.4 Rehabilitation counselors will ensure that instrument limitations are not exceeded and that periodic reassessments are made to prevent stereotyping of clients.
- R7.5 Rehabilitation counselors will make known the purpose of testing and the explicit use of the results to clients prior to administration. Recognizing the right of clients to have test results, rehabilitation counselors will give explanations of test results in language clients can understand.
- R7.6 Rehabilitation counselors will ensure that specific interpretation accompanies any release of individual data. The welfare and explicit prior permission of clients will be the criteria for determining the recipients of the test results. The interpretation of assessment data will be related to the particular goals of evaluation.
- R7.7 Rehabilitation counselors will attempt to ensure, when utilizing computerized assessment services, that such services are based on appropriate research to establish the validity of the computer programs and procedures used in arriving at interpretations. Public offering of an automated test interpretation service will be considered as a professional-to-professional consultation. In this instance, the formal responsibility of the consultant is to the consultee, but the ultimate and overriding responsibility is to clients.
- R7.8 Rehabilitation counselors will recognize that assessment results may become obsolete. They make every effort to avoid and prevent the misuse of obsolete measures.

## Canon 8 - RESEARCH ACTIVITIES

Rehabilitation counselors shall assist in efforts to expand the knowledge needed to more effectively serve people with disabilities.

### Rules of Professional Conduct

- R8.1 Rehabilitation counselors will ensure that data for research meet rigid standards of validity, honesty, and protection of confidentiality.
- R8.2 Rehabilitation counselors will be aware of and responsive to all pertinent guidelines on research with human subjects. When planning any research activity dealing with human subjects, rehabilitation counselors will ensure that research problems, design, and execution are in full compliance with such guidelines.
- R8.3 Rehabilitation counselors presenting case studies in classes, professional meetings, or publications will confine the content to that which can be disguised to ensure full protection of the identity of clients.
- R8.4 Rehabilitation counselors will assign credit to those who have contributed to publications in proportion to their contribution.
- R8.5 Rehabilitation counselors recognize that honesty and openness are essential characteristics of the relationship between rehabilitation counselors and research participants. When methodological requirements of a study necessitate concealment or deception, rehabilitation counselors will ensure that participants understand the reasons for this action.

## Canon 9 - COMPETENCE

Rehabilitation counselors shall establish and maintain their professional competencies at such a level that their clients receive the benefit of the highest quality of services the profession is capable of offering.

### Rules of Professional Conduct

- R9.1 Rehabilitation counselors will function within the limits of their defined role, training, and technical competency and will accept only those positions for which they are professionally qualified.
- R9.2 Rehabilitation counselors will continuously strive through reading, attending professional meeting, and taking courses of instruction to keep abreast of new developments, concepts, and practices that are essential to providing the highest quality of services to their clients.
- R9.3 Rehabilitation counselors, recognizing that personal problems and conflicts may interfere with their professional effectiveness, will refrain from undertaking any activity in which their personal problems are likely to lead to inadequate performance. If they are already engaged in such activity when they become aware of their personal problems, they will seek competent professional assistance to determine whether they should suspend, terminate or limit the scope of their professional activities.
- R9.4 Rehabilitation counselors who are educators will perform their duties based on careful preparation so that their instruction is accurate, up-to-date and scholarly.
- R9.5 Rehabilitation counselors who are educators will ensure that statements in catalogs and course outlines are accurate, particularly in terms of subject matter covered, bases for grading, and nature of classroom experiences.
- R9.6 Rehabilitation counselors who are educators will maintain high standards of knowledge and skill by presenting rehabilitation counseling information fully and accurately, and by giving appropriate recognition to alternative viewpoints.

## Canon 10 - CRC CREDENTIAL

Rehabilitation counselors holding the Certified Rehabilitation Counselor (CRC) designation shall honor the integrity and respect the limitations placed upon its use.

### Rules of Professional Conduct

- R10.1 Certified Rehabilitation Counselors will use the Certified Rehabilitation Counselor (CRC) designation only in accordance with the relevant GUIDELINES promulgated by the Commission on Rehabilitation Counselor Certification.
- R10.2 Certified Rehabilitation Counselors will not attribute to the mere possession of the designation depth or scope of knowledge, skill, and professional capabilities greater than those demonstrated by achievement of the CRC designation.
- R10.3 Certified Rehabilitation Counselors will not make unfair comparisons between a person who holds the Certified Rehabilitation Counselor (CRC) designation and one who does not.
- R10.4 Certified Rehabilitation Counselors will not write, speak, nor act in ways that lead others to believe Certified Rehabilitation Counselors are officially representing the Commission on Rehabilitation Counselor Certification, unless such written permission has been granted by the said Commission.
- R10.5 Certified Rehabilitation Counselors will make no claim to unique skills or devices not available to others in the profession unless the special efficacy of such unique skills or device has been demonstrated by scientifically accepted evidence.
- R10.6 Certified Rehabilitation Counselors will not initiate or support the candidacy of an individual for certification by the Commission on Rehabilitation Counselor Certification if the individual is known to engage in professional practices which violate this Code.

### Acknowledgement

*Referenced documents, statements, and sources for the development of this revised Code are as follows: National Rehabilitation Counseling Association Code of Ethics, National Academy of Certified Clinical Mental Health Counselors, and the Ethical Standards of the American Association for Counseling and Development. Portions of the Code are also derived from the American Psychological Association "Ethical Principles of Psychologists."*

**STANDARDS OF PRACTICE**  
**NEUROPSYCHOLOGICAL ASSESSMENT AND REHABILITATION SERVICES**

1. Staff will be familiar with, observe and discuss with their patients the limitations and potential benefits of services offered so as to facilitate honest and open communications and realistic expectations.
2. Staff will respect the rights and reputation of any institution, organization or firm with which they are associated when making oral or written statements, and when critical of particular policies, will attempt to seek change through constructive actions.
3. Staff will be obligated to promote access for persons with disabilities in all areas of their lives, assuring accessibility of programs or facilities at the time of referral, striving to eliminate attitudinal barriers and enhancing their own sensibility and awareness towards persons with disabilities.
4. Staff will function within the limits of their defined role, training and technical competency, accepting only those positions for which they are professionally qualified and seeking consultation and supervision as appropriate and necessary.
5. Staff will respect the confidentiality of information obtained from patients as well as informing them of the limits of confidentiality at the onset of the counseling relationship.
6. Confidentiality will only be broken when the conditions or actions of patients indicate that there is clear and imminent danger to themselves or others.
7. Staff will safeguard the maintenance, storage, and disposal of all patient records and must have written permission from patients or their legal guardians in order to forward any confidential information.
8. Staff will recognize that each test or inventory demands specific levels of competence for administration, scoring, and interpretation, and will recognize the limits of their competence and perform only those functions for which they are qualified.
9. Staff will consider carefully the validity, reliability and appropriateness of tests (inventories) when selecting and administering them for use in a given situation or with particular patients. Staff will proceed with caution when attempting to evaluate and interpret the performance of persons who are not represented in the standardized norm groups and will recognize the effects of socioeconomic, disability and cultural factors on test scores.
10. Staff will make known the purpose of testing and the explicit use of the results to patients prior to administration. Following testing, staff will interpret test results in an understandable, empathic, and reality-based manner.
11. Staff and their patients will work jointly in devising an integrated, individualized treatment plan which offers reasonable promise of success and is consistent with the abilities and circumstances of clients. Staff will consistently monitor treatment plans every four months to ensure their continued viability and effectiveness, remembering that patients have the right to make choices.

12. Staff will work with patients in considering rehabilitation objectives that are consistent with the patients' overall abilities, limitations, temperament, interests, and other relevant characteristics and needs.
13. Staff will recognize that families are an important factor in a patient's rehabilitation and will strive to enlist family understanding and involvement as a positive resource in promoting rehabilitation goals. The permission of clients will be secured prior to family involvement.
14. Staff will ensure that data for research, case study presentations, professional meetings, and publications meet rigid standards of validity, honesty and protection of confidentiality.
15. Staff will ensure that there is mutual understanding of the rehabilitation plan by all agencies and clinicians cooperating in the treatment and rehabilitation of patients including the sharing and procurement of patient information as appropriate.
16. Staff who are Certified Rehabilitation Counselors will function in accordance with the GUIDELINES promulgated by the Commission on Rehabilitation Counselor Certification.

## Introduction

Educational and psychological testing represents one of the most important contributions of behavioral science to our society. It has provided fundamental and significant improvements over previous practices in industry, government, and education. It has provided a tool for broader and more equitable access to education and employment. Although not all tests are well-developed, nor are all testing practices wise and beneficial, available evidence supports the judgment of the Committee on Ability Testing of the National Research Council that the proper use of well-constructed and validated tests provides a better basis for making some important decisions about individuals and programs than would otherwise be available.

Educational and psychological testing has also been the target of extensive scrutiny, criticism, and debate both outside and within the professional testing community. The most frequent criticisms are that tests play too great a role in the lives of students and employees and that tests are biased and exclusionary. In consideration of these and other criticisms, the *Standards* is intended to provide a basis for evaluating the quality of testing practices as they affect the various parties involved.

## Participants in the Testing Process

Educational and psychological testing involves and significantly affects individuals, institutions, and society as a whole. The individuals affected include students, parents, teachers, educational administrators, job applicants, employees, patients, supervisors, executives, and evaluators. The institutions affected include schools, colleges, businesses, industry, and government agencies. Individuals and institutions benefit when testing helps them achieve their goals. Society, in turn, benefits when the achievement of individual and institutional goals contributes to the general good.

The interests of the various parties in the testing process are usually, but not always, congruent. For example, when a test is given for counseling purposes or for job placement, the interests of the individual and the institution often coincide. However, when a test is used to select from among many individuals for a highly competitive job or educational or training program, the preferences of an applicant may be inconsistent with those of an employer or admissions officer.

There are generally three main participants in the testing process: the *test developer*, who develops, publishes, markets, and often administers and scores the test; the *test user*, who requires the test results for some decision-making purpose; and the *test taker*, who takes the test by choice, direction, or necessity. Often there is a *test sponsor*, which may be a board that represents institutions or a governmental agency, that contracts with a test developer for a specific instrument or service. In addition there may also be a *test administrator*, who handles the actual administration of the test, and a *test reviewer*, who conducts a scholarly review to evaluate the suitability of the test for the uses proposed.

The roles of test developer, test taker, test user, and test sponsor are sometimes combined and sometimes further divided. In counseling, the test taker is typically the primary user of the test results. Sometimes the test administrator is an agent of the test developer, and sometimes the test administrator is also the test user. When an industrial organization prepares its own employment tests, it is both the developer and the user. Sometimes a test is developed by a test author but published, advertised, and distributed by an independent publisher, though in most cases the publisher plays an active role in the test development.

## The Purpose of These Standards

Recent controversies over testing make the development of the *Standards* vitally important to all participants in the testing process. Many issues need to be addressed in a way that does not preempt the political process. In general, the *Standards* advocates that, within feasible limits, the necessary technical information be made available so that those involved in policy debate may be fully informed. The *Standards* does not attempt to provide psychometric answers to policy questions. However, complete separation of scientific and social concerns is not possible. The requirement in

the *Standards* for documentation and scientific analysis may sometimes, in itself, place a greater burden on one side of a policy issue than on another.

The purpose of publishing the *Standards* is to provide criteria for the evaluation of tests, testing practices, and the effects of test use. Although the evaluation of the appropriateness of a test or application should depend heavily on professional judgment, the *Standards* can provide a frame of reference to assure that relevant issues are addressed. The *Standards* does not attempt to assign precise responsibility for the satisfaction of individual standards. To do so would be difficult, especially since much work in testing is done by contractual arrangement. However, all professional test developers, sponsors, publishers, and users should make reasonable efforts to observe the *Standards* and to encourage others to do so.

The *Standards* is not meant to prescribe the use of specific statistical methods. Where specific statistical reporting requirements are mentioned, the phrase "or equivalent" should always be understood. For concreteness, the standards sometimes refer to a common method of achieving specific reporting objectives. In particular situations, however, more desirable alternatives may be available.

### Cautions To Be Exercised in Using These Standards

The *Standards* is a technical guide that can be used as the basis for evaluating testing practices. Evaluating the acceptability of a test or test application does not rest on the literal satisfaction of every primary standard in this document, and acceptability cannot be determined by using a checklist. Specific circumstances affect the importance of individual standards. Individual standards should not be considered in isolation. Therefore, evaluating acceptability involves the following: professional judgment that is based on a knowledge of behavioral science, psychometrics, and the professional field to which the tests apply; the degree to which the intent of this document has been satisfied by the test developer and user; the alternatives that are readily available; and research and experiential evidence regarding feasibility.

The use of the standards in litigation is inevitable; it should be emphasized, however, that in legal proceedings and elsewhere professional judgment based on the accepted corpus of knowledge always plays an essential role in determining the relevance of particular standards in particular situations. The *Standards* is intended to offer guidance for such judgments.

It would not be appropriate for test developers or test users to state that a test, manual, or procedure satisfies or follows these standards. That judgment is more appropriately made by others in the professional community.

These standards are concerned with a field that is evolving. Therefore, there is a continuing need for monitoring and revising this document as knowledge develops. There are some areas in which new developments are particularly likely, such as gender-specific or combined-gender norms, cultural bias, computer based test interpretation, validity generalization, differential prediction, and flagging test scores for people with handicapping conditions.

### Categories of Standards

In previous versions of the *Standards*, the classifications "essential," "highly desirable," and "desirable" were used to indicate the relative importance of the individual standards. In the 1985 *Standards*, new categories and labels are used, in part to avoid the troublesome distinction between desirable and highly desirable and to avoid the label "essential." The standards are now categorized either as being of primary or of secondary importance. Importance is viewed largely as a function of the potential impact that the testing process has on individuals, institutions, and society.

*Primary standards* are those that should be met by all tests before their operational use and in all test uses, unless a sound professional reason is available to show why it is not necessary, or technically feasible, to do so in a particular case. Test developers and users and, where appropriate,

sponsors, are expected to be able to explain why any primary standards have not been met.

*Secondary standards* are desirable as goals but are likely to be beyond reasonable expectation in many situations. Although careful consideration of these standards will often be helpful in evaluating tests and programs and in comparing the usefulness of competing instruments, limitations on resources may make adherence to them infeasible in many situations. Some secondary standards describe procedures that are beneficial but not often used. Test developers and users are not expected to be able to explain why secondary standards have not been met.

The importance of some standards for test construction and evaluation will vary with application. These standards are designated as *conditional*. Such standards should be considered primary for some situations and secondary for others. In deciding whether to take an individual conditional standard as primary or secondary, one should consider carefully the feasibility of meeting that standard in relation to the potential consequences to all parties involved in the testing process. It may be infeasible technically or financially for some testing programs to observe some conditional standards, particularly those programs that conduct low-volume tests. However, if the use of a test is likely to have serious consequences for test takers, especially if a large number of people may be affected, conditional standards assume increased importance.

The categories in which standards are placed should be viewed as imperfect. Where testing has a limited role in a larger assessment procedure (e.g., tests conducted by a clinical, industrial, or school psychologist), some primary standards, especially those dealing with documentation, should be considered as having a secondary designation.

Ideally all relevant primary standards should be met at publication or first operational use of each test. Because the development of a test for widespread use is an extensive undertaking, a requirement that all relevant primary standards be satisfied at first operational use would be likely to stifle both the development of new instruments and progress in the field. Furthermore, a testing professional who is put in charge of a new or continuing program that does not meet relevant primary standards cannot be expected to remedy all that program's shortcomings immediately.

When judging the short-term acceptability of a test or program under development or redevelopment, the test user should determine that the test is on a par with readily available alternatives. In addition, the test developer or publisher should determine that

1. advertising for a test or program recommends only applications supported by the test's research base;
2. necessary cautions are given in the manual or elsewhere to encourage sufficiently limited reliance on the test results, particularly when the use of the new test will have significant impact on the test takers; and
3. there is clear indication of continuing and significant improvement in the research base directed toward observance of the standards.

The major new sections in the 1985 *Standards* relate to test use. The *Standards* emphasizes that test users should have a sound technical and professional basis for their actions, much of which can be derived from research done by test developers and publishers. In selecting a test, a potential user should depend heavily upon the developer's research documentation that is clearly related to the intended application. Although the test developer should supply the needed information, the ultimate responsibility for appropriate test use lies with the user.

Tests include standardized ability (aptitude and achievement) instruments, diagnostic and evaluative devices, interest inventories, personality inventories, and projective instruments. The 1966 and 1974 *Standards* noted that the same general types of information are needed for all these varieties of published diagnostic, prognostic, and evaluative devices. Sim-

Tests and Test Uses  
to Which These  
Standards Apply

ilarly, a more appropriate choice among assessment devices and subsequent use will be facilitated if there is reasonable comparability in the kinds of information made available to users.

In the *Standards* three broad categories of test instruments are covered: constructed performance tasks, questionnaires, and to a lesser extent, structured behavior samples. Constructed performance tasks are designed to isolate and assess particular educational and psychological constructs without having to simulate actual environmental or social situations in which such constructs are typically expressed. Printed answer sheets and pencil are the mediums most often used; however, oral exchange, oral recordings, and manipulatable objects form parts of some individually administered tests, and computerized test administration is becoming increasingly common. The performance tasks are often designed to be interpreted as maximum performance assessments. Conventional standardized ability tests are the most common examples. There are also constructed performance measures of some cognitive style and personality constructs.

Questionnaires and inventories are designed to provide a convenient medium through which people can be asked to report personal opinions, interests, attitudes, and typical reactions to situations and problems that have been or might be faced in everyday life. Personality or interest inventories, composed of lists of printed questions that the respondent answers by checking a defined degree of agreement or interest, are the most common examples.

Observable behavior can also be sampled directly to provide systematic, standardized assessments of personal skills and styles relevant to clinical, employment, and educational decision making. Such tests are called structured behavior sample tests. Social skills, speaking and writing skills, and the skills involved in artistic expression are examples of performance domains in which structured behavior samples have been used. Job sample tests have been used often in industry and in the military. Writing samples are now used widely in education. Tests of characteristic styles of performance under stress, in the face of complexity, or in situations where leadership is required provide other examples. Sometimes structured behavior samples are taken by observing behavior in real-world situations. In other instances, such situations are simulated to aid in standardization or for reasons of economy.

The need for reasonable comparability of the information provided to users is particularly compelling for the new uses of computers in testing that are being developed. Instruments developed initially in paper-and-pencil or interview form are being administered, scored, and in some instances, interpreted, by computers. There are also computerized adaptive tests and interviews. Although in some instances specific standards have been stated for tests administered by computer, all the standards apply with equal force to such tests. In many instances, the switch from paper and pencil to computer assessment will require additional evidence that relevant standards have been met in the new testing mode.

Although these standards apply primarily to constructed performance tasks, questionnaires, and structured behavior samples, they may also be usefully applied in varying degrees to the entire range of assessment techniques. It will generally not be possible, however, to apply the standards with the same rigor to the broad range of unstructured behavior samples that are used in some forms of clinical and school psychological assessment and to instructor-made tests that are used to evaluate student performance in education and training.

The term "test" usually refers to measures of either the constructed performance or structured behavior sample type, in which test takers are expected or instructed to try their best. Instruments for identifying interests and personality characteristics through self-report are typically and properly entitled "inventories," "questionnaires," or "checklists" rather than tests. In textual material, such as in the *Standards*, these self-report instruments may be called tests in order to simplify the language. The

## Organization of This Volume

are called tests here to indicate that the standards also apply to these instruments. The term "test" should generally be avoided, however, in describing such instruments, especially in their titles.

Part I of the *Standards*, "Technical Standards for Test Construction and Evaluation," contains standards for validity, reliability, test development, scaling, norming, comparability, equating, and publication. Part II presents "Professional Standards for Test Use." Part III, "Standards For Particular Applications," contains standards for testing linguistic minorities and people with handicapping conditions. The technical and professional standards discussed in Parts I and II are relevant to the particular applications in Part III. Part IV, "Standards for Administrative Procedures," contains standards regarding test administration, scoring, and reporting, as well as standards for the protection of test takers' rights. Although all four parts deal with technical issues, each also addresses how technical issues, professional practice, and professional ethics interface. The interface of standards with issues of professional practice is most evident in Part II and that with professional ethics in Part IV.

Each chapter begins with introductory text that provides background for the standards that follow. This text is meant to assist in the interpretation of the standards, not to impose additional standards. Many of the standards are followed by comments. These comments are not meant to impose additional requirements, only to explain the standards they follow.

The *Standards* also contains a glossary, a bibliography, and an index. The glossary provides definitions for terms as they are used in this volume specifically.

## 6. General Principles of Test Use

### Background

Although a distinction is made in the *Standards* between test development and test use, that distinction is not always clear in application. For example, test administration, scoring, and reporting may be done by the test developer or the test user. Also users need to be aware of standards governing test development so that they can more easily evaluate the tests they contemplate using. This chapter contains general standards applicable to test use in professional practice. Succeeding chapters in this section present standards more specific to specialty areas.

In applying standards to test use, as opposed to test development, more flexibility and use of professional judgment are required. The appropriateness of specific test uses cannot be evaluated in the abstract but only in the context of the larger assessment process. The principal questions to be asked in evaluating test use are whether or not the test is appropriate (valid) for its specific role in the larger assessment process and whether or not the test user has accurately described the extent to which the score supports any decision made or administrative action taken.

Although it is not appropriate to tell a test user that particular levels of predictive validity and reliability need to be met, it is appropriate to ask the user to ascertain that procedures result in adequately valid predictions or reliable classifications for the purposes of the testing. Cost-benefit compromises become as necessary in test use as they do in test development. However, as with standards for test development, when test standards are not met in test use, reasons should be available. Here again, the criteria of impact on test takers applies. The greater the potential impact, the greater the need to satisfy relevant standards.

The test user, in selecting or interpreting a test, should know the purposes of the testing and the probable consequences. The user should know the procedures necessary to facilitate effectiveness and to reduce bias in test use. Although the test developer and publisher should provide information on the strengths and weaknesses of the test, the ultimate responsibility for appropriate test use lies with the test user. The user should become knowledgeable about the test and its appropriate uses and also communicate this information, as appropriate, to others.

---

### Standard 6.1

Test users should evaluate the available written documentation on the validity and reliability of tests for the specific use intended. (*Primary*)

**Comment:**

The degree of reliability or validity required of a test depends on its role in the assessment process and the impact of the process on the parties involved. There may be situations in which, in a user's professional judgment, decisions or inferences should be based, in part, on tests for which there is little evidence of reliability or validity for the intended use. In these situations, the user should take great care not to imply that the decisions or inferences made are based on test results of known reliability or validity. When feasible, repeated use of such tests should include efforts to develop the appropriate evidence.

---

### Standard 6.2

When a test user makes a substantial change in test format, mode of administration, instructions, language, or content, the user should revalidate the use of the test for the changed conditions or have a rationale supporting the claim that additional validation is not necessary or possible. (*Primary*)

**Standard 6.3**

When a test is to be used for a purpose for which it has not been previously validated, or for which there is no supported claim for validity, the user is responsible for providing evidence of validity. *(Primary)*

**Comment:**

The individual who makes the claim for validity is responsible for providing the necessary evidence. Evidence of validity sufficient for test use may often be obtained from a well-documented manual. If previous evidence is not sufficient, then additional data should be collected. The provisions of this standard should not be construed to prohibit the generation of hypotheses from test data. For example, though many clinical tests have limited or contradictory validity evidence for common uses, clinicians generate hypotheses based appropriately on responses to such tests. These hypotheses should, however, be labeled clearly as such.

---

**Standard 6.4**

Test users should accurately portray the relevance of a test to the assessment and decision-making process and should not use a test score to justify an evaluation, recommendation, or decision that has been made largely on some other basis. *(Primary)*

---

**Standard 6.5**

Test users should be alert to probable unintended consequences of test use and should attempt to avoid actions that have unintended negative consequences. *(Primary)*

**Comment:**

For example, test users should act to counter the tendency of people to attach unsupported surplus meanings to test scores. Obviously, test users cannot anticipate every unintended consequence. What is required is an attempt that is reasonable and made in good faith to avoid unintended consequences that might be anticipated.

---

**Standard 6.6**

Responsibility for test use should be assumed by or delegated only to those individuals who have the training and experience necessary to handle this responsibility in a professional and technically adequate manner. Any special qualifications for test administration or interpretation noted in the manual should be met. *(Primary)*

**Comment:**

This standard has special significance in areas such as clinical testing, testing for special education, testing of handicapped people, and other such situations where potential impact is great.

---

**Standard 6.7**

Test users should verify periodically that changes in populations of test takers, objectives of the testing process, or changes in available techniques have not made their current procedures inappropriate. *(Conditional)*

---

**Standard 6.8**

When test results are released to the news media, those responsible for releasing the results should provide information to help minimize the possibility of the misinterpretation of the test results. *(Primary)*

---

**Standard 6.9**

When a specific cut score is used to select, classify, or certify test takers, the method and rationale for setting that cut score, including any technical analyses, should be presented in a manual or report. When cut scores are based primarily on professional judgment, the qualifications of the judges also should be documented. *(Primary)*

**Comment:**

In employment and some other testing applications there may be no pre-specified cut score; the number of individuals to be selected is determined by the number of available openings.

---

**Standard 6.10**

In educational, clinical, and counseling applications, test administrators and users should not attempt to evaluate test takers whose special characteristics--ages, handicapping conditions, or linguistic, generational, or cultural backgrounds--are outside the range of their academic training or supervised experience. A test user faced with a request to evaluate a test taker whose special characteristics are not within his or her range of professional experience should seek consultation regarding test selection, necessary modifications of testing procedures, and score interpretation from a professional who has had relevant experience. *(Primary)*

---

**Standard 6.11**

In school, clinical, and counseling applications, a test taker's score should not be accepted as a reflection of lack of ability with respect to the characteristic being tested for without consideration of alternate explanations for the test taker's inability to perform on that test at that time. *(Conditional)*

**Comment:**

Many test manuals point out variables that should be considered in interpreting test scores, such as clinically relevant history, school record, vocational status, and examiner or test taker differences. Influences associated with variables such as socioeconomic status, ethnicity, cultural background, language, age, or gender may also be relevant. In addition, medication, visual impairments, or other handicapping conditions may affect a test taker's performance on, for example, a paper-and-pencil test of mathematics. Such alternate explanations for a test taker's level of performance should be considered before interpreting the test taker's score as reflecting ability level with respect to the skills being tested.

---

**Standard 6.12**

In school, clinical, and counseling applications, tests developed for screening should be used only for identifying test takers who may need further evaluation. The results of such tests should not be used to characterize a person or to make any decision about a person, other than the decision for referral for further evaluation, unless adequate reliability and validity for these other uses can be demonstrated. *(Primary)*

---

**Standard 6.13**

**Test users should not use interpretations of test results, including computer-interpreted test results, unless they have a manual for that test that includes information on the validities of the interpretations for the intended applications and on the samples on which they were based. (Primary)**

**Comment:**

The user of a special service has the obligation to be thoroughly familiar with the principles on which interpretations are derived and should have the ability to evaluate a computer-based interpretation of test performance in light of other evidence. Considerable professional judgment is needed to use computer-based interpretations appropriately.

## 7. Clinical Testing

### Background

The use of tests as part of a clinical assessment is characterized mainly by the fact that the choice of tests is individualized and usually only one person at a time is tested. The test taker may be a child, adolescent, or adult; the setting may be a school, mental health or outpatient clinic, hospital, prison, or private practitioner's office. In any event, tests are chosen to provide information useful for assessment and decision making for that specific individual, taking into account his or her special background and characteristics.

A wide range of tests and procedures is employed, including tests of aptitudes or abilities, attitudes, and personality characteristics; projective techniques; interview schedules; checklists; behavioral observations; rating scales; and others. Tests are used to make decisions about diagnostic classification; presence of neurological impairment; suitability for particular types of treatment or educational instruction; identification of intellectual and personality assets that can be used in rehabilitative, therapeutic, or educational planning; eligibility for parole or probation; and evaluation of treatment outcomes. In many clinical situations decision making is fluid in that treatment yields additional information that can serve to modify the decisions. In other circumstances clinical testing may be involved in decisions having a powerful and lasting impact on people's lives (e.g., parole, sentencing, civil commitment, competency to stand trial, and child custody).

Projective techniques and many interview and behavioral observation techniques are often used as aids in clinical assessment and treatment selection. Each of these methods yields multiple hypotheses regarding the behavior of the subject in various situations as they arise, with each hypothesis modifiable on the basis of further information. When one of these measures is so used, interpretations are judged by its total contribution to the clinical understanding of an individual rather than by the validity of each hypothesis.

Computers are being used increasingly to administer, score, and interpret tests. However, whether clinicians do the testing themselves or employ a computer or an assistant, they have the responsibility of selecting the appropriate tests for a specific individual in accordance with that person's unique characteristics, the setting, and the nature of the question posed. Clinicians are also responsible for ensuring that the testing conditions are appropriate. For example, such matters as whether a client who needs glasses or a hearing aid has them available during testing can affect the validity of test results. Is the client capable of reading at the level required by the test? Is the test material suitable for this elderly or young client? In addition, it is the clinician's responsibility to assure confidentiality, assess the suitability of test results and computer interpretations, and communicate them in appropriate terms to the client and concerned others.

A number of special problems arise in the use of instruments for clinical assessment. Such instruments are often multiply scored. Intercorrelations among the resulting scales are often high due to the common format, item overlap, and overlapping constructs. Furthermore, even though scores may be standardized with respect to a reference group, interpretations are often based on the absolute level of standard scores or of their differences rather than on scores relative to those obtained by others. Appropriately, manuals sometimes contain the warning that score levels should be interpreted with caution and that interpretations obtained by examining several independently obtained sources is desirable.

Another area requiring special attention is that of open-ended responses. Examples of clinical instruments involving these are sentence completion forms, analyses of verbal material obtained from tape record-

ings or videotapes of interviews or therapy sessions, and ratings of behavior in natural or contrived settings. Special care is needed with such approaches to ensure that the instruments are administered in a facilitating atmosphere without suggestions or cues that might influence the response given, unless such prompting is specifically planned as part of the test. Furthermore, the scoring categories used in open-ended response instruments need to be defined clearly, and special training may be needed for coding the responses.

Chapter 1 describes the three categories of evidence of test validity that should be considered in interpreting test scores. Of these, construct-related evidence is of primary importance for clinical and personality tests. Interpretations of personality traits, attitudes, underlying personality tendencies, and psychiatric classifications are all constructs requiring evidence of validity. Content-related and criterion-related evidence may sometimes be a part of construct evidence.

Clinicians deal not only with the diagnostic uses of tests, but also with the prediction of behavior and with response to treatment. When clinical instruments are used in decision making, that use is constrained by the same consideration of criterion-related evidence of validity as is any other use of tests.

---

**Standard 7.1**

Clinicians should not imply that interpretations of test data are based on empirical evidence of validity unless such evidence exists for the interpretations given. *(Primary)*

**Comment:**

This standard should not be construed to prohibit interpretations of test data presented as hypotheses or clinical judgments.

---

**Standard 7.2**

When validity is appraised by comparing the level of agreement between test results and clinical diagnoses, the diagnostic terms or categories employed should be carefully defined or identified, and the method by which a diagnosis was made should be specified. If diagnosis was made based on judgments, information on the training, experience, and professional status of the judges and on the nature and extent of the judges' contacts with the test takers should be included. *(Primary)*

---

**Standard 7.3**

When differential diagnosis is needed, the user should choose, if possible, a test for which there is evidence of the test's ability to distinguish between the two or more diagnostic groups of concern rather than merely to distinguish abnormal cases from the general population. *(Primary)*

**Comment:**

Test users will find it particularly helpful if validity information is in a form that enables them to determine how much confidence can be placed in judgments regarding an individual. Differences between group means and their statistical significance give inadequate information regarding validity for diagnostic purposes. Further information might consist of a table showing the degree of overlap of predictor distributions among different criterion groups.

**Standard 7.4**

Test users should determine from the manual or other reported evidence whether the construct being measured corresponds to the nature of the assessment that is intended. *(Primary)*

---

**Standard 7.5**

Clinicians should share with their clients test results and interpretations, as well as information about the range of error for such interpretations when such information will be beneficial to the client. Such information should be expressed in language that the client (or client's legal representative) can understand. *(Secondary)*

---

**Standard 7.6**

Criterion-related evidence of validity for populations similar to that for which the test will be used should be available when recommendations or decisions are presented as having an actuarial, as well as a clinical, basis. *(Primary)*

## 9. Test Use in Counseling

### Background

Uses of tests in counseling differ from most other test uses in that the test taker is viewed as the primary user of test results. Accumulated experience and research evidence have shown that standardized tests can be a valuable part of the counseling process. If used appropriately, tests can provide useful information to clients. However, because test takers do not typically have professional testing knowledge and skill, they need assistance and guidance from counselors and developers of interpretive materials who have a unique role in facilitating the appropriate and effective use of tests.

Counselors are concerned with a range of assessment and guidance activities related to the life-span development and decision-making activities of individuals. Typical counseling concerns include the individual's personal and social skills, educational achievement, developed abilities, educational and vocational interests, occupational knowledge and preferences, occupational values, career development, study skills, coping and problem solving skills, and plans and values for other important roles in adult life, such as relationships with others, work, and parenting. These characteristics of the individual are assessed in counseling by a variety of formal and informal procedures--paper-and-pencil inventories, tests, work samples, interviews, card sorts, checklists, and so on. All such measures that yield classifications and raw or converted scores that result in suggestions for exploration or recommendations for action are considered tests and require evidence of reliability and validity.

Counselors work in a variety of settings: schools, government, industry, agencies, and private practice. They may assist individuals in examining educational, career, work, family, leisure, and retirement choices. One important function in schools is that of consulting with administrators, teachers, parents, and students to assist individual students in the selection of educational programs. When tests are an important part of the decision process, the tests may, in effect, become the basis for the placement of students. School counselors may play a similar role in assisting individuals in choosing colleges and in making decisions about college programs. In these cases the standards for the use of tests in educational classification and placement may be appropriate.

All interpretive reports, whether provided in printed form or on video display terminals, are an extension of the individual profiles and score reports that are part of the counseling testing program. They may be used to provide the results of tests to students and parents, as well as to professional staff. Depending on the availability of counselors and other school staff who are trained in test interpretation and use, students who receive computer-based interpretation reports may or may not receive further interpretation of such reports. For many tests used in schools, therefore, test developers need to take into account the likelihood that students will receive little or no professional assistance in interpreting test results other than that provided by the computer-based interpretation reports. The test taker, who has no technical training in testing, must be able to interpret and use test information accurately and must depend largely on materials accompanying the computer-based interpretation report. The developers of such tests or computer-based interpretations should provide comprehensive and easily understandable interpretive and instructional material.

Computer-assisted guidance systems are also within the scope of the *Standards*. These systems may incorporate test-like tasks or existing interest or ability measures. Results of rating scales, ability measures, or estimates may be used to structure the search for occupations. Occupations are sometimes presented or recommended to users on the basis of measures of occupational attributes. Manuals should spell out the procedures by which occupational characteristics were developed, the system by which

occupational attributes were linked to individual characteristics, and evidence on the validity of particular recommendations.

Test interpretations and test uses in counseling for vocational, career, and life development are influenced by the experiences of the individual test taker and of the professionals who provide information in this process. To some degree these experiences, in interactions with peers and adults and in schools and other settings, have been group-linked and related to fixed characteristics of individuals (e.g., gender, race or ethnicity, or socioeconomic background). Test interpretation and test use may similarly be limited by perceptions and experiences related to group membership. This issue is of particular concern in uses of tests in counseling. Both counselor and test taker should consider whether learning experiences leading to the development of preferences and competencies have been stereotyped by expectations of behaviors considered appropriate for females and males, for racial and ethnic minorities, based on socioeconomic status, or for people with handicapping conditions.

---

**Standard 9.1**

Testing for counseling should have as its primary goals the acquisition of relevant information and the reporting of that information with appropriate interpretations so that clients from diverse backgrounds can be assisted in making important educational, personal, and career decisions. *(Primary)*

---

**Standard 9.2**

Counselors should review the interpretive materials provided to clients to evaluate accuracy, clarity, and usefulness of the materials. Manuals for tests or computer-based interpretations should be evaluated for evidence for the validity of specific interpretations made. *(Primary)*

**Comment:**

A counselor should determine, for example, whether classifications for particular vocational courses are based on cut scores supported by evidence of successful course completion or on other criteria. Are occupational suggestions based on empirical study of people entering the occupations? The bases of such interpretations should be stated clearly, perhaps by presenting expectancy tables or probability statements. For some tests this information may vary for groups of test takers. Qualified professional users should have access to explicit information on the accuracy of the classifications used as the basis of interpretations. If data to support such interpretive statements have not been collected, that fact should be stated clearly.

---

**Standard 9.3**

Counselors should review technical data and develop a rationale for the decision to use combined or separate norms for females and males in reports to test takers. *(Primary)*

**Comment:**

This standard is concerned with the possible effect of prior experience on present choices. For example, in tests that are used for choosing vocational courses, scores for female test takers may reflect present status but may not predict future performance in a vocational course. One way to examine this possibility is to compare an individual's standing relative to others in the same gender group. Comparing both norm groups provides an opportunity to discuss the influence of prior

experiences on test scores and to assess the accuracy of the score for an individual student.

For some interest inventories, not all occupational scales will have both female and male criterion-group norms. However, providing scores on all scales, based on clearly identified female or male criterion groups, facilitates the counseling use of the inventory with all clients.

---

**Standard 9.4**

If a publisher packages tests that are to be used in combination for counseling, the counselor should review the manual for the rationale for the specific combination of tests used and the justification of the interpretive relationships among the scores. *(Primary)*

**Comment:**

For example, if measures of developed abilities (e.g., achievement or specific or general abilities) are used with interest measures to suggest a requisite combination of scores for success, then supporting validity data for this combination should be available.

---

**Standard 9.5**

Counselors should examine test manuals for any available information about how suggested or implied career options (i.e., the vocational program or occupation suggested by the highest scores on the test) are distributed for samples of the typical respondents of each gender and relevant racial or ethnic groups. *(Primary)*

---

**Standard 9.6**

Counselors should review the test materials that are provided to the test takers to be sure that such materials properly caution the test taker not to rely on the test scores solely when making life-planning decisions. The counselor should encourage the test taker to consider other relevant information on personal and social skills, values, interests, accomplishments, experiences, and on other test scores and observations. *(Primary)*

**Comment:**

It is important to recognize that vocational interests, abilities, and choices may be influenced by environmental and cultural factors, including early socialization, traditional sex-role expectations of society, and the experiences typical of members of various gender, racial, ethnic, handicapped, and socioeconomic groups. For example, female clients in general may have had fewer science- and mathematics-related experiences. Counselors in some instances may suggest and encourage exploratory experiences in those areas where interests have not had a chance to develop. For many high school students particularly, test results should be used to expand options rather than to narrow options prematurely.

---

**Standard 9.7**

Counselors should encourage multiple valid assessments of an individual's abilities, social skills, and interests. *(Primary)*

**Comment:**

School or work performance, extracurricular activities, and hobbies are examples of indicators that might be used to lessen a test user's and a test taker's reliance on a single measure of important characteristics.

**Standard 9.8**

Counselors should review the interpretive materials for ability or interest measures and for other tests that are used with people who are reentering employment or education or changing work settings for their appropriateness for these clients. A counselor should consider the age, experience, and background of the client as they are compared with the characteristics of the norm groups on which the scores are based.  
*(Primary)*

**Comment:**

For example, for the majority of inventories and ability tests, normative data are based on younger test takers. Although these tests may be useful with older test takers, scores should be interpreted cautiously.

---

**Standard 9.9**

Counselors should review interpretive materials for tests to ensure that case studies and examples are not limited to illustrations of people in traditional roles. *(Secondary)*

**Comment:**

For example, counselors might look for case studies and examples of men and women of different ages, and in different ethnic, racial, or handicapped groups. Where tests are used widely in adult counseling, such as for men and women reentering education or the labor force or changing careers, case studies and examples that are relevant for these clients should be sought.

## 14. Testing People Who Have Handicapping Conditions

### Background

Tests are administered to people who have handicapping conditions in a variety of settings and for diverse purposes. There are a number of modifications of tests and test administration procedures that make it possible for people with certain handicapping conditions to take tests developed originally for the general population. Some modified tests, with accompanying research, have been made available by the major national testing programs for a number of years. Although the development of tests and testing procedures for such people is encouraged by the *Standards*, it should be noted that all relevant individual standards given elsewhere in this document are fully applicable to the testing applications considered in this chapter.

Some of the modifications in the way a test is administered alter the medium in which the test instructions and questions are presented to the test takers. For visually impaired people a variety of modifications may be needed. The test booklet may be produced in large print, high-quality regular print, or braille, or the test may be tape-recorded or read aloud to the test taker.

Many hearing-impaired individuals, especially the prelingually deaf, have difficulty in understanding written as well as spoken language; therefore, the intelligibility of the instructions for tests, whether written or spoken, should be considered when tests are modified for hearing-impaired test takers. Modifications of test administration for deaf and hearing-impaired people often include having an interpreter who signs or otherwise interprets the test instructions and, occasionally, the test questions.

The method used to record a response may also need to be modified. Test takers who cannot record their answers to test questions are assisted most commonly by a person who writes or marks the answers. Other ways of obtaining a response include having the respondent use a tape recorder, a typewriter, or a braillewriter. A test may have to be modified to allow a test taker to point to the response of his or her choice.

Nearly all national testing programs that provide modified test procedures for handicapped people provide additional time to take the test. Reading braille and using a cassette recorder or a reader take longer than reading regular print. Reading large type may or may not be more time consuming, depending on the layout of the material and on the nature and severity of the impairment.

Although modifications in the time allowed for tests are considered among the appropriate test options, there are few data available to support any conclusions about the effects of modifications in time, number of sittings, or number of recesses on the test results. Furthermore, little is known about how much time people with various handicapping conditions actually need because records of the time actually used are rare, and empirical studies to set time limits are even more rare.

Changes in test content are sometimes required for test takers with visual or hearing impairments. Items may be unnecessarily difficult for visually impaired people if they use visual stimuli to measure knowledge acquired through other senses. This problem can be identified and corrected by simply reviewing the items, spotting the offenders, and substituting nonvisual stimuli. Because the substitutions may alter other characteristics of the items, however, the modified items should be tried out before they are used in operational testing situations. In certain situations the test may also cause problems if it measures knowledge, skills, or concepts learned primarily through vision.

Verbal tests may create more severe problems for test takers who are prelingually deaf than for those with visual impairments. However, finding appropriate nonverbal tests to measure the same abilities or to predict the same behavior may be extremely difficult. Although this is a testing problem, it reflects more fundamental difficulties in understanding the nature of abilities, what abilities are needed in certain situations, and what existing abilities may compensate for impaired abilities in certain circumstances.

Many of the modifications in the ways tests are administered for handicapped people necessitate that the tests be given individually rather than to groups of respondents. The reasons for having an individual administration include the absence of a practical or convenient way to use a group administration, the desire not to interfere with others taking a test in a group, and the desire to reduce the anxiety handicapped people may have about the test. Some additional alterations may be required: for example, changing the location of the standard testing site if it is not accessible to people in wheelchairs; providing tables or chairs that make test takers with certain physical disabilities more comfortable; and altering lighting conditions and associated space needs for people with some visual impairments.

Despite the history of attempts to modify tests for handicapped people, significant problems remain. First, there have been few empirical investigations of the effects of special accommodations on the resulting scores or on their reliability and validity. Strictly speaking, unless it has been demonstrated that the psychometric properties of a test, or type of test, are not altered significantly by some modification, the claims made for the test by its author or publisher cannot be generalized to the modified version. The major reason for the lack of research is the relatively small number of handicapped test takers. For example, there are usually not enough students with handicapping conditions entering one school in any given year to conduct the type of validation study that is usually conducted for college admission tests.

Although modifying tests for individuals with handicapping conditions is generally regarded as desirable, sometimes some very basic, unanswered questions should be confronted. When tests are administered to people with handicapping conditions, particularly those handicaps that affect cognitive functioning, a relevant question is whether the modified test measures the same constructs. Do changes in the medium of expression affect cognitive functioning and the meaning of responses?

Of all the aspects of testing people who have handicapping conditions, reporting test scores has created the most heated debate. Many test developers have argued that reporting scores from nonstandard test administrations without special identification (often called "flagging" of test scores) violates professional principles, misleads test users, and perhaps even harms handicapped test takers whose scores do not accurately reflect their abilities. Handicapped people, on the other hand, have generally said that to identify their scores as resulting from nonstandard administrations and in so doing to identify them as handicapped is to deny them the opportunity to compete on the same grounds as nonhandicapped test takers, that is, to treat them inequitably. Until test scores can be demonstrated to be comparable in some widely accepted sense, there is little hope of happily resolving from all perspectives the issue of reporting scores with or without special identification. Professional and ethical considerations should be weighed to arrive at a solution, either as an interim measure or as continuing policy.

---

BEST COPY AVAILABLE

**Standard 14.1** People who modify tests for handicapped people should have available to them psychometric expertise for so doing. In addition, they should have available to them knowledge of the effects of various handicapping conditions on test performance, acquired either from their own training or experience or from close consultation with handicapped individuals or those thoroughly familiar with such individuals. *(Primary)*

---

**Standard 14.2** Until tests have been validated for people who have specific handicapping conditions, test publishers should issue cautionary statements in manuals and elsewhere regarding confidence in interpretations based on such test scores. *(Primary)*

---

**Standard 14.3** Forms of tests that are modified for people who have various handicapping conditions should generally be pilot tested on people who are similarly handicapped to check the appropriateness and feasibility of the modifications. *(Conditional)*

**Comment:**

Although useful guides to modifying tests are available, they do not provide a universal substitute for trying out a modified test or validating the modified version of a test. Even when such tryouts are conducted on samples inadequate to produce norm or validity data, they should be conducted to check the mechanics of the modifications.

---

**Standard 14.4** Interpretive information that accompanies modified tests should include a careful statement of the steps taken to modify tests in order to alert users to changes that are likely to alter the validity of the measure. *(Conditional)*

**Comment:**

If empirical evidence of the nature and effects of changes resulting from modifying standard tests is lacking, it is impossible to enumerate significant modifications that are to be documented in manuals. Therefore, test developers should take care to document all changes made and be alert to indications of possible effects of those modifications. Documentation of the procedure used to modify tests will not only aid in the administration and interpretation of the given test but will also inform others who are modifying tests for people with specific handicapping conditions.

---

**Standard 14.5** Empirical procedures should be used whenever possible to establish time limits for modified forms of timed tests rather than simply allowing handicapped test takers a multiple of the standard time. Fatigue should be investigated as a potentially important factor when time limits are extended. *(Secondary)*

---

**Standard 14.6**

When feasible, the validity and reliability of tests administered to people with various handicapping conditions should be investigated and reported by the agency or publisher that makes the modification. Such investigations should examine the effects of modifications made for people with various handicapping conditions on resulting scores, as well as the effects of administering standard unmodified tests to them. *(Secondary)*

**Comment:**

In addition to modifying tests and test administration procedures for people who have handicapping conditions, validating these tests is urgently needed. Validation is the only way to amass knowledge about the usefulness of tests for people with handicapping conditions. The costs of validating these tests should be weighed against those of not having usable information regarding the meanings of scores for handicapped people.

---

**Standard 14.7**

Those who use tests and those who interact professionally with potential test takers with handicapping conditions (e.g., high school guidance counselors) should (a) possess the information necessary to make an appropriate selection of alternate measures, (b) have current information regarding the availability of modified forms of the test in question, (c) inform individuals with handicapping conditions, when appropriate, about the existence of modified forms, and (d) make these forms available to test takers when appropriate and feasible. *(Primary)*

---

**Standard 14.8**

In assessing characteristics of individuals with handicapping conditions, the test user should use either regular or special norms for calculating derived scores, depending on the purpose of the testing. Regular norms for the characteristic in question are appropriate when the purpose involves the test taker's functioning relative to the general population. If available, however, special norms should be selected when the test takers' functioning relative to their handicapped peers is at issue. *(Primary)*

## 15. Test Administration, Scoring, and Reporting

### Background

Interpretations of test results, like those of experimental results, are most reliable when the measurements are obtained under standardized or controlled conditions. Without standardization, the quality of interpretations will be reduced to the extent that differences in procedure influence performance. To be sure, in some circumstances testing conditions may be changed systematically in order to improve the understanding of an individual's performance. Accurate scoring and reporting are essential in all circumstances. Computerized test administration and reporting can introduce some special difficulties.

---

### Standard 15.1

In typical applications, test administrators should follow carefully the standardized procedures for administration and scoring specified by the test publisher. Specifications regarding instructions to test takers, time limits, the form of item presentation or response, and test materials or equipment should be strictly observed. Exceptions should be made only on the basis of carefully considered professional judgment, primarily in clinical applications. *(Primary)*

---

### Standard 15.2

The testing environment should be one of reasonable comfort and with minimal distractions. Testing materials should be readable and understandable. In computerized testing, items displayed on a screen should be legible and free from glare, and the terminal should be properly positioned. *(Primary)*

**Comment:**

Testing sessions should be monitored where appropriate both to assist the test taker when a need arises and to maintain proper administrative procedures. Noise, disruption in the testing area, extremes of temperature, inadequate work space, illegible materials, and so forth are among the conditions that should be avoided in testing situations. In the context of computer-administered tests, the novelty of the presentation may have an unknown effect on the test administration.

---

### Standard 15.3

Reasonable efforts should be made to assure the validity of test scores by eliminating opportunities for test takers to attain scores by fraudulent means. *(Primary)*

**Comment:**

In large-scale testing programs where the results may be viewed as having important consequences, these efforts should include, when appropriate and practicable, simultaneous administration to all individuals taking the same form, stipulating requirements for identification, constructing seating charts, assigning test takers to seats, requiring appropriate space between seats, and providing continuous monitoring of the testing process. Test administrators should note and report any significant instances of testing irregularity.

---

### Standard 15.4

In school situations not involving admissions and in clinical and counseling applications, any modification of standard test administration procedures or scoring should be described in the testing

reports with appropriate cautions regarding the possible effects of such modifications on validity. *(Primary)*

---

Standard 15.5 Test scoring services should document the procedures that were followed in order to assure accuracy of scoring. The frequency of error should be monitored and reported on request. *(Conditional)*

---

Standard 15.6 When the score report may be the basis on which decisions would be made in the near future and a material error is found in test scores or other important information released by a testing organization or other institution, a corrected score report should be distributed as soon as it is practicable. *(Primary)*

---

Standard 15.7 Test users should protect the security of test materials. *(Primary)*

Comment:  
Those who have test materials under their control should take all steps necessary to assure that only individuals with a legitimate need for access to test materials are able to obtain such access.

---

Standard 15.8 In educational admissions and licensing or certification applications, in which important decisions depend on performance on a given test, a means of checking the accuracy of the scoring should be available to test takers. When the test itself and the scoring key cannot be released, some other means of verification should be provided. *(Conditional)*

---

Standard 15.9 When test data about a person are retained, both the test protocol and any written report should also be preserved. *(Primary)*

---

Standard 15.10 Those responsible for testing programs should provide appropriate interpretations when test score information is released to students, parents, legal representatives, teachers, or the media. The interpretations should describe in simple language what the test covers, what scores mean, common misinterpretations of test scores, and how scores will be used. *(Primary)*

Comment:  
Test users should consult the interpretive material prepared by the test developer or publisher and should revise or supplement the material as necessary to present the local and individual results accurately and clearly.

---

Standard 15.11 Organizations that maintain test scores on individuals in data files or in an individual's records should develop a clear set of policy guidelines on the duration of retention in an individual's records, availability, and use over time of such scores. *(Primary)*

Comment:  
In some instances test scores become obsolete over time and should not be used or be available. In other cases test scores obtained in past years can be extremely useful, for example, in longitudinal assessment. The key issue is the valid use of the information.

## 16. Protecting the Rights of Test Takers

### Background

Certain broad principles regarding access to test scores are now widely accepted. Some technical requirements necessary to satisfy these principles are stated as specific standards in this chapter. The issues of test security and the cancellation of test takers' scores because of testing irregularities are also addressed.

---

### Standard 16.1

Informed consent should be obtained from test takers or their legal representatives before testing is done except (a) when testing without consent is mandated by law or governmental regulation (e.g., statewide testing programs); (b) when testing is conducted as a regular part of school activities (e.g., schoolwide testing programs and participation by schools in norming and research studies); or (c) when consent is clearly implied (e.g., application for employment or educational admissions). When consent is not required, test takers should be informed concerning the testing process. (*Primary*)

#### Comment:

Informed consent implies that the test takers or representatives are made aware, in language that they can understand, of the reasons for testing, the type of tests to be used, the intended use and the range of material consequences of the intended use, and what testing information will be released and to whom. When law mandates testing but does not require informed consent, test users should exercise discretion in obtaining informed consent, but test takers should always be given relevant information about a test when it is in their interest to be informed.

Young test takers should receive an explanation of the reasons for testing. Even a child as young as two or three and many mentally retarded test takers can understand a simple explanation as to why they are being tested. For example, an explanation such as "I'm going to ask you to try to do some things so that I can see what you know how to do and what things you could use some more help with" would be understandable to such test takers.

---

### Standard 16.2

In school, clinical, and counseling applications, test users should provide test takers or their legal representative with an appropriate explanation of test results and recommendations made on the basis of test results in a form that they can understand. (*Primary*)

#### Comment:

This standard requires both the use of the appropriate language with non-English speaking test takers and the use of conceptually understandable explanations with all types of test takers. Even children and many mentally retarded test takers can understand a simple explanation of test results.

---

### Standard 16.3

Test results identified by the names of individual test takers should not be released to any person or institution without the informed consent of the test taker or an authorized representative unless otherwise required by law. Scores of individuals identified by name should be made

available only to those with a legitimate, professional interest in particular cases. *(Primary)*

**Comment:**

Information may be provided to researchers if a test taker's anonymity is maintained and the intended use is not inconsistent with the conditions of the test taker's informed consent.

- 
- Standard 16.4** In educational, clinical, and counseling applications, when test scores are used to make decisions about individuals, the affected person or legal representative should be able to obtain transmittal of this test score and its interpretation for any appropriate use. *(Secondary)*
- 
- Standard 16.5** Test data maintained in data files should be adequately protected from improper disclosure. Use of time-sharing networks, data banks, and other electronic data processing systems should be restricted to situations in which confidentiality can be reasonably assured. *(Primary)*
- 
- Standard 16.6** When score reporting includes assigning individuals to categories, the categories chosen should be based on carefully selected criteria. The least stigmatizing labels, consistent with accurate reporting, should always be assigned. *(Primary)*
- 
- Standard 16.7** Under certain conditions it may be desirable to cancel a test taker's score or to withhold it because of possible testing irregularities, including suspected misconduct. The type of evidence and procedures to be used to determine that a score should be canceled or withheld should be explained fully to all test takers whose scores are being withheld or canceled. *(Primary)*
- 
- Standard 16.8** In educational admissions and licensing and certification applications, when a score report will be delayed beyond a brief investigative period because of possible irregularities such as suspected misconduct, the test taker should be notified, the reason given, and reasonable efforts made to expedite review and to protect the interests of the test taker. *(Primary)*
- 
- Standard 16.9** In educational admissions and licensing and certification applications, before a score is canceled or its report is withheld beyond a brief investigative period, test takers should be given advance warning and an opportunity to provide evidence that the score should not be canceled or withheld. All evidence considered in deciding upon the intended action, including evidence that might lead to a contrary decision, should be made available to the test taker on request. *(Primary)*
- Comment:**  
Some testing organizations offer the option of a prompt and free retest or arbitration of disputes.
-

**Standard 16.10**

**In educational admissions and licensing and certification applications, when testing irregularities are suspected, all available data judged to be relevant should be considered. (Primary)**

**Comment:**

Allegations of testing irregularity that involve copying are sometimes based on a comparison of the distractors chosen by two test takers on items answered incorrectly by both. This method should not be used as the sole basis for decisions since it ignores other evidence that might indicate that copying did not take place. Reasonable efforts should be made to obtain contrary, as well as supporting, evidence to settle the matter of irregularity as well as the validity of the questioned score.

**INTERNSHIP REQUIREMENTS**

1280

# CLINICAL INTERNSHIPS PSYCHIATRIC REHABILITATION

Full-time paid, 6 month clinical internships in Psychiatric-Vocational Rehabilitation will be offered each year for three years to students completing their Master's program in Rehabilitation Counseling. Internships are located within the Neuropsychological Assessment and Rehabilitation Services Program, Western Psychiatric Institute and Clinic/Presbyterian University Hospital. While the six month clinical internships are geared toward master's level students in their final semester of academic coursework at various universities throughout the country and Puerto Rico, there may be staff in the field who would opt for such a supervised field work experience. Stipends total \$800 per month.

Internship experience will include:

- administration and interpretation of vocational and psychoeducational test batteries
- conducting career counseling and vocational exploration on an individual and group basis
- providing job seeking skills training and job coaching for selected clients/patients involved in transitional and supported employment
- exposure to and involvement in job development activities
- liaison work with the local VR agency
- attendance at formal lecture series on the Principles of Psychiatric Rehabilitation
- participation in ongoing clinical research studies
- involvement with advocacy and consumer groups

Credits earned for the internship experience will be determined by the student's college or university program. Students will be paid for their work at the internship site and in all cases will have agreed to a year's commitment pay-back at a qualifying rehabilitation agency or facility.

Training will be conducted in facilities that are architecturally barrier free and accessible. When appropriate and necessary, accommodations will be made for participants with special needs. All application materials will provide individuals with the opportunity to indicate needs for special assistance and services.

If interested, please write or call for Application materials:

Psychiatric Rehabilitation and  
Assessment Services

Dear Applicant:

Enclosed please find an application form for the Clinical Internship Training Program in Psychiatric/Vocational Rehabilitation which is being sponsored by the Psychiatric Rehabilitation and Assessment Services Department of Western Psychiatric Institute and Clinic, University of Pittsburgh Medical Center, under the direction of Michelle Geckle, M.Ed., CRC.

Each year (for 3 years) a total of six students will be accepted into the internship program. Therefore, in Year 03 (1995-1996), three students will be accepted to begin in August, 1995 and three students will be accepted to begin in February, 1996. For those of you applying for August, 1995 enrollment, application materials are due June 2, 1995. For those of you applying for February, 1996 enrollment, application materials are due October 30, 1995.

Listed below is the Registration Process. Please follow these instructions carefully.

1. Complete the enclosed Application Form.
2. Send a copy of your undergraduate and graduate transcripts.
3. Send two (2) letters of reference. These may be obtained from an academic program faculty member and/or Practicum Supervisor.
4. Send all materials to:

Michelle Geckle, M.Ed., CRC  
PRAS/WPIC  
3811 O'Hara Street  
Pittsburgh, PA 15213

If you have any questions regarding the registration process, please do not hesitate to call me at (412) 624-2842.

Sincerely,

Michelle Geckle, M.Ed., CRC  
Program Director

Lori Kroeger  
2495 Rocky Hollow Lane  
Deatsville, AL 36022

Dear Ms. Kroeger:

You have been selected to enter the Rehabilitation Services Administration (RSA) funded "Clinical Internship Training Program in Psychiatric Vocational Rehabilitation" at Western Psychiatric Institute and Clinic. Your internship is scheduled to begin Monday, February 19, 1996, and will continue until Monday, August 19, 1996. Please report to the Psychiatric Rehabilitation and Assessment Services clinic, 505 Iroquois Building, 3600 Forbes Avenue, at 8:30 a.m. on Monday, February 19, 1996. Clinic hours are 8:30 a.m. - 5:00 p.m., Monday through Friday. You will be paid a stipend of \$897 per month for your internship.

As an RSA scholarship recipient, you are required to "payback" your assistance through employment in a State rehabilitation agency or nonprofit or related facility or agency providing services under an agreement with a state rehabilitation agency. You must sign an agreement with the University of Pittsburgh, which states that you are required to work not less than two years for each year of RSA support. As a clinical internship student you will receive 6 months of support, therefore your payback time will be 12 months or one year. If you do not work for one of the approved types of agencies, you will be required to repay the RSA funds that you received.

We are very pleased that you have been chosen for this award and look forward to having you with us.

Sincerely,

Michelle Geckle, M.Ed., CRC  
Project Director,  
Clinical Internship Supervisor

**CLINICAL INTERNSHIP TRAINING PROGRAM IN  
PSYCHIATRIC VOCATIONAL REHABILITATION  
RSA GRANT No. H129H30003**

**AGREEMENT**

This agreement is made and entered on this 22, August 1995 by and between the University of Pittsburgh and its Rehabilitation Services Administration Clinical Internship Training Program in Psychiatric Vocational Rehabilitation and its scholarship recipients. As required by the Code of Federal Regulations Title 34, Part 386, Section 4, the following agreement is in effect.

Linda Karen Criss understand that:

- (1) Within the ten-year period after cessation of my enrollment in the course of study for which my scholarship was awarded, I Linda Karen Criss will obtain and maintain employment in a State rehabilitation agency providing services to individuals with handicaps under an agreement with a State agency or in a non-profit rehabilitation or related agency providing services to individuals with handicaps under an agreement with a State agency. My obligation is based on the established formula that for each academic year for which a scholarship is received, I will pay back in employment, two years. I have received a scholarship for six months, therefore my employment obligation is for one year.
- (2) I understand that until I have satisfied the employment obligation as described in Provision 1, I will inform the Project Director of this RSA funded long term training grant (Michelle Geckle, M.Ed., CRC, or her designee) of any change of name, address or employment status and I will document employment satisfying the terms of the agreement.
- (3) I also understand that subject to the provisions in Section 386.45 regarding a waiver of deferral, when I enter repayment status under Section 386.47 (e) of the program regulations, the amount of the scholarship that has not been retired through eligible employment will constitute a debt owed the United States that:
  - (a) Will be repaid by me, including interest and costs of collection as provided in Section 386.47 of the program regulations; and
  - (b) May be collected by the Secretary in accordance with 34 CFR Part 30, in the case of my failure to meet the obligation of Section 386.47 of the program regulations.

I have read and agree to the above contract.

Project Director,

WPIC Program Placement: Psychiatric Rehabilitation and Assessment Services (PRAS)

Dates of Placement: 8-22-95 to 2-16-96

WPIC Supervisor: Michelle Geckle, M.Ed., CRC

Brief Description of Student Activity: (Where possible, include number of hours per week expected of student.)

Internship experience will include:

- administration and interpretation of vocational and psychoeducational test batteries
- conducting career counseling and vocational exploration on an individual and group basis
- providing job seeking skills training and job coaching for selected clients/patients involved in transitional and supported employment
- exposure to and involvement in job development activities
- liaison work with the local VR agency
- attendance at formal lecture series on the Principles of Psychiatric Rehabilitation
- participation in ongoing clinical research studies
- involvement with advocacy and consumer groups
- one hour individual and two hour group supervision per week

PLEASE RETURN THIS FORM TO THE OFFICE OF VOLUNTEER AND STUDENT SERVICES, ROOM 126, WPIC.

Reviewed 5/94

WPIC STUDENT AGREEMENT

Having entered into an agreement for a student placement at Western Psychiatric Institute and Clinic, I understand that I am expected to function under the guidelines and/or limitations described by my supervisor, follow all WPIC rules and regulations and meet regularly with my supervisor. I agree to treat as confidential any information or data which is obtained during my stay at WPIC.

If performance evaluations are completed by my WPIC supervisor, I will be afforded the opportunity to review these evaluations and to consent to their release to other persons or agencies requesting them.

I have had a physical examination within the past year and have no communicable disease including tuberculosis, nor any other health condition which will significantly affect my performance as a student. I understand that WPIC has no responsibility for my health care except to provide for emergency treatment in the event of an accident while at the Institute. I will be financially responsible for such care.

I understand that Western Psychiatric Institute and Clinic is in no way liable for any claims or demands resulting from any act or omission on my part related to my training placement at WPIC. It is my personal responsibility or that of the academic institution in which I am enrolled to carry professional liability insurance against such claims.\*

I understand that the perception of patients and the public are affected by appearance. When working in a clinical setting at WPIC, I will dress in accordance with a professional appearance and will not wear leisure clothing such as blue jeans, sweat shirts, T-shirts, etc.

Failure to comply with WPIC student policies may be cause for dismissal from the WPIC student placement.

RE: Registration of trainees and students for Fall 1993 academic term

Registration is necessary for all clinical students and trainees (except University of Pittsburgh medical students or work-study students) who will be placed at WPIC. Registration and agreement forms to be used are attached.

Please send students such as Masters level trainees, social work, special education, pharmacy and nursing students with completed forms to the Office of Volunteer and Student Services, 2nd floor, WPIC. We will inform trainees of responsibilities including:

1. How to obtain a TB test
2. OSHA requirements regarding Fire Safety and Universal Precautions
3. How to obtain an I.D. badge
4. How to obtain a clinic key

All other students (e.g. undergraduates) should come to our office to fill out an application regardless of whether or not they plan to earn credit. The attached agreement does not apply to them. We will inform undergraduates and other students about the TB test, ID badge and orientation about WPIC policies and OSHA requirements.

## CONTRACTS

Before a student can be accepted for internship at WPIC, we must have a signed student training contract with his/her college or university. Over the years WPIC has entered into contractual agreements with most of the schools in the area, plus several from further afield. Please call 624-2145 as to the status of any school if you are not sure a contract has been signed, and we will facilitate this process if necessary.

Thank you for your cooperation.

LETTER OF AGREEMENT BETWEEN

AND

WESTERN PSYCHIATRIC INSTITUTE AND CLINIC  
OF PRESBYTERIAN UNIVERSITY HOSPITAL

THIS AGREEMENT is between \_\_\_\_\_ and WESTERN PSYCHIATRIC INSTITUTE AND CLINIC OF PRESBYTERIAN UNIVERSITY HOSPITAL (hereinafter referred to as WPIC). The parties agree that WPIC will receive students of the \_\_\_\_\_ Department of \_\_\_\_\_ for the mutual goal of training students.

(Please include brief statement of the goals of the student placement)

THIS AGREEMENT will commence on \_\_\_\_\_, and will continue indefinitely (OR will terminate on \_\_\_\_\_), unless terminated sooner by either party with thirty (30) days written notice.

Therefore it is understood and agreed between the parties that the responsibilities of \_\_\_\_\_ shall be:

1. Provide WPIC with a statement of the current curriculum and course objectives of the students placed at WPIC.
2. Indemnify and hold harmless, WPIC, its officers, directors, agents and employees from and against any and all claims, demands and liabilities for personal injuries, deaths or damage to property arising out of any act or omission of any student.

NOTE: If the Institution maintains liability insurance for students or requires that students provide for personal liability coverage, a statement to that effect, including the extent of coverage should be added.

3. Advise students that WPIC requires that they be in good health and have had a physical examination within the past year including a tuberculin skin test.
4. Advise students that they are responsible for the costs of their health care including emergency treatment for any accident sustained during their WPIC placement.

1291

5. Advise students of their responsibility to comply with the rules and regulations of WPIC.
6. Advise students of their responsibility to respect the confidential nature of all information which they may obtain during the course of their student placement at WPIC.

Responsibilities of WPIC:

1. Provide the assigned students with the opportunity to pursue the goals defined above.
2. Provide staff supervision consistent with the above goals.
3. Render emergency medical care or triage to any student or supervising faculty for any injury or sudden illness occurring during the course of a work related activity, the cost of which will be borne by the injured party.
4. Evaluate the performance of the student according to the requirements of \_\_\_\_\_.
5. Retain the right to reject or terminate the student placement for failure to meet the standards of the WPIC program or for a breach of WPIC rules and regulations.

Counselor Evaluation Form - Masters

NAME OF COUNSELOR \_\_\_\_\_ DATE \_\_\_\_\_

SUPERVISOR \_\_\_\_\_ AGENCY \_\_\_\_\_

LEVEL: Practicum/Internship \_\_\_\_\_ ADVISOR: \_\_\_\_\_

Below are statements reflecting some of the important areas of knowledge and skill that are necessary to function effectively as a professional rehabilitation counselor. We realize that not all agencies can provide students with an opportunity to engage in all of these rehabilitation tasks, and thus one or more items may not be applicable to a particular agency. Please rate the counselor's performance in those rehabilitation tasks that are appropriate to your agency, compared with other counselors at this level of training and experience that you have supervised. Use the space beneath each item to make specific recommendations or to provide further comment.

Please review evaluations with your student(s) at mid-term and at the end of the term.

	N.A.	Poor	Average	Above Average	Excellent
Is knowledgeable about counseling theories?	0	1	2	3	4

Comment:

Is able to demonstrate counseling skills (please indicate if student engaged in group and/or family counseling)?	0	1	2	3	4

**STUDENT COUNSELOR EVALUATION OF SUPERVISOR\***

**SUGGESTED USE:** The field work supervisor could obtain feedback on his/her supervision by asking student counselors to complete this form. The evaluation could be done at mid-term and/or final. The purposes are twofold: (1) to provide feedback for improving supervision, and (2) to encourage communication between the supervisor and the student counselor.

Name of Internship Supervisor \_\_\_\_\_

Period covered: \_\_\_\_\_ to \_\_\_\_\_

**DIRECTIONS:** The student counselor when asked to do so is to make an evaluation of the supervision received. Circle the number which best represents how you, the student counselor, feel about the supervision received. After the form is completed, the supervisor may suggest a meeting to discuss the supervision desired.

| 1   | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |         |      |
12. Extent to which the instructional materials (handouts, resources) were well-organized and comprehensive. N/A
- |     |   |   |   |   |   |   |   |   |    |         |      |
|-----|---|---|---|---|---|---|---|---|----|---------|------|
| Low |   |   |   |   |   |   |   |   |    | Average | High |
| 1   | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |         |      |
13. Degree of openness, spontaneity, humor and energy exhibited by the instructor. N/A
- |     |   |   |   |   |   |   |   |   |    |         |      |
|-----|---|---|---|---|---|---|---|---|----|---------|------|
| Low |   |   |   |   |   |   |   |   |    | Average | High |
| 1   | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |         |      |
14. Degree to which the instructor encouraged cohesiveness, trust and responsiveness in the students. N/A
- |     |   |   |   |   |   |   |   |   |    |         |      |
|-----|---|---|---|---|---|---|---|---|----|---------|------|
| Low |   |   |   |   |   |   |   |   |    | Average | High |
| 1   | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |         |      |

15. Extent to which the instructor fielded responses and questions from students with sensitivity and respect. N/A

Low									High	
1	2	3	4	5	Average	6	7	8	9	10

16. Degree to which you felt able to openly and freely express your opinions to your instructor. N/A

Low									High	
1	2	3	4	5	Average	6	7	8	9	10

17. Degree to which the methods employed to evaluate your performance and effectiveness in the course were fair. N/A

Low									High	
1	2	3	4	5	Average	6	7	8	9	10

18. Compared to other instructors you have had, this instructor's teaching effectiveness is:

Low									High	
1	2	3	4	5	Average	6	7	8	9	10

What did your instructor do particularly well in this course? \_\_\_\_\_

\_\_\_\_\_  
\_\_\_\_\_

What did your instructor do rather poorly in this course? \_\_\_\_\_

\_\_\_\_\_  
\_\_\_\_\_

What did you find to be the most valuable experience(s) during the course? \_\_\_\_\_

\_\_\_\_\_  
\_\_\_\_\_

What did you find to be the least valuable experience(s) during the course? \_\_\_\_\_

\_\_\_\_\_  
\_\_\_\_\_

Please make any comments or suggestions for change or improvement in this course which you would like. \_\_\_\_\_

\_\_\_\_\_  
\_\_\_\_\_

**RECORD KEEPING**

1313

APPROVED BY THE MEDICAL RECORD COMMITTEE ON 01/13/94

UPMC APPROVED ABBREVIATIONS LIST

<u>a</u>	A wave
<u>a</u>	before
AA	aplastic anemia
aa	of each
AAA	abdominal aortic aneurysm
AAO	awake, alert & oriented
AAROM	active assistive range of motion
abd	abduction
abd.	abdomen
ABG	arterial blood gases
Abn	abnormal
Abor	abortion
ABP	arterial blood pressure
abst.	abstract
A/C	assist/control ventilation
ac	before meals
a.c.	anterior chamber
acc., accom.	accommodation
Accu✓	accucheck
ACD	anticoagulant citrated dextrose
AC IOL	anterior chamber intra-ocular lens
AC joint	acromioclavicular joint
ACL	anterior cruciate ligament
ACT	activated clotting time
ACTH	adrenocorticotrophic hormone
AD	right ear
ad lib	as desired
ADA	American Diabetes Association
Adapt. Equip.	Adaptive Equipment
ADD	addition
add.	adduction
ADD. Therapy	additional therapy
ADHD	attention deficit hyperactivity disorder
ADL	activities of daily living
adm.	admission, admitted
AFB	acid-fast bacillus
AFBY	aorta bifemoral bypass
AFib	atrial fibrillation
A-flut	atrial flutter
AFM	aerosol face mask
AFM x 2	double aerosol face mask
A.F.O.	ankle foot orthosis
A-G ratio	albumin - globulin ration
AGH	Allegheny General Hospital
AgNo <sub>3</sub>	silver nitrate

1314

AIDS	Acquired Immunodeficiency Syndrome
AIHA	autoimmune hemolytic anemia
Air Con	<b>A</b> ir Contrast
AJ	ankle jerk
AK	above the knee
AKA	above knee amputation
A.L.	arterial line
ALB	albumin
ALL	Acute lymphocytic leukemia
ALN	anterior lower neck
allo	allogeneic
ALP	<b>Alkaline Phosphatase</b>
ALS	amyotrophic lateral sclerosis
ALT	<b>Alanine Aminotransferase</b>
ALTP	Argon laser trabeculoplasty
AM	before noon
A-M prothesis	Austin Moore Prosthesis
AMA	against medical advice
amb.	ambulatory
ambu	ambulate
AMI	acute myocardial infarction
AML	acute myeloblastic leukemia
AMML	acute monomyeloblastic leukemia
amp.	ampule
amt.	amount
AMYL	amylase
ANA	antinuclear antibodies
ANB	naphtyl butyrate
Anes	anesthesia
angio	angiogram
ANLL	acute non-lymphocytic leukemia
ant	anterior
AODM	adult onset diabetes mellitus
AP	anterior to posterior
A & P	auscultation and percussion
AP & Lat	anterior-posterior, lateral (x-ray)
APC	atrial premature contractions
APTT	activated partial thromboplastin time
ARA-A	vidarabine (Vira - A)
ARA-C	cytarabine (Cytosar)
ARC	AIDS related complex
ARDS	adult respiratory distress syndrome
ARF	acute renal failure
ARMD	age related macular degeneration
AROM	active range of motion
ART	arterial
Arthro	arthrogram
AS	left ear
A.S.	aortic stenosis
AS-D CA	naphtyl chloracetate

ASA	acetylsalicylic acid
ASA, I, II, III, IV, V, VI, E	American Society of Anesthesiologists class I, II, III, IV, V, VI, E
ASAP	as soon as possible
ASB	anesthesia standby
ASCVD	arteriosclerotic cardiovascular disease
ASHD	arteriosclerotic heart disease
Asmt	assessment
ASO	arteriosclerosis obliterans
asp.	aspirate
ASPVD	arteriosclerotic peripheral vascular disease
<b>A</b>	<b>Assist</b>
AST	aspartate aminotransferase
ASTRO	astrocytoma
ASVD	arteriosclerotic vascular disease
AT	applanation tonometry
ATA	atmosphere absolute
ATG	Antithymocyte globulin
Atmos	atmospheric
ATN	acute-tubular necrosis
A.U.	both ears
Au	gold
auto	autologous
AV	arterial ventricular
AVM	arterial venous malformation
AVR	aortic valve replacement
A & W	alive and well
AWMI	anterior wall myocardial infarction
ax.	axillary
AX FEM By	axilo femoral bypass
AXIL or AX	axilla

=====

## B

<b>B</b>	Black
<b>B</b>	Both
Ba E or BE	barium enema
BaS	barium swallow
basos	basophils
BAT	brightness acuity test
BBB	Bundle Branch Block
B.B.B.	Blood-Brain Barrier
BBR	bibasilar rales
BBS	bilateral breath sounds
B cell	bone marrow derived lymphocytes

B/C/L	bun, creatinine, lytes
BC/BS	Blue Cross/Blue Shield
BCNU	carmustine
BE/LGI	barium enema
BGDR	background diabetic retinopathy
bid	twice daily
bicarb	bicarbonate
bilat or b	bilateral
BiVAD	<b>Bi-Ventricular Assist Device</b>
BJ	biceps jerk
BK	below knee
BKA	below knee amputation
bld	blood
blk	block
BM	bowel movement
B.M.	bone marrow
BMR	basal, metabolic rate
BMT	bone marrow transplant
BOS	<b>Base of Support</b>
BP	blood pressure
BPH	benign prostatic hypertrophy
BPPN	<b>Benign paroxysmal positional nystagmus</b>
BPPV	<b>Benign paroxysmal positional vertigo</b>
BR	bedrest
BRJ	brachioradialis jerk
BRM	biological response modifier
BRP	bathroom privileges
BS	blood sugar
B.S.	bowel sounds
BSC	bedside commode
BSER	brainstem evoked response
BSO	bilateral salpingo-oophorectomy
BSP	bromsulphalein test
BSu	blood sugar
BSS	balanced salt solution
BSS Plus	balanced salt solution Plus
BSW	bedscale weight
BTFS	breast tumor frozen section
BUN	blood-urea-nitrogen
BVR	Bureau of Vocational Rehab.
Bx	biopsy

=====

C

C <sub>1</sub> C <sub>2</sub>	1st cervical vertebrae/2nd cervical vertebrae
C + DB	cough & deep breathe
C	complement
C.	centigrade

C. Diff	C. difficile toxin
$\bar{c}$	with
CA	carcinoma
Ca+	calcium
CABG	coronary artery bypass graft
CAD	coronary artery disease
CAH	chronic active hepatitis
cal	calorie
cap.	capsule
CAPD	chronic ambulatory peritoneal dialysis
Carot	carotid
CAT	cataract
CAT Scan/CT	computerized axial tomograph
CAVH-D	<b>Continuous Arterial to Venous Hemofiltration w/Dialysis</b>
CAX	central axis
c/d	cup-disc ratio
CAVH	continuous arterial venous hemofiltration
CBC	complete blood count
CBD	common bile duct
CBR	complete bed rest
CC	chief complaint
cc	cubic centimeter
cc/HR	cubic centimeter per hour
CCNU	lomustine (Cee-Nu)
CCU	Coronary Care Unit
C.D.	closed drainage
cent.	central
cerv	cervical
CF	finger counting
CH <sub>50</sub>	total hemolytic complement
CHB	complete heart block
Chemo/BRM	chemotherapy biological response
Chest PT	chest physical therapy
CHF	congestive heart failure
CHOP	(chemotherapy medications)
CHP	Cytosin, Adriamycin, Oncovin, Prednisone
CISI	Children's Hospital of Pittsburgh
C.L.A. (ASCP)	Central Imaging Services, Inc.
CI	Clinical Laboratory Assistant
CLL	chloride
C.L.S. (NCA)	chronic lymphocytic leukemia
C.L.T. (NCA)	Clinical Laboratory Scientist
C.L.T. (HEW)	Clinical Laboratory Technician
CM	Clinical Laboratory Technician
cm.	commercial insurance
CMC	centimeter
CML	carpal metacarpal
CMV	chronic myelocytic leukemia
C.M.V.	cytomegalovirus
	controlled mechanical ventilation

CNRN	Certified Neuroscience Registered Nurse
CNS	central nervous system
C.N.S.	Clinical Nurse Specialist
Co-57 or <sup>57</sup> Co	Cobalt - 57
Co-60 or <sup>60</sup> Co	Cobalt - 60
C/O	complains of
CO	carbon monoxide
C.O.	cardiac output
CO <sub>2</sub>	carbon dioxide
coag	coagulation studies
COLD	chronic obstructive lung disease
conj.	conjunctiva
COP	Cytosan, Oncovin, Prednisone
cop	colloid oncotic pressure
COPD	chronic obstructive pulmonary disease
COTA/L	Certified Occupational Therapy Assistant/Licensed
CP	chest pain
CPAP	continuous positive airway pressure
CPFT	Certified Pulmonary Function Technician
CPK	creatinine phosphokinase
CPMM	continuous passive motion machine
CPR	cardiopulmonary resuscitation
CP's	contact lenses
C.P.T.	chest physical therapy
CPX	complex
Cr-51 or <sup>51</sup> Cr	Chromium - 51
CRA	central retinal artery
creat	creatinine
CRF	chronic renal failure
CRNA	Certified Registered Nurse Anesthetist
CRNP	Certified Registered Nurse Practitioner
CRRT	<b>Continuous Renal Replacement Therapy</b>
CRST	cutaneous systemic sclerosis syndrome
crt.	hematocrit
CRTT	Certified Respiratory Therapy Technician
CRV	central retinal vein
CRVT	central retinal vein thrombosis
C & S	culture & sensitivity
CS	contact spot
C.S.	central supply
CSA	cyclosporine level
CSF	cerebrospinal fluid
C.S.F.	colony stimulating factor
CSG	chronic simple glaucoma
C-spine	cervical spine
CT	completed tomography
C.T.	chest tube
ct.	count
CTB	cease to breathe
CVA	cerebrovascular accident

CVI	central venous insertion
CVMH	Conemaugh Valley Memorial Hospital
CVP	central venous pressure
CVVH	continuous venous-to-venous hemofiltration
CVVH-D	Continuous venous to venous hemofiltration w/Dialysis
CX or CERV	cervical
cx	culture
cx.	circumflex
CXR	chest x-ray
CYCLO	cyclopropane
CYA	Cyclosporine (Cyclosporin-A)

=====

D

D <sub>1</sub> D <sub>2</sub> , etc.	1st dorsal vertebrae/2nd dorsal vertebrae
D <sub>5</sub>	dextrose 5%
D <sub>5</sub> <sup>1</sup> / <sub>4</sub> NS	dextrose 5% in 1/4% saline
D <sub>5</sub> <sup>1</sup> / <sub>2</sub> NS	dextrose 5% in 1/2% saline
D <sub>5</sub> NSS	dextrose 5% in normal saline solution
D <sub>5</sub> R	dextrose 5% in Ringers
D <sub>5</sub> LR	dextrose 5% in lactated Ringer's
D	deltoid
D & I	dry and intact
DAD	diffuse alveolar damage
DAFM	double aerosol face mask
DB	deep breathing
Dbl	double
D & C	dilatation and curettage
D/C	discontinue
D.C.	direct current
decub	decubitus
def.	deficits
Dept.	department
DES	diethylstilbestrol
dex.	dextrose
DF	dorsiflexion
DFA	dorsiflexion assist
D.F.A.	D. fluorescent antibody
DI	diabetes insipidus
DIC	disseminated intravascular coagulation
Diff	differential
Dig	digitalis
dil	dilute
D.I.P.	distal interphalangeal
DIST	distal
div. or +	divide
DJD	degenerative joint disease
DL	danger list

di	deciliter
DL & B	direct laryngoscopy and bronchoscopy
DM	diabetes mellitus
Dmax	dose at the point of electronic equilibrium (i.e. depending upon context usage)
D/NSS	dextrose in normal saline solution
DNR	Do Not Resuscitate
DOA	dead on arrival
DOB	date of birth
DOE	dyspnea on exertion
dop	doppler
DOS	dosimetry
doz.	dozen
DPA	Dept. of Public Assistance
dr. or	dram
Dr. 7	doctor
D.R.	diabetic retinopathy
DRG	Diagnosis-Related Group
Drng.	drainage
drsg.	dressing
DO	Doctor of osteopathy/resident
D/S	dextrose & saline
DSD	dry, sterile dressing
dsch	discharge
DSR	double side rail
DST	daylight saving time
DTIC	dacarbazine
DTR	deep tendon reflexes
D.T.R.	dietetic technician registered
duo	duotube
Dup	duplicate
DVT	deep venous thrombosis
Dx	diagnosis

=====

E

ea.	each
EBL	estimated blood loss
E.C.	enteric coated
ECCE	extra capsular cataract extraction
E.C.F.	Extended Care Facility
ECG/EKG	electrocardiogram
E.Coli	escherichia coli
ECMO	extra-corporeal membrane oxygenator
ECOG	Eastern Cooperative Oncology Group
ect.	Ectopic

ED	Emergency Department
EDV	end diastolic volume
EEG	electroencephalogram
EEIP	Eye & Ear Institute Pavilion
EENT	eyes, ears, nose and throat
eg.	for example
EHL	electrohydrocalculi lithotripsy of the bladder
E.H.L.	extensor hallucis longus
EKC	epidemic keratoconjunctivitis
elix.	elixir
EMG	electromyogram
EMMV	extended mandatory minute volume
ENA	extractable nuclear antigens
ENDO	endotracheal
endo	endoscopy
ENG	electronystagmograph
Enh	enhanced
E.N.T.	ear-nose-throat
EOG	electro-oculo gram
EOM	extraocular muscles
EOR/ER	Emergency Room
eos	eosinophils
EPC	<b>extra corporeal-chemophotopheresis</b>
EPI	epinephrine
EPS	electrophysiological studies
(ER)	<b>External Rotation</b>
ERA	evoked response audiometry
ERCp	endoscopic retrograde choleangio pancreatography
ERG	electro retino gram
ERRL	equal, round, reactive to light
ESOPH	esophageal
ESR	estimated sedimentation rate
ESRD	end stage renal disease
est.	estimated
E.S.T.	Eastern Standard Time
ESV	end systolic volume
ESWL	extracorporeal shock wave lithotripsy
et (al)	and (other; etiology)
ET	endotracheal tube
E.T.	esotropia
etc.	etcetera
ETOH	ethyl alcohol
ETT	endotracheal tube
EVD	external ventricular drain
exam.	examination
ext	extremities
(EXT) or /	Extension

F

5-FC	flucytosine
5-FU	fluorouracil
F	female
F.	fahrenheit
FABR	fabrication
FAL	femoral arterial line
FAT	fluorescent antibody test
F/B	followed by
FB	foreign body
FBS	fasting blood sugar
FCR	flexor carpi radialis tenodesis
fdgs	feedings
FDP	fibrin degradation products
Fe	iron
fem.	femoral
FEM-POP bypass	femoral-popliteal bypass
FEM-TIB-By	femoral tibial bypass
FeSO <sub>4</sub>	Ferrous sulfate
FEV <sub>1</sub>	forced expiratory volume in 1 second
FEV <sub>3</sub>	forced expiratory volume in 3 seconds
F <sub>i</sub> O <sub>2</sub>	fractional inspired oxygen concentration
FFF	fresh frozen plasma
FH	family history
fib	fibrillation
fkn	function
Fl. ext	fluid extract
FLD	field
flex	flexion
F - N	finger to nose
FLUO	Fluothane
fluoro	fluoroscopy
FM	face mask
FMG	fine mesh gauze
FSH	follicle stimulating hormone
FSW (fsw)	feet of sea water (pressure)
ft.	foot
FTA	fluorescent treponemal antibody
f/u	follow up
FUDR	floxuridine
FUO	fever of unknown origin
FVC	forced vital capacity
F.W.B.	full weight bearing
Fx	fracture

H-BIG	hepatitis-B immune globulin (human)
HB, hb, Hgb	hemoglobin
HBO	hyperbaric oxygen (high pressure O)
HBP	high blood pressure
HC	Home Care
HCG	human chorionic gonadotropin
HCT	hematocrit
HCV	hepatitis C virus
HDR	heparin dose response
HEENT	head, eyes, ears, nose, throat
heme	hemetest
hep	heparin
hep flush	heparin flush
hep lock or HL	heparin lock
H-Flu	hemophilus influenzae
Hg.	mercury
HG	handgrasp
Hgb	hemoglobin
HGES	handgrasp equal & strong
HGH	human growth hormone
HIV	human immunodeficiency virus
hlth. teach	health teaching
HM	head movement
HN	Head Nurse
HNP	Herniated nucleus pulposus
HO	House Officer
HOB	head of bed
HOH	hard of hearing
HPI	history of present illness
HPNS	high pressure nervous syndrome
HPT	heparin protamine titration
HR	heart rate
hr.	hour
HRC	Harmarville Rehab Center
HS	Hamstring sets
hs	hour of sleep
Ht	height in centimeters
ht	height
HTN	hypertension
Hx	history

## S.O.A.P. Format for Writing Contact Sheets

**Subjective:** Your subjective impressions of the client, i.e., appearance, mood and affect, mental status, motivation, receptivity to engagement/rapport/session activities; symptom/clinical presentation and changes therein.

**Example Statements:**

1. Patient arrived on time, casually dressed, neatly groomed, dysphoric and occasionally tearful throughout session; psychomotor slowing and response latency evident, described self as feeling "helpless and hopeless" but firmly denied SI/intent/plan.
2. 20 minutes late, poorly groomed with strong body odor; mood/affect/energy all WNL; eager to engage in discussion of educational possibilities.

**Objective:** Objectively, the content of the session, i.e.:

1. educational and employment hxs. discussed at length
2. vocational assessment begun with administration of academic achievement and occupational interest measures
3. treatment plan goals were discussed and agreed upon
4. impact of earned income upon various benefits was discussed
5. sample employment application was completed

**Assessment:** Your assessment of the situation, i.e.:

1. appears to be experiencing prodromal sx's.
2. could benefit from vocational assessment and counseling, R/O LD
3. could benefit from assistance in job seeking skills
4. could benefit from increased opportunities for social interaction and peer support

**Plan:** Plan of action derived from S, O, and A above, i.e.,

1. encourage consultation with primary clinician ASAP, consider decrease from full- to part-time status in college
2. begin psychoeducational assessment and request specialized assessment through NARS to R/O LD
3. begin same, pt. to complete sample job application for next session
4. referral to Renaissance Center discussed and agreed upon

**CONSENT FOR RELEASE OF INFORMATION**

*(All parts of this form must be completed in compliance with  
the revised regulations pursuant to the Mental Health Procedures Act)*

I hereby authorize \_\_\_\_\_ to release information  
(name of facility, agency, school or person)  
from the records of \_\_\_\_\_ / \_\_\_\_\_  
(name of patient) (birthdate)

For the purpose of \_\_\_\_\_

Other \_\_\_\_\_

HIV-related information and drug and alcohol information contained in the parts of the record indicated above will be released through this consent unless otherwise indicated.  Do not release.

PLEASE FORWARD INFORMATION TO ATTENTION OF: \_\_\_\_\_  
(name of facility, agency, or person)  
\_\_\_\_\_  
\_\_\_\_\_  
(address)

I have been told that, in order to protect the limited confidentiality of records, my agreement to obtain or release information is necessary and that this permission is limited for the purposes and to the person listed above, and will be effective for 90 days after the date of my signature, unless specified below. I also understand that this consent is revocable except to the extent that action has been taken in reliance thereon.

This consent shall be in effect from \_\_\_\_\_ until \_\_\_\_\_

_____ Date of Signature	_____ Signature of Patient (14 years of age or older)
_____ Signature of Staff Member	_____ Signature of Parent - Legal Guardian - Authorized Representative (when applicable)

**ORAL CONSENT**  
**(Not Applicable to HIV-Related Information)**  
*For Persons Physically Unable to Provide a Signature*

I witnessed that the person understood the nature of this release and freely gave his/her oral consent. (Two witnesses are required.)

_____ Date of Signature	_____ Signature of Witness
_____ Date of Signature	_____ Signature of Witness

AGREEMENT TO CONTACT ADULT PATIENT'S FRIEND/RELATIVE

WPIC recognizes and respects the patient's right to confidentiality.

However, if during your treatment here at WPIC, we feel that your illness would interfere with the course of your treatment and welfare, to the point that we would become concerned about you, we would like you to list friends or relatives we could contact (in compliance with applicable Pennsylvania law) to see if you are alright.

We would possibly contact your friend/relative if:

- you are missing appointments without notifying us and we cannot reach you either by phone or mail
- we are concerned that you may be suicidal.

We do not intend to call your friend or relative unless we feel it is absolutely necessary.

## University of Pittsburgh

### WESTERN PSYCHIATRIC INSTITUTE AND CLINIC CONSENT FORM

(To be completed by the Responsible Clinician)

Western Psychiatric Institute and Clinic (WPIC) produces audio/visual materials for educational and research purposes as well as for therapeutic reasons. These materials are distributed for professional use and are not therefore intended for general public consumption.

The purpose of this form is to obtain your permission as (a patient) (the guardian of a patient) (the parent(s) of a patient) at WPIC to produce (photographs) (sound motion pictures) (closed circuit television interviews) (sound video tapes) (other -- specify: \_\_\_\_\_) which involve patient participation and to distribute the results for professional use in the furtherance of medical science, research, education, practice and knowledge. The name(s) of patient(s) (will) (will not) be included. Illness, problems and treatment will be included. Even if the patient's name is not used, you should understand that it is possible for the patient to be recognized by someone from the sound of voice, mannerisms or physical characteristics.

The recordings or photo session will take place on \_\_\_\_\_ (date) at \_\_\_\_\_ (location). The following equipment will be used: (still camera) (movie camera) (television camera) (tape recorder) (other -- specify: \_\_\_\_\_). The clinician directly responsible for the activity is \_\_\_\_\_ (name) and he or she will explain this form to you prior to your signing it. The WPIC employee technician directly responsible for the production is \_\_\_\_\_ (name): Both of these people will be present at the production to answer any questions which participating patients may have. It is expected that \_\_\_\_\_ (number) patients and \_\_\_\_\_ (number) authorized WPIC staff members will be present at the production.

Upon completion of the production, including editing, the results will be processed as a resource for future professional use both inside and outside of WPIC including other medical and educational institutions and professional publication and presentations. The results become the property of WPIC and any other professional organization to which WPIC may distribute them.

By signing this form you are agreeing to the following items:

1. A complete understanding of the information provided above and the fact that your willingness or unwillingness to sign this form will in no way influence the provision of health care to you or the patient you represent at WPIC.
2. Participation without financial remuneration in the applicable patient activity identified above.

3. Production by WPIC of the activity in the manner indicated above.
4. Ownership of production results by WPIC.
5. Distribution of production results inside and outside of WPIC for professional use in the furtherance of medical science, research, education, practice and knowledge, and not for general public use.
6. Reasonable control by WPIC over the storage and distribution of the results for purposes stated.
7. Release of WPIC, the University of Pittsburgh and its employees, from any claims for damages resulting from dissemination, distribution, display, reproduction, production, publication or showing of the audio/visual production described above.
8. Production by WPIC in the manner indicated above, but discussion by you with therapist(s) after production but before use, release and distribution of production results for the purposes stated above. My second signature on this form is my authorization for the use, release and distribution of production results for the purpose stated above. If I do not provide such authorization, the production results will be destroyed.

I have read all of the above statements and I have had the opportunity to ask questions. I fully understand them and I voluntarily consent therein.

OPTIONAL

# COGNITIVE FUNCTIONING INVENTORY

Evaluate each item on the basis of performance of the subject on the various questions or tests listed under each heading. Numbers within parentheses identify test cards to be used. For each subitem or test used, make a (✓) for correct or an (X) for incorrect, in the space provided. Make allowances for native language and cultural factors. Impairment rating scale: **N** = Absent: fully correct or a minor error; **1** = Mild: mostly correct with a few minor errors; **2** = Moderate: a gross error or several minor errors; **3** = Severe: gross and multiple errors; **?** = Unknown: uncertain or not tested.

Item	IMPAIRMENT				
	ABSENT/ NORMAL	MILD	MODERATE	SEVERE	UNKNOWN/ UNCERTAIN
<b>1. Level of consciousness</b> (N=awake & alert; 1=awake but inattentive; 2=lethargic; 3=stuporous or comatose)	N	1	2	3	?
<b>2. Orientation to person</b> name _____ age _____ date of birth _____	N	1	2	3	?
<b>3. Orientation to time</b> day of week _____ day _____ month _____ year _____ season _____ time of day _____	N	1	2	3	?
<b>4. Orientation to place</b> building _____ type of institution _____ (e.g. hospital/hotel) floor _____ city _____ part of city _____	N	1	2	3	?
<b>5. Learning and memory</b> repeat four words (brown, cold, flower, car) allow up to 4 trials, discontinue after 2 correct trials (Trials: 1 _____, 2 _____, 3 _____, 4 _____) Recall after 2 minutes _____ and 10 minutes _____  Expose drawing for 10 seconds (1) draw from memory _____ recall after 15 minutes _____ recall at end of session _____ Recall story (2) _____ recall at end of session _____	N	1	2	3	?
<b>6. Remote memory and general information</b> president _____ before him _____ before him _____ governor _____ major events in past 10 years (e.g. Watergate) _____ name familiar faces (3-7) _____ weeks in year _____	N	1	2	3	?
<b>7. Concentration and attention span</b> tap for every A (8) _____ digit span (9) forward _____ backward _____ starting at 1 count by 3 _____	N	1	2	3	?
<b>8. Language function</b> spontaneous speech (fluency _____, grammar _____ content _____), comprehension _____ naming colors (10) _____, objects (11-23) _____ write name _____ address _____, sentence _____ numbers _____	N	1	2	3	?
<b>9. Constructional ability</b> copy drawing (24-25) _____ draw clock _____ set time to 20 to 1 (or 12:40) _____ copy pipe (26) _____	N	1	2	3	?
<b>10. Abstraction</b> similarities (27) _____, proverbs (28) _____	N	1	2	3	?
<b>11. Judgment</b> (29) _____	N	1	2	3	?
<b>12. Specific cerebral dysfunction</b> (test only if specifically indicated). frontal lobe tests (30) _____ right/left orientation (31) _____, praxis (32) _____ arithmetic (33) _____, reading (34-36) _____ repetition of words and phrases (37) _____ language comprehension (38) _____	N	1	2	3	?

**FAMILY HISTORY** (Past and current psychiatric and chronic major physical disorders in the family. First ask about family history of mental/emotional illness in general; then for specific relatives, inquire about a positive history of untreated psychiatric disorder, psychiatric ambulatory care and hospitalization, completed suicide, and type of psychiatric disorder such as depression, alcoholism, and schizophrenia; and finally inquire about chronic major physical disorders, including those that may have caused deaths.)

For each group of relatives, circle all applicable options

RELATIVES	PSYCHIATRIC DISORDERS							Chronic Major Physical Disorders	Not Known
	U=Untreated	O=With outpatient care	H=with hospitalization	C=completed suicide	D=Depression	A=Alcoholism	S=Schizophrenia	y=yes	
FATHER	U	O	H	C	D	A	S	Y	?
MOTHER	U	O	H	C	D	A	S	Y	?
SIBLINGS	U	O	H	C	D	A	S	Y	?
OFFSPRING	U	O	H	C	D	A	S	Y	?
EXTENDED FAMILY	U	O	H	C	D	A	S	Y	?

Family with three or more members with any specifically reported psychiatric and/or neurologic disorders

**PERSONAL AND SOCIAL HISTORY** (Developmental, educational, marital, sexual, military, occupational, and legal history. Current family structure and social support system [availability of confidant, group and community support]. Assets [talents, adaptive means of coping, motivation for treatment, etc.] useful for treatment planning.)

	NO	YES	NOT KNOWN
1. Perinatal problems	N	Y	?
2. Developmental delays	N	Y	?
3. Broken family or serious family problems while growing up	N	Y	?
4. Academic difficulties at school	N	Y	?
5. Behavioral, discipline and social problems at school	N	Y	?
6. Difficulties during military service or less than "honorable" discharge	N	Y	?
7. Considerable past periods of unemployment or poor work performance	N	Y	?
8. History of marital disharmony or divorce	N	Y	?
9. Arrests with convictions	N	Y	?
10. Lack of confidant	N	Y	?
11. Lack of supportive interpersonal and community resources	N	Y	?

1357

**INSTRUCTIONS FOR DSM-III AXES I AND II**

Axes I and II comprise the entire classification of mental disorders. Axis II includes Personality Disorders and Specific Developmental Disorders (listed within boxes on this page and on the back of page 7). All other disorders and conditions are included in Axis I.

On both Axes I and II multiple diagnoses may be made to describe the current psychiatric condition. Within each axis, diagnoses should be listed as primary, secondary and so forth, in order, with that being the focus of attention or treatment listed first.

The *Principal* diagnosis is that chiefly responsible for occasioning the evaluation or admission to clinical care. It will be assumed to be the first diagnosis on Axis I, unless the first diagnosis on Axis II is followed by "(Principal Diagnosis)".

The clinician may wish to indicate a significant degree of diagnostic uncertainty by writing "(Provisional)" following a given codable diagnosis in the main formulation section. Additionally, for each codable diagnosis, alternatives to be ruled out in a differential diagnosis process may be mentioned within the boxed sections of the diagnostic summary.

**LIST OF AXES I AND II CATEGORIES AND CODES**

**LIST OF AXES I AND II CATEGORIES AND CODES**

For most disorders, the DSM-III and ICD-9-CM codes are essentially the same. Whenever there is a substantial difference, the ICD-9-CM code is provided in parentheses after the diagnostic term. To ensure retrieval of DSM-III specificity, use always the codes to the left of the diagnostic terms. Data entry into the computer will include codes for both diagnostic systems.

The long dashes indicate the need for a fifth-digit subtype or other qualifying term.

**DISORDERS USUALLY FIRST EVIDENT IN INFANCY, CHILDHOOD OR ADOLESCENCE**

**Mental Retardation**

(Code in fifth digit: 1 = with other behavioral symptoms [requiring attention or treatment and that are not part of another disorder], 0 = without other behavioral symptoms.)

- 317.0(x) Mild mental retardation, \_\_\_\_\_
- 318.0(x) Moderate mental retardation, \_\_\_\_\_
- 318.1(x) Severe mental retardation, \_\_\_\_\_
- 318.2(x) Profound mental retardation, \_\_\_\_\_
- 319.0(x) Unspecified mental retardation, \_\_\_\_\_

**Attention deficit disorder**

- 314.01 with hyperactivity
- 314.00 without hyperactivity
- 314.80 residual type

**Conduct disorder**

- 312.00 undersocialized, aggressive
- 312.10 undersocialized, nonaggressive
- 312.23 socialized, aggressive
- 312.21 socialized, nonaggressive
- 312.90 atypical

**Anxiety disorders of childhood or adolescents**

- 309.21 Separation anxiety disorder
- 313.21 Avoidant disorder of childhood or adolescence
- 313.00 Overanxious disorder

**Other disorders of infancy, childhood or adolescence**

- 313.89 Reactive attachment disorder of infancy
- 313.22 Schizoid disorder of childhood or adolescence
- 313.23 Elective mutism
- 313.81 Oppositional disorder
- 313.82 Identity disorder

**Eating disorders**

- 307.10 Anorexia nervosa
- 307.51 Bulimia
- 307.52 Pica
- 307.53 Rumination disorder of infancy
- 307.50 Atypical eating disorder

**Stereotyped movement disorders**

- 307.21 Transient tic disorder
- 307.22 Chronic motor tic disorder
- 307.23 Tourette's disorder
- 307.20 Atypical tic disorder
- 307.30 Atypical stereotyped movement disorder

**Other disorders with physical manifestations**

- 307.00 Stuttering
- 307.80 Functional enuresis
- 307.70 Functional encopresis
- 307.46 Sleepwalking disorder
- 307.49 Sleep terror disorder (307.46)

**Pervasive developmental disorders**

Code in fifth digit: 0 = full syndrome present; 1 = residual state.

- 299.0x Infantile autism, \_\_\_\_\_
- 299.9x Childhood onset pervasive developmental disorder, \_\_\_\_\_

- 299.8x Atypical, \_\_\_\_\_

**Specific developmental disorders**

Note: These are coded on Axis II.

- 315.00 Developmental reading disorder
- 315.10 Developmental arithmetic disorder
- 315.31 Developmental language disorder
- 315.39 Developmental articulation disorder
- 315.50 Mixed specific developmental disorder
- 315.90 Atypical specific developmental disorder

**ORGANIC MENTAL DISORDERS**

Section 1. Organic mental disorders whose etiology or pathophysiological process is listed below (taken from the mental disorders section of ICD-9-CM).

**Dementias arising in the senium and presenium**

Primary degenerative dementia, senile onset.

- 290.30 with delirium
- 290.20 with delusions
- 290.21 with depression
- 290.00 uncomplicated

code in fifth digit

1 = with delirium, 2 = with delusions, 3 = with depression, 0 = uncomplicated

- 290.1x Primary degenerative dementia, presenile onset, \_\_\_\_\_
- 290.4x Multi-infarct dementia, \_\_\_\_\_

**Substance induced**

- Alcohol
- 303.00 intoxication
- 291.40 idiosyncratic intoxication
- 291.80 withdrawal
- 291.00 withdrawal delirium
- 291.30 hallucinations
- 291.10 amnesic disorder

Code severity of dementia in fifth digit

1 = mild; 2 = moderate; 3 = severe; 0 = unspecified.

- 291.2x Dementia associated with alcoholism, \_\_\_\_\_

- Barbiturate or similarly acting sedative or hypnotic
- 327.00 intoxication (305.40)

- 327.01 withdrawal (292.00)
- 327.02 withdrawal delirium (292.00)
- 327.04 amnesic disorder (292.63)

**Opioid**

- 327.10 intoxication (305.50)
- 327.11 withdrawal (292.00)

**Cocaine**

- 327.20 intoxication (305.60)

**Amphetamine or similarly acting sympathomimetic**

- 327.30 intoxication (305.70)
- 327.32 delirium (292.81)
- 327.35 delusional disorder (292.11)
- 327.31 withdrawal (292.00)

**Phencyclidine (PCP) or similarly acting aricyclohexylamine**

- 327.40 intoxication (305.90)
- 327.42 delirium (292.81)
- 327.49 mixed organic mental disorder (292.90)

**Hallucinogen**

- 327.56 hallucinosis (305.30)
- 327.55 delusional disorder (292.11)
- 327.57 affective disorder (294.84)

**Cannabis**

- 327.60 intoxication (305.20)
- 327.65 delusional disorder (292.11)

**Tobacco**

- 327.71 withdrawal (292.00)

**Caffeine**

- 327.60 intoxication (305.90)

**Other or unspecified substance**

- 327.90 intoxication (305.90)
- 327.91 withdrawal (292.00)
- 327.92 delirium (292.81)
- 327.93 dementia (292.26)
- 327.94 amnesic disorder (292.63)
- 327.95 delusional disorder (292.11)
- 327.96 hallucinosis (292.12)
- 327.97 affective disorder (292.84)
- 327.98 personality disorder (292.89)
- 327.99 atypical or mixed organic mental disorder (292.90)

Section 2. Organic brain syndromes whose etiology or pathophysiological process is either noted as an additional diagnosis from outside the mental disorders section of ICD-9-CM or is unknown.

- 293.00 Delirium
- 294.10 Dementia
- 294.00 Amnesic syndrome
- 293.81 Organic delusional syndrome
- 293.82 Organic hallucinosis
- 293.83 Organic affective syndrome
- 310.10 Organic personality syndrome
- 294.60 Atypical or mixed organic brain syndrome

**NARRATIVE ASSESSMENT SUMMARY**

Lined area for narrative assessment summary.

Evaluator's confidence in the information obtained:  High  Adequate  Marginal  Poor

**PROBLEMS** (*Psychopathological, physical, and social*)  
 See separate treatment plan form

**RECOMMENDATIONS** (*Further diagnostic studies and treatment modalities. Instructions given to patient/family*)

Table with two columns: PROBLEMS and RECOMMENDATIONS. Both columns contain horizontal lines for text entry.

**PLANS FOR FAMILY MEMBERS**

See separate social evaluation form

Lined area for plans for family members.

**LIST OF AXES I AND II CATEGORIES AND CODES (CONTINUATION)**

**SUBSTANCE USE DISORDERS**

Code in fifth digit 1 = continuous, 2 = episodic, 3 = in remission, 0 = unspecified

- 305.0x Alcohol abuse, \_\_\_\_\_
- 303.9x Alcohol dependence (Alcoholism), \_\_\_\_\_
- 305.4x Barbiturate or similarly acting sedative or hypnotic abuse, \_\_\_\_\_
- 304.1x Barbiturate or similarly acting sedative or hypnotic dependence, \_\_\_\_\_
- 305.5x Opioid abuse, \_\_\_\_\_
- 304.0x Opioid dependence, \_\_\_\_\_
- 305.6x Cocaine abuse, \_\_\_\_\_
- 305.7x Amphetamine or similarly acting sympathomimetic abuse, \_\_\_\_\_
- 304.4x Amphetamine or similarly acting sympathomimetic dependence, \_\_\_\_\_
- 305.9x Phencyclidine (PCP) or similarly acting arylcyclohexylamine abuse, \_\_\_\_\_ (328.4x)
- 305.3x Hallucinogen abuse, \_\_\_\_\_
- 305.2x Cannabis abuse, \_\_\_\_\_
- 304.3x Cannabis dependence, \_\_\_\_\_
- 305.1x Tobacco dependence, \_\_\_\_\_
- 305.9x Other, mixed or unspecified substance abuse, \_\_\_\_\_
- 304.6x Other specified substance dependence, \_\_\_\_\_
- 304.9x Unspecified substance dependence, \_\_\_\_\_
- 304.7x Dependence on combination of opioid and other non-alcoholic substance, \_\_\_\_\_
- 304.8x Dependence on combination of substances, excluding opioids and alcohol, \_\_\_\_\_

**SCHIZOPHRENIC DISORDERS**

Code in fifth digit 1 = subchronic, 2 = chronic, 3 = subchronic with acute exacerbation, 4 = chronic with acute exacerbation, 5 = in remission, 0 = unspecified.

- Schizophrenia, \_\_\_\_\_
- 295.1x disorganized, \_\_\_\_\_
- 295.2x catatonic, \_\_\_\_\_
- 295.3x paranoid, \_\_\_\_\_
- 295.9x undifferentiated, \_\_\_\_\_
- 295.6x residual, \_\_\_\_\_

**PARANOID DISORDERS**

- 297.10 Paranoia
- 297.30 Shared paranoid disorder
- 298.30 Acute paranoid disorder
- 297.90 Atypical paranoid disorder

**PSYCHOTIC DISORDERS NOT ELSEWHERE CLASSIFIED**

- 295.40 Schizophreniform disorder
- 298.80 Brief reactive psychosis
- 295.70 Schizoaffective disorder
- 298.90 Atypical psychosis

**AFFECTIVE DISORDERS**

Major affective disorders

Code major depressive episode in fifth digit 6 = in remission, 4 = with psychotic features (the unofficial non-ICD-9-CM fifth digit 7 may be used instead to indicate that the psychotic features are mood-incongruent), 3 = with melancholia, 2 = without melancholia, 0 = unspecified

Code manic episode in fifth digit 6 = in remission, 4 = with psychotic features (the unofficial non-ICD-9-CM fifth digit 7 may be used instead to indicate that the psychotic features are mood-incongruent), 2 = without psychotic features, 0 = unspecified

- Bipolar disorder, \_\_\_\_\_
- 296.6x mixed, \_\_\_\_\_
- 296.4x manic, \_\_\_\_\_
- 296.5x depressed, \_\_\_\_\_
- Major depression, \_\_\_\_\_
- 296.2x single episode, \_\_\_\_\_
- 296.3x recurrent, \_\_\_\_\_

Other specific affective disorders

- 301.13 Cyclothymic disorder
- 300.40 Dysthymic disorder (or Depressive neurosis)

Atypical affective disorders

- 296.70 Atypical bipolar disorder
- 296.82 Atypical depression

**ANXIETY DISORDERS**

- Phobic disorders (or Phobic neuroses)
- 300.21 Agoraphobia with panic attacks
- 300.22 Agoraphobia without panic attacks
- 300.23 Social phobia
- 300.29 Simple phobia

Anxiety states (or Anxiety neuroses)

- 300.01 Panic disorder
- 300.02 Generalized anxiety disorder
- 300.30 Obsessive compulsive disorder (or Obsessive compulsive neurosis)

Post-traumatic stress disorder

- 308.30 acute
- 308.81 chronic or delayed
- 300.00 Atypical anxiety disorder

**SOMATIFORM DISORDERS**

- 300.81 Somatization disorder
- 300.11 Conversion disorder (or Hysterical neurosis, conversion type)
- 307.80 Psychogenic pain disorder
- 300.70 Hypochondriasis (or Hypochondriacal neurosis)
- 300.71 Atypical somatiform disorder (300.70)

**DISSOCIATIVE DISORDERS (OR HYSTERICAL NEUROSES, DISSOCIATIVE TYPE)**

- 300.12 Psychogenic Annesia
- 300.13 Psychogenic fugue
- 300.14 Multiple personality
- 300.60 Depersonalization disorder (or depersonalization neurosis)
- 300.15 Atypical dissociative disorder

**PSYCHOSEXUAL DISORDERS**

Gender identity disorders

Indicate sexual history in the fifth digit of Transsexualism code:

- 1 = sexual, 2 = homosexual, 3 = heterosexual, 0 = unspecified.
- 302.5x Transsexualism, \_\_\_\_\_
- 302.60 Gender identity disorder of childhood
- 302.85 Atypical gender identity disorder

Paraphilias

- 302.81 Fetishism
- 302.30 Transvestism
- 302.10 Zoophilia
- 302.20 Pedophilia
- 302.40 Exhibitionism
- 302.82 Voyeurism
- 302.83 Sexual masochism
- 302.84 Sexual sadism
- 302.90 Atypical paraphilia

Psychosexual dysfunctions

- 302.71 Inhibited sexual desire
- 302.72 Inhibited sexual excitement
- 302.73 Inhibited female orgasm
- 302.74 Inhibited male orgasm
- 302.75 Premature ejaculation
- 302.76 Functional dyspareunia
- 306.51 Functional vaginismus
- 302.70 Atypical psychosexual dysfunction

Other psychosexual disorders

- 302.00 Ego-dystonic homosexuality
- 302.89 Psychosexual disorder not elsewhere classified

**FACTITIOUS DISORDERS**

- 300.16 Factitious disorder with psychological symptoms
- 301.51 Chronic factitious disorder with physical symptoms
- 300.19 Atypical factitious disorder with physical symptoms

**DISORDERS OF IMPULSE CONTROL NOT ELSEWHERE CLASSIFIED**

- 312.31 Pathological gambling
- 312.32 Kleptomania
- 312.33 Pyromania
- 312.34 Intermittent explosive disorder
- 312.35 Isolated explosive disorder
- 312.39 Atypical impulse control disorder

**ADJUSTMENT DISORDER**

- 309.00 with depressed mood
- 309.24 with anxious mood
- 309.28 with mixed emotional features
- 309.30 with disturbance of conduct
- 309.40 with mixed disturbance of emotions and conduct
- 309.23 with work (or academic) inhibition
- 309.83 with withdrawal
- 309.90 with atypical features

**PSYCHOLOGICAL FACTORS AFFECTING PHYSICAL CONDITION**

Specify physical condition on Axis III.  
318.00 Psychological factors affecting physical condition

**PERSONALITY DISORDERS**

Note: These are coded on Axis II

- 301.00 Paranoid
- 301.20 Schizoid

- V81.10 Marital problem
- V81.20 Parent-child problem
- V81.80 Other specified family circumstances
- V62.81 Other interpersonal problem

**ADDITIONAL CODES**

- 300.90 Unspecified mental disorder (nonpsychotic)
- V71.09 No diagnosis or condition on Axis I
- 799.90 Diagnosis or condition deferred on Axis I

- V71.09 No diagnosis on Axis II
- 799.90 Diagnosis deferred on Axis II

**INSTRUCTIONS FOR DSM-III AXIS III: PHYSICAL DISORDERS**

Axis III includes any current physical disorders or conditions relevant to the understanding or management of the individual. Such conditions are catalogued in the non-mental disorder sections of the International Classification of Diseases (ICD-9-CM). Physical conditions identified for an individual should be described in standard terms and will be coded later. Past disorders that are not currently active should be described in the Medical History but not listed in the diagnostic formulation.

## INSTRUCTIONS FOR DSM-III AXIS IV: PSYCHOSOCIAL STRESSORS

Axis IV assesses psychological stressors (both discrete events and ongoing strains) judged to be significant in the development or exacerbation of the Present disorder.

First, identify relevant stressors during the past 12 months as specifically as possible and list them (up to 4) in order of importance. To accomplish this, ask for a summary of events and strains from the patient, and then probe specifically to clarify the patient's initial report and to inquire about areas of the patient's life which may not have been mentioned spontaneously. Situations which mainly reflect the patient's symptomatology or dysfunction should be excluded.

Please consider the following categories of stressors:

- 1 **Health:** e.g. acute or chronic physical illness or injury either to the patient or to someone close to the patient, mental illness in significant others. A physical disorder, which is listed as such on Axis III, can also be a psychosocial stressor if it creates a considerable strain on the patient's life.
- 2 **Bereavement:** e.g., death of parent, extended family member, or significant other.
- 3 **Love and marriage:** e.g., separation, divorce, persistent marital discord.
- 4 **Parental:** e.g., pregnancy, birth of a child, loss of custody of child, behavior problems in children.
- 5 **Family stressors for children and adolescents:** e.g., cold or hostile relationship between parents, cold or hostile parental behavior towards child, stressful family situation.
- 6 **Other familial relationships:** e.g., acute or chronic serious family arguments other than with immediate relative, change in the frequency of family interaction.
- 7 **Other relationships outside the family:** e.g., terminating a close friendship, terminating organizational activities, serious disruptions in social relationships.
- 8 **Work:** e.g., demotion or promotion at work, significant changes in work conditions, having a difficult supervisor, becoming retired, lack of employment opportunities.
- 9 **School:** e.g., began or changed a school or training program, failed an important academic milestone, completing or failing a school or training program.
- 10 **Financial:** e.g., significant decrease in income, took a large loan or mortgage, foreclosure on a loan.
- 11 **Legal:** e.g., court appearances, major lawsuits, arrests, sentenced to (or served) a jail term.
- 12 **Housing/environmental:** e.g., change in residence, significant deterioration in living conditions, eviction or threat of eviction.
- 13 **Miscellaneous:** e.g., being victim of a crime or assault, facing a new culture.

Next, rate the severity (from 1 to 7) of the summed effect of all the psychosocial stressors listed. This rating should be based on your assessment of the "objective" stress represented by the events or strains, not on the patient's "subjective" vulnerability to the stressors. The level of stress rated should be that likely to be experienced by an "average" person of similar socio-cultural circumstances as the patient and confronting the same events and strains. The following examples may be used as a guide in making your ratings.

Code	Term	Adult examples	Child or adolescent examples
1	None	No apparent psychosocial stressors	No apparent psychosocial stressors
2	Minimal	Minor violation of the law, small bank loan	Vacation with family
3	Mild	Argument with neighbor, change in work hours	Change in schoolteacher, new school year
4	Moderate	New career, death of close friend, pregnancy	Chronic parental fighting, change to new school, illness of close relative, birth of sibling
5	Severe	Serious illness in self or family, major financial loss, marital separation, birth of child	Death of peer, divorce of parents, arrest, hospitalization, persistent and harsh parental discipline
6	Extreme	Death of close relative, divorce	Death of parent or sibling, repeated physical or sexual abuse
7	Catastrophic	Concentration camp experience, devastating natural disaster	Multiple family deaths
0	Unspecified	No information or not applicable	No information, or not applicable

In summing the effect of all stressors, it may be necessary to take into account both the number and the severity of stressors. For example, one moderate stressor would receive a rating of 4, while a combination of 3 moderate stressors might receive a rating of 5 or 6 (the same rating which a single more severe stressor would receive).

## INSTRUCTIONS FOR DSM-III AXIS V: HIGHEST LEVEL OF ADAPTIVE FUNCTIONING IN PAST YEAR

Axis V assesses an individual's highest level of adaptive occupational and social functioning (for at least a few months) during the past year.

Recommended rating steps:

- 1 Identify the best couple of months of adaptive functioning during the past 12 months and focus attention on that period for making the following assessments.
- 2 Separately judge the individual's performance and degree of impairment in the following two regards:
  - a) **Occupational Functioning:** This encompasses consistency and effectiveness of performance of expected role as worker, student, and/or homemaker. If an individual is unemployed, not primarily because of inability to hold a job but because of unavailability of employment, his occupational assessment should focus on alternative roles, e.g., homemaker.
  - b) **Social Relations:** This encompasses frequency and quality of social interaction, i.e., meeting, communicating, and sharing common activities with family members and with other individuals and groups.
- 3 Combine the occupational functioning and social relations ratings using the scale below for obtaining the overall highest level of adaptive functioning in the past year. As noted, use of leisure time is considered only for the highest levels of functioning and essential self-care only for the poorest.

Code	Term	Description
1	Superior	Unusually effective functioning in occupational functioning, social relations, and use of leisure time
2	Very Good	Better than average functioning in occupational functioning, social relations, and use of leisure time
3	Good	No more than slight impairment in either occupational or social functioning
4	Fair	Moderate impairment in either occupational functioning or social relations, or some impairment in both
5	Poor	Marked impairment in either occupational functioning or social relations, or moderate impairment in both
6	Very Poor	Marked impairment in both occupational functioning and social relations
7	Grossly Impaired	Gross impairment in virtually all areas of functioning, including essential self-care
0	Unspecified	

## INSTRUCTIONS FOR AXIS VI: CURRENT FUNCTIONING

Axis VI assesses current levels of functioning at work, school, or homemaking, and relations with family and with other individuals or groups.

Separately judge the individual's performance during the past month in the following three regards:

- a) **Occupational Functioning:** This encompasses consistency and effectiveness of performance of expected role as worker, student, and/or homemaker. If an individual is unemployed, not primarily because of inability to hold a job but because of unavailability of employment, his occupational assessment should focus on alternative roles, e.g., homemaker.
- b) **Functioning with Family:** This encompasses frequency and quality of interaction with family members (i.e., meeting, communicating, and sharing common activities with them).
- c) **Functioning with Other Individuals and Groups:** This encompasses frequency and quality of interaction with non-family individuals and groups (i.e., meeting, communicating, and sharing common activities with them).

Determine the individual's current functioning level in each of these regards by using the scale given below.

Code	Functioning Level	Occupational Functioning	Functioning with Family and with Other Individuals and Groups
1	Superior	Highly regular and competent work	Very frequent and close personal contacts
2	Adequate	Acceptable work regularity and competence	Acceptable frequency and closeness of personal contacts
3	Slightly Impaired	Occasionally misses work and/or has some difficulty with competence	Rather restricted or irregular frequency and closeness of personal contacts
4	Moderately Impaired	Misses work frequently and/or shows moderate incompetence	Infrequent and superficial or troubled personal contacts
5	Markedly Impaired	Works rarely or not at all and/or is grossly incompetent	Almost non-existent or grossly disturbed personal contacts
0	Unspecified

Instructions (All spaces are required to be completed; if left blank, it will be assumed the information was not asked)

## DEMOGRAPHIC - COMPLETED BY THE RECEPTIONIST (upon arrival of the patient)

**Date:** Month/day/year  
**Time:** Fill in time patient arrived in the DEC; use military time (e.g., 10:45 p.m. is 22:45)  
**Seq #:** Indicates patient sequence of arrival to the DEC, in relation to other patients  
**Demo:** Implies the following information is basic demographic information of the identified patient)  
 \_\_\_ yr (year) old - Fill in age of patient  
 Circle one: S (single) M (married) W (widow/widower) D (divorced) Sep (separated)  
 Circle one: White / Black / Hisp (hispanic)/Other: (identify race on this line)  
 Circle one: M (male) F (female)

**Catchment:** Patient's base service unit area, (ie. 9-C1 for WPIC); identified by their current address

**DEC Alert:** Circle one: Y N / SCF (special concern file) / TxPlan (treatment plan)

**Legal:** Specify arrival legal status: 201/30\_\_\_ (circle and/or complete with 302, 303, 304, 304C, etc.)

**Current Treatment:** Circle one: Y N (No implies patient is not in current outpatient treatment)

**Clinic:** Unknown or (if known specify Clinic/Phone:

**Active:** Circle one: Y N (N indicates No current outpatient treatment is active)

**ICM/R/C/Phone:** Circle ICM (Intensive Case Manager) or RC (Resource coordinator), to identify if the patient has either. Identify name of ICM/R/C and phone number if known, otherwise write "unknown"

**Clinician/Phone:** If in current treatment, identify name of clinician and phone number if known, otherwise write "unknown"

**Psychiatrist/Phone:** If in current treatment, identify name of Psychiatrist and phone number if known, otherwise write "unknown"

**Primary MD/Phone:** If in current treatment, identify name of Primary MD and phone number if known, otherwise write "unknown"

**Insurance:** Circle one: Greenspring/MA (medical assistance) / BC (blue cross) / MC (medicare) or (fill in insurance name)

**PreCert:** (PreCertification) Approved: Circle one: Y N (Yes or No)

**Searched:** Circle one: Y N (Yes or No) Indicates whether or not initial Safety Search was completed

**Referred by/Organization:** Fill in the blank of name of referral; if patient referred themselves, indicate "self"

**Scheduled:** Circle one: Y N (Yes or No) Indicates whether or not patient's visit to the DEC was scheduled

## TRIAGE - COMPLETED BY THE TRIAGE CLINICIAN

**Reason for Evaluation:** Identify WHY the patient is currently seeking treatment/what is the crisis

**Acuity:** Circle one: Mild/Priority/Urgent (scale used in the DEC to determine acuity level of patient)

**Vitals:** Time: Write military time vital signs were completed in triage

Breathalyzer: Write in percentage; indicate if not necessary

Weight: (necessary on all inpatients otherwise, on an as needed basis)

**Immediate Concerns/Social Concerns/Medical Concerns:** Place a check or 'x' in the appropriate boxes based on triage evaluation

## PSYCHIATRIC HISTORY - COMPLETED BY THE CLINICIAN/MD

**Sources of Information:** Name all sources including WPIC records, etc.

**Current Crisis:** "WHAT BROUGHT THE PT TO THE ER, TODAY?"

**Lethality:** Address use of firearms.

**Pertinent Psychiatric History:** Expand on relevant history

**Substance Use:** Specify type, quantity, frequency of each substance; specify last use: date/time

**Other History:** Discuss past psychiatric history, family psychiatric history, social history (employment, education, home environment), personality/characterological traits, and custody/guardianship concerns.

**Legal Charges (current), Physical/Sexual/Emotional Abuse:** Identify physical/sexual/elder/parental/spousal/psychological abuse

**Mental Status Examination:** Record detailed description of identified patient

**Orientation:** Check all boxes that apply MMSE (Mini Mental Status Exam). Write the total points/total possible. Note problem areas for patient.

**Primary Diagnosis:** Specify DSM-IV Axis and Code.

**Secondary Diagnoses:** Specify all other DSM-IV diagnoses and codes (for Axis I and II)

**Rule Outs:** Specify rule out DSM-IV diagnoses and codes (for Axis I and II)

**AXIS III: Medical Problems:** Specify all current medical problems (no coding is required)

**Meds:** List for current medications: name, route, time, dose (mg), last dose, and recent changes. List known allergies, non allergic drug reactions

**Axis IV:** List psychosocial/environmental problems (i.e. divorce, death, homelessness, etc.) List strengths also

**Assessment:** Summarize findings from current evaluation. Note the Appt (appointment) Date/Time or circle "unknown".

**Priority:** Circle Urgent (within 24 hours), Priority (within 72 hours) Routine (per clinic schedule) to identify scheduling time frame.

**Inpatient Concerns:** Circle all that apply to alert inpatient unit of potential issues or problems

**Patient Left @:** Identify military time patient left the evaluation center or check incomplete evaluation

**Reported to:** Identify the inpatient staff taking the admission report or the outpatient intake worker collecting the information

**Symptom Inventory Checklist:** Check all that apply for current evaluation

1367

BEST COPY AVAILABLE

In order to comply with the Child Protective Service Law (Act 33), applicants who are residents of Pennsylvania and are applying for positions providing child care services must submit with their application copies of the following obtained within the preceding year:

1. A report of criminal history record information from the Pennsylvania State Police stating that the central repository contains no such information relating to the applicant (form attached)
2. Certification from the Department of Public Welfare as to whether the applicant is a perpetrator of a founded or indicated report of child abuse (form attached)

Non-residents of Pennsylvania must submit a copy of a report of federal criminal history record information from the Federal Bureau of Investigation with their employment application.

Applicants are required to provide the original document (s) prior to employment. No offer of employment is valid without the above information. Please forward a copy of the original document (s) to:

PERSONNEL DEPARTMENT  
WESTERN PSYCHIATRIC INSTITUTE  
AND CLINIC  
3811 O' Hara Street  
Pittsburgh, PA 15213

# INSTRUCTIONS FOR THE COMPLETION OF THE PENNSYLVANIA CHILD ABUSE HISTORY CLEARANCE

The Child Protective Services Law requires that the child abuse history of applicants to child care programs be verified within 30 days from the date of hire. The clearance is also required for persons wishing to be foster or adoptive parents. In addition, individuals may request voluntary certification which indicates the status of child abuse history and criminal history.

To request the clearance, the applicant must complete, in ink, Section I only of the attached "Pennsylvania Child Abuse History Clearance" and submit it to the Department of Public Welfare with a \$10.00 check or money order. Cash will not be accepted. Incomplete or illegible applications will be returned unprocessed.

Another form must be completed for Criminal History Clearance through the Pennsylvania State Police. Out-of-state residents must also obtain clearance through the FBI files. You may write or call ChildLine (717-783-6211) for all of the necessary forms.

Please refer to the information below when completing the application or when reviewing the Department's response. Please type or print except where signature is required. The completed clearance is valid for one year for employment, adoption, foster care, or CWEP purposes. A Voluntary Certification is valid for two years.

## SECTION I - APPLICANT IDENTIFICATION (To be completed by applicant)

Check one box which best describes the reason for requesting the clearance:

- **EMPLOYMENT** - Check block #1 if you need the clearance as a candidate for child care program employment/operation.
- **ADOPTION** - Check block #2 if you need the clearance for purposes of adopting a child who is a non-relative. The clearance is not required if you are adopting a child who is already related to you, by birth or marriage.
- **FOSTER CARE** - Check block #3 if you need the clearance in order to be approved as a foster parent.
- **VOLUNTARY** - Check block #4 if you need a voluntary clearance as a participant in a service such as a Big Brothers/Big Sisters program. You must include a copy of the "Request For Criminal History Record Information" obtained from the Pennsylvania State Police. Out-of-state residents must also include a copy of their FBI clearance.
- **CWEP** - Check block #5 if you are a Community Work Experience Program participant who will be assigned to a child care program. An official of your County Assistance Office must sign the application. No fee is required.

### RETURN ADDRESS BLOCK

- Print your full legal name (first, middle, last, do not use initials) and your entire current address. Your P.O. Box No., Apt. No., and Zip Code must be included.

### SOCIAL SECURITY NUMBER

- Enter your complete social security number. The disclosure of your Social Security Number is voluntarily sought to verify your identity pursuant to the authority of the Child Protective Services Law, 11 P.S. § 2214 (i).

### AGE AND DATE OF BIRTH

- Enter your current age and exact date of birth.

### SEX

- Check the appropriate block.

### COUNTY OF CURRENT RESIDENCE

- Enter the name of the county where you currently live.

### LENGTH OF TIME AT CURRENT ADDRESS

- Enter the number of years and months you have resided at your current address.

### DAYTIME TELEPHONE NO.

- Enter the telephone number where you can be reached between 8:00 a.m. and 4:00 p.m. Include area code.

### OTHER NAMES USED BY APPLICANT SINCE 1975

1369

- Enter all other names you have used since 1975. Include maiden name, nicknames, and aliases.

## FORMER ADDRESSES

- List all former addresses where you lived or received mail since November 1975.
- List the most recent address first. Do not include current address.
- Include approximate dates you resided at each address.
- Use a second page if necessary.

## MEMBERS OF APPLICANT'S HOUSEHOLD

- Enter the full name (no initials please), relationship to you, age, and sex of all persons who live with you at your current address or who have lived with you at any of your former addresses.
- Use a second page if necessary.

## APPLICANT'S SIGNATURE AND DATE

- Read the sentence preceding the signature line.
- Sign and date the application. The application must contain your original signature; copies are unacceptable. Your application will be returned unprocessed if signed by anyone other than the applicant.
- Detach instructions and mail the completed application along with a \$10.00 check or money order payable to the "Department of Public Welfare." Do not send cash. Mail to:

Department of Public Welfare  
P.O. Box 8170  
Harrisburg, PA 17105-8170

## SPECIAL NOTES

DUE TO THE NATURE AND CONFIDENTIALITY OF THE INFORMATION REQUESTED, CHILD ABUSE CLEARANCES MUST BE RETURNED DIRECTLY TO THE APPLICANT. BEFORE MAILING YOUR APPLICATION TO THE DEPARTMENT OF PUBLIC WELFARE, PLEASE MAKE ONE COPY AND GIVE TO YOUR EMPLOYER IF YOU ARE BEING HIRED ON A PROVISIONAL BASIS.

YOUR ORIGINAL PENNSYLVANIA CHILD ABUSE HISTORY CLEARANCE WILL BE RETURNED TO YOU WITH AN OFFICIAL SIGNATURE IN SECTION II. HAVE A COPY OF THE CLEARANCE MADE AND GIVE THE COPY TO THE AGENCY TO RETAIN IN ITS FILE. THE AGENCY MUST ALSO VIEW THE ORIGINAL BUT THE APPLICANT RETAINS THE ORIGINAL.

## SECTION II - RESULTS OF HISTORY CHECK (To be completed by ChildLine Staff Only)

The appropriate block will be checked by ChildLine staff stating whether the applicant's name is contained in the Statewide Central Register as a perpetrator of child abuse.

### REPORTS IDENTIFIED

- The status (Founded or Indicated) and date of incident of all reports will be entered.
- Founded means that a court has determined that a child was abused.
- Indicated means that the Child Protective Services Agency has determined that a child was abused.

### VERIFIER'S SIGNATURE AND DATE

- The Department employee who performed the history clearance will sign and date the form at the time of its completion.

### SUPERVISOR'S SIGNATURE AND DATE

- When an applicant's name is located in the Statewide Central Register, a supervisor will confirm the information and sign the form.

## SECTION III - VOLUNTARY CERTIFICATION (To be completed by ChildLine Staff Only)

The following section will be completed by ChildLine Staff for those applicants who request voluntary certification and have submitted a copy of the clearance(s) obtained from the Pennsylvania State Police and the FBI (out-of-state residents only).

Although child abuse and/or criminal convictions may prohibit hire into a child care position pursuant to the Child Protective Services Law (11. P.S. 2223.1(e)), it is the decision of the parent or guardian who reviews this information to determine whether to use the services of the applicant.

### VERIFIER'S SIGNATURE AND DATE

- The Department employee who performed the history clearance will sign and date the form at the time of completion.

### SUPERVISOR'S SIGNATURE AND DATE

- When an applicant's name is located in either of the three files, a supervisor will confirm the information and sign the form.

DUE TO THE NATURE AND CONFIDENTIALITY OF THE INFORMATION REQUESTED, CHILD ABUSE CLEARANCES MUST BE RETURNED DIRECTLY TO THE APPLICANT.

BEFORE MAILING YOUR APPLICATION TO THE DEPARTMENT OF PUBLIC WELFARE, PLEASE MAKE ONE COPY AND GIVE TO YOUR EMPLOYER IF YOU ARE BEING HIRED ON A PROVISIONAL BASIS.

YOUR ORIGINAL PENNSYLVANIA CHILD ABUSE HISTORY CLEARANCE WILL BE RETURNED TO YOU WITH AN OFFICIAL SIGNATURE IN SECTION II. HAVE A COPY OF THE CLEARANCE MADE AND GIVE THE COPY TO THE AGENCY TO RETAIN IN ITS FILE. THE AGENCY MUST ALSO VIEW THE ORIGINAL BUT THE APPLICANT RETAINS THE ORIGINAL.

SECTION III - VOLUNTARY CERTIFICATION - Childline Use Only

\_\_\_\_\_ has requested a certification which includes a clearance of his/her name against the child abuse and criminal history files.

The results of the child abuse history clearance are listed in Section II on the reverse side. The results of the criminal history clearance(s) is (are) listed below. Out-of-state residents must have criminal history clearance from both the Pennsylvania State Police and the FBI. The voluntary certification may be obtained every two years.

It is the responsibility of parents and guardians to review this information to determine the suitability of the applicant as a substitute caregiver.

PENNSYLVANIA CHILD ABUSE HISTORY CLEARANCE

- Applicant is named as the perpetrator of a "Founded" child abuse report which occurred in the last five years.
- Applicant is named as the perpetrator of a "Founded" child abuse report which occurred over five years ago.
- Applicant is named as the perpetrator of an "Indicated" child abuse report.
- Applicant is not named as the perpetrator of any child abuse reports contained in the Statewide Central Register.

PENNSYLVANIA STATE POLICE CLEARANCE

- Record exists and contains convictions which prohibit hire in a child care position. Report attached.
- Record exists, but convictions do not prohibit hire in a child care position. Report attached.
- Record exists, but convictions are beyond the five year limit and do not prohibit hire in a child care position. Report attached.
- No record exists. Report attached.

FBI CLEARANCE

- Record exists and contains convictions which prohibit hire in a child care position. Report attached.
- Record exists, but convictions do not prohibit hire in a child care position. Report attached.
- Record exists, but convictions are beyond the five year limit and do not prohibit hire in a child care position. Report attached.
- Record exists, but no convictions are shown. This does not prohibit hire in a child care position.
- No record exists. Report attached.

## MENTAL STATUS EXAM

From Trzepacz, P.T & Baker, R.W. (1993) The Psychiatric Mental Status Examination. New York: Oxford University Press

### APPEARANCE, ATTITUDE & ACTIVITY

**Appearance:** Appearance, sounds, odors

Level of consciousness: overall arousal, alertness, responsiveness, (hypervigilance, anxiously attentive, easily startled) or subnormally alert (drowsy, lethargic, clouding of consciousness or a degree of diminished alertness) comatose or vegetative. fluctuating levels of consciousness by history, degree of distractibility, internal preoccupation

Age: to what extent does patient appear stated age

Position & Posture: slouching, rigidly erect, nonverbal cues to mood

Attire & Grooming: (context dependent) hygiene, clothing, make-up, bizarre haircut, discoloration of fingers, teeth. (unkempt, disheveled, neatly dressed)

Eye contact: (culture dependent) degree, staring or avoiding

Physical characteristics: tattoos, needle marks, skin lesions, obvious abnormalities, handicaps, usual demographic descriptors

Facial expression: sad, happy, angry, bored, surprised, confused, anxious, pained

**Attitude:** general demeanor (cooperative, uncooperative, hostile, guarded, suspicious, regressed) degrees of politeness & assertiveness, degree of inhibitedness, vigilance, resistance, manipulateness, degree of splitting (vacillation between idealization and devaluation),

**Activity:** movement ( hyperactivity to bradykinesia, paresis or paralysis), accessory movements (arm-swing, gestures), gait, tremors, restlessness, agitation, bizarre motions (athetoid, choreiform movements, tardive dyskinesia, tics), automatic movements (chewing, lip smacking, picking at clothes), mannerisms (compulsions), posturing, grimacing, gesturing, perseverations,

### MOOD & AFFECT

**Mood:** predominant emotional state, patient's self report & non-verbal behaviors.

typical or atypical, intensity of feeling

changeability of mood states

euthymic=normal, consistent, calm, appropriate

dysphoric=down, sad, despondent, remorseful,

euphoric= cheerful, ecstatic, elated, happy

angry, apathetic, apprehensive

**Affect:** moment-to-moment mood changes, external expression of feelings, behaviors (smiling, frowning, joking, crying). may be concordant with mood or different

Parameters: Appropriateness & congruence with mood  
Intensity: normal, blunted, exaggerated, flat, dramatic  
Mobility: mobile, fixed, constricted, labile  
Range: full or restricted  
Reactivity: reactive & responsive or dulled

### **SPEECH & LANGUAGE**

**Fluency:** initiation and flow of language, aphasias

**Prosody of speech:** rate, rhythm, and stress (musicality, intonation, phrasing, pressure of speech)

**Quality of speech:** loudness (yelling, soft-spoken, whispering)  
pitch & intonation  
amount (sparse to talkative)  
spontaneity  
articulation (pronunciation, slurring)  
dialect  
comprehension  
stuttering, rhyming, word salad, repetition, rhyming,  
alliteration

### **THOUGHT PROCESS, THOUGHT CONTENT & PERCEPTION**

**Thought Process:** inferred from communication or questions, based on whole presentation. Is conversation direct & informative or vague & confused? Is speech spontaneous, flow of ideas smooth?

Disordered connectedness and organization of thought  
circumstantiality, loose associations  
flight of ideas, word salad, tangentiality

Other peculiarities of thought process  
clang associations, echolalia, thought blocking  
neologisms, perseveration

**Thought Content:** especially opening comment and during unstructured time. open-ended questions and specific disturbances. patient may or may not be aware of abnormalities.

Delusions=objectively incorrect beliefs, from bizarre to plausible, evaluate in socio-cultural context, corroborate with family member.

Content: paranoid (persecutory & grandiose), somatic, erotomanic, referential, nihilistic, delusional denial, Schneiderian (external control: thought broadcasting, insertion & insertion--common in Schizophrenia)

Organization & Consistency: stable, systematized or not  
Emotional & Behavioral Impact

Near-Delusional Beliefs: overvalued ideas, magical thinking

Obsessions & Preoccupations: ruminative, doubting, inhibiting,  
Phobias

Violent Ideations (suicidal or homicidal)

**Perception:** hallucinations (auditory, visual, olfactory, gustatory)  
illusions, derealizations, depersonalization, autoscopy, deja vu  
jamais vu

## COGNITION

**Orientation:** person, place & time (Folstein) - neurological screening

**Attention & Concentration:** visual, auditory & verbal

**Memory:** immediate recall, short term, long term (procedural & declarative, recent & remote, episodic & semantic), amnesias, pseudodementia

**Constructional Ability & Visuospatial Function**

**Abstraction & Conceptualization:** ability to analyze information, categorize, compare, hypothesize, & reason (inductive & deductive thinking), abstract thinking, humor

**INSIGHT & JUDGMENT** (handout: Cog. Domains & Representative NY tests); ask few qs from WAIS-R

**Insight:** awareness & understanding of feelings, thoughts, & reactions; of how one's personality & behaviors contribute to symptoms, problems, etc.

Adequate or impaired : level of denial, externalization of blame, not taking responsibility.

**Judgment:** weighing & comparing different aspects of an issue. situation dependent. process that precedes outcome (decision or action). ask simple hypothetical questions. affected by defense mechanisms

# The Mini-Mental State Examination

Name \_\_\_\_\_ Date \_\_\_\_\_

**Orientation:**

		<u>Score</u>	
1. What is the...	Year?	0	1
	Season?	0	1
	Date?	0	1
	Day?	0	1
	Month?	0	1
2. Where are we...	State?	0	1
	County?	0	1
	Town or City?	0	1
	Hospital?	0	1
	Floor?	0	1

**Registration:**

3. Name three objects, taking one second to say each. Then ask the patient all three after you have said them.

**Table-Forest-Dog**

Repeat the answers until the patient repeats all three.

0    1    2    3

**Attention and Calculation:**

4. Serial sevens. Give one point for each correct answer. Stop after five answers. Alternate: spell **WORLD** backwards.

0    1    2    3    4    5

**Recall:**

5. Ask for names of three objects learned in Question 3. Give one point for each correct answer.

0    1    2    3

**Language:**

6. Point to a pencil and a watch. Have the patient name them as you point. 0 1 2
7. Have the patient repeat "No ifs, ands or buts." 0 1
8. Have the patient follow a three stage command: "Take the paper in your right hand. Fold the paper in half. Put the paper on the floor." 0 1 2 3
9. Have the patient read and obey the following: "Close your eyes." (Write in large letters). 0 1
10. Have the patient write a sentence of his or her own choice. (The sentence should contain a subject and an object and should make sense. Ignore spelling errors when scoring.) 0 1
11. Enlarge the design below and have the patient copy it. (Give one point if all sides and angles are preserved and if the intersecting sides form a quadrangle.) 0 1

TREATMENT PLANNING MANUAL

1381

## TREATMENT PLAN

### Policy and Procedures

#### I. POLICY

To assure high quality care, each patient being treated at WPIC shall have a written comprehensive treatment plan recorded in the patient's clinical record which is set forth in language that is understandable to the patient as well as the treating staff. The treatment plan serves not only to document patient care in the clinical record but also as a basis for patient education and as a communication vehicle among staff. At WPIC, responsibility for continuity of care shall reside in the outpatient setting while inpatient services shall represent the acute, intensive, and brief portion of the patient's treatment. The following clinical administrative policies pertain in order to assure continuity of care in the development and implementation of the treatment plan.

1. The treatment planning process utilizes the data from a comprehensive assessment.
2. Each catchment area patient shall have an outpatient clinician in an outpatient program designated as primarily responsible and accountable for the patient's treatment program. In addition to the provision of direct services, this clinician shall be responsible for the coordination of other services required for the patient and the collaboration of service providers working with the patient.
3. The outpatient treatment plan is developed by the primary clinician in collaboration with the attending physician.
4. Patients who require hospitalization during the course of outpatient treatment shall continue to be followed by their primary outpatient clinician who will collaborate with inpatient staff with specific reference to disposition and plans for follow-up care. It is assumed that the patient will return to the outpatient care of this primary clinician to the extent possible.
5. The inpatient treatment plan is developed collaboratively by the multidisciplinary treatment team during the regularly occurring multidisciplinary treatment team meetings.
6. The inpatient treatment plan is developed to address those problems which necessitated the inpatient hospitalization and whose resolution will result in discharge from the inpatient setting. While the patient may experience problems in addition to those precipitating hospitalization, it may not be feasible to address these in an acute care setting.
7. The Nursing Care Plan, based upon the nursing assessment and reflecting current standards of nursing practice will be documented as part of the overall inpatient treatment planning process. Nursing interventions, related to established goals which are based upon the patient needs, problems, capabilities and limitations, will document measures that: (1) facilitate prescribed medical/psychiatric care; (2) relate to other physiological, psychosocial and environmental factors; and (3) deal with patient/family education and patient discharge planning.

- 8. a. Responsibility for written documentation of the Inpatient Treatment Plan shall lie with the respective multidisciplinary team members. In general, written formulation of Problems A and B will reside with the Primary Nurse.
  - b. In the case of the John Merck Unit, B Problems will also be recorded by Developmental Specialists.
  - c. Documentation of Problem C will be the responsibility of the Physician's Assistant, Nurse Practitioner or Resident Physician. In the case of any medical problem which requires nursing interventions, the primary nurse shall be responsible for documenting interventions under the Nursing Interventions section of the treatment plan. Any particular primary nurse, in conjunction with the treatment team, may elect to take responsibility for the actual documentation of the Category C (Medical) Problems.
  - d. Written documentation of Problem D will reside with the individual patient's social worker. Included in D Problems will be issues of disposition planning.
  - e. Documentation of Category E Problems may reside with any member of the professional staff and may include problems in the areas of patient/family education and social and occupational functioning. (1) Developmental Specialists will be responsible for documentation of psychoeducational activities under the E Problem Category on Child and Adolescent Services. (2) Documentation involving activities conducted by Creative and Expressive Arts Therapists, Recreational Therapists, and Milieu Therapists will be found under the Methods section of the treatment plan. The actual written documentation of these activities will be determined by the individual inpatient unit leadership group.
- 9. Patients admitted to inpatient units who do not have a designated primary outpatient clinician shall have by necessity a treatment plan focused only on the brief period of inpatient hospitalization. Arrangements for follow-up will be the responsibility of the inpatient social worker.
  - 10. The patient shall actively participate in the development and revisions of his/her treatment plan and will sign the treatment plan form when possible. Individual patients or family members, in the case of children, may be provided with a copy of the treatment plan as appropriate.

II. PROCEDURES

A. Definition and Formulations of Problems

- 1. Problem areas have been chosen which correspond to the DSM-III-R diagnostic classification system.

<p>AXIS I</p> <p>AXIS II</p>	<p>- Clinical Syndromes</p> <p>- Developmental Disorders and Personality Disorders</p>	<p>A. Problems/Needs related to Axis I Diagnosis</p> <p>B. Problems/Needs related to Developmental/Personality Disorder (Axis II) Diagnosis</p>
------------------------------	--	---

AXIS III	- Physical Disorders and Conditions	C. Physical/Medical Problems
AXIS IV	- Severity of Psychosocial Stressors	D. Family/Social Network; Environmental (Housing, employment, educational, cultural, legal) Problems; nature of stressor is acute (e.g. death in the family) or chronic (e.g. child exposed to persistent parental fighting).
AXIS V	- Global Assessment of Functioning	E. Impairment in Adaptive Functioning: Problems/needs in relation to disability and impairment in the performance of occupational and social roles (e.g. inability to hold a job, difficulty relating to spouse, child rearing problems); nature of impairment is chronic.

2. Problems are formulated in terms of:

- a. Symptoms of a definable diagnostic category or symptoms/deficits, etc. which can be formulated as part of a differential diagnosis.
- b. Need for further evaluation or assessment.
- c. Medical Syndromes/symptoms of a definable diagnostic category, or deficit, which can be formulated as part of a differential diagnosis, described in layman's language when possible.
- d. Areas of need in terms of environmental and/or social network support systems.
- e. Patient assets which are under-utilized or interfered with.

3. Problem statements are generally clustered around the diagnostic formulation. That is, symptoms of depression are presented as a single problem. This principle of clustering also holds true for symptoms/behaviors which are characteristic of other psychiatric diagnoses as well.

4. While problems are designated by date of formulation, category, and problem number, this does not imply a prioritization of problems by importance.

B. Strengths: Definition and Documentation

1. Patient strengths and assets may include factors corresponding to the various domains of the multiaxial diagnostic formulation. It is not necessary to list strengths to reflect each AXIS. Examples are provided to illustrate how one might elicit strengths and assets.

- AXIS I - insight into illness; understands the need for treatment
- AXIS II - above average intelligence; ability to establish personal relationships
- AXIS III - Physical stamina
- AXIS IV - Stable family supports; job to return to
- AXIS V - interpersonal skills; good work history

2. Patient strengths/assets are documented at the beginning of each treatment plan in the space provided. They are to be recorded on page one only of a multi-page treatment plan.

C. Definition and Formulation of Goals

1. Goals, for the purposes of treatment plans, are to be equated with the concept "Long Term Goals." Short term goals, in like manner, are the equivalent of performance statements or measurable objectives. Thus both goals and performance statements must be documented on the treatment plan for the designated problem area or problem/symptom cluster.
2. Long term goals are statements of attainable outcome which are directly related to the resolution of problems cited. There should be a goal statement for each problem. Goals are to be written with the patient's agreement in mind. Goal statements are abstractions whose measurement, quantification, and attainment need to be defined through the specification of short term goals.
3. Short term goals are the performance criteria to be utilized in the measurement of long term goals. They include: (a) patient behaviors which demonstrate movement toward a particular goal; and (b) specific activities which when accomplished by a patient give evidence that the goal has been attained. These performance criteria are usually directly observable behaviors or behaviors about whose presence or absence one can make a direct inference.

D. Methods

Methods answer the question, "How will intervention be carried out to achieve the stated goals?" This involves specifying:

1. Intervention procedures to be utilized (e.g. individual or group therapy, medication, role-playing, diagnostic procedures, checklists, contracts, referrals);
2. Under what conditions (including amount, frequency, duration, setting); and
3. Which staff or program will be involved.
4. Specific nursing interventions (as a function of the nursing care plan) will be documented in the column so designated.

E. Definition and Formulation of Target Dates

Target dates should indicate as precisely as possible the anticipated date for attainment of a given goal as measured by performance criteria.

F. Documentation of Patient and Staff Involvement

Both the patient's name and number should be recorded in the appropriate spaces on the Treatment Plan Review Forms. The patient's (if appropriate) signature and that of the patient's primary clinician, the supervising physician (if different than above) and other participating program staff must be present as well. If the patient is under the age of fourteen years, a family member/guardian shall sign the treatment plan. If there is no family member or guardian, that shall be so indicated on the treatment plan review sheet. If the patient refuses to sign the form, or for medical reasons is unable to do so, this should be so noted on the Review Form.

G. Date

The Treatment Plan is dated with respect to its formulation. Treatment Plan reviews are dated as indicated on the Treatment Plan Review Forms.

H. Timetable for Formulation and Revision of Treatment Plans

The initial inpatient treatment plan must be prepared by inpatient programs within 72 hours of admission. This initial plan must address, at a minimum, presenting problems which fall under either AXIS I or II, and AXIS III. As soon thereafter as is possible, the treatment team will address problems relating to AXIS IV and AXIS V.

Treatment plan reviews will occur within the prescribed time frames designated on the Treatment Plan Review Form for both inpatient and outpatient treatment plans. Treatment plan reviews are required to take place every 4 weeks on the inpatient services.

Treatment plans should be prepared by outpatient programs within 15 days of intake. The timing of Treatment Plan revisions will follow time intervals outlined on Outpatient Treatment Plan Review Forms (every 120 days or 15 visits, whichever comes first).

For Partial Hospitalization patients, the initial Treatment Plan is written by the 10th day of assessment and/or treatment and is reviewed by one month and then every 20th day of treatment or two months, whichever comes first, thereafter.

Clinical reviews/revisions as noted on the Treatment Plan Review Form will include: (1) problems resolved; (2) new problems identified; and (3) target dates revised; followed by particular comments, where appropriate, regarding a patient's progress.

In the case of an outpatient who is hospitalized for a period of time exceeding one month, a new Treatment Plan may be required from the outpatient program, unless the previous Treatment Plan, once reviewed, is still pertinent and timely.

- I. Designation of Minimal Discharge Criteria resides with the multidisciplinary treatment team, physician and primary clinician, as appropriate. Minimal discharge criteria will be designated for A and B problems only, those problems which relate directly to or precipitated the need for inpatient psychiatric hospitalization. Minimal discharge criteria, which is defined as the resolution of problems which meet criteria for discharge or termination of treatment will be indicated on the treatment plan through the use of an asterisk (\*).
- J. Progress Notes
1. Inpatient progress notes reflect the multidisciplinary team approach to treatment. While notes may be signed by the team member, they must reflect a particular team's participation.
  2. Inpatient progress notes should be keyed to Problem Categories and Numbers as listed on the TRAIL sheet which will include problems listed on the treatment plan. The specific reference to Problem Category and Number is documented with each entry.
  3. Progress notes should be dated and authenticated (complete signature and title or discipline of treating staff).
  4. Progress notes should describe the patient's response to the treatment process. Content of the Progress Notes should include the following factors:
    - a. The course of treatment of the disorder and results of treatments should be recorded.
    - b. Progress or lack thereof toward established treatment goals should be documented.
    - c. If there is a lack of progress, documentation of treatment plan revision is noted.
    - d. The patient's progress towards discharge and the development of post discharge plans are documented.

  - are the interpersonal skills?
  - are the financial resources?
  
2. What are the (problems/needs)?
  - are the target behaviors to change?
  - are the medical/psychiatric disabilities?
  - are the baseline behaviors?
  - are the antecedents and consequences of a particular behavior?
  
3. What are the long term (goals)?
  - are the outcome behaviors?
  - are the predictive statements?
  - are the desired results?
  - are the reflections of problem resolution?
  
4. What are the (short term goals) (measurable criteria/observable behaviors) that will let us know that the goals are attained?
  - What do we observe?
  - What do we infer?
  - What can we measure (frequency, duration, decreases, increases)?
  
5. How (Methods) will treatment be carried out?

- diagnostic procedures	- role-playing
- individual psychotherapy	- charts
- group	- contracts
- referral	
  
- By whom?
  
- Where?
  
- How long?
  - Immediacy
  - Frequency
  - Intensity
  - Duration
  
6. When (Time) will goals be achieved?
  - priorities
  - hierarchies

GOAL ANALYSIS PROCEDURE  
EXAMPLE

Step I: Establish the Long Term Goal

To help patient gain more control of impulsive behavior. = Process statement

Patient will have more control of impulsive behavior. = Outcome statement

Step II: "Brain-Storm" ways to measure the long term goals.

No longer striking out at others (hit, kick, bite, pull hair, scratch).  
If agitated, he walks away.  
Less intrusive.  
Able to tolerate meetings.  
Take shower without destroying bathroom.  
More re-directable.  
Able to verbalize.  
Able to "stifle" himself.  
Not changing clothes as often.  
Able to increase number and types of interactions he has.  
Can regulate amount of money spent each day.  
Requests meds. when feeling agitated.  
Doesn't interrupt (disrupt) other groups.  
Eats all of meal.  
Interacts with family members.  
Starts trusting his therapist.  
Talks about feeling vs. acting on them.  
Cooperative about taking meds.  
Stops making attempts to hurt self.  
Doesn't attempt to leave hospital (get on elevator, sign AMA, walk out with visitors, hunt for keys, leave lunchroom)  
Recognizes problem and is willing to deal with it.  
Able to tolerate other patients.

Step III: Sort out short term goals that behaviorally define and measure the attainment of the long term goal.

No longer strikes out at others (hit, kick, bite, pull hair, scratch).  
Removes himself from stimulating situation.  
Waits till after meetings to ask for something.  
Stops walking into meetings or nurses station.  
Waits for turn to speak in meetings.  
Sits through an entire meeting without screaming out or striking out at others.  
Takes showers without destroying bathroom.  
Stops impulsive behavior when requested to do so.  
Can regulate amount of money spent each day.  
Requests medication when agitated.  
Talks about what he is feeling rather than acting out.  
Does not spit out medication when given.  
Stops self-inflicted burns and cuts.  
Stops entering elevators, hunting for keys, threatening to leave.

Step IV: Make coherent statements to describe what you intend for each of the short term goals on your list. (Write a complete statement for each short term goal)

describing the nature, quality, or amount you will consider acceptable.

Long Term Goal: The patient will interact with others in an appropriate manner.

Step IV: Short Term Goals (Performances)

1. The patient will not refer to himself as "a cripple", "nothing", or any other deprecating term more than once per contact.
2. The patient will take whatever steps are necessary to clarify questions or issues about which he is confused. His inquiries will be directed to the appropriate people (e.g., medication questions to M.D. or R.N.).
3. The patient will not apologize unless he can supply a clear, concrete reason for apologizing. He will also not apologize for "almost swearing." If he does swear and feels an apology is necessary, he will apologize only once.
4. The patient will apologize only once per contact for: the slowness of his speech; his inability to remember words; and his inability to do certain things such as carry his tray, which makes it necessary for someone else to do it for him.
5. The patient will not ask the person with whom he is speaking if he or she or anyone else is angry with him unless he can: 1) supply a clear reason why the person might be angry, or 2) clearly explain what the person is doing which leads the patient to believe that he or she is angry.
6. The patient will refrain at all times from expressing his anger in a way that could physically harm himself or another person (e.g., hitting, throwing objects).
7. As soon as possible after an incident which angers the patient, he will verbally express his anger in a calm manner to the person with whom he is angry or someone else. This behavior will be encouraged by staff members whenever they perceive the patient's anger.

EXAMPLES OF PROBLEM STATEMENTS UPON WHICH LONG TERM GOAL WAS BASED

1. The patient often refers to himself in depreciating terms, such as "a cripple" and "nothing."
2. The patient refrains from asking questions because of a fear of "bothering" others and/or appearing "dumb."
3. The patient often apologizes for no apparent reason or for "almost swearing."
4. The patient often apologizes for aspects of his disability, such as the slowness of his speech, his inability to remember words, and his inability to carry his lunch tray.
5. The patient often asks the person with whom he is speaking if he or she or anyone else is angry.
6. The patient often expresses anger in ways that are potentially harmful to himself and/or others (hitting, throwing objects, etc.).
7. The patient does not express his anger in a constructive manner.

Step V: Test the statements with the following question. If a patient/client achieved or demonstrated each of these short term goals, would I be willing to say he or she has achieved the long term goal? When you can answer yes, the analysis is finished.

## INSTRUCTIONS AND DEFINITIONS

### I. Problems

- a. The four categories of problems to be identified are: A. Psychological/ Psychiatric (behaviorally stated); B. Psychophysiological; C. Physical/Medical; D. Family/Social Network; and E. Environmental (e.g. Housing, Employment, Education, Cultural, Legal). Categories may overlap but they are suggested for the purpose of promoting comprehensiveness rather than imposing a categorization system.
- b. Problems can be defined as any event, situation, symptom, behavior, etc. which impairs or interferes with the patient's level of functioning or sense of well being and requires therapeutic intervention.
- c. Psychopathological and social functioning problems are formulated in relationship to behaviors. In most cases problem statements will not be represented by traditional psychiatric diagnostic labels.
- d. Problem statements that are concise, in clear language, and quantifiable are suggested. Those problem definitions that are best lead most readily to goal statements. Problem statements should be made which are relevant to treatment strategies and intervention.
- e. Problems are designated by date of formulation, category and problem number which is not to be thought of as a prioritization of problem importance.

### II. Goals and Performances

- a. Goals are statements of attainable outcome which are directly related to the resolution of problems cited. There should be a goal statement for each problem. Goals are to be written with the patient's agreement in mind. Although goal statements are abstractions, their measurement, quantification and attainment need to be defined under performance statements.

Performance statements describe specific outcomes that, if achieved, will cause you to agree that the goal is achieved. Performance statements are typically descriptions of a single behavior or class of behaviors that will indicate the presence of an alleged performance about which there would be general agreement. Performances are usually directly observable behaviors or behaviors about whose presence or absence one can make a direct inference. In some cases, measurable performances could be documented through laboratory tests.

- b. Performance statements represent observations of frequency, duration, intensity and compliance with respect to the patient's behavior, symptomatology or condition. These performance statements should specify the nature, quality or amount of a particular behavior or condition that is considered acceptable.

### III. Treatment Methods

Methods will answer the question "How will interventions be carried out to achieve the stated goals and performance measures?" This involves specifying (1) which particular intervention procedures will be utilized; (2) under what conditions (including amount, frequency, duration, setting); and (3) which staff or programs will be involved.

### IV. Target and Attainment Dates

Target dates should indicate as precisely as possible the anticipated date for attainment of a given goal as measured by performance criteria.

Attainment date should correspond directly to a review by staff and patient as to the actual accomplishment of the goal and performance measures.

**TREATMENT PLANS**  
**GENERAL DIRECTIONS**

A. On the Treatment Plan Request Form (see example below) please fill in:

- (1) Patient's complete name and preferred first name, separately
- (2) Patient's number
- (3) Treatment Plan file name and number (see attached)
- (4) Problem number (E 1, E 2, etc.)
- (5) Clinician's name
- (6) Date to be returned to clinician

B. Upon receipt of Treatment Plan from clinic secretary:

- (1) Edit; make corrections.
- (2) Write in target date for each short term goal and the overall longterm goal.
- (3) Write in patient's strengths and patient's working diagnoses (Axis I & II).

C. When reviewing Treatment Plans with patient:

- (1) Obtain feedback and make any additional corrections.
- (2) Obtain patient's signature on Treatment Plan review sheet.
- (3) Initial date on Treatment plan review sheet should be 15 days from date of first meeting.
- (4) Review dates must be within 120 days of each other.
- (5) Student and clinician signature must be co-signed by clinic supervisor.
- (6) Give the patient the de-identified copy of the Treatment Plan; Clinic copy to be retained in clinician's file; Patient Record copy to be returned to medical records with Treatment Plan Review sheet attached.

## Index for Treatment Plans

<u>File Name</u>	<u>File #</u>	<u>Description</u>
ABSENCE.TRT	1	lacks nonemployment activities which are meaningful and productive
ASSIST.TRT	2	requests assistance with implementing plan to attend educational/training program
DIFFICUL.TRT	3	is experiencing difficulty in academic/training setting
ACADTRB.TRT	4	reports difficulty in previous attempt(s) at obtaining advanced educational credentials
HI-INTER.TRT	5	expresses high interest in _____ - related jobs but is unsure of current skills and necessary prerequisites
IMPROVE.TRT	6	wishes to improve the following job seeking skills:
NOCOLLEG.TRT	7	college matriculation is currently not a viable option
PRE-VOC.TRT	8	is in need of work readiness activities and developmental work experiences
SKILLS.TRT	9	is dissatisfied with present levels of basic academic skills
SOLITARY.TRT	10	has poorly developed interpersonal skills, i.e.:
UNCERTA.TRT	11	is uncertain regarding career goals and courses of action to take
FEAR.TRT	12	expresses concerns and/or fears about becoming employed, i.e.
WORKMAIN.TRT	13	wishes to maintain employment over extended period of time and increase confidence in own capabilities re: work
SCHOOLMAIN.TRT	16	desires support and advisement while in current educational/training program

Examples of Patient Strengths for use in treatment planning:

- Axis I
1. Compliant with treatment regimen
  2. Understanding of nature of illness
  3. Can identify prodromal symptoms
  - 4.
  - 5.
  - 6.
- Axis II
1. Educational attainment
  2. Above average intelligence
  3. Persistent goal-oriented behavior
  4. Perseveres with tasks
  5. Follows through on plans
  6. Good social judgment
  7. Seeks consultation/help when needed
  8. Highly motivated
  - 9.
  - 10.
  - 11.
- Axis III
1. Physical stamina
  2. Good general physical health
  - 3.
  - 4.
  - 5.
- Axis IV
1. Good interpersonal support system
  2. Currently employed
  3. Stable housing
  4. Adequate income
  5. Receives income maintenance
  6. Reliable child care arrangements
  7. OVR sponsorship
  8. Student financial aid
  9. Good work history
  - 10.
  - 11.
  - 12.

NOTE:

The above lists are not exhaustive and are intended as useful examples. Please individualize as needed in developing individual patient treatment plans.

E \_\_\_\_\_ lacks  
non-employment  
activities  
which are  
meaningful and  
productive

Long Term Goal:

\_\_\_\_\_ will have engaged  
in meaningful and  
productive non-employment  
activities which meet  
personal needs.

Strengths:

Short Term Goals:

1. \_\_\_\_\_ will explore and  
identify interests in the  
areas of:

\_\_\_\_\_ social clubs and  
activities

\_\_\_\_\_ health/fitness

Diagnosis:

\_\_\_\_\_ volunteer services

\_\_\_\_\_ leisure  
learning/self-development

\_\_\_\_\_ entertainment

\_\_\_\_\_ arts and crafts

\_\_\_\_\_ other

NARS clinician, \_\_\_\_\_,  
will meet with \_\_\_\_\_ on a  
\_\_\_\_\_ monthly basis to  
assist in:

a. identifying community  
resources and vocational  
opportunities

b. the development of a  
realistic plan of action.

NARS clinician, \_\_\_\_\_,  
will provide support to  
\_\_\_\_\_ throughout the  
exploration and  
implementation of a plan  
of action.

NARS clinician, \_\_\_\_\_,  
will enlist the input of  
significant others as  
appropriate.

2. \_\_\_\_\_ will identify ways to become involved in high interest areas, i.e., volunteer service, non-credit courses, etc...

3. \_\_\_\_\_ will explore and discuss feelings around the personal meaning of employment and non-employment activities.

4. \_\_\_\_\_ expresses satisfaction with interests and activities.

E \_\_\_\_\_ requests assistance with implementing plan to attend educational/training program, i.e., meeting deadlines, registration process, accessing financial resources, budgeting, course selection.

Strengths:

Diagnosis:

Axis I

---

---

Axis II

---

---

Long Term Goal:

\_\_\_\_\_ will have a thorough understanding of college degree/training program requirements and procedures for meeting these.

Short Term Goals:

1. \_\_\_\_\_ has verified program costs and financial aid sources (PELL, PHEAA, loans, OVR, work study), application forms, deadlines for application, and eligibility criteria (default income/guidelines).

2. \_\_\_\_\_ has verified admission/acceptance criteria (pre-requisites, academic standing, transfer credits, transcripts, deadlines).

NARS clinician, \_\_\_\_\_, will provide on a \_\_\_\_\_ individual outpatient basis:

- a. career counseling and guidance
- b. education regarding community education and training institutions
- c. referral and liaison services as indicated

3. \_\_\_ has verified course registration process (advisor, nature of courses, course selection, credit hours, class time-schedule deadlines).

4. \_\_\_ has verified degree/program requirements (starting times, full or part-time options, length of program curriculum content).

5. \_\_\_ has developed a written workable time activity schedule which allows for educational, mental health, personal, employment and other significant needs and goals.

E\_\_ is experiencing difficulty in academic/training setting, i.e., study habits, class attendance, passing grades; confidence in personal ability to complete educational/training program.

Strengths:

Diagnosis:

Axis I \_\_\_\_\_  
Axis II \_\_\_\_\_

Long Term Goal:

\_\_\_\_\_ will have accommodated to the demands of a particular educational/training program while continuing to meet other life obligations, i.e., good mental and physical health, financial security, family obligations.

Short Term Goals:

1. \_\_\_\_\_ arranges time and activities to allow for 100% attendance of all scheduled classes and homework/study time as indicated by program demands.
2. \_\_\_\_\_ has reviewed requirements for each course (i.e., essay tests, homework assignments, weekly quizzes, term papers, lab reports).

NARS clinician, \_\_\_\_\_, will provide on a monthly basis through individual counseling sessions:

- a. training and assistance with educational survival skills (study skills, note taking strategies, use of resources, test taking strategies)
- b. career exploration assistance
- c. referral and liaison activities as indicated
- d. monitoring of \_\_\_\_\_ progress

3. \_\_\_\_\_ will review current methods of study (i.e., note taking, outlining/organizing course material, study habits) and how to improve them.

4. \_\_\_\_\_ will investigate and utilize available student services/resources, i.e.,  
\_\_\_\_\_  
\_\_\_\_\_

5. \_\_\_\_\_ will review progress in program on a regular basis, identify problem areas, and develop specific interventions for these.

E\_\_ reports difficulty in previous attempt(s) at obtaining:

General Equivalency Diploma (GED)

professional certification

college credits

college degree

Strengths:

Diagnosis:

Axis I  
\_\_\_\_\_  
\_\_\_\_\_  
Axis II  
\_\_\_\_\_  
\_\_\_\_\_

Long Term Goal:  
\_\_\_\_\_ will have an understanding of the necessary requirements to obtain \_\_\_\_\_ and a realistic self-appraisal of the abilities and resources necessary to obtain this goal

Short Term Goals:

1. \_\_\_\_\_ will explore previous attempt(s) to assist with the current appraisal.
2. \_\_\_\_\_ will complete an assessment of current levels of academic skills and use these results in planning.
3. \_\_\_\_\_ will investigate available resources to obtain the stated goal.
4. \_\_\_\_\_ can specifically identify individual strengths and weaknesses and how they relate to the educational objective.

NARS clinician, \_\_\_\_\_, will provide on a \_\_\_\_\_ basis through individual counseling sessions:

- a. an assessment of academic achievement and vocational guidance based on test results
- b. referral and liaison activities as indicated
- c. monitoring and support of \_\_\_\_\_ self-appraisal and resource investigation

E\_\_\_ expresses high interest in \_\_\_ - related jobs but is unsure of current skills and necessary prerequisites

Strengths:

Long Term Goal:

\_\_\_ will have a thorough understanding as to whether the \_\_\_ - related professions are compatible with \_\_\_ 's skills, interests, work preferences, physical limitations, and stress tolerance level.

Short Term Goals:

1. \_\_\_ will explore varied \_\_\_ - related career information via utilization of NARS resource materials.

2. \_\_\_ will participate in formal vocational assessment, review results with NARS clinician, \_\_\_ , and discuss implications for career choice.

Diagnosis:

Axis I

---

---

Axis II

---

---

NARS clinician, \_\_\_ , will provide on a \_\_\_ monthly basis through individual counseling sessions:

a. vocational assessment and guidance

b. career exploration resources

c. education and feedback

d. referral and liaison activities as indicated

e. monitoring of \_\_\_ 's progress

3. \_\_\_\_\_ will list pros/cons of a chosen career direction.
4. If deemed necessary, \_\_\_\_\_ will further explore career information related to assessment results in order to clarify alternatives.
5. \_\_\_\_\_ utilizes volunteer work to aid in career decision making and determining work tolerance level.
6. \_\_\_\_\_ will visit 2-3 job sites where a specific job can be observed.
7. \_\_\_\_\_ will select a specific job site and follow through with shadowing and/or informational interviewing a particular staff member there.

E\_\_\_ wishes to improve the following job seeking skills:

\_\_\_ personal appearance

\_\_\_ conversational skills

\_\_\_ self-confidence

\_\_\_ demonstrating enthusiasm to work

\_\_\_ resume preparation

\_\_\_ job application completion

\_\_\_ generating job leads

\_\_\_ following-up on job leads

Long Term Goal:

\_\_\_ demonstrates specific improved job seeking skills in an active job search.

Short Term Goals:

1. \_\_\_ considers volunteer work to aid in building work tolerance and obtaining a current work reference.

2. \_\_\_ has produced an updated resume and a master sample job application and uses them in an active job search.

3. \_\_\_ has practiced and improved verbal and nonverbal skills essential to the job interviewing process.

NARS clinician, \_\_\_\_, will provide:

a. individual counseling on a \_\_\_ monthly basis.

b. administration of a vocational assessment battery.

c. review of assessment results.

d. career exploration guides and resources.

e. assistance and instruction in the Job Seeking Skills process.

NARS clinician, \_\_\_\_, will conduct a \_\_\_ week Job Seeking Skills Group.

Strengths:

4. \_\_\_\_\_ has learned to generate job leads; i.e., use of want ads, the Pittsburgh Alliance, other community resources, independent searches.

5. \_\_\_\_\_ has followed-up on job leads, i.e., calls employer, sends in resume and cover letter, completes job application forms.

6. \_\_\_\_\_ participates in Job Seeking Skills Group.

7. \_\_\_\_\_ has verified the usability of former work references.

Diagnosis:

Axis I

\_\_\_\_\_  
\_\_\_\_\_

Axis II

\_\_\_\_\_  
\_\_\_\_\_

E\_\_\_ 's  
college matriculation  
currently is  
not a viable  
option; \_\_\_  
needs to learn  
job skills in  
order to  
enhance  
employability

Strengths:

Long Term Goal:

\_\_\_ will have developed  
a realistic and feasible  
rehabilitation plan in  
lieu of pursuing a formal  
academic program at this  
time.

Short Term Goals:

1. \_\_\_ will acknowledge  
that at this point in  
time college level  
academic training is not  
a viable option due to:

\_\_\_ a. concentration  
problems

\_\_\_ b. academic  
deficits

\_\_\_ c. lack of funding

\_\_\_ d. other

Diagnosis:

Axis I

Axis II

NARS clinician, \_\_\_ ,  
will meet with \_\_\_ on a  
\_\_\_ monthly basis in  
order to:

a. administer formal  
vocational assessment

b. review results with  
\_\_\_ and provide  
assistance and guidance  
with integrating results  
into vocational /  
educational planning

c. referral and liaison  
services as needed

Career information  
resources will be  
available in the NARS  
clinic as well as  
instruction on resource  
utilization.

2. \_\_\_\_\_ will engage in vocational assessment in NARS, reviewing results with NARS clinician, \_\_\_\_\_.

3. \_\_\_\_\_ will demonstrate that the results of testing are understood by utilizing the information to list vocational training options which are compatible with documented interests, aptitudes, work values, and academic skills.

4. \_\_\_\_\_ will meet with OVR counselor to determine eligibility for services and subsequent discussion of programming needs.

5. \_\_\_\_\_ will visit job training site to determine whether or not it is suitable.

E\_\_\_ is in need of work readiness activities and developmental work experiences.

Strengths:

Long Term Goal:

\_\_\_ will have demonstrated those basic behaviors, habits, and attitudes, which are required in the role of worker.

Short Term Goals:

- 1. \_\_\_ is able to realistically assess present readiness for employment/training in terms of:

\_\_\_ stamina and mental endurance

\_\_\_ time management

\_\_\_ incorporating work into ongoing life style

\_\_\_ ability to identify/meet demands of employment, i.e., use of sick time, interactions with co-workers, task performance

NARS clinician, \_\_\_\_, will provide \_\_\_ monthly through individual counseling sessions:

- a. vocational assessment and guidance
- b. career exploration resources
- c. education and feedback
- d. referral and liaison activities as indicated
- e. monitoring of \_\_\_'s progress

Diagnosis:

Axis I  
\_\_\_\_\_  
\_\_\_\_\_  
Axis II  
\_\_\_\_\_  
\_\_\_\_\_

realistic  
estimation of own  
capabilities

2.            engages in a  
functional assessment of  
work/training readiness

           participation in a  
structured volunteer  
experience in high  
interest areas

           participation in a  
period of personal work  
adjustment and skill  
training

           completion of a  
single "trial" course in  
a vocational area of  
interest

E—  
       is  
dissatisfied  
with present  
levels of basic  
academic  
skills.

Strengths:

Long Term Goal:

       will follow through  
on a plan to improve  
basic academic skills.

Short Term Goals:

1.        will review  
previous attempts at  
schooling/training as an  
aid in current planning.
2.        will take part  
in an assessment of  
current academic skill  
levels and academic  
survival skills.
3.        will investigate  
and utilize available  
resources for developing  
desired skills, i.e.,  
pre-college programs,  
literacy training,  
developmental courses,  
Adult Basic Education.

Diagnosis:

Axis I  
\_\_\_\_\_  
\_\_\_\_\_

Axis II  
\_\_\_\_\_  
\_\_\_\_\_

NARS clinician, \_\_\_\_\_,  
will provide \_\_\_\_\_  
through individual  
counseling sessions:

- a. academic testing and  
guidance
- b. review of testing  
results
- c. referral and liaison  
activities as indicated
- d. monitoring of \_\_\_\_\_'s  
progress
- e. instruction in  
academic survival skills

4. \_\_\_\_\_ will identify problem areas which interfere with the academic plan, and develop effective ways of dealing with them.

E\_\_

\_\_\_\_\_ has  
poorly developed interpersonal skills, i.e.:  
\_\_\_\_\_ poor eye contact  
\_\_\_\_\_ difficulty starting a conversation  
\_\_\_\_\_ changing affect to meet demands of the situation  
\_\_\_\_\_ sexually provocative comments  
\_\_\_\_\_ inability to judge personal space needs of others

Long Term Goal:

\_\_\_\_\_ will demonstrate an improved ability to interact with others, particularly in the work place.

Short Term Goals:

1. \_\_\_\_\_ will participate in social skills training at \_\_\_\_\_.
2. \_\_\_\_\_ will engage in volunteer work commencing with 4 hours per week and subsequently increasing hours (in 4 hour increments) to \_\_\_\_\_ hours per week.
3. \_\_\_\_\_ will maintain a log of interpersonal experiences (both positive and negative) and discuss specific experiences with NARS clinician.

NARS clinician, \_\_\_\_\_, will:

- a. meet with \_\_\_\_\_ on a \_\_\_\_\_ monthly basis to:
- b. utilize role play activity which will focus on problematic interpersonal situations.
- c. provide referral and liaison activities as indicated.
- d. monitor \_\_\_\_\_'s progress in an ongoing manner, providing feedback as appropriate.
- e. suggest real-life activities in which \_\_\_\_\_ may participate.

Strengths:

4. \_\_\_\_\_ will engage in simulated interpersonal situations with NARS clinician and demonstrate improved conversational/nonverbal behavior.

5. \_\_\_\_\_ will participate in real-life experiences where \_\_\_\_\_ can learn and practice social skills.

Diagnosis:

Axis I

\_\_\_\_\_  
\_\_\_\_\_

Axis II

\_\_\_\_\_  
\_\_\_\_\_

E\_\_\_ is uncertain regarding career goals and courses of action to take:

a. previous academic failures resulting in decreased sense of self-worth

b. unable to return to previous career

c. dissatisfaction with current job; desires to explore alternatives

d. lack of or limited employment experiences

Long Term Goal:

\_\_\_ will have established and followed through on a plan of action to aid in determining specified vocational goal(s).

Short Term Goals:

1. \_\_\_ will review previous educational and vocational experiences to aid in current planning.

2. \_\_\_ will complete a vocational assessment battery.

3. \_\_\_ will utilize results of vocational assessment in career exploration.

4. \_\_\_ will explore areas of high interest and career alternatives/training options utilizing discussion with clinician and career/educational

NARS clinician, \_\_\_ will provide:

individual vocational counseling on a \_\_\_ will monthly basis which will include the administration of a vocational assessment battery, reviewing assessment results, providing career exploration and guidance, providing supportive services regarding \_\_\_'s plan of action, and referral and liaison services as indicated.

e. unclear whether stated career goal is feasible

Strengths:

resource materials.

5.        will investigate employment options while exploring educational opportunities.

6.        will investigate educational options within the local community.

7.        will begin to take classes in an area of interest related to a defined career goal.

8.        can identify personal strengths and abilities and realistically appraise personal limitations.

9.        will identify pros and cons of potential career direction.

10.        will report an increased sense of self confidence.

11.        considers volunteer work to aid in career decision making and determining work tolerance level.

Diagnosis:

Axis I:

\_\_\_\_\_

Axis II:

\_\_\_\_\_

E\_

\_\_\_\_\_ expresses concerns and/or fears about becoming employed, i.e.

\_\_\_\_\_ child care arrangements

\_\_\_\_\_ change in benefits

\_\_\_\_\_ usual activities of daily life

\_\_\_\_\_ ability to meet increased job performance demands

\_\_\_\_\_ leaving volunteer position for paid employment

\_\_\_\_\_ loss of current supports

\_\_\_\_\_ transportation

Long Term Goal:

\_\_\_\_\_ understands and can incorporate the consequences of being employed into current lifestyle and will utilize this information in future career exploration.

Short Term Goals:

1. \_\_\_\_\_ lists current benefits and income from all sources.
2. \_\_\_\_\_ can evaluate and compare potential employment with current benefits and income.
3. \_\_\_\_\_ explores options for ensuring that \_\_\_\_\_ needs are met.
4. \_\_\_\_\_ can discuss feelings about changes in current support system.

NARS clinician, \_\_\_\_\_, will provide vocational counseling and guidance that is focused on:

\_\_\_\_\_ reviewing benefits

\_\_\_\_\_ evaluating employment options

\_\_\_\_\_ identifying stress management activities and resources

\_\_\_\_\_ identifying appropriate community and "natural" supports

\_\_\_\_ other:  
Strengths:

5. \_\_\_\_\_ can identify  
means of dealing with  
increased stressors/  
demands.

E \_\_\_\_\_ desires support and advisement while in current educational/training program.

Strengths:

Diagnosis:

Axis I:

---

---

Axis II:

---

---

Long Term Goal:

\_\_\_\_\_ demonstrates competencies with regard to the ability to make satisfactory adjustments in educational/training related activities.

Short Term Goals:

1. \_\_\_\_\_ has applied in a timely fashion for financial aid (PELL, PHEAA, OVR, work study).

2. \_\_\_\_\_ has registered for appropriate courses and verified degree/program requirements per academic year.

3. \_\_\_\_\_ will review and discuss evaluations, assignments, and feedback received in terms of performance in the classroom setting each semester.

NARS clinician, \_\_\_\_\_, will provide supportive counseling and guidance on an individual outpatient basis ( \_\_\_\_\_):

a. utilize role play activity focused on improving problematic interpersonal skills in the context of the educational/training setting

b. provide career/academic counseling and guidance with respect to course selection and program of study.

c. training and assistance in academic survival skills, i.e. study skills, note taking strategies, test taking strategies, use of resources.

4. \_\_\_\_\_ has learned to request clarification, feedback, and assistance from instructor and/or fellow students when unclear about assignments and performance.

5. \_\_\_\_\_ maintains a log of interpersonal experiences (both positive and negative) which occur in training and discusses these with NARS clinician.

6. \_\_\_\_\_ actively utilizes academic survival skills and strategies in the educational setting.

d. referral and liaison activities with school and rehabilitation personnel as indicated

## CRITICAL SKILLS CHECKLIST

Client name \_\_\_\_\_ Evaluator \_\_\_\_\_

ID Number \_\_\_\_\_ Agency \_\_\_\_\_

Date \_\_\_\_\_

**INSTRUCTIONS:** Circle the appropriate category indicating how well each of the following critical skills are performed according to the definition key below:

Very Poor (1) - skill performance is very poor or absent

Poor (2) - skill performance is poor or inconsistent at best

Adequate (3) - skill performance is adequate (meets current needs)

Good (4) - skill performance is good (effective, consistent/efficient)

Superior (5) - skill performance is highly satisfactory (particular strength)

No (N) - cannot be determined; skill performance in need of further evaluation

The Environmentally Specific Comments section is used to specify environmental and behavioral parameters in summarizing skill performance, i.e., quantity: frequency, duration, consistency, reliability; quality: thoroughness, accuracy, desirability, expediency, efficacy; and level of independence: level/frequency of supervision, prompting. Comments here should further elucidate client strengths which may be capitalized upon, as well as deficit areas which may be targeted for intervention.

Specify the environment for which this assessment was completed: \_\_\_\_\_

**A. LANGUAGE/COMMUNICATION**

- engages in every day conversation 1 2 3 4 5 N
- understands verbal commands, directions 1 2 3 4 5 N
- responds to nonverbal contextual cues 1 2 3 4 5 N
- expresses needs & feelings 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**B. MEMORY AND LEARNING**

- recalls basic environmental information (names, address, telephone and Social Security number, simple directions) 1 2 3 4 5 N
- remembers appointment times and schedule of activities 1 2 3 4 5 N
- recalls long-term information (work or educational history) 1 2 3 4 5 N
- comprehends written materials 1 2 3 4 5 N
- learns from hands-on experience 1 2 3 4 5 N
- learns from verbal instructions 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**C. ATTENTION/CONCENTRATION**

- sustains attention to aurally presented information 1 2 3 4 5 N
- sustains attention to task at hand 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**D. PROBLEM SOLVING AND CONCEPTUALIZATION**

- makes reasonable decisions 1 2 3 4 5 N
- formulates a plan 1 2 3 4 5 N
- carries out a plan 1 2 3 4 5 N
- generalizes a concept across settings 1 2 3 4 5 N
- responds to constructive criticism 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**E. DAILY LIVING**

- attends to personal hygiene (shower, shampoo, deodorant) 1 2 3 4 5 N
- uses a telephone 1 2 3 4 5 N
- engages in leisure time activities 1 2 3 4 5 N
- reads a newspaper 1 2 3 4 5 N
- budgets money 1 2 3 4 5 N
- plans a nutritionally balanced meal 1 2 3 4 5 N
- prepares meals adequately 1 2 3 4 5 N
- shops for personal items 1 2 3 4 5 N
- uses public transportation 1 2 3 4 5 N
- accesses necessary resources (Social Security, Medical care, etc.) 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**F. SELF APPRAISAL AND JUDGMENT**

- evaluates severity of external stressors 1 2 3 4 5 N
- copes with mild stress 1 2 3 4 5 N
- seeks support if unduly stressed 1 2 3 4 5 N
- verbalizes relevant and appropriate personal goals 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**G. STAMINA AND TOLERANCE**

- tolerates a 6-8 hour workday 1 2 3 4 5 N
- lifts objects 35-50 lbs 1 2 3 4 5 N
- traverses 100 yards without fatigue 1 2 3 4 5 N

Environmentally Specific Comments:

---

---

---

**KEY:**

- 1 = Very Poor
- 2 = Poor
- 3 = Adequate
- 4 = Good
- 5 = Superior
- N = In need of further evaluation

## CRITICAL SKILLS CHECKLIST

Client name Sam

Evaluator M. Geckle, M.Ed., CRC

ID Number \_\_\_\_\_

Agency NARS, WPIC

Date 10/10/84

**INSTRUCTIONS:** Circle the appropriate category indicating how well each of the following critical skills are performed according to the definition key below:

Very Poor (1) - skill performance is very poor or absent

Poor (2) - skill performance is poor or inconsistent at best

Adequate (3) - skill performance is adequate (meets current needs)

Good (4) - skill performance is good (effective, consistent/efficient)

Superior (5) - skill performance is highly satisfactory (particular strength)

No (N) - cannot be determined; skill performance in need of further evaluation

Comments here should further elucidate client strengths which may be capitalized upon, as well as deficit areas which may be targeted for intervention.

Specify the environment for which this assessment was completed: Personal Work

Adjustment Training, janitorial, TE and job placement process

© Psychiatric Rehabilitation Training Program, Western Psychiatric Institute and Clinic, University of Pittsburgh

**A. LANGUAGE/COMMUNICATION**

- engages in every day conversation 1 2 ③ 4 5 N
- understands verbal commands, directions 1 ② 3 4 5 N
- responds to nonverbal contextual cues 1 ② 3 4 5 N
- expresses needs & feelings 1 2 ③ 4 5 N

**Environmentally Specific Comments:**  
Janitorial and personal work adjustment training program - may need written cue cards for multi-step tasks and instructions

**B. MEMORY AND LEARNING**

- recalls basic environmental information (names, address, telephone and Social Security number, simple directions) 1 2 ③ 4 5 N
- remembers appointment times and schedule of activities 1 2 ③ 4 5 N
- recalls long-term information (work or educational history) 1 ② 3 4 5 N
- comprehends written materials 1 ② 3 4 5 N
- learns from hands-on experience 1 2 3 ④ 5 N
- learns from verbal instructions 1 ② 3 4 5 N

**Environmentally Specific Comments:**  
All need brief, concise, written instructions throughout training and placement

**C. ATTENTION/CONCENTRATION**

- sustains attention to aurally presented information 1 ② 3 4 5 N
- sustains attention to task at hand 1 ② 3 4 5 N

**Environmentally Specific Comments:**  
Does respond well to redirection to task at hand

**D. PROBLEM SOLVING AND CONCEPTUALIZATION**

- makes reasonable decisions 1 ② 3 4 5 N
- formulates a plan 1 ② 3 4 5 N
- carries out a plan 1 ② 3 4 5 N
- generalizes a concept across settings 1 ② 3 4 5 N
- responds to constructive criticism 1 2 ③ 4 5 N

**Environmentally Specific Comments:**  
Overall greatest deficit area; will need flexible, comprehensive, and long-term case management services

**E. DAILY LIVING**

- attends to personal hygiene (shower, shampoo, deodorant) 1 2 3 ④ 5 N
- uses a telephone 1 2 3 ④ 5 N
- engages in leisure time activities 1 2 3 ④ 5 N
- reads a newspaper 1 ② 3 4 5 N
- budgets money 1 ② 3 4 5 N
- plans a nutritionally balanced meal 1 2 ③ 4 5 N
- prepares meals adequately 1 2 ③ 4 5 N
- shops for personal items 1 2 ③ 4 5 N
- uses public transportation 1 2 3 ④ 5 N
- accesses necessary resources (Social Security, Medical care, etc.) 1 2 ③ 4 5 N

**Environmentally Specific Comments:**  
Needs help with written monthly budget; difficulty reading want-ads and job applications - needs prewritten applications and help with job leads &/or direct, selective placement

**F. SELF APPRAISAL AND JUDGMENT**

- evaluates severity of external stressors 1 ② 3 4 5 N
- copes with mild stress 1 2 ③ 4 5 N
- seeks support if unduly stressed 1 ② 3 4 5 N
- verbalizes relevant and appropriate personal goals 1 2 ③ 4 5 N

**Environmentally Specific Comments:**  
Needs close, active monitoring throughout training and on TE and competitive job; may "oversocialize" at work-spend excessive time conversing with coworkers

**G. STAMINA AND TOLERANCE**

- tolerates a 6-8 hour workday 1 2 ③ 4 5 N
- lifts objects 35-50 lbs 1 2 3 ④ 5 N
- traverses 100 yards without fatigue 1 2 3 4 ⑤ N

**Environmentally Specific Comments:**  
Relative strengths in this area; enjoys work that is physical in nature and outdoors

**KEY:**

- 1 = Very Poor
- 2 = Poor
- 3 = Adequate
- 4 = Good
- 5 = Superior
- N = In need of further evaluation

Specify action necessary around any current symptoms manifestation:

Ongoing monitoring of medications including regular blood levels;  
psychiatrically stable at this time; no noted use of drugs or ETOH since 1971  
 \_\_\_\_\_  
 \_\_\_\_\_

Has the client demonstrated consistent medication compliance?

X Y  N

For how long? 7/82 to present

Intrapersonal Factors:

Can client readily discuss impact of his symptoms on behavior and lifestyle?

X Y  N

If no, does he/she tend to:

- Deny
- Avoid
- Use Sick Role

**Client's personal rehabilitation aims/personal incentives toward change:**

Sam is motivated to increase his real income to improve his family's standard of living. He desires to be productively engaged and to improve his lifestyle - "hangin' out on street corners and gettin' into trouble is just not for me". He is concerned about a pension/retirement plan - he wants to obtain employment with an established, reputable employer and to maintain this job over an extended period of time - "this one I'm going to retire on." Sam is strongly motivated to "stay out of the hospital." He states, "I just want to be like anybody else, have a job."

**Noteworthy disincentives toward maintenance of employment:**

None major at present with the possible exception of: 1) loss of medical coverage under Medical Assistance; 2) part-time (approx. 25 hrs./wk.) employment would net Sam approximately the equivalent per month of his current Public Welfare cash grant (\$195.00) and Food Stamp allotment (\$95.00). Sam greatly desires to increase his real income/month, but is willing to begin any part-time job, even one which pays the minimum wage, if full-time hours and incremental pay raises are realistic/likely possibilities.

Chelume, Heaton and Lehman

SCALE I: MEMORY

Instructions: Please answer each of the following questions by placing a check next to the response which most accurately describes the way you have been recently.

1. How often do you forget something that has been told you within the last day or two?

- (M-1)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

2. How often do you forget events which have occurred in the last day or two?

- (M-2)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

3. How often do you forget people whom you met in the last day or two?

- (M-3)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

4. How often do you forget things that you knew a year or more ago?

- (M-4)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

5. How often do you forget people whom you knew or met a year or more ago?

- (M-5)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

6. How often do you lose track of time, or do things either earlier or later than they are usually done or are supposed to be done?

- (M-6)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

7. How often do you fail to finish something you start because you forgot that you were doing it? (Include such things as forgetting to put out cigarettes, turn off the stove, etc.)

- (M-7)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

8. How often do you fail to complete a task that you start because you have forgotten how to do one or more aspects of it?

- (M-8)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

9. How often do you forget things that you are supposed to do or have agreed to do (such as putting gas in the car, paying bills, taking care of errands, etc.)?

- (M-9)             almost always  
                   very often  
                   fairly often  
                   once in a while  
                   very infrequently  
                   almost never

**SCALE II: LANGUAGE AND COMMUNICATION**

**Instructions:** Please answer each of the following questions by placing a check next to the response which most accurately describes the way you have been recently.

1. How often do you have difficulties understanding what is said to you?

- (LC-1)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

2. How often do you have difficulties recognizing or identifying printed words?

- (LC-2)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

3. How often do you have difficulty understanding reading material which at one time you could have understood?

- (LC-3)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

4. When you speak, are your words indistinct or improperly pronounced?

- (LC-4)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**Note:** If this happens, how often do people have difficulty understanding what words you are trying to say?

- (LC-5)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

5. How often do you have difficulty thinking of the names of things?
- (LC-6)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never
6. How often do you have difficulty thinking of the words (other than names) for what you want to say?
- (LC-7)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never
7. When you write things, how often do you have difficulty forming the letters correctly?
- (LC-8)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never
8. Do you have more difficulty spelling, or make more errors in spelling, than you used to?
- (LC-9)         almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

### SCALE III: USE OF HANDS

**Instructions:** Please answer these questions in the same way as the previous scales. Just put a check next to the response which most accurately describes the way you have been lately.

1. How often do you have difficulty performing tasks with your right hand (including such things as writing, dressing, carrying, lifting, sports, cooking, etc.)?
- (Hands-1)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

2. How often do you have difficulty performing tasks with your left hand?

(Hands-2)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**SCALE III (2): SENSORY-PERCEPTUAL**

1. How often do you have difficulty feeling things with your right hand?

(Percept-1)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

2. How often do you have difficulty feeling things with your left hand?

(Percept-2)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

3. Lately, do you have more difficulty than you used to in seeing all of what you are looking at, or all of what is in front of you (in other words, are some areas of your vision less clear or less direct than others)?

(Percept-3)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**SCALE IV: HIGHER LEVEL COGNITIVE AND INTELLECTUAL FUNCTIONS**

**Instructions:** Please answer these questions in the same way as the previous scales. Just put a check next to the response which most accurately describes the way you have been lately.

1. How often do your thoughts seem confused or illogical?

(CI-1)     almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

1473

2. How often do you become distracted from what you are doing or saying by insignificant things which at one time you would have been able to ignore?
- (CI-2)         almost always  
                  very often  
                  fairly often  
                  once in a while  
                  very infrequently  
                  almost never
3. How often do you become confused about (or make a mistake about) where you are?
- (CI-3)         almost always  
                  very often  
                  fairly often  
                  once in a while  
                  very infrequently  
                  almost never
4. How often do you have difficulty finding your way about?
- (CI-4)         almost always  
                  very often  
                  fairly often  
                  once in a while  
                  very infrequently  
                  almost never
5. Do you have more difficulty now than you used to in calculating or working with numbers (including managing finances, paying bills, etc.)?
- (CI-5)         almost always  
                  very often  
                  fairly often  
                  once in a while  
                  very infrequently  
                  almost never
6. Do you have more difficulty now than you used to in planning or organizing activities (i.e., deciding what to do and how it should be done)?
- (CI-6)         almost always  
                  very often  
                  fairly often  
                  once in a while  
                  very infrequently  
                  almost never

7. Do you have more difficulty now than you used to in solving problems that come up around the house, at your job, etc.? (In other words, when something new has to be accomplished, or some new difficulty comes up, do you have more trouble figuring out what should be done and how to do it?)

- (CI-7)         almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

8. Do you have more difficulty now than you used to in following directions to get somewhere?

- (CI-8)         almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

9. Do you have more difficulty now than you used to in following instructions concerning how to do things?

- (CI-9)         almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

SCALE V: WORK

1. Do you presently hold a job?

- yes -- full time
- yes -- part time
- no (if relative is a student, go on to "E" below; otherwise go on to item "H" below)

2. If you hold a job, please indicate what kind of job it is and briefly describe the duties as best you can:

---

---

---

---

---

3. If you hold a job, please indicate the approximate salary:

---

4. If you hold a job, how much supervision is being given to you now?

- close observation and supervision in almost everything you do
- there is a supervisor around you most of the time, but supervision is not really constant
- receive only occasional supervision while working on a job, though there may be more supervision when a new job is given or after a job is completed
- usually receive supervision only when being given a new job to do, or after a job has been completed
- function very much on your own at work
- is self employed

5. Are you currently a student?

- yes -- full time
- yes -- part time
- no

6. If you are a student, are you currently taking regular academic courses or special education courses?

- all special education courses
- mostly special education courses
- about an equal number of each type of course
- all regular academic courses

7. If you are taking regular academic courses, what is your approximate grade point average now in these courses only (i.e., leaving out grades in special education courses)?

- better than 3.7 (A)
- 3.0 to 3.7 (B to A- minus)
- 2.0 to 2.9 (C to B- minus)
- 1.0 to 1.9 (D to C- minus)
- less than 1.0 (F)

8. What are the main family or home-related duties which you are performing at this time (include such things as planning family activities, disciplining children, managing finances, cooking, lawn care, shopping, etc. -- also indicate whether you perform these duties alone or with help from others)?

---

---

---

**SCALE VI: RECREATION**

1. What leisure time activities do you engage in at this time (include such things as hobbies, sports, reading, TV, clubs, attending church, etc.)?

---

---

---

---

2. What kinds of material have you been reading lately (include examples of specific books or magazines -- if you do not read at all, just indicate that)?

---

---

3. What T.V. programs have you been watching lately (if you do not watch T.V., just indicate that)?

---

---

4. What kinds of music have you been listening to lately?

---

---

**SCALE VII: GENERAL**

1. What are the activities that you need help with at this time?

---

---

---

---

---

---

---

2. What are your major areas of difficulty at this time?

---

---

---

---

---

---

---

---

---

---

---

---

---

1479

Relatives Assessment of Patient Functioning Inventory  
Chelune, Heaton and Lehman

**SCALE I: MEMORY**

Instructions: Answer each of the questions by placing a check next to the response which most accurately describes your relative's recent behavior. As before, if you can think of any examples of the behavior described please write them on the back of the preceding page.

1. How often does your relative do or say something which indicates that he/she has forgotten something that has been told him/her within the last day or two?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

2. How often does your relative do or say something which indicates that he/she has forgotten something that was told him/her a year or more ago?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

3. How often does your relative do or say something which indicates that he/she has forgotten events which have occurred in the last day or two?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

4. How often does your relative do or say something which indicates that he/she has forgotten events which have occurred in the last day or two?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

5. How often does your relative do or say something which indicates that he/she has forgotten people whom he/she has met in the last day or two?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

6. How often does your relative do or say something which indicates that he/she has forgotten people whom he/she has met a year or more ago?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

Note: If this happens, is your relative aware of it?

- yes
- no
- I don't know

7. How often does your relative lose track of time, or do things either earlier or later than they are usually done or are supposed to be done?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

Note: If this happens, is your relative aware of it?

- yes
- no
- I don't know

8. How often does your relative fail to complete tasks he/she starts, apparently because he/she forgot that he/she was doing them? (Include such things as failing to put out cigarettes, turn off stove, etc.)

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

Note: If this happens, is your relative aware of it?

- yes
- no
- I don't know

9. How often does your relative fail to complete tasks that he/she starts, apparently because he/she has forgotten how to do one or more aspects of them? (Here it would be especially helpful if you could give examples of the kinds of tasks your relative seems to have forgotten how to do.)

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

10. How often does your relative lose things or have trouble remembering where they are?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

11. How often does your relative forget things that he/she is suppose to do or has agreed to do (such as putting gas in the car, paying bills, taking care of errands, etc.)?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

SCALE II: LANGUAGE AND COMMUNICATION

Instructions: In each item just place a check next to the response which most accurately describes your relative's recent behavior. Again, if you can provide examples of the behavior described, these will be much appreciated. You should use the back of the preceding page for writing in examples.

1. How often does your relative have difficulties understanding what is said to him/her (for example, he/she may show lack of understanding by looking puzzled or asking for things to be repeated or explained)?

- ( ) almost always  
 ( ) very often  
 ( ) fairly often  
 ( ) once in a while  
 ( ) very infrequently  
 ( ) almost never

Note: If this happens, is your relative aware of it?

- ( ) yes  
 ( ) no  
 ( ) I don't know

Also, if this happens, what specific kinds of spoken information does your relative have difficulty understanding? (i.e., long words versus short words; complicated sentences versus simple sentences; information about specific events, people or things versus information about ideas, opinions or concepts; etc.)

---

---

---

---

---

---

---

---

---

---

2. How often does your relative fail to respond at all when something is said to him/her?

almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

3. How often does your relative have difficulty reading (i.e., identifying written or printed words)?

almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**Note:** If this happens, is your relative aware of it?

yes  
 no  
 I don't know

If your relative does not try to read at all, please indicate the reason for this:

---

---

4. How often does your relative have difficulty understanding what he/she reads?

almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**Note:** If this happens, is your relative aware of it?

yes  
 no  
 I don't know

Also, if this happens, what specific kinds of reading material does your relative have difficulty understanding?

---

5. Is it easier to demonstrate or show things to your relative than it is to tell him/her about them?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

6. When your relative speaks, are his/her words indistinct or improperly pronounced?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

Also, if this happens, how often do you actually have difficulty understanding what words he/she is trying to say?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

7. How often does your relative have difficulty thinking of the names of things?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

8. How often does your relative have difficulty thinking of the words for what he/she wants to say (i.e., other than names)?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

9. When your relative writes things, how often does he/she have difficulty forming the letters correctly?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

Also, if this happens, how often do you actually have difficulty understanding the words he/she has tried to write?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

If your relative does not write at all now, please indicate the reason for this:

---

---

---

10. When your relative writes things, how often does he/she have difficulty spelling, or make errors in spelling?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

Also, if this happens, what specific kinds of words does he/she have difficulty spelling (are they long and complicated, short and simple, etc.)?

---

---

---

1488

**SCALE III: USE OF HANDS**

**Instructions:** Please answer these questions in the same way as in the previous sections. As before, we would like you to use the back of the preceding page to write in any examples you can think of.

1. How often does your relative have difficulties performing tasks with his/her right hand (including such things as writing, dressing, carrying, lifting, sports, cooking, etc.)

- almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**Note:** If this happens, is your relative aware of it?

- yes  
 no  
 I don't know

Also, if this happens, what specific tasks does your relative have difficulty performing with the right hand?

---

---

2. How often does your relative have difficulties performing tasks with his/her left hand?

- almost always  
 very often  
 fairly often  
 once in a while  
 very infrequently  
 almost never

**Note:** If this happens, is your relative aware of it?

- yes  
 no  
 I don't know

Also, if this happens, what specific tasks does your relative have difficulty performing with the left hand?

---

---

**SCALE IV: HIGHER LEVEL COGNITIVE AND INTELLECTUAL FUNCTIONS**

**Instructions:** Please answer these questions in the same way as in the previous sections. Don't forget to give any examples you can think of, because these are very important.

1. How often do your relative's thoughts seem illogical or confused?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

2. How often does your relative become distracted from what he/she is doing or saying by insignificant things which most people would ignore?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

3. How often does your relative become confused about (or be in error about) where he/she is?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

Also, if this happens, please specify whether it occurs more in some places than in others (and give examples):

---

---

---

4. How often does your relative have difficulty finding his/her way about?

- almost always
- very often
- fairly often
- once in a while
- very infrequently
- almost never

**Note:** If this happens, is your relative aware of it?

- yes
- no
- I don't know

Also, if this happens, please give examples of the kinds of places where it tends to occur:

---

---

---

5. To what extent does your relative have difficulty calculating or working with figures (including managing finances, paying bills, etc.)?

- extreme difficulty - cannot do even the simplest calculations
- considerable difficulty even with simplest calculations
- does fairly well with simple calculations, but has much trouble with complicated ones
- has no trouble with simple calculations, but has some difficulty with complicated ones
- only seldom has any difficulty with calculations (even complicated ones)
- almost never has the slightest difficulty with even the most complicated calculations

Note: If your relative does have trouble in this area, is he/she aware of it?

- yes
- no
- I don't know

6. To what extent does your relative have difficulty in planning or organizing activities (i.e., deciding what to do, and how it should be done) for himself/herself and others?

- extreme difficulty - cannot plan or organize even routine activities without help from others
- considerable difficulty even with routine activities
- does fairly well with routine activities, but requires much help with anything new or complicated
- only seldom has any difficulty deciding on his/her own what to do, when to do it, and how it should be done (even in relation to new or complicated activities)
- almost never has the slightest difficulty - is extremely competent at planning and organizing even the most complicated activities

Note: If your relative does have trouble in this area, is he/she aware of it?

- yes
- no
- I don't know

7. Rate your relative's ability to deal effectively with problem situations that come up around the house, at his/her job, etc. (In other words, when something new has to be accomplished, or some new difficulty comes up, how well is your relative able to figure out what should be done and how to do it on his/her own?)

- extreme difficulty - cannot handle even the simplest problem on his/her own
- has considerable difficulty even with simple problems
- does fairly well solving simple problems, but has much difficulty (needs much help) solving new or complicated ones
- has no trouble handling simple problems on his/her own, but does have some difficulty (needs some help) solving new or complicated problems
- only seldom has any difficulty solving problems on his/her own (even new or complicated ones)
- almost never has the slightest difficulty solving even the most complicated and new problems on his/her own

Note: If your relative has trouble in this area, is he/she aware of it?

- yes
- no
- I don't know

8. To what extent does your relative have difficulty following directions to get somewhere?

- extreme difficulty - cannot follow even the simplest directions
- has considerable difficulty following even the simplest directions
- does fairly well with simple directions, but has much difficulty with complicated ones
- has no trouble with simple directions, but has some difficulty following complicated ones
- only seldom has any difficulty following directions  
( ) even complicated ones
- almost never has the slightest difficulty following even the most complicated directions to get somewhere

**Note:** If your relative has trouble in this area, is he/she aware of it?

- yes
- no
- I don't know

9. To what extent does your relative have difficulty following instructions concerning how to do things?

- extreme difficulty - cannot follow even the simplest instructions to do anything
- considerable difficulty carrying out even simple instructions
- does fairly well with simple instructions, but has some difficulty carrying out complicated ones
- has no trouble with simple instructions, but has some difficulty carrying out complicated ones
- only seldom has any difficulty carrying out instructions concerning how to do things (even complicated instructions)
- almost never has the slightest difficulty carrying out even the most complicated instructions

**Note:** If your relative has trouble in this area, is he/she aware of it?

- yes
- no
- I don't know

10. Compared to the way your relative was before his/her accident or present illness, how "bright" would you say that he/she is now? (For example, considering how well he/she can carry on an intelligent conversation, how clever his/her sense of humor is, and so forth.)
- a great deal worse than before - in this respect he/she is not at all the same person
  - considerable worse now than before
  - worse now than before
  - only slightly worse now than before
  - seems to be as bright as ever
  - seems even brighter than before

**Note:** If your relative is not as bright now as he/she was before, is he/she aware of this?

- yes
- no
- I don't know

11. Please use this space to describe any difficulties your relative may be having in driving a car (if there are no difficulties, just say that, if he/she is not driving or cannot drive now please indicate the reason for this.
- 
- 
-

SCALE V: WORK

1. Is your relative presently holding a job?
  - yes -- full time
  - yes -- part time
  - no (if relative is a student, go on to "E" below; otherwise go on to item "H" below)
  
2. If your relative is holding a job, please indicate what kind of job it is and briefly describe the duties as best you can:  

---

---

---

---

---
  
3. If your relative is holding a job, please indicate the approximate salary (if you have no idea, just indicate that):  

---
  
4. If your relative is holding a job, how much supervision is being given to him/her now?
  - is closely observed and supervised in almost everything he/she does
  - there is a supervisor around him/her most of the time, but supervision is not really constant
  - receives only occasional supervision while working on a job, though there may be more supervision when a new job is given or after a job is completed
  - functions very much on his/her own at work
  - is self employed

5. Is your relative currently a student?

- yes -- full time
- yes -- part time
- no

6. If your relative is a student, is he/she currently taking regular academic courses or special education courses?

- all special education courses
- mostly special education courses
- about an equal number of each type of course
- all regular academic courses

7. If your relative is taking regular academic courses, what is his/her approximate grade point average now in these courses only (i.e., leaving out grades in special education courses)?

- better than 3.7 (A)
- 3.0 to 3.7 (B to A- minus)
- 2.0 to 2.9 (C to B- minus)
- 1.0 to 1.9 (D to C- minus)
- less than 1.0 (F)

8. What are the main family or home-related duties which your relative is performing at this time (include such things as planning family activities, disciplining children, managing finances, cooking, lawn care, shopping, etc. -- also indicate whether the relative performs these duties alone or with help from others)?

---

---

---

---

---

---

---

---

---

---

SCALE VI: RECREATION

1. What leisure time activities does your relative engage in at this time (include such things as hobbies, sports, reading, TV, clubs, attending church, etc.)?

---

---

---

---

---

---

---

---

2. What kinds of material is your relative reading lately (include examples of specific books or magazines -- if he/she does not read at all, just indicate that)?

---

---

---

3. What T.V. programs does your relative watch lately (if he/she does not watch T.V., just indicate that)?

---

---

---

4. What kinds of music does your relative listen to lately?

---

---

---

SCALE VII: GENERAL

1. What are the activities that your relative needs help with at this time?

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

2. What do you think are your relative's major areas of difficulty at this time?

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

---

## VOCATIONAL ASSESSMENT FORMAT

The categories below are used in gathering information relevant to rehabilitation of the psychiatrically disabled individual. Information in each of the categories is obtained as it relates specifically to issues in vocational/educational/social rehabilitation as part of the assessment process. These are guidelines only.

### 1. Psychological/Psychiatric

Diagnosis

Onset

Institutionalizations (frequency, duration; voluntary or involuntary)

Forensic evaluation (charges pending; legal obligations)

Self-description (feelings about self; self-statements; perceived strengths and weaknesses)

Medication (type and effects; degree of compliance)

Interpersonal skills (feelings regarding others; ability to get along; difficulties in relationships; one-to-one vs. group interaction)

Problem behaviors (frequency, duration, intensity, etc.)

Attitudes regarding therapy (previous exposure; motivation)

Problem identification (insight; objectivity; motivation)

Appearance (grooming and hygiene)

### 2. Medical

Disability

How and when disabled

Functional limitations (work activities possible; tolerance for work activities; patient concerns regarding limitations as related to work)

Medication (type and effects)

Current diagnosis (attending physician; currently being treated; release for work)

Prognosis

Financial coverage

### 3. Social and Environmental

Current activities (special interests, leisure activities; involvement in community affairs, social and recreational activities)

Living arrangement

Marriage and family (feelings about family, marital compatibility, family attitudes toward rehabilitation)

Child care

Geographic preference

Support systems (family, knowledge of community agencies)

Relevant early history (parental employment; guidance and discipline)

Economic conditions (sources of income, financial resources, dependants, financial obligations; DPA-SSI-SSDI-IC eligibility; insurance)

Transportation (own car, ability to use public transportation, proximity to public transportation)

### Educational

Elementary, High School, College (best/worst subjects; relationship with teachers, students; extracurricular activities; special achievements; toughest problems; how education financed; reasons for choosing major field)

G.E.D. (reasons for leaving school)

Specialized training, on-the-job training (what, when, where)

Recent courses (relationship to career goals; interest in future training)

### Vocational

Work history (includes: list of jobs; likes, dislikes; strengths, problems; interpersonal - supervisors and co-workers)

Military assignments (branch; type of duty; discharge)

Previous OVR exposure

Terminations (employer reasons; patient reactions)

Unemployment (periods; reasons for job changes)

Vocational goal (primary and secondary; related experience; necessary training or experience; necessary skills and licenses; salary expectations)

Job seeking skills (ability to explain/describe: 1. major assets; 2. vocational liabilities; 3. disability; 4. employment gaps; 5. patterns, methods and frequency of job search; 6. appearance and grooming; 7. financial resources)

### Testing

Intellectual, achievement, interest and aptitude tests are administered routinely, for example:

Wechsler Adult Intelligence Scale-Revised  
Wide Range Achievement Test-Revised  
Gates-MacGinitie Reading Comprehension Test  
Strong Campbell Interest Inventory  
Self-Directed Search, COPS, COPS-P

CAPS

## Assessment Instruments (Vocational Rehabilitation Test File)

The following is a <sup>partial</sup> list of instruments and tests utilized in the assessment process. The selection of particular evaluation instruments is dependent upon the nature of the patient's problem and the kinds of data needed in order to thoroughly assess needs, deficits, and strengths for any particular patient referral. In addition, neuropsychological, intellectual, and personality evaluation is available,

### Aptitude

Multidimensional Aptitude Test Battery  
Bennett Mechanical Comprehension Test  
Career Ability Placement Survey (CAPS)  
Differential Aptitude Test Battery (DAT)  
General Aptitude Test Battery (GATB)  
General Clerical Test  
Oral Directions Test (Industrial)  
Minnesota Clerical Test  
Revised Minnesota Paper Form Board  
SRA Pictorial Reasoning Test  
Computer Aptitude, Literacy, and Interest Profile (CALIP)  
General Clerical Test

### Achievement/Educational

College Qualification Test  
Industrial Reading Test  
Wide Range Achievement Test-Revised  
Stanford Achievement Test Series  
~~California Achievement Test~~  
Perceptual-Motor

Bender Gestalt Test  
Benton Visual Retention Test  
Crawford Small Parts Dexterity Test  
Memory for Design Test  
Minnesota Rate of Manipulation Test  
Purdue Pegboard  
Purdue Perceptual Motor Survey  
Lincoln Oseretsky Motor Development Scale  
Southern California Sensory Integration Tests  
Frostig Developmental Test of Visual Perception  
Woodcock, Fristoe and Goldman Test of Auditory Discrimination  
Jordan Left-Right Reversal Test  
*Plus many others*  
Interest

Nelson-Denny Reading Test

# PSYCHOMETRIC APPROACHES TO ASSESSMENT

The tests described and demonstrated in the videotape are listed below. The videotape used to supplement this training contains simulated demonstrations from actual psychological tests. The items, forms, and materials included are the property of the test authors and publishers and should not be duplicated. The test items should be treated as privileged information and not be discussed with non-professionals.

## Intelligence and Achievement Tests

WECHSLER ADULT INTELLIGENCE SCALE-REVISED (WAIS-R). The WAIS-R is an individually administered intelligence test consisting of 11 different subtests: 6 verbal subtests and 5 performance subtests. The WAIS-R usually takes 60 to 75 minutes to administer. Administration and scoring procedures are highly standardized, with detailed instruction provided in the test manual. The 11 WAIS-R subtests include: (Verbal) Information, Comprehension, Arithmetic, Vocabulary, Digit Span, and Similarities; (Performance) Picture Completion, Picture Arrangement, Block Design, Object Assembly, and Digit Symbol.

*David Wechsler*

PEABODY PICTURE VOCABULARY TEST (PPVT). This test is an individually administered, norm-referenced test of hearing vocabulary available in two parallel forms (L and M). Both forms are comprised of five sample items followed by 175 test items arranged in order of increasing difficulty. The subject's task is to select the picture considered to illustrate best the meaning of a stimulus word presented orally by the examiner.

*Lloyd Dunn & Leota Dunn*

WIDE RANGE ACHIEVEMENT TEST-REVISED (WRAT-R). The WRAT-R is a standardized measure of academic abilities. The test measures reading word recognition, written spelling, and arithmetic computation. The three subtests are easily administered and scored, usually in less than 30 minutes. The test yields three raw scores: one for each subtest, reflecting the total number of items completed correctly. Raw scores are converted into grade equivalents, percentiles, and standard scores, using the norm tables provided in the manual. Norms are available from age 5 years 5 months to age 64. Advantages of the WRAT include its ease of administration and scoring, its wide acceptance both in education and psychology, and its large normative sample.

*J. Jastak & S. Jastak*

PEABODY INDIVIDUAL ACHIEVEMENT TEST. A wide-range screening measure of achievement in the areas of mathematics, reading, spelling and general information. The battery is untimed but generally takes 40 minutes to administer. Scores are presented as grade and age equivalents, percentile ranks and standard scores.

*L. Dunn & F.C. Markwardt*

BEST COPY AVAILABLE

WOODCOCK-JOHNSON PSYCHOEDUCATIONAL BATTERY. A comprehensive measure of the cognitive ability and achievement of individuals ranging from preschool level to adult. The battery is composed of 27 subtests including Reasoning, Perceptual Speed, Mathematics and Written Language. Administration time is typically 2 to 2 1/2 hours.

*R. Woodcock & M. Johnson*

GATES-MACGINITIE READING TESTS. This test is a multiple-choice paper-and-pencil test used to assess basic reading skills. The test has a vocabulary section and a reading comprehension section in which the subject reads short paragraphs and answers written questions about the paragraphs. Both sections are timed, with 20 minutes allowed for the vocabulary section and 35 minutes for the reading comprehension section. The reading comprehension test is advantageous in that it appears to tap reading skills required in everyday usage.

*Walter H. MacGinitie*

GRAY ORAL READING TESTS-REVISED. From grades one to college level, the GORT-R has two forms (4 on 1967 GORT), with each form containing thirteen reading selections or passages. The tests are designed to assess oral reading and to aid in diagnosing reading difficulties.

*J.L. Wiederholt & B.R. Bryant*

WOODCOCK READING MASTERY TESTS. Composed of five individually administered reading tests for use from grades K to 12, measuring Letter Identification, Word Identification, Word Attack, Word Comprehension and Passage Comprehension.

*R. Woodcock*

MONROE-SHERMAN READING APTITUDE AND ACHIEVEMENT TESTS. Is a group of individually administered series of tests assessing paragraph understanding, spelling, word discrimination, and arithmetic computation. Scores are presented as grade equivalents.

*M. Monroe & E. Sherman*

## Personality Tests

MINNESOTA MULTIPHASIC PERSONALITY INVENTORY (MMPI). This 566-item true and false questionnaire has been a widely used clinical and research tool. Test results are presented as a profile of validity and clinical scales. Abbreviated versions of the MMPI are also available.

*Starke R. Hathaway & J. Charnley McKinley*

MILLON CLINICAL MULTIAXIAL INVENTORY (MCMI). The MCMI is an objective personality test. Subjects answer true/false questions; interpretations of the resultant profile focus on personality characteristics and psychopathology.

*Theodore Millon*

SIXTEEN PERSONALITY FACTOR QUESTIONNAIRE (16PF). This is a self report inventory assessing personality on sixteen dimensions or scales. A variety of test forms are available.

*Raymond Cattell*

THEMATIC APPERCEPTION TEST (TAT). The TAT consists of vague black and white pictures which the subject is asked to use to generate associated stories. The TAT is one of the most widely used story telling projective tests for adults.

*Henry A. Murray*

RORSCHACH TEST. The Rorschach test is probably the best known of the projective techniques. The subject is shown each ink blot one at a time and is asked to report what the blot reminds him of. A number of scoring systems are available based on major response variables such as number of responses, color and shading, and the verbatim content of the response.

*Hermann Rorschach*

## Neuropsychological Batteries

### HALSTEAD-REITAN NEUROPSYCHOLOGICAL TEST BATTERY

The Halstead-Reitan Neuropsychological Test Battery (HRNTB) consists of a number of individual tests which, when administered together, comprise a battery. The Halstead-Reitan measures large samples of behavior in a number of areas associated with brain function: motor, sensory, visual-spatial, language, memory, auditory-perceptual, and higher level conceptual abilities. Each test may measure a variety of functions which may not be clearly defined. For example, the Speech Sounds Perception Test is a measure of the ability to hear speech sounds and match sounds into their written equivalent, as well as attend for an extended period of time. Errors may result from deficits in any or all of these areas, thus a great deal of clinical judgment is required in the interpretation of results. The battery tends to be a "right hemisphere" oriented battery in that much of the focus is on nonlinguistic, visual-spatial, and sensory/kinesthetic tasks.

The battery was originally developed by Ward Halstead at the University of Chicago in 1935. Halstead began by attempting to develop a test battery to measure "biological intelligence." He performed extensive formal and informal studies on brain damaged individuals, culminating in the introduction of various tests able to measure brain dysfunction. Halstead's original battery consisted of 13 tests, designed to reflect brain impairment. Halstead also developed the Impairment Index, a method of detecting brain impairment by using a combination of psychological test results.

Ralph Reitan, a graduate student of Halstead, made additions and improvements to the battery, and performed studies which clearly documented the validity of the battery in the discrimination of brain damaged and normal individuals.

There are three forms of the Halstead-Reitan battery: the HRNTB for Adults (age 15 and above), the Halstead Neuropsychological Battery for Children (age 9-14), and the Reitan-Indiana Neuropsychological Test Battery for Children (age 5-8). Administration of the battery usually takes between five and eight hours with individual tests ranging from 10 minutes to one hour or more. It involves interactive testing between examiner and subject. The test is tiring and frustrating for subjects, particularly those with significant brain impairment. Because of the amount of time necessary and the sophisticated apparatus required, the Halstead-Reitan is a costly battery to administer.

The Halstead-Reitan Neuropsychological Test Battery is the most widely researched neuropsychological test battery; thus, extensive validity data is available on the identification, lateralization and localization of brain dysfunction. Numerous cross-validations have upheld Reitan's original validity studies. Reliability of the Halstead-Reitan has been less rigorously evaluated. In general, reliability appears good. Test-retest reliability of the individual tests ranges from .59 (TPT localization) to .87 (Trail Making Test, Part B).

This battery of tests includes the original neuropsychological tests developed by Ward Halstead and the modifications and additions of Ralph Reitan. The battery is comprised of the following tests.

CATEGORIES TEST. A test of abstracting ability. Stimulus figures, which vary in size, location, shape, number, color and intensity, and are grouped by abstract principles, are projected on a screen. The task of the subject is to figure out the principle relating stimulus subtests and signal the answer by pressing the appropriate key on a board. The test is an excellent discriminator between brain damaged and neurologically intact groups. The test measures the ability to sustain attention, remember past performance, evaluate past performance and learn from feedback, concentrate, analyze visually presented material, understand spatial relationships, and demonstrate cognitive flexibility in handling a complex, changing problem.

TACTUAL PERFORMANCE TEST. The Tactual Performance Test (TPT) uses a modification of the Seguin-Goddard form board. The subject is blindfolded and is not permitted to see the stimulus material. The task is to fit blocks into the proper spaces on the board using first the preferred hand, then the nonpreferred hand, then both hands. Times are recorded for each trial and also for the total time required for all three trials. The stimulus materials are then put away and the blindfold is removed. The subject is then asked to draw a diagram of the board representing the blocks in their proper spaces. The drawing is based upon the number of blocks correctly reproduced (Memory) and the number correctly placed (Localization). The test requires the ability to recognize forms tactually, perform coordinated movements of the hands and arms, perceive their own movement in space without visual cues, and plan and solve nonverbal kinesthetic problems. Performance of the right and left sides of the body is evaluated on the TPT. The Memory and Localization components require both spatial and incidental memory. The test is sensitive to brain damage and is more likely to discriminate schizophrenics from organics than the Categories test. The Localization score is particularly sensitive to organicity and tends to be much less affected by schizophrenia than other measures with similar levels of sensitivity.

**RHYTHM TEST.** The Rhythm Test is a subtest of the Seashore Test of Musical Talent. The subject must discriminate between 30 pairs of rhythmic beats which are sometimes the same and sometimes different. The task measures alertness to nonverbal auditory stimuli, sustained attention to the task, and the ability to perceive and compare different rhythmic sequences. Because of the attentional component, the Rhythm test is not felt to be an effective discriminator between functional psychiatric disorders and organicity.

**SPEECH SOUNDS PERCEPTION TEST.** The Speech Sounds test consists of 60 spoken nonsense syllables, the beginning and ending consonant sounds of which vary while their "ee" vowel sound remains constant. The subject must underline the spoken syllable, selecting from four alternatives printed on the test form. The test requires attention, auditory perception of verbal material, and the ability to match phonemes with their written equivalents (graphemes).

**FINGER OSCILLATION TEST.** Finger tapping is a measure of fine motor speed which uses a mounted tapper equipped with a counter. The subject is administered several consecutive trials to each hand until attaining a criteria of five trials within a five-point range of each other. The score for the dominant hand and the nondominant hand is the average of the five trials. Fine motor speed, coordination and left-right body comparisons are assessed. Because of the focus on basic (versus complex) neuropsychological functions, schizophrenics are less likely to show impairment similar to that found in organics.

**TRAIL MAKING TEST.** This test consists of two parts, Trails A and Trails B. Trails A consists of 25 circles distributed randomly over a sheet of paper and numbered from 1 to 25. The subject is required to connect the circles with a pencil line in ascending numerical order. Part B also consists of 25 circles, these numbered from 1 to 13 and lettered from A to L. The task is to connect the circles in sequence, alternating between numbers and letters. The scores obtained are the time taken to complete each task and the number of errors. The test measures visual-motor tracking skills, counting ability, spatial skills, sequential and planning ability, cognitive flexibility in shifting between letter and number sets, and the ability to handle verbal material. The test, Trails B in particular, is a sensitive indicator of brain dysfunction. The test is particularly difficult for schizophrenics because of hypothesized motivational difficulties (they fail to complete the test). In a study using the Trail Making Test with a psychiatric population, when motivational and emotional factors were qualified, the discriminative ability to the test was enhanced.

**STRENGTH OF GRIP TEST.** A plunger type dynamometer with a grip adjustable for hand size is used to measure strength. Trials alternating between the dominant and nondominant hand are administered with the score being the average between two trials for each hand. The test measures grip strength as well as providing a comparison of the right and left sides of the body.

**LATERAL DOMINANCE EXAMINATION.** The subject is required to perform a number of tasks with their hands and feet in order to determine preference regarding handedness and footedness. Items include such tasks as name writing, pretended throwing movements and pretended kicking. This test is

given relatively early in the battery in order to determine the order of administration of dominant-nondominant subtests on subsequent tests in the battery.

SENSORY-PERCEPTUAL EXAMINATION. This test measures tactile, auditory, and visual perceptual abilities. The procedures require the subject to perceive unilaterally presented stimuli on each side of the body. Next, stimuli are presented in a bilateral, simultaneous manner to determine the subject's ability to perceive both stimuli. Tactile, visual, and auditory sensitivity are measured, as well as left-right comparisons.

TACTILE FINGER LOCALIZATION. Light tactile stimuli (finger touch) are presented to each finger of the dominant and nondominant hand while the subject's eyes are closed. The subject identifies which finger is touched, using a predetermined numbering system. Each finger on each hand is touched four times and the number of errors are recorded. Tactile perception and right-left comparisons are measured.

FINGERTIP NUMBER WRITING PERCEPTION. The numbers 3,4,5, or 6 are traced on the subject's fingertips. With eyes closed, the subject must identify the numbers presented four times to each hand in a predetermined order. The score is the number of errors. The test provides a measure of graphesthesia and left-right comparisons.

TACTILE FORM RECOGNITION. The subject places one hand through a hole in a board and a plastic chip in one of four forms (circle, cross, square, or triangle) is placed on their fingertips. Without seeing the chip, the subject must point to the corresponding chip displayed on the board. Each of the four chips are presented twice to each hand. The score is the total errors and response time for each hand. The test measures stereognostic abilities and left-right comparisons.

MODIFIED HALSTEAD-WEPMAN APHASIA SCREENING TEST. This procedure provides a measure of several aspects of language ability and usage, including the ability to name common objects, spell, read, identify numbers and letters, write, do arithmetic calculations, articulate, identify body parts, perform pretended movements, understand the meaning of spoken language, follow directions, and differentiate left from right. It also tests visual constructional abilities (drawing) and provides samples of the subject's attempts at reproducing the spatial configuration of several forms.

In addition to the above noted tests, the Wechsler Adult Intelligence Scale-Revised (WAIS-R) and the Wide Range Achievement Test-R (WRAT-R) are administered as part of the Halstead-Reitan Neuropsychological Test Battery.

#### INTERPRETATION OF THE HALSTEAD-REITAN NEUROPSYCHOLOGICAL TEST BATTERY

Results of the Halstead-Reitan Neuropsychological Test Battery are interpreted on a number of levels. The most basic level is to determine whether each single test score falls within a normal or impaired range. This is done through comparison with single cut-off criterion scores established by Reitan. In addition to interpretation of single tests, the Impairment Index, originally designed by Halstead, reflects overall performance on the battery of

tests. The Impairment Index is calculated as the number of tests falling within the impaired range divided by the total number of tests. For the Halsted-Reitan Neuropsychological Test Battery, these seven tests are used in the calculation of the Impairment Index: The Rhythm Test, Speech Sounds Perception Test, dominant hand Finger Oscillation, Category Test, Tactual Performance Test total time, Memory, and Location. The minimum Impairment Index score reflecting no impairment, is 0.0--none of the tests within an impaired range. A maximum score of 1.0 on the Impairment Index indicated that all scores are within the brain damaged range. Reitan suggests that Impairment Index scores above 0.45 are considered indicative of brain damage.

Another method of interpretation of raw Halstead-Reitan scores was introduced by Russell, Neuringer, and Goldstein in 1970. Instead of using a single cut-off score, this system rates each test on a six-point scale (0 - 5). In addition to providing a uniform coding system, the Russell et al. classification adds to Reitan's method of scoring results in that this system allows for severity of impairment rather than tallying the number of tests within the impaired range. Ratings range from 0 (above average) and 1 (no impairment) to 5 (very severe impairment). Ratings of 2, 3, and 4 reflect mild, moderate, and severely impaired levels of performance. Ratings of 2 or more are equivalent to being past the cut-off score for presence of brain dysfunction as established by Reitan's initial validation study.

An Average Impairment Rating is also calculated in the Russell, Neuringer, and Goldstein system. It represents the average of individual test ratings. An Average Impairment Rating of above 1.65 is considered to be indication of the presence of brain dysfunction. To illustrate the advantages of the Russell et al. system, consider two individual subjects obtaining a Halstead Impairment Index of 1.0. Both fall at the maximum level of brain dysfunction possible using the Reitan Impairment Index. However, when converting these same raw scores using the Russell et al. system, it would be possible for the Average Impairment Index to reflect significant performance differences; for example, 2.0 in one subject and 4.5 in another. While the interpretation for the first subject is one of mild, generalized impairment (all scores within a mildly impaired range), subject 2's performance reflects severe, global impairment of brain functions. Thus, this alternative scoring system is able to incorporate broader images of performance, both for clinical and research purposes.

## STRENGTHS AND WEAKNESSES OF THE HALSTEAD-REITAN NEUROPSYCHOLOGICAL TEST BATTERY

Advantages of the HRNTB include its ability to measure a wide variety of brain functions in a highly standardized fashion. The Halstead-Reitan is the most widely researched neuropsychological test battery, thus extensive validation is available. The battery provides for the collection of research data which is objective and standardized. Finally, interpretation and inferences drawn from the Halstead-Reitan allow for the identification of test patterns and relationships, empirically typed to the many variants of brain dysfunction.

The major disadvantage of the Halstead-Reitan Neuropsychological Test Battery is its cost, both in terms of its time of administration and cost of administration and material. Time of administration for the entire battery is

approximately six hours, which presents a significant limitation when testing impaired patients. Cost of materials for the Halstead-Reitan exceeds \$1,300 and the average cost of a single administration of the battery ranges between \$200 and \$500.

Other disadvantages include the dependence on motor skills and the failure of the battery to address significant areas of possible neuropsychological deficit, including memory functions and language skills. A final weakness is its failure to effectively discriminate between schizophrenic and brain damaged populations.

*Excerpted from M. McCue, Assessment services in psychiatric rehabilitation. In L. Katz & M. McCue (Eds.), Psychiatric rehabilitation: A handbook for practitioners. St. Louis: Warren Green, (in press).*

### THE LURIA-NEBRASKA NEUROPSYCHOLOGICAL BATTERY

The Luria-Nebraska Neuropsychological Battery (LNNB) is a test battery which is composed of 269 individual items based upon the neuropsychological test procedures developed by the Russian psychologist, A.R. Luria. In his extensive study of the functions of the brain, Luria developed procedures which he reported could localize disorders of the brain and, because of the specificity of his test items, could contribute valuable information to the planning of rehabilitation treatment. Luria's approach is termed a "qualitative" approach to neuropsychological examination in that the procedure is guided by clinical insight into a particular patient's performance. Tests are administered in a flexible fashion, focusing upon areas of deficit and bypassing areas judged to be intact. Clinical interpretation, rather than comparison with standard normative information, was used by Luria to infer the presence of brain damage and to make specific recommendations for treatment. While Luria was quite effective in using this approach to neuropsychological evaluation, several limitations arise in applying Luria's tests in the United States. The lack of any standardized manner for test administration, standardized materials, normative data for interpretative comparison, or data on the reliability and validity of procedures present significant obstacles to the use of these procedures.

Acknowledging the potential value of Luria's tests in the diagnosis and treatment of brain disorders, Golden and his colleagues undertook a standardization of these tests, which were originally translated from Russian into English by Anne-Lise Christiensen. Golden developed standardized administration procedures and materials for Luria's tests, as well as scoring procedures to allow for quantitative analysis of results and comparisons with normative populations. Original validity studies suggested that the comprehensive Luria-Nebraska Neuropsychological Battery could validly discriminate between persons with and without brain damage.

At the current time, only one form of the Luria-Nebraska Neuropsychological Battery is available, for individuals ages 15 and up although Golden states that the battery has been used effectively with individuals as young as age 12. A version of the LNNB for children and a second version of the adult tests (LNNB Form II) are currently available.

The Luria-Nebraska Neuropsychological Battery is made up of 269 different items, most of which differ in some aspect from other items in the battery. The items make up 52 separate but not totally independent scales: 14 clinical scales, 8 localization scales, and 30 factor scales.

Test items are of varying complexity and degree of difficulty but, in general, each requires only a very short, limited response. Items also vary as to the mode of stimulus input and response output. For example, items might be presented to subjects orally, by written verbal directives, by visually presented designs, or tactually. Subjects also respond by different means including aurally, motorically, or by writing. Some tasks are speeded while others have no time limits.

The 269 items are divided into 11 clinical scales, derived from Luria's basic classification of his own items into broad categories. Each scale represents a complex area of neuropsychological functioning, including motor, rhythm, tactile, visual, receptive speech, expressive speech, writing, reading, arithmetic, memory, and intellectual functions. The following is a more detailed description of the LNNB scales.

MOTOR FUNCTIONS. This scale investigates a number of simple and complex motor functions. The first 4 items deal with simple, rapid movements of the fingers and hands. These tasks are timed and performed with both the left and right hands. The next set of items (4) deals with the ability to use tactile feedback to guide motor activity. The subject's hands and fingers are placed in certain positions while blindfolded. The subject must duplicate the position generated by the examiner. The next group of items (9-20) requires the subject to copy movements modeled by the examiner without verbal directives. Items 21 to 24 involve speeded, coordinated movements of both hands. Items 25 to 27 require the subject to pretend to carry out common, everyday activities, such as pouring and stirring a cup of tea. The next series of 8 items focuses on oral motor skills and included simple movements of the mouth and tongue, pretended movement, and coordination of oral movements, under speed conditions. Items 36 to 48 involve speed and accuracy in drawing common geometric figures (circle, square, triangle) from verbal and visual cues. The final 4 motor items require the subject to carry out various motor activities from spoken commands (e.g., "If I say red, squeeze my hand. If I say green, do nothing").

RHYTHM SCALE. Items on this scale address the ability to perceive and discriminate pitch, musical melodies, and reproduce tone, rhythm, and melody. All items except 2 require the subject to listen to recorded stimulus material from a cassette tape recorder. The first 3 items require the subject to discriminate between either two tones or two melodies, determining if they are the same or different. Items 55 to 57 require the subject to hum tones or sing lines from songs. The next set of items requires the subject to listen and count beeps played from the tape. The final 2 items require the subject to reproduce musical melodies by tapping rhythms with the hands.

TACTILE SCALE. This scale is administered while the subject is blindfolded. The subject is required to discriminate locus of touch on both hands, discriminate between sharp and dull touches and hard and soft touches, discriminate between one and two point stimulation at various widths,

perceive designs, letters and numbers traced on the wrists, and reproduce standard arm positions placed by the examiner. The final items, number 32 to 85, involve stereognosis or the ability to tell by touch the name of four common objects placed in the hands. These final items are also timed.

VISUAL (SPATIAL) SCALE. This scale focuses upon visual perception, spatial orientation, and higher level spatially based problem solving. Items 86 to 91 require the subject to identify items in pictures which vary in complexity and clarity. Items 92 and 93 require analysis of complex visual patterns similar to the Raven's Progressive Matrices under time constraints. Items 94 to 96 involve the reading and drawing of clocks and the ability to detect direction using a compass. Items 97 to 99 involve higher level spatial reasoning and visualization skills. The subject is required to count the number of blocks in various three dimensional block sketches, and mentally rotate geometric figures in order to match them with similar figures, both under speeded conditions.

RECEPTIVE SPEECH. This scale addresses the subject's ability to understand the speech of others. Items 100 to 107 involve the ability to hear and reproduce speech sounds spoken by the examiner, either by speaking or writing the sound, and the ability to discriminate between similar speech sounds. Items 108 to 116 require comprehension of words and commands which vary in complexity (e.g., one-step commands, five-step commands) and in response modality (e.g., pointing to body parts, orally defining words). Items 117 to 132 focus on more complex aspects of language comprehension, including understanding conflicting instructions ("If it is day now, point to the black card, and if it is night now, point to the gray card"), and understanding logical grammatical structures ("Will you tell me whether the 'father's brother' and the 'brother's father' are two persons or the same person?"). These items are administered under speeded conditions.

EXPRESSIVE SPEECH. The Expressive Speech scale examines the subject's ability to use language to effectively express thoughts and ideas. The first 21 items (numbers 133 to 153) require the subject to articulate speech sounds and words from a spoken model or from a written stimulus. Items 154 to 156 require repetition of sentences. Naming and word finding abilities are tapped in Items 157 to 159. Fluency and automatization of speech are assessed in Items 160 to 163 (e.g., counting to 20, saying the days of the week backward). The ability to generate speech about various topics is addressed in Items 164 to 169. The ability to use complex rules of grammar in verbal expression is evaluated in Items 170 to 174.

WRITING. The Writing scale evaluates both motor writing and spelling tasks. Items 177-185 assess motor writing ability, copying, and spelling skills. Items 175 and 176 address phonetic skills and simple spelling skills, from a simple to moderately complex level (e.g., spelling "physiology"). Items 186 - 187 evaluate the subject's ability to write their ideas in a fashion that is grammatically accurate, with proper spelling and logical content.

READING. The Reading scale also assesses phonetic skills (Items 188-189), requiring the subject to describe sounds and words spelled out by the examiner (e.g., "What word is made by the letters 'k-n-i-g-h-t'"). Items 190 to 198 tap reading skills from the identification of letters to the oral reading of unfamiliar words (e.g., "astrocytoma"). Items 199-200 require the subject to read a brief paragraph orally, which is scored for both accuracy and speed.

**ARITHMETIC.** This scale assesses the fundamental aspects of mathematics, including basic number concept, number reading, and number writing (Items 201 to 211) and the ability to solve simple arithmetic problems mentally and on paper (Items 212 to 217). Items 218 to 220 tap understanding of arithmetic operations and signs, and simple algebraic operations. The final 2 items assess the ability to perform serial subtractions under time constraints (Items 221, 222).

**MEMORY.** The Memory scale assesses different aspects of immediate recall and learning ability. Items 223 to 225 require the subject to learn and repeat a series of seven words spoken at a one-per-second pace by the examiner. The task allows up to five presentations of the word list and requires two consecutive correct trials to reach criterion. Item 226 involves the ability to recognize a complex visual stimulus presented on a card for 5 seconds after a 30 second delay. Item 227 requires the subject to draw five geometric designs presented visually for 7 seconds after the visual stimulus is withdrawn. Items 228 to 230 require the recall of rhythmic patterns tapped on the tabletop, hand positions modeled by the examiner, and the repetition of five words presented on a card after a five-second exposure. Items 231 to 233 require word and sentence learning under conditions of interference, and Item 234 taps the ability to recall pertinent facts from an orally presented story. The final Memory scale, item (#236) assesses the ability to form and recall associations between words spoken by the examiner and pictures presented simultaneously to the subject.

**INTELLECTUAL PROCESSES SCALE.** This scale provides a brief assessment of intellectual and conceptual functions with items similar to those found in more extensive intelligence tests. Items 236 and 237 require the subject to verbally explain the activities presented in pictures. Items 238 to 240 are picture arrangement tasks similar to those found on the WAIS, requiring the sequential logical ordering of picture series under time constraints. Items 242 and 243 assess the subject's ability to interpret abstract humor from cartoon drawings. Item 244 to 248 parallel the first 8 items, but are presented aurally rather than pictorially (e.g., "What is meant by the saying 'Don't count your chickens before they have hatched?'"). Items 249 and 250 assess similarities and differences between objects, and Items 251 and 254 assess the ability to comprehend logical relationships (e.g., "If we start with the part 'wall' then the whole will be 'house'. What will the whole be if the parts are 'pages?'"). Items 255 to 257 assess concepts including opposites and analogies. The final 12 items (258 to 269) assess the ability of the subject to perform mental arithmetic word problems under speeded conditions.

In addition to the 11 clinical scales, a pathognomonic scale, and right and left hemisphere sensorimotor scales, made up of items contained in other scales, are included. Scores on 8 empirically derived localization scales (left and right frontal, sensorimotor, parietal-occipital, and temporal lobe scales), and 30 factor scales which allow for more detailed analysis of functions within broad neuropsychological categories are also obtained. Following is a list of the LNNB factor scales.

- M1 Kinesthetic-based Movements
- M2 Drawing Speed
- M3 Fine Motor Speed
- M4 Spatial-based Movement
- M5 Oral Motor Skills
- Rh1 Rhythm and Pitch Perception
- T1 Simple Tactile Sensation
- T2 Stereognosis
- V1 Visual Acuity and Naming
- V2 Visual-Spatial Organization
- Rc1 Phonemic Discrimination
- Rc2 Using Relational Concepts
- Rc3 Concept Recognition
- Rc4 Verbal-Spatial Relationships
- Rc5 Word Comprehension
- Rc6 Logical Grammatical Relations
- E1 Simple Phonetic Reading
- E2 Word Repetition
- E3 Reading Polysyllabic Words
- Rg1 Reading Complex Material
- Rg2 Reading Simple Material
- W1 Spelling
- W2 Motor Writing Skills
- A1 Arithmetic Calculations
- A2 Number Reading
- Me1 Verbal Memory
- Me2 Visual And Complex Memory
- I1 General Verbal Intelligence
- I2 Complex Verbal Arithmetic
- I3 Simple Verbal Arithmetic

## INTERPRETATION

Responses to the LNNB items are converted to a three-point scoring system from "0" reflecting no impairment to "2" reflecting performance which is within a brain-damaged range. Raw scores are converted to T scores with a mean of 50 and a standard deviation of 10. An age and education corrected "critical level" is computed to account for the effects of these factors on test performance. Brain-damaged performance is inferred if scores exceed the subject's critical level. Figure 1 displays a profile of LNNB clinical scores with the "critical level" adjusted for age and education.

The LNNB takes roughly two and one-half hours to administer. The test is amenable to rest breaks, which is particularly important because of potential difficulties in testing psychiatrically disabled subjects.

The test construction and procedures of the LNNB are particularly relevant to assessment of the psychiatrically disabled. Unlike other battery approaches such as the Halstead-Reitan, the LNNB was designed to eliminate as much as possible the effects of psychiatric symptoms, such as anxiety and depression by adopting items that combine demands on motor speed with scoring for accuracy of performance. The use of short, independent items (no task takes longer than two minutes to complete) rather than longer subtests,

serves to minimize the negative effects of attention and concentration deficits, common in patients with psychiatric disorders, upon overall performance. Administration was designed to allow patients to perform at their maximum level by providing frequent breaks when necessary and by allowing the examiner to inform the patient when their test approach is counterproductive to their best score.

*Excerpted from M. McCue, Assessment service in psychiatric rehabilitation. In L. Katz & M. McCue (Eds.), Psychiatric rehabilitation: A handbook for practitioners. St. Louis: Warren Green (in press).*

## Attention Tests

PERCEPTUAL SPEED. This cancellation task differs from others in that the target shifts with each line. The test consists of two pages of 25 rows of 30 randomized digits. The first digit in a line is the target digit. The PS measures both speed of visual tracking and ability to shift attention.  
*L.J. Moran & R.B. Mefferd, Jr.*

PACED AUDITORY SERIAL ADDITION TEST (PASAT). This test simply requires that the subject add 60 pairs of randomized digits so that each is added to the digit immediately preceding it. The digits are presented at four rates of speed (ranging from 1.2 seconds to 2.4 seconds).  
*D.M.A. Gronwall*

THE STROOP COLOR-WORD TEST. This is a measure of concentration and mental control which requires the subject to label colors of print which spell out conflicting names of colors. Raw scores are obtained for 45-second preliminary reading and naming trials, and for 45-second interference trial. An interference score is also calculated.  
*Charles Golden*

MATCHING FAMILIAR FIGURES TEST (MFFT). The test is essentially a measure of impulsivity. Subjects are required to select the two matching figures from a series of six figures. Quick response times suggest impulsivity and inattention to detail.  
*J. Kagan, B. Rosman, et al.*

DIVIDED ATTENTION. This task requires a subject to attend to two different response sets simultaneously (for example remembering a numerical series while identifying each digit as even or odd). Mental flexibility and auditory attention are assessed.  
*D. Wechsler*

CONTINUOUS PERFORMANCE TEST (CPT). This task measures the capacity to sustain attention or concentration. Letters are randomly presented on a micro-computer monitor at the rate of one every two seconds. Whenever a target stimulus appears after a designated stimulus (e.g., "X" following a "T"), the subject must depress the computer keyboard space bar as quickly as possible. The task is given under two different conditions: a) nondistracting, and b) distracting. In the nondistracting condition, the subject responds only to the stimuli ("X" following a "T"). In the

distractor condition the subject must ignore randomly interspersed auditory tones of varying duration and frequency generated from the computer. This latter task is particularly useful for clarifying if there is a susceptibility to distraction in individuals as is suggested from the available evidence. Each part takes 15 minutes.

*Adapted by R. Tarter, et. al. from the work of J. Rosvold, A. Mirsky, et. al.*

## Memory Tests

RIVERMEAD BEHAVIOURAL MEMORY TEST. This test was developed to detect impairment in everyday memory functioning and has been used to monitor change following treatment for memory difficulties. The items involve either remembering to carry out some everyday task or retaining the type of information needed for adequate everyday functioning (e.g., remembering a name, appointment, face). These items are combined with conventional memory measures such as digit span, logical memory and paired associate learning. Four versions of the RBMT are available to reduce the practice effects of repeated testing.

*Barbara Wilson, Janet Cockburn, Alan Baddeley*

THE WECHSLER MEMORY SCALE. Is used to assess immediate and delayed (intermediate) recall of verbal material presented aurally in story form (Logical Memory), related and unrelated word pairs presented aurally (Paired Associational Learning), and recall and reproduction (drawing) of geometric figures presented visually. Delayed recall (30 minutes) may also be administered consistent with procedures developed by Russell (1975).

*David Wechsler & C.P. Stone*

CALIFORNIA VERBAL LEARNING TEST (CVLT). This memory test assesses recall of word lists under a variety of conditions including free recall, interference, categorical cues and delayed recall

*D. Delis, J. Kramer, et al.*

## Language Tests

BOSTON DIAGNOSTIC APHASIA TEST (BDAE): NAMING AND FLUENCY TASKS. These tasks require the subject to name various items from visual and verbal cues, repeat phrases, and generate words from specified categorical areas such as words beginning with a designated letter or kinds of animals. The tests are taken from the Boston Diagnostic Aphasia Examination (Goodglass & Kaplan, 1983).

*Harold Goodglass*

TOKEN TEST. The Token Test involves presenting a display of colored tokens of various colors and shapes and asking the subject to follow instructions for manipulating the tokens (e.g., "Put the red circle on the green square"). The test is a measure of attention and comprehension of spoken language.

*F. Boller & L.A. Vignolo*

## Visual Perceptual Tests

COMPLEX FIGURE TEST (CFT). The CFT (Osterrieth, 1944) is a complex drawing task in which the subject is required to copy a figure consisting of 18 scoreable components. The test is untimed but time to complete is recorded. Data are available on normal adult performance. Each of 18 components are scored from 2 (correct and properly placed) to 0 (absent or not recognizable). A maximum of 36 points is attainable. The procedure usually takes less than 10 minutes to administer.

*A. Rey & P.A. Osterrieth*

JUDGMENT OF LINE ORIENTATION. This test examines the ability to estimate angular relationships between line segments by visually matching angled line pairs in 11 numbered radii forming a semi-circle. Two forms of the test are available.

*Arthur Benton & Colleagues*

TEST OF FACIAL RECOGNITION. This test was developed to examine the ability to recognize faces without involving a memory component. The subject matches identical front views, front with side views and front views taken under different lighting conditions. Administration time ranges from 10-20 minutes depending on subject's response rate and cautiousness in making choices.

*Arthur Benton & Colleagues*

VISUAL FORM DISCRIMINATION. This test examines the ability to match complex geometric patterns. Subject responses are scored as correct, peripheral error, major rotation or a major distortion.

*Arthur Benton & Colleagues*

HOOPER VISUAL ORGANIZATION TEST. This is a test requiring conceptual reorganization of disarranged pieces. This test is comprised of thirty pictures of more or less readily recognizable cut-up objects. The subject is asked to name each object verbally or by writing the name of the object on the test booklet.

*H. Elston Hooper*

## Problem Solving Tests

SYMBOL DIGIT MODALITIES TEST. A substitution task in which the subject must fill in as rapidly as possible numbers for geometric symbols in conformity with a code provided. Although similar to the WAIS Digit Symbol subtest, it is normed for brain damaged and non-brain damaged patients and involves substitution of numbers for symbols rather than the reverse. This test may also be given orally by having a subject call out the numbers.

*Aaron Smith*

PORTEUS MAZES. The maze tracing task was designed to yield data about the highest levels of mental functioning involving planning and foresight. There are three sets of the Porteus Maze Test to compensate for practice effects in retesting. To achieve a successful trial, the subject must trace the maze without entering any blind alleys.

*S.D. Porteus*

WISCONSIN CARD SORTING TEST (WCST). The WCST is a test devised to study abstract thinking and the ability to shift mental sets. The subject is given a pack of 64 cards on which are printed one of four symbols, triangle, star, cross, or circle, in red, green, yellow, or blue. No two cards are identical. The subject's task is to place them one by one under four stimulus cards - one red triangle, two green stars, three yellow crosses, and four blue circles - according to a principle that the subject must determine from the pattern of the examiner's response to the placement of the cards. The examiner shifts between principles based upon concepts of form, color, and number. Scoring is the number of correct categories achieved by using a pack of 128 cards. The number of perseverative responses may also be scored. This score is useful in documenting problems in forming concepts, profiting from correction, and conceptual flexibility.

*David A. Grant & Esta A. Berg*

## Summary of Test Score Characteristics

Score	Description	Example	Limitations
Raw Score	The number of questions answered correctly.	A raw score of 40 means that the student answered 40 of the test questions correctly.	Raw scores are meaningful only within the context of a test's length and difficulty. Raw scores for one test or subtest should not be compared with those for another test or subtest.
PR (Percentile Rank)	Indicates where a raw score fits within the range of scores obtained by the national norming group. Tells the percentage of students in the same grade in the norming group whose raw scores were lower.	A PR of 60 means that the student's raw score was higher than that of 60% of the students in the same grade in the norming group.	PRs should not be averaged directly; a group PR can be obtained by averaging ESSs and finding the PR that corresponds to the average ESS. Should not be used to compare scores.
NCE (Normal Curve Equivalent)	A statistical (normalized) transformation of PRs in which the range of reading achievement is divided into 99 equal units with a mean of 50 and a standard deviation of 21.06.*	An NCE of 60 means the raw score is about one-half standard deviation above average. (It corresponds to a PR of 68.)	
Stanine	A statistical (normalized) transformation of PRs in which the range of reading achievement is divided into 9 equal units with a mean of 5 and a standard deviation of 2.*	A stanine of 6 means that the raw score is above average. (It corresponds to the group of PRs that range from 61-76.)	Each stanine provides only a broad measure of achievement. Stanines are more useful for individual than for group scores.
ESS (Extended Scale Score)	An equal-unit scale extending from the lowest achievement in Grade 1 to the highest achievement in Grade 12. Developed so that progress in reading can be followed over a period of years.	ESSs have no direct normative meaning. One can learn, from the norms tables, the ESSs that are characteristic of the grade level of the students being tested.	An unfamiliar scale. Vocabulary, Comprehension, and Total ESSs are not comparable.
GE (Grade Equivalent)	Tells the grade level for which the score would have been the median score, if the test had been given at that grade level. Scores range from 1.0 to 12.9. Scores below Grade 1 are labeled K (Kindergarten); scores above Grade 12 are labeled PHS (Post High School).	A GE of 6.0 means that the student's score is about the same as would be expected of an average student in September of Grade 6, if that student had taken the same test.	Less meaningful when GEs are not within the intended grade ranges of the test level taken, the next lower level, and the next higher level. GEs should not be averaged directly; a group GE can be obtained by averaging ESSs and finding the GE that corresponds to the average ESS. Should not be used to compare scores.

\*The lowest and highest NCE and stanine units are larger than the others, since they include all extreme scores at the ends of the scales.

# Types of Test Scores

## Raw Scores

The raw score is the number of questions answered correctly. In itself, a raw score for a test does not tell much about a student's reading achievement; its meaning lies in the other scores that can be derived from it by using the tables of norms. To say that June got a raw score of 37 is to say very little about how well June did. This is because the meaning of the raw score, the level of achievement that it represents, depends on how long, and how hard, the test is.

Because tests differ in length and difficulty, a raw score of 37 on one test is not likely to be equivalent to a raw score of 37 on another. So comparing raw scores on different tests is likely to result in misunderstanding the relationship between the scores.

The derived scores were developed from raw scores that were obtained during the standardization testing by a nationwide, representative group of students—the students in the norming group. Since the derived scores are based on the percentages of the students who obtained each possible raw score, they measure how well a student has done *in comparison with the students in the norming group*. Thus, they provide a statement of the comparative level of achievement that each raw score represents.

For example, in October, 84% of the Grade 11 norming group students got raw scores below 37 on the Level 10/12, Form K Vocabulary Test. The derived scores for 37 (stanine of 7, NCE of 71, PR of 84, Post High School GE, and ESS of 680) all indicate that a Grade 11 student with a raw score of 37 on that test in October reads quite well, in comparison to the students in the norming group. The student's level of achievement is quite high for his or her grade.

Of course, in using any test scores, it is important for teachers and others in the schools to take into account whatever else is known about the students who took the test.

## Derived Scores

### Percentile Ranks (PRs)

A percentile rank (PR) indicates where a raw score fits within a range of scores; it describes the position of a raw score obtained by a particular student in a particular grade within the set of scores obtained during the standardization testing by students in the same grade. The PR for a particular raw score tells the percentage of students in that same grade whose raw scores were lower.<sup>1</sup>

Earl's raw score corresponds to a PR of 40; 40% of the students in Earl's grade who took the test during the standardization had a raw score lower than Earl's. Put another way, Earl's raw score was higher than the scores of 40% of these students.

<sup>1</sup>Any one raw score was, in fact, obtained by many students in the norming group. So, in computing a PR for a particular raw score, the group of students who got that particular raw score was divided in half; half was included with students who got lower raw scores, and half with students who got higher raw scores.

The PR that corresponds to any one raw score on a particular test decreases from fall to spring, and from grade to grade. This is because students learn more about reading as they progress through school. Students who take the same test at the beginning and at the end of the year usually get higher raw scores at the end of the year. As a result, at the end of the year, fewer students have raw scores lower than any given raw score. So the PR that corresponds to any one raw score is lower at the end of the year than it is at the beginning.

For example, a Vocabulary Raw Score of 28 on Level 7/9, Form K corresponds to a PR of 68 for a Grade 7 student in the fall; at that time, 68% of the students in the norming group got raw scores below 28. By the spring, fewer Grade 7 students get raw scores below 28. So, in the spring of Grade 7, the same raw score of 28 corresponds to a PR of only 58. To have a PR of 68 in the spring of Grade 7—to do better than 68% of seventh graders in the spring—a student would have to get a raw score of 31.

Percentile ranks do not represent equal units of reading achievement the way that meters represent equal units of distance. A PR unit (the difference between one PR and the next) that is near 50 (near the average) is smaller than one that is near 10 or 90.<sup>2</sup> So, for example, the difference in reading achievement between PRs of 50 and 60 is small; if the PRs were 80 and 90, the difference would be much larger. It follows that using PRs to make comparisons is likely to be misleading.

Susan has a PR of 35; Jason, a PR of 50; and Michael, a PR of 20. Susan's PR is numerically halfway between Jason's and Michael's. Susan's level of reading achievement, however, is closer to Jason's than to Michael's.

Because PR units are not equal, PRs should not be averaged.

### NCEs (Normal Curve Equivalents)

Like PRs, NCEs describe a student's level of reading achievement in terms of relative standing within a group of students at the same grade level. NCEs, in fact, are based on PRs. They are PRs that have been transformed statistically into a scale of *equal* units of reading achievement.<sup>3</sup> The NCE scale is designed so that NCEs of 1, 50, and 99 coincide with PRs of 1, 50, and 99. Although NCEs can actually be lower than 1 and higher than 99, they are limited to a range of 1 through 99 in the tables of norms to conform to typical guidelines for program evaluation.

Except for NCEs of 1 and 99, each NCE unit is the same throughout the scale. So NCEs are suitable for computing averages; they are also suitable for making comparisons between scores.

---

<sup>2</sup>The reason that PRs near the average represent smaller differences in achievement is that most students are about average in reading; relatively few have a high or low level of reading achievement. A student who has made a modest increase in reading achievement (relative to the norming group) will have made a considerable gain in PR if the student was about average to begin with; that is because he or she will have surpassed the achievement of many others whose achievement was also about average. A student who is well above average to begin with, and who makes the same modest increase in reading achievement, will gain only slightly in PR; he or she will have surpassed the achievement of relatively few others whose achievement was also well above average.

<sup>3</sup>NCEs are normalized standard scores with a mean of 50 and a standard deviation of 21.06.

## Stanines

Stanines, like PRs and NCEs, describe a student's level of achievement in relation to the achievement of other students in the same grade. Like NCE units, each unit in the stanine scale is equal, except for the lowest and highest units.<sup>4</sup> But *stanines* divide the continuum of reading achievement into only *nine* score segments. Since stanines measure reading achievement in relatively broad bands, they tend to discourage focusing on score differences that may be not meaningful. And because stanines are broad bands, they are more useful for individual than for group scores.

The figure below shows the difference between PRs on the one hand, and standard scores, such as NCEs and stanines, on the other. In a normal distribution of reading achievement, PRs are close to each other near the middle, and more distant at the extremes; most students are about average, and few are exceptional. The NCEs and stanines are equally spaced; they measure achievement in equal units.

Relation between Stanines, NCEs, and PRs

## Extended Scale Scores (ESSs)

The extended scale scores (ESSs) were developed so that progress in reading can be followed over a period of years on a single, continuous scale. Percentile ranks, NCEs, and stanines rank a student's achievement within his or her own grade group. ESSs, in effect, rank a student's achievement within a group that includes all the students in all the grades; they relate a student's achievement to the entire range of achievement during the school years. The ESS scale, like the NCE scale, measures reading achievement in equal units, so that a difference of, say, 50 ESS units represents the same difference all along the scale.

<sup>4</sup>Stanines are normalized standard scores with a mean of 5 and a standard deviation of 2. Each stanine (except 1 and 9) is one-half standard deviation wide. A stanine of 5 includes a quarter of a standard deviation both above and below the mean.

Scales of the ESS type are usually developed by choosing a group of students near the middle of the achievement continuum, say, Grade 5 or Grade 6 students, and using the norms for that group as a basis for the entire scale. Several names, such as "expanded standard scores," "growth scale," "universal scale scores," and "developmental scale scores" are used for scores of this type.

For the *Gates-MacGinitie Reading Tests*, there are three ESS scales—one for Vocabulary, one for Comprehension, and one for Total Score. The scales are based on the raw score distributions of the Grade 5 norming group for the Second Edition. Average achievement (NCE of 50) at the beginning of Grade 5 (5.1) was represented by an ESS of 500; average achievement at the beginning of Grade 6 (6.1), by 525. Thus, a difference of 25 ESS units anywhere on the scales represents the difference between the achievement of beginning Grade 5 and beginning Grade 6 students at the time the Second Edition was standardized.<sup>5</sup> To provide for continuity from one edition of the test to the next, the same scales have been used for the Third Edition.

Since the rate of reading achievement growth tapers off during the school years, one would not expect the gain in ESSs to be the same from year to year; since the course of achievement growth is different for vocabulary and comprehension, one would not expect the gains in ESSs for Vocabulary and Comprehension to be the same; and, since the rate of growth is different for students who do not read well than it is for students who do, the gains in ESSs will not be the same from student to student. In order to interpret ESSs, you must know the Vocabulary and Comprehension ESSs that are characteristic of students at the grade level you are teaching.

---

<sup>5</sup>To understand ESSs, it is useful to know how they were developed for the Second Edition. As an example, take the Total Score ESSs: An ESS of 500 was assigned to a Total NCE of 50 at Grade 5.1; an ESS of 525 was assigned to a Total NCE of 60 (the Grade 5.1 equivalent of a Grade 6.1 NCE of 50). Other ESSs were assigned proportionately to other Grade 5.1 NCEs (and their corresponding raw scores).

The scale was then extended to other test levels on the basis of special equating testing. In this testing, groups of students took two adjacent levels of the tests, so that equivalent raw scores and NCEs for adjacent level tests could be determined.

For example, one large group of students took both the fourth through sixth grade test (Level D) and the seventh through ninth grade test (Level E). Since 70% of these students got a total raw score below 73 on the Level D test, and 70% of the same students got a total raw score below 58 on the Level E test, the two raw scores, and the NCEs that corresponded to those raw scores, were considered equivalent. Thus, since Level D and Level E total raw scores of 73 and 58 were considered equivalent, their corresponding NCEs—a Grade 5.1 NCE of 80 and a Grade 7.1 NCE of 61—were also considered equivalent.

The ESS already assigned to a Grade 5.1 NCE was the basis for the ESS assigned to the equivalent Grade 7.1 NCE. However, though ESSs for the two equivalent NCEs are similar, they are not identical, because the linear relationship between *all* the Grade 5.1 NCEs and their Grade 7.1 equivalents was applied in computing the Grade 7.1 ESSs.

In the example, an ESS of 578 had been assigned to the Grade 5.1 NCE of 80; the ESS of 577 that was computed for the equivalent Grade 7.1 NCE is similar.

The equating of scores and assigning of ESSs to equivalent NCEs for different test levels was then carried out repeatedly, until ESSs were assigned to appropriate NCEs, and to corresponding raw scores, for each test level.

You can find this kind of information for Levels 7/9 and 10/12 in the norms tables. For example, the ESS (576) that corresponds to an average Total score (PR of 50) at the beginning of Grade 8 can be found by reading across the row that contains 50 in the Fall PR column in the Grade 8 norms for Level 7/9. The ESS (588) that corresponds to an average Total score near the end of the year can be found by reading across the row that contains 50 in the Spring PR column.<sup>6</sup> Similarly, you can find ESSs that correspond to any other PR at the beginning and end of any grade for which norms are given. Simply read across the rows that contain that particular PR.

Neither the month nor the grade in which a student takes the test changes the ESS; a particular raw score on a particular level and form of a test will always correspond to the same ESS.

### Grade Equivalents (GEs)

Grade equivalents (GEs), like ESSs, rank a student's achievement within a group that includes the students in all the grades. They do this by estimating the grade level of the group whose median ESS would be the same as the student's ESS.

Lisa, whose Comprehension GE is 8.6, has an achievement level estimated to be equivalent to the achievement level of an average student who has been in Grade 8 for 6 months.

The whole number in a GE represents the grade; the decimal fraction represents a month in the school year (or roughly a tenth of the school year). For a school year beginning in September, the decimal values corresponding to the different months are

Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr.	May	June
.0	.1	.2	.3	.4	.5	.6	.7	.8	.9

GEs for October and April, the months of the standardization testing, represent the median scores achieved in those months by the norming group. Thus, a GE of 9.1 corresponds to the median ESS of the Grade 9 norming group in October; a GE of 9.7 corresponds to the group's median ESS in April. GEs for other months are estimates; they correspond to ESSs that would be the median scores if increases in scores were the same from month to month. Of course, actual growth in reading achievement is not necessarily constant throughout the school year.

As with ESSs, neither the month nor the grade in which a student takes the test changes the GE; a particular raw score on a particular level and form of a test will always correspond to the same GE. Of course, a Grade 6 student whose score on a Level 7/9 test corresponds to a GE of 9.6 is reading well above average, while a Grade 11 student who got the same score on the test is reading slightly below average.

<sup>6</sup>In the Level 7/9, Form K Total Score norms for Grade 8, a PR of 50 is not actually listed for spring. A PR of 50 would be about two-thirds of the way between 48 and 51, which are listed. So the ESS that corresponds to a PR of 50 in the spring would be about two-thirds of the way between ESSs of 586 and 589, which correspond to spring PRs of 48 and 51.

GEs can be useful scores, but before you interpret them, you should understand the following characteristics and limitations.<sup>7</sup>

1. GEs within the intended grade range of a test level or of one level above or below it are relatively meaningful; they are based on the scores of students who took a test with similar content.

If Kai-Sun gets a GE of 12.6 on the Level 7/9 Comprehension Test, he had a raw score like the score that a typical Grade 12 student would probably get on the same Level 7/9 test in the middle of the twelfth-grade year. He can probably read many high school materials successfully.<sup>8</sup>

The table of "Norms Available for Each Level" on page 64 shows the intended grade range for each test level.

2. As GEs extend beyond the intended grade range of a test level and the levels immediately above and below it, their grade-level associations become increasingly less meaningful. A GE of, say, 10.1 for Level 4 is based on the scores of the Grade 10 norming group that took a Level 10/12 test—a test that is very different in content from the Level 4 test. GEs far from the intended grade level(s) of the test that was taken are based on scores on tests that may be much easier, or much more difficult, than the test that the student took.

Thus, GEs far from the grade level(s) of the test that was taken should not be interpreted as indicating that a student can read, or can only read, like a student at a specified level far above or far below the grade level of the test.

Wilma, who is in Grade 11, got a GE of 4.5 on a Level 10/12 Comprehension Test. This GE means that Wilma reads *very* poorly for an eleventh grader. It does *not* mean that she understands only those language structures that a typical student in the middle of Grade 4 understands; it does *not* mean that she has the interests of a fourth grader or that she should be given fourth-grade materials.

---

<sup>7</sup>To avoid misinterpreting GEs, it is useful to know how they are computed. The method used to compute GEs for the *Gates-MacGinitie Reading Tests* consisted of the following steps:

1. GEs for each grade were determined from the ESSs of students in the same grade who took the test level designed for that grade during the standardization.

For example, a GE of 9.1 was assigned to the median ESS of Grade 9 students who took a Level 7/9 test in October; a GE of 9.7 was assigned to the median ESS of Grade 9 students who took the same test in April. Similarly, GEs of 10.1 and 10.7 were assigned to median ESSs of Grade 10 students who took a Level 10/12 test in October and in April. GEs between 9.1 and 9.7, 9.7 and 10.1, and 10.1 and 10.7 were assigned to intermediate ESSs on the assumption that score increases are constant during each of those periods.

Thus, GEs for each grade level were assigned to ESSs until the continuous ESS scale was accompanied by a parallel and corresponding GE scale that ranged from 1.0 to 12.9.

2. Once the GE scale was established, the GEs were applied, through their corresponding ESSs, to raw scores for other test levels. Of course, the lower test levels are not difficult enough to have GEs of 12.9 applied to any raw score; and, in the higher levels, some low GEs are applied to chance level raw scores that may not be good estimates of students' reading achievement.

<sup>8</sup>GEs are not estimates of instructional level. The grade level of appropriate instructional materials usually lies between a student's actual grade and his or her GE.

Martha, who is in Grade 6, took a Level 5/6 test and got a Comprehension GE of 12.1. She reads very well for a Grade 6 student; she has certainly learned more of what has been taught in Grades 1-6 than has the average sixth grader. The test she took, however, was one based on reading materials designed for the range of abilities and interests of most students in Grades 5 and 6. She is not necessarily reading in the same way, or capable of reading the same material, as the students who are actually in Grade 12. And, of course, her interests may not coincide with the interests that Grade 12 materials deal with.

3. GEs, like PRs, do not represent equal units of reading achievement. A gain of one grade level at the Grade 1 end of the GE scale represents a greater gain in achievement than a gain of one grade level at the Grade 12 end of the scale. This is because students typically learn most about reading in the primary grades, when they are first learning how to read and are applying to written language what they already know about spoken language. Then, as they move through the grades, the yearly change in what they know about reading usually becomes progressively smaller.

Julio, in Grade 5, who is reading one year above grade level, is farther ahead of his grade group than is Lucy, in Grade 11, who is also reading one year above grade level.

Because GEs do not represent equal units, they should not be used to compute averages.

4. The GE scale reflects the yearly growth of achievement of *average* students. Thus, the difference between 8.2 and 9.2 represents about a year's growth for an average student progressing through Grade 8 to Grade 9. Students who are considerably above average, however, typically grow in achievement at a faster rate; students who are considerably below average typically grow at a slower rate. The yearly growth of a student with a PR of 10 is likely to be less than one grade level, measured in GE units; similarly, the yearly growth of a student with a PR of 90 is likely to be more than one grade level, measured in GE units.
5. Like other derived scores, GEs are based on averages; they are not standards or criteria of performance. They do not tell how well a particular student *should* read; they tell how well the average student in a particular grade *does* read. The nature of averages dictates that about half the students in a typical class will have scores that are above the national average, and about half will have scores that are below average. So, in a typical Grade 9 class tested in April, many students will obtain GEs above 9.7 and many will obtain GEs below 9.7.

6. Comparing Vocabulary GEs with Comprehension GEs is likely to be misleading, because the relation between GEs on the one hand and PRs or NCEs on the other is different for Vocabulary and Comprehension. The table below gives an example of this difference. Vincent, Risa, and Masao took the Level 7/9, Form K Vocabulary and Comprehension Tests in the fall of Grade 7. Vincent's scores on both tests were close to the national average; for both tests, his PR was at, or close to, 50, and his GEs (7.0 and 7.1) were essentially at grade level. Risa's scores were both well above average, but she did better on Vocabulary (PR 91), in comparison with other students in her grade, than she did on Comprehension (PR 80). Yet, even though her Vocabulary PR was higher than her Comprehension PR, her GE (10.5) was the same for both tests. Masao's scores were also well above average; his PRs on the two tests were almost identical (91 and 90), but his Vocabulary GE (10.5) was lower than his Comprehension GE (12.6).

**Relation between GEs and PRs  
for Vocabulary and Comprehension  
(Level 7/9, Form K, Fall of Grade 7)**

	Vocabulary			Comprehension		
	Raw Score	PR	GE	Raw Score	PR	GE
Vincent	23	49	7.0	27	50	7.1
Risa	36	91	10.5	35	80	10.5
Masao	36	91	10.5	38	90	12.6

As the example shows, the same GE for Vocabulary and Comprehension does not necessarily indicate the same relative standing within a grade group; and the same relative standing is not necessarily reflected in the same GE. This is because the range of achievement relative to the rate of achievement growth is different for vocabulary and comprehension. The range of achievement in comprehension among students at any one grade level is broad, and the growth from grade to grade is relatively small compared to that range; the range of achievement in vocabulary is more narrow, and the growth from grade to grade is relatively large. It may be that vocabulary achievement depends more on what is specifically taught in school than comprehension achievement does.

# WECHSLER ADULT INTELLIGENCE SCALE—REVISED (WAIS-R)

Co-authored by Joseph J. Ryan

*When I was a boy of 14, my father was so ignorant I could hardly stand to have the old man around. But when I got to be 21, I was astonished at how much he had learned in seven years.*

Summary

The Wechsler Adult Intelligence Scale—Revised (WAIS-R; Wechsler, 1981) is the latest edition of an instrument introduced in 1939. In its original version, it was called the Wechsler-Bellevue Intelligence Scale—Form I (Wechsler, 1939), after David Wechsler and Bellevue Hospital in New York City, where Wechsler served as chief psychologist. A second form of the Wechsler-Bellevue, Form II, was published in 1946. Form I was revised in 1955 and again in 1981. The WISC-R and WPPSI are also derivatives of the 1939 adult scale. Because this textbook focuses on testing children, use of the WAIS-R with examinees 16 to 17 years old will be highlighted.

The WAIS-R contains 11 subtests grouped into Verbal and Performance sections. The six Verbal Scale subtests are Information, Digit Span, Vocabulary, Arithmetic, Comprehension, and Similarities; the five Performance Scale subtests are Picture Completion, Picture Arrangement, Block Design, Object Assembly, and Digit Symbol. (Digit Symbol is similar to Coding B on the WISC-R.) The WAIS-R covers an age range from 16 years, 0 months to 74 years, 11 months. It overlaps with the WISC-R from 16 years, 0 months to 16 years, 11 months.

The WAIS-R is similar to the 1955 Wechsler Adult Intelligence Scale (WAIS; Wechsler, 1955). About 80 percent of the items are the same or only slightly modified. Some of the new items and revised procedures were developed on the basis of cultural considerations. For example, two of the WAIS-R Information items make reference to famous black Americans (Louis Armstrong and Martin Luther King). WAIS items that had proved to be either too easy or too hard were eliminated from the WAIS-R. Also, scoring procedures on the WAIS-R Digit Span were altered to increase the variability of scores.

## STANDARDIZATION

The WAIS-R was standardized on 1,880 white and non-white Americans equally divided with respect to gender, selected to be representative of the U.S. late adolescent and adult population during the 1970s. The demographic characteristics used to obtain a stratified sample were age, sex, race (white = 1,664, black = 192, and Asians plus native Americans = 24), geographic region (Northeast, North Central, South, and West), education, and urban-rural residence. In the standardization sample, there were nine different age groups (16–17, 18–19, 20–24, 25–34, 35–44, 45–54, 55–64, 65–69, and 70–74), with 160 to 300 individuals in each group.

## DEVIATION IQS AND SCALED SCORES

The WAIS-R, like the WISC-R and the WPPSI, employs the Deviation IQ ( $M = 100$ ,  $SD = 15$ ) for the Verbal, Performance, and Full Scales and standard scores for the subtests ( $M = 10$ ,  $SD = 3$ ). In order to obtain Deviation IQs, one first converts raw scores into scaled scores, using a table on the front of the WAIS-R record booklet or Table 19 in the WAIS-R manual. These scaled scores are based on a reference group of subjects in the standardization sample who were 20 to 34 years of age. The scaled scores are then summed, and the sum and the examinee's age are used to find Deviation IQs in Table 20 in the WAIS-R manual. Verbal Scale IQs are based on the sum of the six Verbal subtests, Performance Scale IQs on the sum of the five Performance subtests, and Full Scale IQs on all 11 subtests.

## Prorating Procedure

The WAIS-R manual provides a table (Table 23) for prorating the scores when five of the Verbal Scale subtests are administered, or when four of the Performance subtests are administered. When even fewer subtests are administered, IQs should be computed by using the special short-form procedure described later in this chapter.

## Scaled Score Equivalents for Age Groups

The WAIS-R manual (Table 21) also provides scaled score equivalents ( $M = 10$ ,  $SD = 3$ ) of raw scores for each of the nine age groups in the standardization sample. This table is useful in conducting profile analysis and in comparing an individual's performance *directly* with that of age peers; however, *the age-corrected scaled scores should not be used to calculate IQs. Age-corrected subtest scaled scores should be used only to make subtest interpretations and comparisons.* These age-corrected scores, in addition to the reference group scaled scores, should be recorded for every WAIS-R protocol to avoid interpretive errors.

## RELIABILITY

The WAIS-R provides highly reliable IQs. Each of the three IQ scales has an internal consistency reliability coefficient of .88 or above in the standardization group over the entire age range covered by the scale. Reliability coefficients, based on a formula for computing the reliability of a composite group of tests, range from .95 to .97 (average .96).

$r_{rr} = .97$ ) for the Verbal IQ, from .88 to .94 (average  $r_{rr} = .93$ ) for the Performance IQ, and from .96 to .98 (average  $r_{rr} = .97$ ) for the Full Scale IQ. (Similar findings have been reported for a clinical sample by Ryan, Prifitera, and Larsen, 1982.)

The reliabilities for the individual subtests are less satisfactory than those for the IQs. They range from a low of .52 for Object Assembly at ages 16-17 to a high of .96 for Vocabulary at six of the nine age groups. The average reliability coefficients range from .68 for Object Assembly to .96 for Vocabulary (*Mdn*  $r_{rr} = .83$ ). Similar findings have been reported for a clinical sample (Ryan et al., 1982). Table 10-1 presents the reliability coefficients for each subtest and scale for ages 16 to 17 and for the average of the standardization sample.

The highest reliabilities are found among the Verbal Scale subtests (average reliabilities range from .83 to .96).

Block Design is the most reliable subtest ( $r_{rr} = .87$ ) in the Performance Scale (average reliabilities in the Performance Scale range from .68 to .87). The reliability coefficients for 9 of the 11 subtests are split-half correlations corrected by the Spearman-Brown formula. For Digit Span and Digit Symbol, reliabilities are based on test-retest correlations because the items in these subtests do not lend themselves to the split-half calculation procedure.

#### Standard Errors of Measurement

The standard errors of measurement ( $SE_m$ ) in IQ points, based on the average of the nine age groups, are 2.53 for the Full Scale IQ, 2.74 for the Verbal IQ, and 4.14 for the Performance IQ. Thus, more confidence can be placed in the Full Scale IQ than in either the Verbal or the Performance Scale IQ. The Verbal Scale subtests (average  $SE_m$ 's

**Table 10-1**  
Reliability Coefficients and Standard Errors of Measurement for WAIS-R Subtests and Scales for 16- to 17-Year-Olds and for the Average of the Nine Age Groups in the Standardization Sample

WAIS-R subtest or scale	Reliability coefficient		Standard error of measurement	
	16- to 17- year-olds	Average of standardization group	16- to 17- year-olds	Average of standardization group
Information	.90	.89	.84	.93
Digit Span	.70	.83	1.44	1.23
Vocabulary	.96	.96	.49	.61
Arithmetic	.73	.84	1.20	1.14
Comprehension	.78	.84	1.16	1.20
Similarities	.80	.84	1.29	1.24
Picture Completion	.71	.81	1.43	1.25
Picture Arrangement	.66	.74	1.47	1.41
Block Design	.87	.87	.97	.98
Object Assembly	.52	.68	1.91	1.54
Digit Symbol	.73	.82	1.53	1.27
Verbal IQ	.95	.97	3.30	2.74
Performance IQ	.88	.93	5.18	4.14
Full Scale IQ	.96	.97	2.96	2.53

*Note.* Reliability coefficients for 9 of the 11 subtests (all but Digit Span and Digit Symbol) are split-half correlations. For Digit Span and Digit Symbol, coefficients are based on test-retest data obtained on subsamples from the standardization group of 48 to 80 individuals in four age groups who were retested after a 1- to 7-week interval. Verbal, Performance, and Full Scale reliability coefficients are based on a formula for computing the reliability of a composite group of tests.

Source: Adapted from Wechsler (1981).

range from .61 to 1.24 scaled score points) usually have smaller standard errors of measurement than do the Performance Scale subtests (average  $SE_m$ 's range from .98 to 1.54 scaled score points). Within the Verbal Scale, Vocabulary and Information have the smallest average  $SE_m$ 's (.61 and .93 scaled score points, respectively); within the Performance Scale, Block Design and Picture Completion have the smallest average  $SE_m$ 's (.98 and 1.25 scaled score points, respectively).

### Stability

The stability of the WAIS-R was assessed by retesting two groups (71 individuals between the ages of 25 and 34 and 48 individuals between the ages of 45 and 54) in the standardization sample after an interval of two to seven weeks (Wechsler, 1981). The stability coefficients for ages 25 to 34 were .95 for the Full Scale IQ, .94 for the Verbal IQ, and .89 for the Performance IQ. For the 11 subtests, the stability coefficients ranged from .69 for Picture Arrangement to .93 for Vocabulary. The stability coefficients for ages 45 to 54 were generally similar to those for the younger group. For the three IQs, the stabilities again were high: .96 for the Full Scale IQ, .97 for the Verbal IQ, and .90 for the Performance IQ. Of the 11 subtests, Object Assembly had the lowest stability coefficient ( $r_{xx} = .67$ ) and Information had the highest ( $r_{xx} = .94$ ). The Verbal, Performance, and Full Scale test-retest IQs, standard deviations, and test-retest score changes for the two groups are shown in Table 10-2.

In the combined sample, the mean changes upon retest after two to seven weeks were 3.3 points on the Verbal IQ, 8.4 points on the Performance IQ, and 6.2 points on the Full Scale IQ (Matarazzo & Herman, 1984a). These differ-

ences likely reflect short-term practice effects. The practice effect was greater for the Performance Scale than for the Verbal Scale. The range of change was -12 to +15 for the Verbal Scale IQ, -12 to +28 for the Performance Scale IQ, and -12 to +20 for the Full Scale IQ. Thus, both gains and losses occurred on retest. Similar findings have been reported with adult clinical groups (Ryan, George-miller, Geisser, & Randall, 1985).

The test-retest stability coefficients for the three IQs were all highly significant, yet considerable within-subject variability was demonstrated. These findings underscore the distinction between psychometric and clinical retest stabilities (Matarazzo & Herman, 1984a). High psychometric stability is reflected by a sizable test-retest correlation, whereas high clinical stability is demonstrated by the absence of meaningful score change. For the standardization sample, psychometric stability was satisfactory, but clinical stability was unimpressive: over 80 percent of the subjects showed changes in Full Scale IQ that exceeded the average  $SE_m$ . The WAIS-R IQ appears to be less stable than one might infer from the test-retest coefficients alone, and large changes in IQ can occur upon retesting. Additional behavioral or clinical corroborative data are needed for valid interpretation of test-retest changes.

### Precision Range

Table C-25 in Appendix C shows the 68, 85, 90, 95, and 99 percent confidence intervals for each scale for all age groups and for the average of the nine age groups in the standardization sample. The examinee's specific age group should be used to obtain the most accurate confidence level.

Table 10-2  
Test-Retest WAIS-R IQs for Two Groups

Age	Scale	First testing		Second testing		Change
		M IQ	SD	M IQ	SD	
25-34 years (N = 71)	Verbal IQ	102.0	14.0	105.3	14.3	+3.3
	Performance IQ	103.0	15.6	111.9	17.2	+8.9
	Full Scale IQ	102.4	15.0	109.0	16.8	+6.6
45-54 years (N = 48)	Verbal IQ	101.0	14.9	104.1	15.7	+3.1
	Performance IQ	97.3	12.9	105.0	15.6	+7.7
	Full Scale IQ	99.0	13.5	104.7	16.1	+5.7

## VALIDITY

The criterion validity of the WAIS-R has been investigated in a variety of studies by correlating the WAIS-R with the WAIS, WISC-R, Stanford-Binet: Fourth Edition, other intelligence tests, measures of achievement, and years of schooling. Evidence of construct validity has been provided by: (a) the level and pattern of intercorrelations between WAIS-R subtests and scales; (b) the observation that scores on the WAIS-R are distributed in a manner consistent with theoretical expectations; and (c) the results of factor analyses applied to the intercorrelations of the 11 subtests.

### WAIS-R and WAIS

A sample of 72 individuals in the 35 to 44 age group of the standardization sample were administered the WAIS-R and WAIS in counterbalanced order within a three- to six-week period (Wechsler, 1981). The correlations between the tests were .91 for the Verbal Scale, .79 for the Performance Scale, and .88 for the Full Scale. For the 11 subtests, correlations ranged from a low of .50 for Picture Arrangement to a high of .91 for Vocabulary ( $Mdn\ r = .79$ ). Subtests on the Verbal Scale have higher correlations (range of .71 to .91,  $Mdn\ r = .86$ ) than do those on the Performance Scale (range of .50 to .85,  $Mdn\ r = .66$ ). The high correlations are not surprising, because most items are the same in both tests. What is less clear is why the correlations are relatively low for some Performance Scale subtests. Shifts in scores on the Performance Scale may be due to practice effects.

For each of the three scales, mean IQs were *lower* on the WAIS-R than on the WAIS. The difference was 6.9 points on the Verbal Scale (101.8 vs. 108.7), 8.0 points on the Performance Scale (105.4 vs. 113.4), and 7.5 points on the Full Scale (103.8 vs. 111.3). These results were based on a small sample of the standardization group (those aged 35 to 44) and should **not** be generalized to other age groups.

Studies that have compared the WAIS-R and the WAIS within a variety of populations almost uniformly indicate that the WAIS-R provides *lower* scores than does the WAIS ( $Mdn$  differences = -6.6, -6.4, and -6.8 for the Verbal, Performance, and Full Scale IQs, respectively), but correlations between the two scales are *high* ( $Mdn\ r = .94$  for the Verbal Scale, .86 for the Performance Scale, and .94 for the Full Scale) (Edwards & Klein, 1984; Kelly, Montgomery, Felleman, & Webb, 1984; Lewis & Johnson, 1985; Lippold & Claiborn, 1983; Mishra & Brown, 1983; Mitchell, Grandy & Lupo, 1986; Prifitera & Ryan, 1983; Rabourn, 1983; Rogers & Osborne, 1984; Ryan, Rosen-

berg, & Heilbronner, 1984; Simon & Clopton, 1984; Smith, 1983; Urbina, Golden, & Ariel, 1982; Warner, 1983; Wechsler, 1981). Full Scale IQ differences were larger for persons of average and low average ability ( $Mdn = -8.4$ ) than for those of high average ( $Mdn = -5.3$ ) or superior ( $Mdn = -3.7$ ) ability. In contrast, in a study with mentally retarded subjects, the WAIS-R Verbal (+3.9) and Full Scale (+2.1) IQs were found to be higher than corresponding WAIS values. Thus studies suggest that different relationships may exist between the WAIS-R and the WAIS at different points on the intelligence distribution. Overall, WAIS-R and WAIS IQs are not interchangeable.

In assessing individuals who have received an initial evaluation with the WAIS and are later retested with the WAIS-R, it is important to keep in mind that individuals are likely to obtain lower scores on the WAIS-R. *If the WAIS-R IQ equals or exceeds the previously obtained WAIS IQ, the probability is high that an improvement in cognitive efficiency has occurred. If, however, the WAIS-R IQ is lower than the WAIS IQ, do not infer automatically that intellectual deterioration has occurred.* Consider the extent of the difference. A WAIS-R IQ that is *much* lower than the WAIS IQ may suggest some loss of functioning, but this hypothesis must be supported by clinical data.

### WAIS-R and WISC-R

The relationship between the WAIS-R and the WISC-R was discussed in Chapter 6. The research suggests that the WAIS-R yields *slightly higher* IQs than does the WISC-R, particularly with low-functioning individuals. More research is needed on the comparability of the two scales, however.

### WAIS-R and Stanford-Binet: Fourth Edition

A sample of 47 normal individuals ( $M$  age = 19.5) were administered the WAIS-R and Stanford-Binet: Fourth Edition (Thorndike et al., 1986b) within a two-week interval. The mean composite score on the Stanford-Binet: Fourth Edition was 98.7, and the WAIS-R Verbal, Performance, and Full Scale IQs were 100.2, 103.7, and 102.2, respectively. Correlations between the Stanford-Binet and WAIS-R scales were .90 for the Verbal IQ, .85 for the Performance IQ, and .91 for the Full Scale IQ.

In another study, 21 mentally retarded individuals ( $M$  age = 19.6) were administered the WAIS-R followed by the Stanford-Binet: Fourth Edition, with a median interval of three weeks between the two test administrations

(Thorndike et al., 1986b). The mean Stanford-Binet composite score was 63.8, and the WAIS-R Verbal, Performance, and Full Scale IQs were 74.0, 74.2, and 73.1, respectively. Correlations between the composite score and the Verbal, Performance, and Full Scale IQs were .74, .68, and .79, respectively. Like those for normal subjects, results for retarded individuals suggest that the WAIS-R yields *higher* scores than does the Stanford-Binet: Fourth Edition.

### Other Concurrent Validity Studies

Table 10-3 summarizes the results of studies that have correlated the WAIS-R with tests of ability, tests of achievement, and years of formal education (*ability*: Edinger, Shipley, Watkins, & Hammett, 1985; Fowles & Tunick, 1986; Gregg & Hoy, 1985; Heinemann, Harper, Friedman, & Whitney, 1985; Hiltonsmith, Hayman, & Kleinman, 1984; Klett, Watson, & Hoffman, 1986; Kling & Kupersmith, 1984; Maxwell & Wise, 1984; Retzlaff, Slicner, & Gibertini, 1986; Zachary, Crumpton, & Spiegel, 1985; *achievement*: Ryan & Rosenberg, 1983; *formal education*: Matarazzo & Herman, 1984b). The studies indicate that the WAIS-R has satisfactory concurrent validity with intelligence tests, picture vocabulary tests, achievement measures, and years of education. Median correlations shown in Table 10-3 between the various measures and the WAIS-R Full Scale IQ range from .43 to .94.

### Construct Validity of the WAIS-R

One way to assess construct validity is to determine whether scores from the WAIS-R conform to the expectations or predictions of a viable theory of intelligence. The Cattell-Horn theory (see Chapter 3) postulates that fluid intelligence involves the ability to solve novel problems and process new material, whereas crystallized intelligence involves the retrieval of well-learned facts. Fluid intelligence is believed to decline with advancing age, whereas crystallized intelligence is said to show little or no age-related deterioration.

The age norms for the 11 WAIS-R subtests indicate that with advancing age verbal ability declines much less than perceptual organization and motor skills (Sattler, 1982a). Corrections for age-related decrements are minimal on the Verbal Scale, with the exception of the Similarities subtest (see Table 10-4). Conversely, marked changes are shown on the Performance Scale subtests, for which additional scaled score points are awarded as a function of age. If the Performance Scale is considered a measure of fluid intel-

ligence and the Verbal Scale a measure of crystallized intelligence, then the WAIS-R age norms are consistent with the Cattell-Horn theory: fluid intelligence, but not crystallized intelligence, shows a marked decrement with advancing age.

Factor analysis can also assist in construct validation because it provides a method for determining the structure and components of intelligence measured by a given test. Factor analysis of the WAIS-R standardization sample indicates that all 11 subtests measure general intelligence (*g*) with a moderate to high degree of success (Blaha & Wallbrown, 1982; Gutkin, Reynolds, & Galvin, 1984; O'Grady, 1983; Parker, 1983; Silverstein, 1982a). These results provide support for interpretation of the Full Scale IQ as a global measure of intelligence. Evidence support-

Object Assembly	0	1	2	4	4
Digit Symbol	1	2	3	5	6

Note. The results in Table 10-4 indicate that raw scores yielding a scaled score of 10 in the WAIS-R reference group yield, in nearly every case, the same or higher scaled scores in the five age groups over 34 years. The greatest change is at ages 70 to 74 years. For example, in the reference group, a raw score of 57 on Digit Symbol yields a scaled score of 10, but at ages 70 to 74 this same raw score yields a scaled score of 16. The 6 additional scaled-score points awarded at ages 70 to 74 change the percentile for a raw score of 57 from the 50th to the 98th. Digit Symbol exhibits the most change of any WAIS-R subtest, showing a steady increment in scaled-score points from ages 35 to 74.

The greatest changes are consistently shown on the Performance Scale subtests. On the Verbal Scale subtests, the increment in scaled-score points is never greater than 1 point, except for Similarities. For this subtest, two additional scaled-score points are awarded at ages 65 to 69, and three additional scaled-score points are awarded at ages 70 to 74 for a performance that is average in the reference group.

The increments in Table 10-4 actually reflect a *decline* in performance ability. The decline is more graphically revealed when we examine the raw-score points needed at the various age groups to obtain an average scaled score. For example, in the reference group, a Digit Symbol raw score of 57 yields a scaled score of 10. At ages 70 to 74, however, a raw score of only 29 is required to obtain a scaled score of 10. Thus, individuals in the oldest age group need 28 fewer raw-score points than do those in the reference group to obtain average status in their age group. Source: From J. M. Sattler, "Age effects on Wechsler Adult Intelligence Scale—Revised tests." *Journal of Consulting and Clinical Psychology*, 1982, 50, p. 786. Copyright 1982 by the American Psychological Association. ing interpretation of the Verbal and Performance IQs as separate entities is also available (Atkinson & Cyr, 1984; Beck, Horwitz, Seidenberg, Parker, & Frank, 1985; Ryan, Rosenberg, & DeWolfe, 1984; Silverstein, 1982a), although some researchers suggest that the Verbal and Performance IQs do not always constitute the most accurate

subdivision of the WAIS-R subtests (see the section on factor analysis later in this chapter). The available research provides substantial support for the construct validity of the WAIS-R.

## INTERCORRELATIONS BETWEEN SUBTESTS AND SCALES

The WAIS-R manual provides tables that show the intercorrelations between the 11 subtests and three scales for each of the nine age groups and for the average of the nine age groups. At ages 16 to 17 the subtest intercorrelations range from a low of .21 to a high of .79 (*Mdn* = .43). The six highest subtest intercorrelations are for Vocabulary and Information (.79), Similarities and Vocabulary (.74), Comprehension and Vocabulary (.74), Information and Similarities (.71), Similarities and Comprehension (.66), and Information and Comprehension (.65). The six lowest subtest intercorrelations are for Object Assembly and Digit Symbol (.21), Picture Arrangement and Digit Symbol (.23), Picture Arrangement and Object Assembly (.25), Picture Arrangement and Digit Span (.28), Object Assembly and Arithmetic (.29), and—in a tie—Object Assembly and Information (.30) and Block Design and Picture Arrangement (.30).

The intercorrelations among the six Verbal Scale subtests at ages 16 to 17 range from .36 to .79 (*Mdn* = .61), whereas the intercorrelations among the five Performance Scale subtests range from .21 to .57 (*Mdn* = .36). The Verbal Scale subtests are therefore more highly intercorrelated than are the Performance Scale subtests. Correlations between the 11 subtests and the Full Scale range from a low of .46 (Picture Arrangement and Object Assembly) to a high of .82 (Vocabulary). Five of the six Verbal Scale subtests (Digit Span is the exception) correlate more highly with the Full Scale than do any of the Performance Scale subtests. Of the five Performance Scale subtests, Block Design has the highest correlation with the Full Scale (.67).

The trends observed at ages 16 to 17 are also evident in the intercorrelations based on the average of the nine age groups. Intercorrelations range from .33 to .81 (*Mdn* = .48). The Verbal Scale subtests have higher intercorrelations (.45 to .81, *Mdn* = .61) than do the Performance Scale subtests (.38 to .63, *Mdn* = .47). The Verbal Scale subtests correlate more highly with the Full Scale (.58 to .81, *Mdn* = .75) than do the Performance Scale subtests (.57 to .68, *Mdn* = .61). Vocabulary correlates

 Source: Adapted from Chastain and Reynolds (1984).

more highly (.81) with the Full Scale than does any other subtest. The subtests with the lowest correlations with the Full Scale are Object Assembly (.57) and Digit Symbol (.57).

**WAIS-R IQS AND STRATIFICATION VARIABLES**

The relationship of WAIS-R IQs to various stratification variables used in the standardization sample is shown in Table 10-5 (Chastain & Reynolds, 1984). Differences between the mean IQs for males and females on the three scales were less than 3 points. Likewise, less than 3 points separated the IQs for the urban and rural subjects of the normative sample. Slightly larger differences emerged when area of geographic residence was considered, the most sizable one being the 3.8 Full Scale IQ points that separated subjects living in the Northeast (*M* Full Scale IQ = 101.7) from those residing in the South (*M* Full Scale IQ = 97.9). Differences attributed to sex, urban versus rural residence, and geographic location are not large enough to assume any practical significance and, in most cases, may be ignored for interpretive purposes.

Mean IQs show a much clearer relation to race, occupation, and education. For example, white subjects in the standardization sample scored about 15 points higher than black subjects on the Full Scale (101.4 vs. 86.8). The IQs of those employed in professional/technical jobs were 22 points higher on average than those of laborers (111 vs. 89). The most striking difference—33 points—was between those with less than 8 years of education and those

with 16 or more years of education (82 vs. 115). Table 10-6 presents a breakdown of IQs on the three scales according to sex and race for 16- to 17-year-olds. As in the total sample, sex differences are minimal. Race differences are similar to those for the total group.

The correlation between years of school completed and the Full Scale IQ was .54 for the total standardization sample (Matarazzo & Herman, 1984b). There was a progressive increase in mean Full Scale IQ as a function of years of school completed: 8 or fewer years of education, *M* IQ = 86.4; 9–11 years, *M* IQ = 96.4; 12 years, *M* IQ = 100.1; 13–15 years, *M* IQ = 107.4; 16 or more years, *M* IQ = 115.3. Matarazzo and Herman recommend that *when you need a crude estimate of an adult examinee's premorbid (before the onset of disease) WAIS-R IQ, you can use the mean IQ values reported above to arrive at an estimate of such a WAIS-R IQ value. This should be done only when no other estimates are available (such as high school transcripts or test scores).*

**FACTOR ANALYSIS**

Numerous factor analytic investigations of the WAIS-R have been conducted on the standardization sample (Blaha & Wallbrown, 1982; Glass, 1982; Gutkin et al., 1984; O'Grady, 1983; Parker, 1983; Silverstein, 1982) as well as on various clinical samples (Atkinson & Cyr, 1984; Faulstich, McAnulty, Gresham, Veitia, Moore, Bernard, Waggoner, & Howell, 1986; Ryan, Prifitera, & Rosenberg, 1983; Ryan, Rosenberg, & DeWolfe, 1984; Ryan & Schneider, 1986). Results of these studies indicate that the WAIS-R may be characterized as either a two- or a three-

**Table 10-6**  
Relationship of WAIS-R IQs to Sex and Race for 16- to 17-Year-Olds

Demographic variables		N	Verbal IQ		Performance IQ		Full Scale IQ	
			M	SD	M	SD	M	SD
Sex	Males	100	100.9	16.0	101.2	15.9	101.1	16.3
	Females	100	99.4	13.6	99.5	14.1	99.2	13.4
Race and sex	White males	85	103.4	14.6	103.8	14.6	103.3	14.3
	Black males	14	86.4	16.9	85.6	15.6	85.4	16.4
	White females	87	100.5	13.2	100.8	13.3	100.4	13.8
	Black females	12	90.5	13.9	88.0	12.8	88.7	13.1

Source: Adapted from Chastain and Reynolds (1984).

factor battery. A three-factor solution is useful for clinical and psychoeducational tasks, but when individual protocols are being interpreted, any hypotheses based on factor analytic findings should be supplemented with clinical judgment.

The three WAIS-R factors are similar to those on the WISC-R—namely, Verbal Comprehension (Information, Vocabulary, Comprehension, and Similarities), Perceptual Organization (Picture Completion [except at 18–19 years], Block Design, and Object Assembly), and Freedom from Distractibility (Digit Span and Arithmetic) (see Table 10-7). The subtests comprising the factors, however, differ somewhat for the two scales. Coding loads on the Freedom from Distractibility factor on the WISC-R, but its counterpart on the WAIS-R, Digit Symbol, does not. Similarly, Picture Arrangement is one of the subtests in the Perceptual Organization factor on the WISC-R, but not on the WAIS-R. There is no simple explanation for these findings. (All factor analytic findings presented in Table 10-7 and below are based on work by the chapter authors.)

### WAIS-R Subtests as Measures of *g*

As shown in Table 10-8, all of the WAIS-R subtests are either good or fair measures of *g* (the general intelligence factor). Based on the average of the nine age levels, the subtests with the highest *g* loadings are Vocabulary (.86), Information (.81), Similarities (.79), Comprehension (.78), Arithmetic (.75), and Block Design (.72). The subtests with fair *g* loadings are Picture Completion (.70), Picture Arrangement (.63), Digit Span (.62), Object Assembly (.61), and Digit Symbol (.59). Overall, the Verbal subtests are better measures of *g* than are the Performance subtests.

### Subtest Specificity

Subtest specificity refers to the proportion of a subtest's variance that is both reliable (that is, not due to errors of measurement) and distinctive to the subtest. Although individual subtests overlap in their measurement properties (that is, the majority of reliable variance for most subtests is common factor variance), many of them possess a relatively high degree of specificity, which justifies interpretation of specific subtest functions (see Table 10-9). Some subtests have either ample or adequate specificity throughout the entire age range covered by the WAIS-R (Digit Span, Vocabulary, Picture Completion, Block De-

sign, and Digit Symbol), whereas others have inadequate specificity at one or more ages (Information, Arithmetic, Comprehension, Similarities, Picture Arrangement, and Object Assembly). Subtests with inadequate specificity should not be interpreted as measuring specific functions, and cautious interpretation is required for subtests falling within the adequate specificity category. These subtests can be interpreted as measuring *g* and the appropriate principal factor, however (Verbal Comprehension, Perceptual Organization, and Freedom from Distractibility, respectively).

### Factor Scores

Factor scores can be obtained from the WAIS-R, permitting the identification of meaningful psychological dimensions. The Verbal Comprehension factor score measures verbal knowledge and understanding obtained by formal and informal education and reflects the ability to apply verbal skills to new situations. The Perceptual Organization factor score reflects the ability to interpret and organize visually perceived material while working against a time limit. The Freedom from Distractibility factor score measures the ability to attend or concentrate, but also may involve numerical proficiency and sequencing skills. These factor scores are discussed more fully in Chapter 8.

The preferred way to obtain the three factor scores is to use the following combinations of subtests:

- Verbal  
Comprehension = Sum of age-corrected scaled scores on Information, Vocabulary, Comprehension, and Similarities at all ages
- Perceptual  
Organization = Sum of age-corrected scaled scores on Block Design, Object Assembly, and Picture Completion at every age level (except 18–19, where the last subtest should be omitted from the factor score)
- Freedom from  
Distractibility = Sum of age-corrected scaled scores on Digit Span and Arithmetic

The sums of the respective age-corrected subtest scaled scores comprising the three factors can be converted into Deviation IQs ( $M = 100$ ,  $SD = 15$ ). Table C-23 in Appen-

Table 10-7  
**WAIS-R Subtest Loadings on Factor A (Verbal Comprehension), Factor B (Perceptual Organization), and Factor C (Freedom from Distractibility) for Nine Age Levels and the Average Following Varimax Rotation**

Table 10-8  
WAIS-R Subtests as Measures of *g*

<i>Good measure of g</i>			<i>Fair measure of g</i>		
<i>Subtest</i>	<i>Median g loading</i>	<i>Proportion of variance attributed to g (%)</i>	<i>Subtest</i>	<i>Median g loading</i>	<i>Proportion of variance attributed to g (%)</i>
Vocabulary	.87	76	Picture Completion	.71	50
Information	.82	67	Picture Arrangement	.67	45
Similarities	.79	62	Object Assembly	.63	40
Comprehension	.78	61	Digit Span	.62	38
Arithmetic	.76	58	Digit Symbol	.60	36
Block Design	.73	53			

Note. These are median loadings based on the nine age groups in the standardization sample. The square of the median coefficients provides the proportion of each subtest's variance that may be attributed to *g*.

dix C provides for a rapid conversion of the three factor scores into Deviation IQs for ages 16 to 17 and for the average of the nine age groups.

### ADMINISTERING THE WAIS-R

The general procedures discussed in Chapter 5 for administering psychological tests are also useful in administering the WAIS-R, as are the guidelines in Chapters 6 and 7 for administering the WISC-R. Be careful not to confuse the administration procedures of the WISC-R with those of the WAIS-R, however—different instructions and time limits are used on some subtests of the same name. The general problems in administering the WISC-R also apply to the WAIS-R. The suggestions shown in Exhibit 10-1 should aid you in learning how to administer the WAIS-R. (Figure 10-1 shows the cover of the WAIS-R record booklet.)

#### Physical Abilities Required for the WAIS-R

Adequate hearing and language functions are required for the Verbal Scale subtests, and adequate vision and visual-motor ability are needed for the Performance Scale subtests. The suggestions presented in Chapters 6 and 7 for administering the WISC-R to handicapped examinees (see particularly Table 6-11) should be carefully studied.

#### Subtest Sequence

In most situations subtests should be administered in the standard sequence, as specified in the WAIS-R manual. If warranted, however, all of the Verbal subtests can be administered first followed by the Performance subtests. This order may be less stressful for examinees who have minor motor problems that may interfere with the Performance subtests. It is also permissible to adjust the order of administration for examinees who fatigue easily (for example, the elderly or physically ill) or display marked anxiety about the testing situation. Examinees who fatigue easily may be given certain subtests (for example, Arithmetic, Digit Span, or Digit Symbol) early in the session when their energy levels and attention-concentration skills are best. Anxious examinees may be started with subtests that are relatively nonthreatening and do not have strict time limits (for example, Information, Comprehension, or Vocabulary).

Some examinees with psychiatric or neurological disorders may not be able to complete the entire WAIS-R in a single session. In such cases, schedule breaks to coincide with the end of a subtest so that testing can easily be resumed at a later time. In the rare instances where a subtest must be interrupted prior to completion, resume administration of the subtest where you stopped, except on Similarities, Block Design, and Picture Arrangement. On these subtests, the easy items provide some examinees with the practice they need to succeed at more difficult items. Therefore, if Similarities, Block Design, or Picture Arrangement is interrupted, the first few items should be

**Table 10-9**  
Amount of Specificity for WAIS-R Subtests

WAIS-R subtest	Ample specificity	Adequate specificity	Inadequate specificity

Information	—	16-44, 55-74, Average	45-54
Digit Span	16-74, Average	—	—
Vocabulary	—	16-74, Average	—
Arithmetic	20-34, 45-74, Average	18-19, 35-44	16-17
Comprehension	45-54	25-44, 65-74, Average	16-24, 55-64
Similarities	25-34	18-19, 35-74, Average	16-17, 20-24
Picture Completion	16-74, Average	—	—
Picture Arrangement	16-19, 25-64, 70-74, Average	—	20-24, 65-69
Block Design	16-34, 55-69, Average	35-54, 70-74	—
Object Assembly	18-19	—	16-17, 20-74, Average
Digit Symbol	16-64, 70-74, Average	65-69	—

repeated at the next session so that the examinee can reestablish the mental set necessary to succeed on the harder items. Naturally, you must consider how any administrative irregularity will affect the accuracy of the test results.

### Starting Rules

Eight of the 11 subtests are started with the first item. The remaining three subtests (Information, Vocabulary, and Arithmetic) are started with the fifth, fourth, and third items, respectively. On these three subtests, score the

entry-point items as soon as they are administered. Credit is automatically given for the unadministered early items when the entry-point items (the first two, three, or four items administered) are answered correctly. If the entry-point items are answered incorrectly, it is necessary to administer the earlier items before continuing the subtest.

### Discontinuance Rules

Nine of the 11 subtests have discontinuance rules—the subtest is discontinued after a specified number of consecutive items are failed. (Object Assembly and Digit Symbol are the two subtests without discontinuance rules.) If you administer additional items in a subtest because you are not sure whether the items at the discontinuance point were failed, use the following rule to score the additional items (Wechsler, 1981, p. 54): *If subsequent scoring of the items indicates that the additional items were administered unnecessarily, do not give credit for any items passed after the discontinuance point.* This rule, which is also followed in the WISC-R, helps to maintain standardized procedures.

### Repetition of Items

Use judgment in deciding when to repeat questions. The Digit Span items are the only verbal items that *cannot* be repeated.

### Use of Probing Questions and Queries

Use probing questions when responses are ambiguous, vague, or indefinite, or when probing is indicated by a "(Q)" in the various scoring criteria appendices in the WAIS-R manual.

### Testing-of-Limits Procedures

Use modifications in test procedures designed for testing-of-limits only *after* all of the subtests have been administered according to standardized procedures

### Scoring WAIS-R Responses

Arriving at accurate scores for WAIS-R subtests and scales is no simple matter. Scoring errors can have a significant impact on the accuracy of WAIS-R IQs. A study indicated that graduate students and experienced psychologists differed by 4 to 18 IQ points in the scores they gave to two

## Exhibit 10-1

## Supplementary Instructions for Administering the WAIS-R

1. Complete the top of the record booklet.
2. Calculate the chronological age (CA) and put it in the box provided.
3. Administer the subtests in the order presented in the WAIS-R manual, except in rare circumstances. Do not change the wording on any subtest. Read the directions and material from the manual. Do not ad lib.
4. Start with the appropriate item on each subtest and follow discontinuance criteria. This means that you must know the scoring criteria before you administer the scale.
5. Write out all responses completely and legibly. Do not use unusual abbreviations. Record time accurately.
6. Question all ambiguous or unscorable responses, using the words suggested in the WAIS-R manual for questioning. You may need to question on Information, Vocabulary, Comprehension, and Similarities. Whenever you ask a question, write (Q) after the questioned response.
7. Carefully score each protocol, recheck scoring, and transfer subtest scores to the front of the record booklet under Raw Score. If you have failed to question a response when you should have and the response is obviously not a 0 response, give the examinee the most appropriate score.
8. If a subtest was spoiled, write *spoiled* by the subtest total score and on the front cover where the raw scores and scaled scores appear. If for some reason a subtest was not administered, write *N/A* in the margin in the record booklet and on the front cover.
9. Raw scores are transformed into scaled scores through use of the table on the front of the record booklet (or Table 19 on page 90 of the WAIS-R manual). Be sure to use the correct row and column for each transformation.
10. The Verbal score is based on the total of the scaled scores on the six Verbal Scale subtests. The Performance score is based on the total of the scaled scores on the five Performance Scale subtests. Add the Verbal score and the Performance score to get the Full Scale score.
11. If it should be necessary to prorrate either the Verbal or Performance section, follow the explicit directions given on page 88 of the WAIS-R manual.
12. The IQs are obtained from Table 20 (pages 92 through 109) of the WAIS-R manual. There is a Verbal section, a Performance section, and a Full Scale section. Be sure to use the correct section of the table for each of the three IQs. Record the IQs. Next, recheck all of your work. If any IQs were prorated, write *PRO* beside the appropriate IQs.
13. If you want to compare the examinee to the reference group, make a profile of the examinee's scaled scores on the record booklet. A profile of age-corrected scaled scores can also be made.
14. Look up the confidence intervals for the Full Scale IQ, Verbal Scale IQ, and Performance Scale IQ in Table C-25 in Appendix C.
15. Look up the percentile rank and classification for each of the IQs in Tables BC-1 and BC-2 on the inside back cover of this text.

WAIS-R protocols (Ryan, Prifitera, & Powers, 1983). Additionally, both groups of raters converted scaled scores to IQs incorrectly, gave credit for individual items incorrectly, and added raw scores incorrectly. In another study additional scoring problems included failing to credit responses that appeared in the manual and assigning credit for symbol pairings on Digit Symbol incorrectly (Franklin et al., 1982). Obviously, you should guard against making such errors.

Judgment is important in scoring WAIS-R responses, especially when ambiguous responses are encountered on the Vocabulary, Comprehension, and Similarities subtests. Carefully study the scoring criteria, scoring guidelines, and scoring examples in the WAIS-R manual.

### Extrapolated IQs

Because the lowest scaled score is 1 point, the sum of scaled scores cannot be lower than 6 for the Verbal Scale or 5 for the Performance Scale when proration procedures are used. Consequently, the minimum sum of scaled scores is shown in the WAIS-R manual. When the sum of scaled scores is higher than the highest sum shown in Table 20 of the WAIS-R manual, report the IQ as "over 150" (Wechsler, 1981). In some cases, however, you can extrapolate the IQ. Table C-30 in Appendix C extends the sum of scaled scores and IQs up to the maximum possible sum of scaled scores for the Verbal, Performance, and Full Scales separately for each of the nine age groups. As noted in Chapter 6, extrapolated IQs must be used cautiously.

## WAIS-R SHORT FORMS

Short forms of the WAIS-R have the same advantages and disadvantages as do short forms of the WISC-R. Chapter 6 thoroughly discusses the use of short forms; review this material as needed.

### Selecting the Short Forms

Table C-34 in Appendix C provides the 10 best short form combinations of two, three, four, and five WAIS-R subtests. For all practical purposes, the short forms of a given length are mutually interchangeable in terms of psychometric properties. The choice of a short form should be based on the considerations discussed in Chapter 6.

After the short form has been selected, follow the procedures outlined in Chapter 6 (see Exhibit 6-3) to convert the composite scores to Deviation Quotients. Use Table C-36 in Appendix C to obtain the appropriate  $a$  and  $b$  constants. To obtain  $r_{jk}$ , use the section of the WAIS-R correlation table (Table 15) that corresponds to the examinee's age group.

### Satz-Mogel Abbreviated Procedure

The Yudin short form procedure, which reduces the number of items within subtests, is known as the Satz-Mogel short form when applied to the WAIS-R (Satz & Mogel, 1962). Table C-35 in Appendix C shows the specific procedures for obtaining this WAIS-R short form. Validity coefficients and standard errors of measurement, based on the entire standardization sample, are .94 and  $\pm 5.1$  for the Verbal IQ, .89 and  $\pm 6.8$  for the Performance IQ, and .95 and  $\pm 4.7$  for the Full Scale IQ, respectively (Silverstein, 1982d). Although the Satz-Mogel approach is a useful screening device for estimating the Full Scale IQ, it should not be used to interpret individual subtest scores. Poor correlations have been reported between estimated subtest scaled scores and actual obtained scores. Additionally, estimated scaled scores have been found to exceed the range of  $\pm 2$  scaled score points from actual obtained scores in over 25 percent of 81 cases studied (Evans, 1985).

### Vocabulary plus Block Design Short Form

A two-subtest combination that is popular as a short form screening instrument is Vocabulary plus Block Design. These two subtests have moderate (Block Design) and high (Vocabulary) correlations with the Full Scale, have consis-

tently high reliabilities, and are good measures of  $g$ . If this combination is chosen, Table C-37 in Appendix C can be used to convert the sum of *age-corrected scaled scores* directly into an estimated Full Scale IQ (Brooker & Cyr, 1986). The reliability of the composite is impressive ( $r_{xx} = .94$  for the average of nine age groups) with an  $SE_m$  in IQ points of 3.58 for 16- to 17-year-olds and 3.64 for the average of all nine age groups (Silverstein, 1985b). The Vocabulary plus Block Design short form consistently overestimates the average Full Scale IQ of clinical samples by approximately 3 points, however (Margolis, Taylor, & Greenlief, 1986; Roth, Hughes, Monkowski, & Crosson, 1984; Ryan, Larsen, & Prifitera, 1983; Thompson, Howard, & Anderson, 1986).

### Vocabulary, Block Design, and Information

A useful three-subtest short form is Vocabulary, Block Design, and Information. Table C-38 in Appendix C can be used to convert the sum of the three *age-corrected subtest scaled scores* into an estimated Full Scale IQ.

### Vocabulary, Block Design, Arithmetic, and Similarities

A useful four-subtest short form is Vocabulary, Block Design, Arithmetic, and Similarities. Table C-39 in Appendix C can be used to convert the sum of the four *age-corrected subtest scaled scores* into an estimated Full Scale IQ.

### Information, Arithmetic, Picture Completion, and Block Design Short Form

Another potentially useful short form combination is Information, Arithmetic, Picture Completion, and Block Design (Reynolds, Willson, & Clark, 1983). Table C-40 in Appendix C can be used to convert the sum of the four *age-corrected subtest scaled scores* into an estimated Full Scale IQ. The reliability of the composite is adequate ( $r_{xx} = .88$  for the average of nine age groups), and estimated stability over time is excellent (.95 for 71 standardization subjects between 25 and 34 years of age; .96 for 48 standardization subjects between 45 and 54 years of age). The  $SE_m$  in IQ points is 5.73 for 16- to 17-year-olds, and 5.26 for the average of the nine age groups in the standardization sample. This four-subtest short form is a valid predictor of the Full Scale IQ in normal subjects (Reynolds et al., 1983) and neurologically impaired patients (Ryan, 1985).

## WAIS-R SUBTESTS

### Information

The Information subtest contains 29 questions which sample a broad range of general knowledge, including literary, historical, and geographical facts and dates. All examinees start with item 5. All items are scored 1 or 0 (pass-fail), and the subtest is discontinued after five consecutive failures. The questions usually can be answered with a simply stated fact. The examinee is not required to find relationships between facts in order to receive credit.

**Rationale.** The rationale presented for the WISC-R Information subtest applies to the WAIS-R Information subtest (see Chapter 7).

**Factor analytic findings.** Information is the second-best measure of *g* in the scale (67 percent of its variance may be attributed to *g*). It has adequate subtest specificity in every age range with the exception of 45 to 54 years, where its specificity is inadequate. Information contributes substantially to the Verbal Comprehension factor (*Mdn* loading = .76).

**Reliability and correlational highlights.** Information is a reliable subtest ( $r_{xx} = .89$ ). It correlates more highly with Vocabulary ( $r = .81$ ) than with any other subtest. It correlates moderately with the Full Scale IQ ( $r = .76$ ), the Verbal Scale IQ ( $r = .79$ ), and the Performance Scale IQ ( $r = .62$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations presented for the WISC-R Information subtest are also relevant for the WAIS-R (see Chapter 7).

### Digit Span

The Digit Span subtest has two parts: Digits Forward, which contains series ranging in length from three to nine digits, and Digits Backward, which contains series ranging in length from two to eight digits. The examinee listens to a sequence of digits given orally by the examiner and then repeats the digits. There are two sets of digits of each length. Digits Forward is administered first, followed by Digits Backward. On the WAIS-R Digit Span is a regular subtest, whereas on the WISC-R it is supplementary.

All series are scored 2, 1, or 0. On both parts of the

subtest, testing is discontinued after failure on both trials of any series. Scaled scores and age-corrected scores are not provided separately for Digits Forward and Digits Backward.

**Rationale.** The rationale presented for the WISC-R Digit Span subtest applies to the WAIS-R Digit Span subtest (see Chapter 7).

**Factor analytic findings.** The Digit Span subtest is a fair measure of *g* (38 percent of its variance may be attributed to *g*). It has ample subtest specificity across the entire age range to permit specific interpretation of its functions. Digit Span has a high loading on the Freedom from Distractibility factor (*Mdn* loading = .56).

**Reliability and correlational highlights.** Digit Span is a reliable subtest ( $r_{xx} = .83$ ). It correlates more highly with Arithmetic ( $r = .56$ ) and Vocabulary ( $r = .52$ ) than with the remaining subtests. It has a relatively low correlation with the Full Scale IQ ( $r = .58$ ), the Verbal Scale IQ ( $r = .57$ ), and the Performance Scale IQ ( $r = .50$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations presented for the WISC-R Digit Span subtest are also relevant for the WAIS-R (see Chapter 7).

### Vocabulary

The Vocabulary subtest contains 35 words arranged in order of increasing difficulty. Each word is presented orally and in writing, and the examinee is asked to explain aloud its meaning. All examinees start with the fourth word, except those who seem to have poor verbal ability. Each word is scored 2, 1, or 0, and the subtest is discontinued after five consecutive failures.

**Rationale.** The rationale presented for the WISC-R Vocabulary subtest applies to the WAIS-R Vocabulary subtest (see Chapter 7).

**Factor analytic findings.** The Vocabulary subtest is the best measure of *g* in the scale (76 percent of its variance may be attributed to *g*). The subtest has an adequate amount of subtest specificity across the entire age range and contributes substantially to the Verbal Comprehension factor (*Mdn* loading = .83).

**Reliability and correlational highlights.** Vocabulary is the most reliable subtest in the scale ( $r_{cr} = .96$ ). It correlates more highly with Information ( $r = .81$ ) than with any other subtest. It has high correlations with the Full Scale IQ ( $r = .81$ ) and the Verbal Scale IQ ( $r = .85$ ) and a moderate correlation with the Performance Scale IQ ( $r = .65$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations presented for the WISC-R Vocabulary subtest generally apply to the WAIS-R (see Chapter 7). On the WAIS-R Vocabulary subtest, however, the examinee looks at a word list as the examiner pronounces each word. Also, when the examinee gives a 0- or 1-point definition on the first word, no help is provided by the examiner.

Study carefully the "Sample Responses" section of Appendix A of the WAIS-R manual so that you will know which responses require further inquiry, indicated by "(Q)." The examples indicate that many 0- and 1-point responses should be queried. When a 2-point response is accompanied by a "(Q)," it is the entire response including the elaboration that is worth 2 points.

### Arithmetic

The Arithmetic subtest contains 14 problems: 13 are given orally and the other one involves blocks. All examinees start with item 3. All problems are timed, with items 1 through 4 having a time limit of 15 seconds; items 5 through 9, 30 seconds; items 10 through 13, 60 seconds; and item 14, 120 seconds. All items are scored 1 or 0, with up to 2 additional time-bonus points possible on items 10 through 14.

**Rationale.** The rationale presented for the WISC-R Arithmetic subtest applies to the WAIS-R Arithmetic subtest (see Chapter 7).

**Factor analytic findings.** Arithmetic is a good measure of  $g$  (58 percent of its variance may be attributed to  $g$ ). The subtest has ample subtest specificity to permit interpretation of its functions at ages 20 to 34 years and 45 to 74 years. It has only adequate specificity at ages 18 to 19 years and 35 to 44 years, and it has inadequate specificity at ages 16 and 17 years. Arithmetic has a high loading on the Freedom from Distractibility factor ( $Mdn$  loading = .53) and a moderate loading on the Verbal Comprehension factor ( $Mdn$  loading = .45).

**Reliability and correlational highlights.** Arithmetic is a reliable subtest ( $r_{cr} = .84$ ). It correlates best with Vocabulary ( $r = .63$ ) and Information ( $r = .61$ ). It correlates moderately with the Full Scale IQ ( $r = .72$ ), the Verbal Scale IQ ( $r = .70$ ), and the Performance Scale IQ ( $r = .62$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations discussed for the WISC-R Arithmetic subtest generally apply to the WAIS-R (see Chapter 7). A booklet is not used to present any of the WAIS-R items to the examinee, however.

### Comprehension

The Comprehension subtest contains 16 questions covering a wide range of situations and proverbs. Questions deal with such issues as government operations and laws, health standards, and social mores. All examinees begin the subtest with item 1, and all items are scored 2, 1, or 0. The subtest is discontinued after four consecutive failures.

**Rationale.** The rationale presented for the WISC-R Comprehension subtest applies to the WAIS-R Comprehension subtest (see Chapter 7).

**Factor analytic findings.** The Comprehension subtest is a good measure of  $g$  (61 percent of its variance may be attributed to  $g$ ). Subtest specificity varies with age. There is ample specificity at ages 45 to 54, adequate specificity at ages 25 to 44 and 65 to 74, and inadequate specificity at ages 16 to 24 and 55 to 64. Consequently, specific interpretation of the subtest's functions is appropriate only at some ages. The Comprehension subtest has a high loading on the Verbal Comprehension factor ( $Mdn$  loading = .69).

**Reliability and correlational highlights.** Comprehension is a reliable subtest ( $r_{cr} = .84$ ). It correlates more highly with Vocabulary ( $r = .74$ ), Information ( $r = .68$ ), and Similarities ( $r = .68$ ) than with any other subtests. It correlates moderately with the Full Scale IQ ( $r = .74$ ), the Verbal Scale IQ ( $r = .76$ ), and the Performance Scale IQ ( $r = .61$ ).

**Administrative and interpretive considerations.** Administrative and interpretive considerations presented for the WISC-R Comprehension subtest are not relevant to the WAIS-R. Study carefully the "Sample Responses" section of Appendix B of the WAIS-R manual.

know which responses require further inquiry, indicated by "(Q)." The examples indicate that some 0- and 1-point responses should be queried.

### Similarities

The Similarities subtest contains 14 pairs of words; the examinee is asked to explain the similarity between the two words in each pair. All examinees start with the first item. All items are scored 2, 1, or 0, depending on the conceptual level of the response. The subtest is discontinued after four consecutive failures.

**Rationale.** The rationale described for the WISC-R Similarities subtest applies to the WAIS-R Similarities subtest (see Chapter 7).

**Factor analytic findings.** Similarities is the third-best measure of *g* in the scale (62 percent of its variance may be attributed to *g*). The subtest has ample subtest specificity at ages 25 to 34, adequate specificity at ages 18 to 19 and 35 to 74, and inadequate specificity at ages 16 to 17 and 20 to 24. Specific interpretation of the subtest's functions is inappropriate at ages 16 to 17 and 20 to 24. Similarities contributes substantially to the Verbal Comprehension factor (*Mdn* loading = .67).

**Reliability and correlational highlights.** Similarities is a reliable subtest ( $r_{xx} = .84$ ). It correlates best with Vocabulary ( $r = .72$ ) and Comprehension ( $r = .68$ ). It correlates moderately with the Full Scale IQ ( $r = .75$ ), the Verbal Scale IQ ( $r = .74$ ), and the Performance Scale IQ ( $r = .64$ ).

**Administrative and interpretive considerations.** Most of the administrative and interpretive considerations presented for the WISC-R Similarities subtest apply to the WAIS-R (see Chapter 7). The major difference is that on the WAIS-R all items are scored 2, 1, or 0, whereas on the WISC-R a 2 may be given only on items 5 to 17. Considerable skill is required to score Similarities responses.

Appendix C in the WAIS-R manual merits careful study. First, the general scoring principles, which give the rationale for scores of 2, 1, and 0, should be thoroughly mastered. Second, the sample responses section should be studied carefully so that responses that should be queried, indicated by "(Q)," can be recognized readily.

### Picture Completion

The Picture Completion subtest consists of 20 drawings of common objects (such as a door, a boat, and a leaf), each of which lacks a single essential element. The examinee's task is to name or point to the missing portion of the picture. There is a 20-second time limit for each picture. All examinees start with the first item. Each item is scored 1 or 0 (pass-fail), and the subtest is discontinued after five consecutive failures.

**Rationale.** The rationale described for the WISC-R Picture Completion subtest applies to the WAIS-R Picture Completion subtest (see Chapter 7).

**Factor analytic findings.** The Picture Completion subtest is a fair measure of *g* (50 percent of its variance may be attributed to *g*). The subtest has ample specificity at all ages to permit specific interpretation of its functions. Picture Completion contributes substantially to the Perceptual Organization factor at all the age levels except 18 to 19 (*Mdn* loading = .51).

**Reliability and correlational highlights.** Picture Completion is a reliable subtest ( $r_{xx} = .81$ ). It correlates more highly with Vocabulary ( $r = .55$ ) than with any other subtest. It correlates moderately with the Full Scale IQ ( $r = .67$ ), the Performance Scale IQ ( $r = .65$ ), and the Verbal Scale IQ ( $r = .61$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations presented for the WISC-R Picture Completion subtest generally apply to the WAIS-R (see Chapter 7). However, whereas on the WISC-R three different guiding statements may be given by the examiner when the examinee gives an incorrect response, on the WAIS-R only one type of guiding statement is permitted (asking for the most important part missing when an unessential missing part is given).

### Picture Arrangement

The Picture Arrangement subtest requires the examinee to place a series of pictures in a logical sequence. The 10 series are similar to short comic strips. The individual pictures are placed in a specified disarranged order, and the examinee is asked to rearrange the pictures in the "right" order to tell a story. One set of cards is presented at

a time. There is little motor action required, as the pictures must simply be shifted to make a meaningful story.

All examinees start with item 1. The first item has two trials and is scored 2, 1, or 0. For the remaining items (2 to 10), 2 points are given for each correct arrangement completed within the time limit. On items 2, 5, 8, and 9, 1 point is given for an acceptable variation of the correct arrangement. Items 1 to 4 have a 60-second time limit; items 5 to 8, a 90-second time limit; and items 9 and 10, a 120-second time limit.

**Rationale.** The rationale presented for the WISC-R Picture Arrangement subtest applies to the WAIS-R Picture Arrangement subtest (see Chapter 7).

**Factor analytic findings.** The Picture Arrangement subtest is a fair measure of *g* (45 percent of its variance may be attributed to *g*). The subtest has ample specificity at ages 16 to 19, 25 to 64, and 70 to 74 to warrant specific interpretation of its functions at these ages. It has inadequate specificity at ages 20 to 24 and 65 to 69. Picture Arrangement has modest loadings on the Verbal Comprehension (*Mdn* loading = .40), Perceptual Organization (*Mdn* loading = .33), and Freedom from Distractibility (*Mdn* loading = .22) factors. Picture Arrangement cannot be uniquely allocated to any one of the three factors, however.

**Reliability and correlational highlights.** Picture Arrangement is relatively reliable ( $r_{xx} = .74$ ). It correlates more highly with Picture Completion ( $r = .51$ ) and Vocabulary ( $r = .51$ ) than with the other subtests. It correlates moderately with the Full Scale IQ ( $r = .61$ ) and to a lesser degree with the Performance Scale IQ ( $r = .56$ ) and the Verbal Scale IQ ( $r = .57$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations presented for the WISC-R Picture Arrangement subtest generally apply to the WAIS-R (see Chapter 7). However, the bonus points awarded on the WISC-R subtest for speed are not awarded on the WAIS-R subtest.

### Block Design

The Block Design subtest contains nine items. The examinee is shown two-dimensional, red-and-white pictures of abstract designs and then must assemble a design that is identical to each picture, using three-dimensional red and white plastic blocks. All examinees start with item 1. On this item only, the examinee is required to reproduce a design from a model constructed by the examiner.

The patterns are arranged in order of increasing difficulty. Four blocks are used for the first five designs, and nine for the last four designs.

All items are timed. The first five items have a time limit of 60 seconds; the last four items have a time limit of 120 seconds. On items 1 and 2, the examinee is given 2 points for successful completion on the first trial or 1 point for successful completion on the second trial. On items 3 to 9, 4 points are given for a correct completion, with up to 3 (items 3 and 4) or 4 (items 5 through 9) additional time-bonus points awarded for quick execution. The subtest is discontinued after three consecutive failures.

**Rationale.** The rationale presented for the WISC-R Block Design subtest applies to the WAIS-R Block Design subtest (see Chapter 7).

**Factor analytic findings.** The Block Design subtest is the best measure of *g* among the Performance Scale subtests (53 percent of its variance may be attributed to *g*). The subtest has either ample or adequate specificity across the entire age range to permit specific interpretation of its functions. The Block Design subtest contributes substantially to the Perceptual Organization factor (*Mdn* loading = .74).

**Reliability and correlational highlights.** Block Design is a reliable subtest ( $r_{xx} = .87$ ). It correlates more highly with Object Assembly ( $r = .63$ ) than with any other subtest. It correlates moderately with the Full Scale IQ ( $r = .68$ ), the Performance Scale IQ ( $r = .70$ ), and the Verbal Scale IQ ( $r = .61$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations described for the WISC-R Block Design subtest generally apply to the WAIS-R (see Chapter 7). Timing and bonus points differ on the two subtests.

### Object Assembly

In the Object Assembly subtest, the examinee must put jigsaw pieces together to form common objects: a manikin (6 pieces), a profile of a face (7 pieces), a hand (7 pieces), and an elephant (6 pieces). The items are presented one at a time, with the pieces presented in a specified disarranged pattern. Examinees are administered all four items.

All items are timed. The time limit is 120 seconds for the first two items and 180 seconds for the last two items. Up to 3 time-bonus points may be awarded on each item for quick execution. The manikin has a maximum score of 3.

the face, 12; the hand, 10; and the elephant, 11. Points are also awarded for partially correct performances.

**Rationale.** The rationale presented for the WISC-R Object Assembly subtest applies to the WAIS-R Object Assembly subtest (see Chapter 7).

**Factor analytic findings.** The Object Assembly subtest is a fair measure of *g* (40 percent of its variance may be attributed to *g*). The subtest has ample specificity to permit specific interpretation of its functions only at ages 18 to 19. At all other ages, subtest specificity is inadequate. The Object Assembly subtest has a high loading on the Perceptual Organization factor (*Mdn* loading = .71), which makes it interpretable as a measure of perceptual organization.

**Reliability and correlational highlights.** Object Assembly is the least reliable of the WAIS-R subtests ( $r_{rr} = .68$ ). It correlates more highly with the Block Design subtest ( $r = .63$ ) than with any of the other subtests. Its correlation is relatively low with the Full Scale IQ ( $r = .57$ ), moderate with the Performance Scale IQ ( $r = .62$ ), and low with the Verbal Scale IQ ( $r = .49$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations described for the WISC-R Object Assembly subtest generally apply to the WAIS-R.

### Digit Symbol

The Digit Symbol subtest is similar to Coding B on the WISC-R. The subtest requires the copying of symbols that are paired with numbers. The sample (or key) consists of nine boxes, each of which contains one of the numbers 1 through 9 and a symbol. Each test box contains a number in the upper portion and an empty space in the lower portion. In the empty space, the examinee must draw the symbol that was paired with the number in the key. There are seven practice boxes, followed by 93 boxes in the subtest proper.

Both examiner and examinee should use pencils without erasers. It is important that the examinee have a smooth drawing surface. One point is allotted for each correct item. The time limit is 90 seconds; no time-bonus points are awarded.

**Rationale.** The rationale for the WISC-R Coding subtest applies to the WAIS-R Digit Symbol subtest (see Chapter 7).

**Factor analytic findings.** The Digit Symbol subtest is a fair measure of *g* (36 percent of its variance may be attributed to *g*). It has either ample or adequate specificity across the entire age range to permit specific interpretation of its functions. Digit Symbol has modest loadings on the Verbal Comprehension (*Mdn* loading = .38), Perceptual Organization (*Mdn* loading = .41), and Freedom from Distractibility (*Mdn* loading = .26) factors. Digit Symbol cannot be uniquely allocated to any one of the three factors, however.

**Reliability and correlational highlights.** Digit Symbol is a reliable subtest ( $r_{rr} = .82$ ). It correlates more highly with Block Design ( $r = .47$ ) and Vocabulary ( $r = .47$ ) than with any other subtests. It has a relatively low correlation with the Full Scale IQ ( $r = .57$ ), the Performance Scale IQ ( $r = .52$ ), and the Verbal Scale IQ ( $r = .54$ ).

**Administrative and interpretive considerations.** The administrative and interpretive considerations for the WISC-R Coding B subtest generally apply to the WAIS-R Digit Symbol subtest (see Chapter 7).

## INTERPRETING THE WAIS-R

Almost all of the material in Chapter 8 on interpreting the WISC-R pertains to the WAIS-R. For example, the successive level approach to test interpretation, profile analysis, Verbal-Performance Scale comparisons, factor score comparisons, and subtest comparisons are essentially the same for both tests. The estimated percentile ranks for subtest scaled scores are shown in Table C-41 in Appendix C. This table also shows suggested qualitative descriptions associated with scaled scores. Table BC-2 on the inside back cover shows the classifications associated with WAIS-R IQs. In Appendix C, Table C-13 summarizes the functions associated with each subtest (substituting Digit Symbol for Coding), Table C-42 presents information about the three scales and factor scores, and Table C-43 gives suggested remediation activities for combinations of Wechsler subtests.

### Profile Analysis

As noted above, approaches to profile analysis on the WAIS-R are basically the same as those on the WISC-R (see Chapter 8). The only difference is that different tables in Appendix C must be used.

1. *Comparing Verbal and Performance Scale IQs.* Table C-26 in Appendix C provides the critical values for com-

paring the Verbal and Performance IQs: 12 at the .05 level and 16 at the .01 level at ages 16 to 17, and 10 at the .05 level and 13 at the .01 level for the average of the nine age groups. Verbal-Performance IQ differences are essentially similar in male and female groups in the standardization sample (Matarazzo, Bornstein, McDermott, & Noonan, 1986). This finding means that similar interpretations can be given to the Verbal-Performance profiles of both males and females. Probabilities associated with various Verbal-Performance Scale differences are shown in Table C-32 of Appendix C.

2. *Comparing each Verbal subtest age-corrected scaled score with the mean Verbal age-corrected scaled score.* Table C-27 in Appendix C provides the critical values for comparing Verbal subtests with the mean of the Verbal subtests (all age-corrected scores). They range from 1.8 to 3.0 at the .05 level and from 2.1 to 3.5 at the .01 level for the six Verbal subtests.

3. *Comparing each Performance subtest age-corrected scaled score with the mean Performance age-corrected scaled score.* Table C-27 in Appendix C provides the critical values for comparing Performance subtests with the mean of the Performance subtests (all age-corrected scores). They range from 2.5 to 3.0 at the .05 level and from 3.0 to 4.2 at the .01 level for the five Performance subtests.

4. *Comparing each subtest scaled score with the mean of the 11 age-corrected subtest scaled scores.* Table C-27 in Appendix C provides the critical values for comparing subtests with the mean of all the subtests (all age-corrected scores). They range from 1.9 to 3.5 at the .05 level and from 2.2 to 4.8 at the .01 level for the 11 subtests.

5. *Comparing sets of individual age-corrected subtest scaled scores.* Table C-26 in Appendix C provides the critical values for comparing sets of subtest scores (all age-corrected scores). They range between 2 and 5 at the .05 level and between 3 and 6 at the .01 level. The values in Table C-26 in Appendix C for subtest comparisons are overly liberal (that is, they lead to too many significant differences) when more than one comparison is made. They are most accurate when a priori planned comparisons are made, such as Comprehension versus Picture Arrangement or Digit Span versus Arithmetic. (See Chapter 8 for additional information that can guide interpretations of subtest comparisons.)

Silverstein (1982c) advises that when you make multiple subtest comparisons you first determine the difference between the highest and lowest age-corrected subtest scores. If this difference is 6 or more age-corrected points,

it is significant at least at the .05 level. Differences of 6 or more points between subtests can then be interpreted. If the difference between the highest and lowest subtest score is less than 6 points, multiple comparisons between individual subtests should not be made.

### Other Approaches to Profile Analysis

The supplementary approaches to WAIS-R profile analysis described in this section are similar to those discussed for the WISC-R (see Chapter 8).

**Base rate differences between each subtest score and an average subtest score in the WAIS-R standardization sample.** Table C-31 in Appendix C allows you to see how frequently a particular difference between a subtest score and an average WAIS-R Verbal, Performance, or overall score occurred in the standardization sample. Differences of approximately 3 to 4 points between each subtest score and the respective average Verbal or Performance Scale score were obtained by 5 percent of the standardization sample. *This table should be used only to evaluate differences that have first been found to be reliable.* (See numbers 2, 3, and 4 in the preceding section on profile analysis.)

**Base rate Verbal-Performance differences (or probability-of-occurrence approach).** Table C-33 in Appendix C presents the empirically observed percentage of individuals in the standardization sample who obtained a given discrepancy between Verbal and Performance Scales. The percentages are shown for five IQ groups and for the total group. For example, 37.8 percent of the individuals in the standardization sample had a 10-point difference between the two IQs.

**Comparisons of factor scores.** To compare factor scores, you must first convert them to Deviation IQs (see Table C-28 in Appendix C for the conversion table). Table C-26 in Appendix C provides the differences required for significance at the .05 and .01 levels between the three factors (Verbal Comprehension, Perceptual Organization, and Freedom from Distractibility) for ages 16 to 17 and for the average of the nine age groups. Finally, Table C-29 in Appendix C provides the difference scores needed to determine whether any of the individual age-corrected subtest scaled scores that comprise the three factors are significantly different (at the .05 and .01 levels) from the average of all the age-corrected scores that comprise each factor for ages 16 to 17 and for the average of the nine age groups.

As in the WISC-R, factor scores should be compared with other factor scores and not with the Verbal and Performance Scale IQs, to guard against the use of overlapping subtests.

#### Use of Norm Tables

The norm tables allow each examinee to be compared with his or her age group. The transition point between two normative age groups may affect scores, however, and lead to interpretive problems in some test-retest situations. For example, whereas an examinee aged 19 years, 11 months, 29 days who earns a WAIS-R scaled score total of 100 points receives a Full Scale IQ of 99, the same examinee at 20 years, 0 months receives a Full Scale IQ of 92 for the identical scaled score total. If the same examinee is tested at 19 and 20 years of age, an examiner might be inclined to interpret the drop of 7 points as suggesting a lowering in functioning, when in fact the change is an artifact of the test norms. Such considerations are important to keep in mind when one is evaluating practice effects or conducting psychoeducational reevaluations.

### ASSETS OF THE WAIS-R

The WAIS-R is a well-standardized test, with good reliability and validity. It divides the 11 subtests into two sections and provides three IQs—Verbal, Performance, and Full Scale. This procedure is helpful in clinical and psychoeducational work and in the assessment of brain-behavior relationships. The fact that all examinees take a comparable battery of subtests is a valuable feature of the test. Parts of the test also can be administered to examinees limited by sensory impairments (for example, the Verbal Scale to blind individuals or those with motor handicaps; the Performance Scale to deaf individuals).

1. *Good validity.* Concurrent validity data are uniformly positive. WAIS-R IQs correlate significantly with scores from other intelligence tests, measures of academic achievement, and years of formal education. Factor analytic studies indicate that the Full Scale IQ is an excellent measure of *g*, and in most situations the division of the subtests into Verbal and Performance sections is appropriate. Inspection of the age norms for the test indicates that if the Performance Scale subtests are considered as measures of fluid intelligence and the Verbal Scale subtests as measures of crystallized intelligence, then the WAIS-R norms are consistent with predictions based on the Cattell-Horn theory of intelligence.

2. *High reliabilities.* The WAIS-R Full Scale IQ has

excellent reliability (average  $r_{xx} = .97$ ). The  $SE_m$ 's of the IQs on the three scales are consistently less than 5 points. The WAIS-R manual provides reliability data,  $SE_m$ 's, and intercorrelations of subtest scores for the nine age groups as well as for the average of the nine age groups, permitting evaluation of the test's properties throughout the entire age range covered by the scale. Confidence intervals can be established for IQs for each of the nine age groups (as well as for the average of the nine groups); thus estimates can be made that are applicable to the examinee's specific chronological age group.

3. *Excellent standardization.* The standardization procedures were excellent, sampling four geographic regions, both sexes, white and nonwhite populations, urban and rural residents, and the entire range of socioeconomic classes.

4. *Good administration procedures.* The prescribed procedures for administering the WAIS-R are excellent. Examiners actively probe responses in order to evaluate the breadth of the examinee's knowledge and determine whether the examinee really knows the answer. On items that require two reasons for maximum credit, the examinee is asked for another reason when only one reason is given. These procedures prevent examinees from being penalized for not fully understanding the demands of the question. The emphasis on probing questions and queries is extremely desirable.

5. *Good manual.* The WAIS-R manual is easy to use; it provides clear directions and tables. The examiner's instructions are printed in a different color to facilitate reading of the directions. Helpful suggestions are provided about abbreviations to use in recording responses, such as "Q" for question, "DK" for don't know, "Inc" for incomplete, and "NR" for no response. The test materials are interesting to adolescents and adults.

6. *Helpful scoring criteria.* The criteria for scoring replies have been carefully prepared. The Vocabulary, Comprehension, and Similarities scoring guidelines, for example, give the rationale for the use of 2, 1, and 0 scores and are accompanied by a number of examples that demonstrate the application of the scoring principles. Many typical responses are scored, and those deemed to need further inquiry are indicated by a "(Q)." Studying the scoring sections will aid you not only in scoring responses but also in administering the test.

### LIMITATIONS OF THE WAIS-R

Although the WAIS-R is an excellent instrument, some problems exist with the test and the manual.

1. *Limited floor and ceiling.* The range of Full Scale IQs (45 to 150) is insufficient both for moderately to severely retarded persons and for extremely gifted persons. The test is designed so that examinees receive 1 scaled score point on each subtest, even if they give no correct answers. Thus the WAIS-R may not be an appropriate measure for the examinee who earns 0 or 1 raw score point on most subtests.

2. *Nonuniformity of subtest scores.* The range of scaled scores on all subtests is not uniform. At the reference age group (ages 20 to 34) used to obtain scaled scores to calculate IQs, a scaled score of 19 can be earned on only five subtests: Digit Span, Vocabulary, Comprehension, Block Design, and Digit Symbol. The maximum scaled score is 18 on Information, Similarities, and Object Assembly, and 17 on Arithmetic, Picture Completion, and Picture Arrangement. For purposes of profile analysis, the scaled score range is more uniform at ages 16 to 17. At this age group, a scaled score range of 19 can be obtained on nine of the 11 subtests. On the two remaining subtests—Picture Completion and Picture Arrangement—18 is the maximum scaled score.

Nonuniformity is also a problem with the age-corrected subtest scores. The restriction of scores occurs for each of the nine age groups. For example, at ages 45 to 54, scores of 19 can be earned on only six subtests: Digit Span, Vocabulary, Comprehension, Block Design, Object Assembly, and Digit Symbol. At ages 65 to 69, scores of 1 can be obtained on only six subtests: Information, Digit Span, Vocabulary, Comprehension, Object Assembly, and Digit Symbol. The lack of uniformity of available scaled scores and age-corrected scores makes profile analysis more difficult to apply, particularly to the profiles of retarded and gifted examinees. It may be misleading to apply profile techniques uniformly to all subtests for every examinee, because the same number of scaled score points, or age-corrected score points, cannot be obtained on all subtests.

3. *Difficulty of scoring responses.* When responses on the Vocabulary, Comprehension, and Similarities subtests differ from those that appear in the WAIS-R manual, they may be difficult to score. Such difficulties may lead to halo effects in scoring and may contribute to other types of examiner bias. Although mastering the scoring criteria is important for all subtests, it is particularly crucial for these three. Close attention must also be given to the mechanics of scoring.

4. *Lack of normative data for raw scores.* The WAIS-R manual fails to give means, standard deviations, and frequency distributions for the raw scores.

5. *Failure to describe the procedure for establishing*

*discontinuance criteria.* The WAIS-R manual states that discontinuance criteria were established using data from the standardization sample. The procedure is not described further, however.

## TEST YOUR SKILL

The WISC-R Test-Your-Skill Exercises in Chapter 8 also apply to the WAIS-R. You are encouraged to review these exercises.

## SUMMARY

1. The revised edition of the Wechsler Adult Intelligence Scale, the WAIS-R, is similar to its 1955 predecessor, with 80 percent of the original items retained. The WAIS-R is applicable to individuals from ages 16-0 to 74-11. Standardization of the scale was excellent, including both white and nonwhite individuals.

2. Reliabilities for the IQs associated with the Verbal, Performance, and Full Scales are extremely high for the standardization sample (average  $r_{rr}$  of .97, .93, and .97, respectively), with  $SE_m$ 's for the Full Scale of about 2.5 IQ points.

3. Practice effects (after a two- to seven-week test-retest interval) for standardization subjects were about 3.3 points on the Verbal Scale, 8.4 points on the Performance Scale, and 6.2 points on the Full Scale.

4. Concurrent and construct validity studies of the WAIS-R have been uniformly positive. The scale correlates significantly with education and with other ability measures. Moreover, the distribution of the age norms is consistent with theory-based expectations, and factor analysis indicates that all 11 subtests measure  $g$  with a moderate to high degree of success.

5. The WAIS-R tends to provide lower IQs than the WAIS and slightly higher IQs than the WISC-R and Stanford-Binet: Fourth Edition, especially for low-functioning individuals.

6. Higher intercorrelations are observed among the Verbal subtests than among the Performance subtests. Within their respective scales, Vocabulary and Block Design show the highest correlations with the Full Scale IQ (.82 and .67, respectively, at ages 16 to 17).

7. A study of WAIS-R IQs in relation to various stratification variables showed that mean differences between males and females were less than 3 points; the IQs of white subjects were higher than those of black subjects by about 15 points (101.4 vs. 86.8); the mean Full Scale IQ of persons in the highest occupational group was 22 points higher, on average, than that of persons in the lowest occupational group (111.0 vs. 89.0); urban-rural differences and geographic region differences were small, and Full Scale IQs of persons with 16 or more years of education

were, on average, 33 points higher than those of persons with less than 8 years of education.

8. Factor analyses of the WAIS-R usually yield three factors—Verbal Comprehension, Perceptual Organization, and Freedom from Distractibility—but some also report two-factor solutions.

9. The subtests that provide the best measure of *g* are Vocabulary, Information, Similarities, Comprehension, Arithmetic, and Block Design. The remaining subtests are fair measures of *g*.

10. Only some of the subtests have ample subtest specificity at ages 16 to 17 and at other ages throughout the scale. At ages 16 to 17, seven of the subtests have ample or adequate subtest specificity (Information, Digit Span, Vocabulary, Picture Completion, Picture Arrangement, Block Design, Digit Symbol), and four (Arithmetic, Comprehension, Similarities, Object Assembly) have inadequate subtest specificity.

11. Somewhat purer factor scores can be obtained by use of Table C-28 in Appendix C, which converts age-corrected scores into Deviation Quotients as follows: (a) Information, Vocabulary, Comprehension, and Similarities into a Verbal Comprehension Deviation Quotient; (b) Block Design, Object Assembly, and Picture Completion (at every age level except 18 to 19, where the latter subtest should be omitted) into a Perceptual Organization Deviation Quotient; and (c) Digit Span and Arithmetic into a Freedom from Distractibility Deviation Quotient.

12. Although the administrative procedures for the WAIS-R are generally similar to those for the WISC-R, there are some differences. Be sure to use the appropriate procedures for each scale.

13. Table C-30 in Appendix C presents extrapolated IQs for scaled scores that are above those shown in the WAIS-R manual.

14. Numerous WAIS-R short forms have been developed. Tables C-34 through C-40 in Appendix C provide information to assist you in the selection and use of WAIS-R short forms.

15. The rationale and administrative and interpretive considerations for each WAIS-R subtest are similar to those for the respective WISC-R subtests. Consult Chapter 7 for a discussion of these issues.

16. Information is a good measure of *g* and contributes to the Verbal Comprehension factor. Subtest specificity is adequate except at ages 45 to 54. Information is a reliable subtest and correlates highly with Vocabulary.

17. Digit Span is a fair measure of *g*, and contributes to the Freedom from Distractibility factor. Subtest specificity is ample at all ages. Digit Span is a reliable subtest and correlates highly with Arithmetic.

18. Vocabulary is the best measure of *g* in the scale and contributes to the Verbal Comprehension factor. Subtest specificity is adequate at all ages. Vocabulary is the most reliable subtest in the scale and correlates highly with Information.

19. Arithmetic is a good measure of *g* and contributes to the Freedom from Distractibility factor. It has ample or adequate subtest specificity except at ages 16 to 17. Arithmetic is a reliable subtest and correlates best with Vocabulary and Information.

20. Comprehension is a good measure of *g*, and contributes to the Verbal Comprehension factor. Subtest specificity is ample or adequate except at ages 16 to 24 and 55 to 64. Comprehension is a reliable subtest and correlates highly with Vocabulary, Information, and Similarities.

21. Similarities is a good measure of *g* and contributes to the Verbal Comprehension factor. Subtest specificity is ample or adequate except at ages 16 to 17 and 20 to 24. Similarities is a reliable subtest and correlates best with Vocabulary and Comprehension.

22. Picture Completion is a fair measure of *g* and contributes to the Perceptual Organization factor at all ages except 18 to 19. Subtest specificity is ample at all ages. Picture Completion is a reliable subtest and correlates highly with Vocabulary.

23. Picture Arrangement is a fair measure of *g*. Subtest specificity is ample except at ages 20 to 24 and 65 to 69. Picture Arrangement is a reasonably reliable subtest and correlates highly with Picture Completion and Vocabulary.

24. Block Design is a good measure of *g* and contributes to the Perceptual Organization factor. Subtest specificity is ample or adequate at all ages. Block Design is a reliable subtest and correlates highly with Object Assembly.

25. Object Assembly is a fair measure of *g* and contributes to the Perceptual Organization factor. Subtest specificity is ample only at ages 18 to 19. Object Assembly is the least reliable subtest in the scale and correlates highly with Block Design.

26. Digit Symbol is a fair measure of *g*. Subtest specificity is either ample or adequate at all ages. Digit Symbol is a reliable subtest and correlates more highly with Block Design and Vocabulary than with the other subtests.

27. The methods described in Chapter 7 for interpreting the WISC-R also pertain, for the most part, to the WAIS-R.

28. The norm tables should be carefully studied in test-retest situations.

29. The assets of the WAIS-R include its good concurrent validity, high reliabilities, excellent standardization, good administration procedures, good manual, and helpful scoring criteria.

30. Limitations of the WAIS-R include limited floor and ceiling, nonuniformity of subtest scores, difficulty of scoring responses, lack of normative data for raw scores, and failure to describe the procedure for establishing discontinuance criteria.

## KEY TERMS, CONCEPTS, AND NAMES

Wechsler-Bellevue Intelligence Scale (p. 220)

WAIS-R standardization (p. 220)

WAIS-R Deviation IQ (p. 220)

WAIS-R scaled scores (p. 220)

Prorating procedure (p. 220)

Scaled score equivalents for age groups (p. 220)

Reliability of the WAIS-R (p. 220)

Standard errors of measurement of the WAIS-R (p. 221)

Stability of the WAIS-R (p. 222)

Precision range of WAIS-R IQs (p. 222)  
 Criterion validity of the WAIS-R (p. 223)  
 Relationship between the WAIS-R and the WAIS, the WISC-R,  
 and the Stanford-Binet: Fourth Edition (p. 223)  
 Construct validity of the WAIS-R (p. 224)  
 Cattell-Horn theory (p. 224)  
 WAIS-R subtest intercorrelations (p. 225)  
 WAIS-R IQs and stratification variables (p. 227)  
 Premorbid estimation of WAIS-R IQ (p. 227)  
 Factor analysis of the WAIS-R (p. 227)  
 WAIS-R Verbal Comprehension factor (p. 228)  
 WAIS-R Perceptual Organization factor (p. 228)  
 WAIS-R Freedom from Distractibility factor (p. 228)  
 WAIS-R subtests as measures of *g* (p. 228)  
 Subtest specificity on the WAIS-R (p. 228)  
 WAIS-R factor scores (p. 228)  
 Starting rules on the WAIS-R (p. 231)  
 Discontinuance rules on the WAIS-R (p. 231)  
 Extrapolated IQs on the WAIS-R (p. 232)  
 WAIS-R short forms (p. 234)  
 Satz-Mogel abbreviated procedure for the WAIS-R (p. 234)  
 WAIS-R Information (p. 235)  
 WAIS-R Digit Span (p. 235)  
 WAIS-R Vocabulary (p. 235)  
 WAIS-R Arithmetic (p. 236)  
 WAIS-R Comprehension (p. 236)  
 WAIS-R Similarities (p. 237)  
 WAIS-R Picture Completion (p. 237)

WAIS-R Picture Arrangement (p. 237)  
 WAIS-R Block Design (p. 238)  
 WAIS-R Object Assembly (p. 238)  
 WAIS-R Digit Symbol (p. 239)  
 Profile analysis (p. 239)  
 Base rate Verbal-Performance differences (probability-of-  
 occurrence approach) (p. 240)

### STUDY QUESTIONS

1. Discuss the following topics with respect to the WAIS-R: standardization, Deviation IQs, scaled score equivalents for age groups, reliability, and validity.
2. Describe WAIS-R factor analytic findings.
3. Discuss some important factors involved in administering the WAIS-R.
4. Discuss WAIS-R short forms. Include a discussion of their values and limitations.
5. Discuss the rationale, factor analytic findings, reliability and correlational highlights, and administrative considerations for each of the following WAIS-R subtests: Information, Digit Span, Vocabulary, Arithmetic, Comprehension, Similarities, Picture Completion, Picture Arrangement, Block Design, Object Assembly, and Digit Symbol.
6. Discuss the intent of profile analysis, methods of profile analysis, and approaches to profile analysis on the WAIS-R.
7. Discuss the assets and limitations of the WAIS-R.

WISC or WAIS AGE-SCALE FACTOR INTERPRETATIONS - For Educational and Vocational Guidance

Note: A score of 10 is the norm for a person of this age. The following student rating scale is based on a standard deviation of three.

<u>Age-Scale Score</u>	<u>Student Rating</u>	<u>IQ</u>	<u>%ile Range</u>
$SD=3, \bar{X}=10$		$\bar{X}=100, SD=15$	
16 and up	Very Superior	130 $\uparrow$	95 - 99
14 and 15	Superior	120 - 129	85 - 94
12 and 13	High Average	110 - 119	70 - 84
9, 10, and 11	Average	90 - 109	30 - 69
7 and 8	Low Average	80 - 89	15 - 29
5 and 6	Boarderline	70 - 79	5 - 14
4 and below	Mentally Deficient	69 $\downarrow$	1 - 4

<u>VERBAL SCALE</u>	<u>Age Scale Score</u>	<u>Student Rating</u>	<u>Mental Process Explanation</u>
Information			Memory for previously <u>acquired everyday knowledge</u> . Reflects alertness of world about person, social and educational background.
Comprehension			Utilization of practical information in everyday <u>problem solving</u> situations. Requires judgement in deciding how to meet a situation.
Similarities			Discrimination in selecting fundamental from superficial in <u>abstract thinking</u> . Shows logical thinking and verbal concept formation.
Vocabulary			Recall of previously acquired <u>word meanings</u> . Shows ability to express verbal ideas at the varying levels of word difficulty. Shows organization as well as expression of ideas. Quality of ideas and mode of expression revealed.
Arithmetic			<u>Mental arithmetic reasoning</u> (ordinary business arithmetic transactions - 7th grade level of difficulty - under stress of time limits.) Requires concentration free from emotional reaction.
Digit Span			Shows <u>attention span</u> , auditory receptivity, concentration, rote memory and immediate recall.

PERFORMANCE   Age Scale   Student  
SCALE            Score        Rating

Mental Process Explanation

Picture  
Arrangement

Ability to comprehend (perceive and conceive) a total social situation in terms of sequence of events. Involves logical planning based on anticipation and social insight.

Picture  
Completion

Utilizes past experience in the ability to see a picture as a whole and then differentiate between essential and unessential detail in detection of a missing part. This is perceptual and conceptual abilities tested by pictures.

Block Design

Involves ability to perceive and analyze patterns in multiple relationships under time requirements. This is analytic in perception and synthetic in putting the design together with the multiple colored blocks. Trial and error persistency and visual-motor coordination are reflected.

Object  
Assembly

Initiative in seeking and achieving an unknown goal. Conception and perception of parts of a familiar configuration. Requires ability to organize and re-organize under speed requirements.

Digit Symbol

Speed of working with symbols, associating unfamiliar symbols with familiar numerals. Shows visual-motor coordination and psycho-motor speed. Aptitude for clerical-like tasks.

Implication For Functional Use Of The WAIS With The Severely Mentally Ill (SMI) Clients

MEASURE	TASK	BEHAVIOR REQUIRED	FUNCTIONAL IMPLICATIONS	SMI PERFORMANCE
Information	Answer questions of fact	Wealth of factual data, verbal expressiveness, long term memory	Mental alertness, ability to express ideas verbally, index of premorbid level of functioning	Schizophrenics do less well on items requiring judgment rather than simple recall
Comprehension	Solve verbal problems and interpret proverbs	Judgement and logical thinking, abstract thinking, long term memory, ability to express ideas verbally	common sense, judgment, and problem solving, ability to form or understand abstractions, ability to express ideas verbally	schizophrenics do poorly, because of poor judgment— High scores on comprehension with CMI suggest good reality contact, an <u>index of stability</u> for rehabilitation planning
Similarities	Detect similarities between two familiar objects or concepts	Logical thinking, verbal concept formation, ability to generalize between two objects of a common class	Ability to make generalizations from one situation to another, ability to see relationships between things	The complex cognitive skills required are particularly sensitive to deterioration in persons with CMI.— High scores in persons with schizophrenia associated with good prognosis
Vocabulary	Provide (orally) definitions of words	Ability to recall word meanings previously learned	Verbal facility, ability to communicate effectively with others, comprehension of verbal material, <u>estimate of premorbid abilities</u>	Vocabulary is the primary "hold" test in that it is <u>very resistant to changes and mental deterioration</u>

1567

1568

Implication For Functional Use Of The WAIS With The Severely Mentally Ill (SMI) Clients (Continued)

MEASURE	TASK	BEHAVIOR REQUIRED	FUNCTIONAL IMPLICATIONS	SMI PERFORMANCE
Arithmetic	Mental calculation of arithmetic word problems	Number concept, attention, concentration, and freedom from distractibility	Ability to attend and concentrate on mental tasks, ability to solve functional arithmetic problems	Highly sensitive to emotional states (anxiety, depression)
Digit Span	Immediate recall of number series, forward and backward	Attention, concentration, learning memory, nonverbal spatial skills (reverse ordering of number series)	The ability to pay attention and concentrate, the ability to hold and manipulate information mentally	Subtest is very sensitive to brain damage and anxiety — major depressives and deteriorated schizophrenics do poorly
Picture Completion	Identifying missing elements in sketches	Visual, acuity, visual perception, visual scanning, attention	The ability to discriminate what is important from what is nonessential and screen out what is not important, the ability to concentrate on and make sense of a visual image	Decreased performance is noted in persons with deteriorated schizophrenia — Persons with paranoid schizophrenia insist there are no missing parts

BEST COPY AVAILABLE

Implication For Functional Use Of The WAIS With The Severely Mentally III (SMI) Clients (Continued)

MEASURE	TASK	BEHAVIOR REQUIRED	FUNCTIONAL IMPLICATIONS	SMI PERFORMANCE
Picture Arrangement	Arrange sets of cartoon pictures to tell logical stories	Visual acuity and perception, sequential logic and planning, cognitive flexibility	The ability to size up social situations in terms of sequences of events (social awareness and insight), planning skills, organizing skills, the ability to form hypotheses and test them	Many provide qualitative information about social judgment problems in persons with SMI
Block Design	Arrange six-sided, colored blocks to match designs presented on cards	Attention, concentration, motor coordination, visual analysis, spatial reasoning, visual construction	The ability to pay attention to and persist in a trial-and-error fashion on a nonverbal problem solving task, the ability to comprehend and perform nonverbal, spatial problems as required in such occupations as engineering or drafting -- severe deficits may be associated with directional or time problems	Test is very sensitive to brain damage -- Persons with schizophrenia tend to do well, making it a good discriminator between functional schizophrenia and structural brain disease

1571

1572

Implication For Functional Use Of The WAIS With The Severely Mentally Ill (SMI) Clients (Continued)

MEASURE	TASK	BEHAVIOR REQUIRED	FUNCTIONAL IMPLICATIONS	SMI PERFORMANCE
Object Assembly	Solve jigsaw-type puzzles requiring assembly of familiar forms	Visual perception and construction, motor coordination, cognitive flexibility	The ability to make sense of visual patterns and translate visual concepts into motor action, persistence, solving a problem from part-to-whole	Persons with schizophrenia do poorly because of speed requirements - the effects of neuroleptic medication may have a negative effect
Digit Symbol	Record symbols matched with numbers using a code	Visual perception, eye-hand speed and coordination, memory, attention	Ability to learn new material, pay attention, persistence and diligence, visual-motor quickness	Very sensitive to anxiety and psychomotor retardation - Also sensitive to even mild forms of brain disease

REPORT WRITER'S HELPER

# Macros and Text Blocks

## MACROS

Word Perfect macros are special files containing commands in the Word Perfect language (text may be embedded within the string of commands). Each macro's function is to reduce a set of many keystrokes to a small number of keystrokes. This is especially useful in cases where a particular task is performed repeatedly. All Word Perfect macro files have the filename extension "WPM". The file name is also the name of the macro with the exception of the <ALT> key macros which are named ALT<letter>.WPM. In the PRAS clinic, all true Word Perfect macros are stored in a separate directory: C:\WP51\WPM.

## TEXT BLOCKS

Word perfect allows the inclusion of other documents into the document that is being worked on. This is simply a matter of retrieving the appropriate file (<SHIFT><F10>). Over the course of many years, Dr. Katz and her staff have created a considerable number of small (sometimes larger) pieces of text that have been used over and over in reports and other documents. [Such blocks of text are often called boilerplate.] These came to be known as "macros" although they are not true Word Perfect macros (see above), but simply files of formatted text. In PRAS these files have been collected into a special directory (C:\WP51\TEXTBLK) and compiled into a printout alphabetized by file name. A macro has been created to facilitate the retrieval of these text blocks. The following procedure is used:

Place the cursor at the point you want the text to appear  
<ALT> A  
enter the full name of the text block  
<ENTER>

Because these text blocks were created over many years and on many systems, the formatting may not work very well for you. I have tried to make the more recently used text blocks completely portable (assuming a base font size of 12 point or smaller); any text block file dated later than mid-1993 should act reasonably. Older files may produce rather peculiar results. Check it out in Reveal Codes. Where a text block contains a tabular format I have set explicit tabs at the beginning of the table and reset the tabs to the default at the end.

Children's Category Test

**ABSTRACT.ABL**

The Halstead-Reitan also provides us with tests geared toward the evaluation of abilities in abstraction, reasoning, logical analysis, flexibility and planning. In Reitan's view the best measures of those functions are the Category Test, Part B of the Trail Making Test, and the Coding subtest from the Wechsler Scale. These tests generally assess the integration of neuropsychological functions as well as problem-solving skills. The Category Test requires the subject to view a series of designs, discern common elements that form the basis for a consistent application of an organizing principle, and finally, apply the principle to the apparently diverse stimulus configurations. This test heavily emphasizes abstraction, reasoning, and logical analysis. Part B of the Trail Making Test requires the individual to keep the alphabetical and numerical sequences in mind, shifting back and forth while integrating them and simultaneously searching the page for the correct stimulus item, all under the pressure of doing the task as quickly as possible. This test emphasizes flexibility in organizing stimulus material, keeping two sequences in mind at the same time, and accomplishing the task quickly. The Coding subtest achieves its organizational component from the requirement to observe, select, and match stimuli that come from rather different domains.

**ACADEMI.TXT**Academic Skills:

Having delineated areas of information processing strengths and deficits, we can now address the specific academic deficiencies displayed. We encounter an individual who has not developed beyond the basic linkages between sound and symbol relationships. Levels of grapheme-phoneme correspondence are adequate for vowels and consonants, but where "blends" or "chains" of sound-symbol relationships are concerned there are significant problems. When asked to write phonemes, gross dysphonetic errors were encountered. Thus, the rudimentary "phonics" skills essential to reading and spelling are very critically underdeveloped in this individual.

We can infer that multiple factors likely coalesce to limit expression of primary academic skill competencies. These include a central auditory information processing deficit manifest primarily in very weak sequential information processing, a fundamental impairment in grapheme-phoneme correspondence, and subtle-residual visuo-perceptual dysfunction secondary to an ocular motor problem.

Considering this individual's age, the severity of this mixed academic disability, and the complexity of the underlying information processing deficits, we would not encourage a significant investment in remedial educational efforts. Compensatory instructional strategies incorporating whole word recognition (i.e., a "look-say approach to reading) or building fundamental primary math skills via the use of a calculator should certainly be considered. Further development of academic skill competencies beyond "survival skill levels" is reviewed as otherwise quite limited. We would instead refocus vocational rehabilitation efforts on opportunities to develop skills and competencies in occupational categories which make minimal demands on literacy skills.

**ARTS.PRO**

**Professional Arts** occupations involve individualized expression of creative or musical talent. They include the fields of design, fine arts and performing arts. Sample occupations include Dance Instructor, Music Teacher, and Display Manager.

---

**ARTS.SKL**

**Skilled Arts** occupations involve application of artistic skill in the fields of photography, graphic arts and design. Sample occupations include Layout Planner (printing), Sign Printer, and Commercial Photography.

---

**BANNA**

Bannatyne recategorization of WAIS-R scores looks at three cognitive factors which have been linked with and are utilized in the processing of information and learning and a fourth factor labeled, Acquired Knowledge. The three primary factors consist of spatial, conceptual, and sequential ability areas, each of which is summarized by way of a mean rating. The spatial category is based upon the Block Design, Object Assembly, and Picture Completion subtests; the Conceptual category is based upon the Vocabulary, Similarities, and Comprehension subtests; and the sequential category is comprised of the Digit Span, Digit Symbol, and Arithmetic subtests. The final category, Acquired Knowledge is based upon the Information, Arithmetic, and Vocabulary subtests and thus generally reflects the impact of formal academic experiences. 's Bannatyne recategorized scores result in the following profile:

Spatial	>	Conceptual	>	Sequential	Acquired Knowledge
M =		M =		M =	M =

## BODER.TXT

The Boder Test is based on the premise that the dyslexic reader has a characteristic pattern of cognitive strengths and weaknesses in two distinct components of the reading process: the visual gestalt function and the auditory analytic functions. The visual gestalt function underlies the ability to develop a sight vocabulary through visual perception and memory for whole words; the auditory analytic function underlies the ability to develop phonic word-analysis skills. Thus, via the Boder Test one can (1) differentiate specific reading disability from nonspecific reading disability through reading and spelling performance; (2) classify dyslexic readers into one of three subtypes based on their reading-spelling patterns (dysphonetic, dyseidetic, Mixed Dysphonetic-Dyseidetic); and (3) assist in providing guidelines for remediation of the four reading disability subtypes identified by the test (the nonspecific reading disability plus the three dyslexic reading groups).

## BODERIII.TXT

Boder's Group III dyslexics show the combined deficits of dysphonetics and dyseidetics. They have weaknesses in both visual gestalt and the auditory analytic functions (which may not be equally severe), with resulting disability in developing both sight vocabulary and phonic skills. The reading errors typical of dyslexics in this category are wild guesses from minimal clues ("fish" for *father*) and visuospatial reversals ("on" for *no*, "pig" for *big*). Their typical spelling errors are phonetically accurate and often bizarre ("r" for *stop*). They are usually the most severely handicapped, educationally, of all dyslexic readers and may not be able to read either at sight or by ear, though they may be either more audile or more visile. Like dyseidetic readers, Group III dyslexics have difficulty learning what the letters sound like. In addition, like Group II readers, they often have persistent visuospatial difficulties. They tend to confuse reversible letters (b-d, p-q, m-w, and n-u), reversible words ("saw" for *was*), and letters with subtle graphic differences (h-n and v-y).

Without intensive remedial reading instruction, severe Group III dyslexics may remain nonreaders, or virtually alexic, even in high school. The words that they recognize at sight or can write correctly are typically on the primer or preprimer level. Characteristically, their response to initial remedial teaching is painfully slow, but their ultimate prognosis for functional reading and spelling can be quite favorable with skillful and appropriate remediation. The spelling pattern of Group III dyslexics is phonetically inaccurate, like that of Group I, but their misspellings are even more unusual--- commonly a sequence of letters unrelated to the dictated word, one wrong initial letter, or a scribble. In the same sense that they are nonreaders, they are nonspellers. Group III readers can be differentiated from Group I by the much lower grade level of their sight vocabulary and from Group II by their lack of phonic skills. They often appear to have a sense of defeat and exhibit a phobic withdrawal from reading and writing tasks.

Although many factors are involved in the prognosis for a dyslexic child, the four diagnostic reading-spelling patterns have been found in long-term observation to have definite prognostic implications that differ for each reader subtype. As might be expected, the prognosis for Groups I and II, in which only one sensory channel function (gestalt or analytic) is deficient, is usually more favorable than the prognosis for Group III, in which both visual

and auditory channel functions are impaired, though not necessarily to the same extent. Without intensive long-term remedial teaching, severe Group III dyslexics may remain nonreaders and nonspellers even in high school. With appropriate remediation, however, the prognosis for acquiring functional reading and spelling skills, even for severe Group III dyslexics, has proved to be favorable. According to Boder, a number of highly motivated, intelligent Group III dyslexics have been able to attain fifth- or sixth-grade sight vocabularies in high school. Although the severity of the dyslexic problem in the three subtypes is not determined by overall mental ability, children with above average intelligence are consistently found to be better able to develop compensatory mechanisms in overcoming their reading-spelling disability than children with below average intelligence.

---

### **BUSINESS.FIN**

**BUSINESS, Finance** occupations involve activities concerned with the control of monies and accounting for the finances of large businesses and government bureaus. Sample occupations include Accountant, Financial Planner, Economist and Market-Research Analyst.

---

### **BUSINESS.MAN**

**BUSINESS, Management** occupations involve activities concerned with the organization, direction and administration of the operation of large businesses and government bureaus. Sample occupations include Benefits Manager, Contracts Manager, Hotel Manager, and College-Business Manager.

---

### **BUSINESS.PRO**

**Professional Business** occupations include positions of high responsibility in the organization, administration and efficient functioning of business and governmental bureaus. They involve finance and accounting, management, and business promotion. Sample occupations include Accountant, Management, and Medical Records Administrator.

---

### **BUSINESS.SKL**

**Skilled Business** occupations involve sales, promotion and marketing and the correlated financial and organizational activities of business. Sample occupations include Salesperson, Appraiser, Broker, and Wholesaler.

---

**CAPS-ALT.TXT**

Scores on the CAPS help to evaluate relative strengths and weaknesses in terms of the eight abilities briefly described below.

- MR Mechanical Reasoning measures understanding of basic mechanical facts and principles and the laws of physics. This ability is important in technical and mechanical fields, skilled trades and industrial arts, as well as many scientific and agricultural pursuits.
- SR Spatial Relations measures the ability to visualize or think in three dimensions and mentally picture the position of objects in space from a two-dimensional diagram or picture. This ability is important in the arts, industrial arts, skilled trades, engineering and many scientific occupations.
- VR Verbal Reasoning measures how well an individual can reason logically with words given facts and possible conclusions which may be drawn from those facts, and facility for understanding and using concepts expressed in words. The ability to reason accurately is important in general academic success, jobs requiring written or oral communication, science, service and business.
- NA Numerical Ability measures basic computational skills, mathematical reasoning, and the ability to use numbers and work with quantitative materials and ideas. This ability is important in many school courses and is required in varying degrees in almost all of the scientific, technical, business and clerical fields.
- LU Language Usage measures how well an individual can recognize and use standard English grammar, punctuation, and capitalization. This ability is important in jobs requiring written or oral communication, clerical jobs, professional level science occupations, and in all levels of business and service.
- WK Word Knowledge measures how well a person can understand the meaning and precise use of words. This is important in communications and all professional level occupations involving high levels of responsibility and decision making.
- PSA Perceptual Speed and Accuracy measures how well an individual can perceive small details rapidly and accurately with a mass of letters, numbers and symbols. This ability is important in office work and other jobs requiring fine visual discrimination.
- MSD Manual Speed and Dexterity measures the ability to make rapid and accurate movements with the hands. This ability is important in Arts-Skilled and Technology-Skilled occupations and other jobs requiring speed and dexterity in the use of the hands.

**CAPS.TXT**

On the CAPS, a measure of eight primary ability areas associated with the Occupational Clusters presented in the CCOPS vocational aptitude and interest battery, the following aptitude scores were derived:

	<u>Primary Ability</u>	<u>Stanine Score</u>	<u>Percentile Score</u>	<u>Range</u>
MR	Mechanical Reasoning			
SR	Spatial Relations			
VR	Verbal Reasoning			
NA	Numerical Ability			
LU	Language Usage			
WK	Word Knowledge			
PSA	Perceptual Speed and Accuracy			
MSD	Manual Speed and Dexterity			

Enclosed with this report is a print-out of scores including Percentile Scores and those Occupational Clusters within which scores are high enough to consider them as potential areas for career exploration, dependent of course on expressed vocational interests and work values.

Also enclosed with the print-out are estimated scores on the General Aptitude Test Battery (GATB), as well as interpretive aids and statements useful in career counseling and exploration.

**CCOPS.TXT**

As an aid in vocational planning the California Career Occupational Preference System was utilized. The CCOPS is comprised of a vocational aptitude measure (CAPS), an interest inventory (COPS), and a work values inventory (COPES). Specific vocational aptitudes are plotted against expressed interests and work-related values in the context of 14 major occupational cluster areas. These occupational cluster areas range from the Professional Science area to that of Service occupations and have been successfully correlated with the General Aptitude Test Battery and its resultant Occupational Aptitude Patterns. Scores are expressed as Stanines (1-9, with 9 being the highest score obtainable) and as Percentiles; those above the 75th Percentile and below the 25th Percentile are judged to be particularly relevant in the overall interpretation of test results.

**CLERICAL**

Clerical occupations involve recording, posting and filing of business records requiring great attention to detail, accuracy, neatness, orderliness and speed. They include office work and contact with customers in keeping records. Sample occupations include Medical Secretary, Data Processor, Payroll Clerk, and Cashier.

**COMMUN. ORL**

**COMMUNICATION, Oral** occupations involve activities concerned with skill in the use of spoken language and the oral interpretation and communication of knowledge and ideas. Sample occupations include Lawyer, Radio or Television News Director and Announcer.

---

**COMMUN. WRI**

**COMMUNICATION, Written** occupations involve activities concerned with skill in the use of written language especially in the creation or interpretation of literature and the written communication of knowledge and ideas. Sample occupations include Copy Writer, Editorial Assistant, Librarian, Technical Writer, Editor, and Reporter.

---

**COMMUNIC. SHN**

**Communication** occupations involve language skill in the creation or interpretation of literature, or in the written and oral communication of knowledge and ideas. Sample occupations include Library Assistant, Technical Writer, and Communications Center Operator.

---

**COMPUT**

**COMPUTATION** occupations involve activities concerned with statistical analysis and use of mathematics and computation in research and business. Sample occupations include Actuary, Financial Analyst, Computer Programmer, and Statistician.

---

**CONSUMER.ECO**

**Consumer Economics** occupations involve the preparation and packaging of foods and beverages. They also include the production and care of clothing and textile products. Sample occupations include Dietetic Technician, Food Service Supervisor, and Dry Cleaner.

---

**COPEs.TXT**

The Career Orientation Placement and Evaluation Survey (COPEs) was administered in order to assess those personal values which have been repeatedly demonstrated to reflect major dimensions of job satisfaction. In conjunction with interests, what one would "like" to do, those domains which one values or perceives as important and worthwhile play an important role in career choice and job satisfaction. Work values measured by the COPEs are described below.

**INVESTIGATIVE vs. ACCEPTING:** Intellectual curiosity and the challenge of solving a complex task are major values of persons scoring high on this scale. The need for information is very important to such people. Low scorers value clear cut activities in which they see the concrete results of their work and do not need to solve many complex problems.

**PRACTICAL vs. CAREFREE:** Showing proper appreciation for one's personal belongings and appreciation of practical and efficient ways of doing things are major values of persons scoring high on this scale. Such persons value activities in which they take good care of their property and work with things to make them more practical and efficient. Low scorers value activities where others take care of equipment and keep things in good working order.

**INDEPENDENCE vs. CONFORMITY:** Independence from rules, regulations, and social conventions, and the freedom to work on their own are major values of persons scoring high on this scale. Such persons value activities in which they are relatively free of rules and regulations and are not restricted by social obligations. Low scorers value working under careful supervision where clear directions and regulations can be followed.

**LEADERSHIP vs. SUPPORTIVE:** Making decisions, directing others, and speaking for the group are major values of persons scoring high on this scale. Such persons have a need to be seen as important and usually take positions of leadership. Low scorers value activities in which they can be a good follower and do not need to direct others or tell others what to do.

**ORDERLINESS vs. NON-COMPULSIVE:** Orderliness and keeping things neat and in their proper place are major values of persons scoring high. Such persons value activities in which they keep things tidy and do what they are expected to do. Low scorers value activities in which they can take things as they come and do not need to keep things orderly.

**RECOGNITION vs. PRIVACY:** To become well known and famous and to know important people are major values of persons scoring high on this scale. Such persons seek the admiration of others, as well as the rewards of honorary degree. Low scorers value keeping their activities private and are not concerned with being considered a famous person.

**AESTHETIC vs. REALISTIC:** Artistic appreciation and the enjoyment of music and the arts are major values of persons scoring high on this scale. Such persons value activities in which they appreciate beauty, show artistic and emotional sensitivity, and appreciate music and the arts. Low scorers value activities in which they do not rely on their senses and in which they are not involved with appreciation of artistic qualities.

**SOCIAL vs. SELF-CONCERN:** Helping others and appreciating the work of charitable service groups are major values of persons scoring high on this scale. Working with people in a friendly situation is important to such persons. Low scorers value activities in which they spend time on their own projects and tend to their own affairs rather than helping others.

Work and/or activity which incorporates value preferences is seen to be intrinsically worthwhile and indicative of job satisfaction for the majority of individuals. The work related values which are most important to \_\_\_\_\_ are listed below; preference for the underlined work value is indicated by percentile rank.

Work Value Scale

Percentile Rank

Investigative vs. Accepting  
Practical vs. Carefree  
Independence vs. Conformity  
Leadership vs. supportive  
Orderliness vs. Non-Compulsive  
Recognition vs. Privacy  
Aesthetic vs. Realistic  
Social vs. Self-Concern

---

**COPS**

The COPS is a self-report measure which allows the individual to select and more carefully define the kind of work which he/she may be interested in doing. Choices are given regarding a variety of activities which are performed and/or are a part of many and diverse occupations. The individual is asked to make choices based on personal interests rather than on consideration of factors such as salary, social standing, or future advancement. These many activities are then categorized with respect to the fourteen occupational clusters detailed in the CCOPSystem and reported as percentile ranks. \_\_\_\_\_'s highest reported vocational interest areas fall under the career clusters of:

- 1.
- 2.
- 3.
- 4.
- 5.

Percentile

1604

---

**COPS-P**

The COPS-P is a self-report measure which allows the individual to select and more carefully define the kind of work which he/she may be interested in doing. Choices are given regarding a variety of activities which are performed and/or are a part of many and diverse occupations. The individual is asked to make choices based on personal interests rather than on consideration of factors such as salary, social standing, or future advancement. These many activities are then categorized with respect to the sixteen professional-level occupational clusters detailed in the CCOPSystem and reported as percentile ranks. 's highest reported vocational interest areas fall under the career clusters of:

	<u>Percentile</u>
1.	
2.	
3.	
4.	
5.	

---

**COPSP.II**

The COPSP is a self-report measure which allows the individual to select and more carefully define the kinds of work which he/she may be interested in doing. Choices are given regarding a variety of activities which are performed and/or are a part of many and diverse professional or college-oriented occupations. The COPSP yielded the following percentile levels of interest across 16 major professional-level occupational clusters.

<u>Career Group</u>	<u>Percentile</u>
1 Science, Medical-Life	
2 Science, Physical	
3 Technology, Electrical	
4 Technology, Mechanical	
5 Technology, Civil	
6 Outdoor, Nature	
7 Outdoor, Agribusiness

**DTLA.TAB**

The third edition of the Detroit Tests of Learning Aptitude (DTLA-3) is designed as a battery to measure a variety of developed abilities, a term coined by Anastasi to convey a means of looking at the fundamental similarities between traditional achievement and aptitude tests and specifically focusing on discrete, special abilities which underlie the learning process. The DTLA-3 is a battery of 11 subtests that measure different but interrelated mental abilities. In addition to the 11 subtests, a General Mental Ability Composite score can be derived from combining the standard scores of all 11 subtests. An Optimal Level Composite score can also be derived by looking at the four largest standard scores made by the individual on the subtests. Finally, three Domain scores are derived: Linguistic (Verbal and Nonverbal); Attentional (Attention-enhanced--concentration and short term memory; Attention-reduced--long term memory); and Motoric (Motor-enhanced--complex manual dexterity; Motor-reduced--motor free, oral or pointing responsivity). Thus, results from the DTLA-3 are useful in describing an individual's relative strengths and weaknesses, an adjunct to intelligence testing, and as a predictive measure of future performance.

's scores on the DTLA-3 are as follow:

**GENERAL MENTAL ABILITY****OPTIMAL****LINGUISTIC**

VERBAL

NONVERBAL

**ATTENTIONAL**

ENHANCED

REDUCED

**MOTORIC**

ENHANCED

REDUCED

**DYSEIDET.RDR**

Dyseidetic readers show strengths in the auditory analytic function and weaknesses in the visual gestalt function. They show a deficit in visual memory and perception for letters and whole words, with resulting disability in developing a sight vocabulary. Their typical reading errors are phonetic misreadings of nonphonetic words ("lowg" for laugh) and visuospatial reversals of reversible letters and words ("dig" for big, "was" for saw). Their typical spelling errors are good phonetic equivalents of the dictated words. Dyseidetics read slowly, as if seeing each word for the first time. Unlike dysphonetic readers, who have difficulty learning what the letters sound like, dyseidetic readers have poor memory for the visual configurations of letters and words and thus have difficulty learning what the letters look like. They are analytic readers and read by ear rather than by whole-word configurations. They read laboriously, sounding out familiar as well as unfamiliar combinations of letters. Dyseidetic readers, like dysphonetic readers, spell poorly but not

bizarrely. They spell as they read - by ear. Thus their typical misspellings are phonetically accurate, and the original words can usually be recognized. Their occasional phonetically inaccurate or bizarre misspellings of nonphonetic words seem to be the result of their efforts to spell words in their sight vocabularies by revisualizing them and thus failing to make use of their more efficient auditory channel.

---

### **DYSPHO.RDR**

Dysphonetic readers show strengths in the visual gestalt function and weaknesses in the auditory analytic function. They have difficulty integrating symbols with their sounds, and as a result they are unable to develop phonic decoding skills without remedial instruction. Dysphonetic readers typically have a function though relatively limited sight vocabulary of whole words that they recognize on flash presentation and read fluently. They read words globally, as whole-word gestalts, rather than analytically. No matter how common or phonetic a word may be, if it is not yet in their sight vocabulary, they are typically unable to decipher it. They may have learned the fundamental sound-symbol associations, but they lack phonic word-analysis skills; they are still unable to sound out and blend the component letters and syllables of a word and offer more misreadings than either of the other two dyslexic subtypes. They may guess at a word from minimal graphic clues, typically from the first and last letter and the length of the word, resulting in global or gestalt substitutions such as "monkey" for money and "stop" for step. Their most striking substitutions--which occur primarily in reading but also in spelling--are semantic substitutions. These words are similar in meaning to the original words but are unlike them phonetically; for example, "person" may be substituted for human and "airplane" for train. Semantic substitutions are so characteristic in this group of dyslexics that they are virtually diagnostic.

Dysphonetic readers attempt to spell by sight alone and not by ear, for they have difficulty in learning what the letters sound like. They cannot spell phonetically because they cannot read phonetically. Just as they are typically unable to analyze the visual gestalt of a written word, they are unable to analyze, or segment, a spoken word (the auditory gestalt) into its component sounds and syllables; that is, they are unable to syllabicate. Their misspellings are therefore phonetically inaccurate and include such errors as extraneous letters, omitted syllables, auditory discrimination errors, syllable reversals, letter-order errors, and other auditory sequencing errors. They spell correctly to dictation only those words in their sight vocabularies that they can revisualize, phonetic or not. These words seldom total as much as 50 percent of their sight vocabulary at treading level and usually far less.

Visuospatial reversals, including letter reversals, mirror-reading and mirror-writing, are not characteristic of dysphonetic readers. Like normal beginning readers, they tend to overcome these errors before the age of eight, and they have no difficulty learning what the letters look like. They do tend to persist, however, in making syllable and letter-order reversals (for example, "interver" for inventor and "wirters" for writers), though they do this less in reading than in spelling.

---

**GATB.TXT**

The General Aptitude Test Battery (GATB) is a multiaptitude test battery for use in vocational counseling and guidance. The following interpretive statements should assist the individual to understand current vocational aptitude scores and how these relate to a wide variety or groups of occupations. It must be noted that this instrument does not take into account any other factors which figure in occupational success, such as educational or training requirements, social skills, or specific work-related stressors.

Listed below are the letters used as the symbol to identify each aptitude and the definitions of the nine aptitudes measured by the GATB:

**APTITUDE**

- G General Learning Ability - The ability to "catch-on" or understand instructions and underlying principles; the ability to reason and make judgments. Closely related to doing well in school (formal educational settings).
- V Verbal Aptitude - The ability to understand the meaning of words and to use them effectively. The ability to comprehend language, to understand relationships between words, and to understand meanings of whole sentences and paragraphs.
- N Numerical Aptitude - The ability to understand and perform arithmetic operations quickly and accurately.
- S Spatial Aptitude - The ability to think visually of geometric forms and to comprehend the two-dimensional representation of three-dimensional objects. The ability to recognize the relationships resulting from the movement of objects in space.
- P Form Perception - The ability to perceive pertinent detail in objects or in pictorial or graphic material. The ability to make visual comparisons and discriminations, and to see slight differences in the shapes and shadings of figures, widths, and lengths of lines.
- Q Clerical Perception - The ability to perceive pertinent detail in verbal or tabular material. The ability to observe differences in copy, to proofread words and numbers, and to avoid perceptual errors in arithmetic computation. Also a measure of speed of perception.
- K Motor Coordination - The ability to coordinate eyes and hands or fingers rapidly and accurately in making precise movements with speed. The ability to make a movement response accurately and swiftly.
- F Finger Dexterity - The ability to move the fingers, and manipulate small objects with the fingers, rapidly or accurately.
- M Manual Dexterity - The ability to move the hands easily and skillfully. Ability to work with the hands in placing and turning motions.

Aptitude scores may be broadly interpreted according to the following scale:

<u>APTITUDE SCORE</u>	<u>RANGE</u>
120 and above	High
76-119	Medium
75 and below	Low

The GATB aptitude norms for use in counseling and guidance are referred to as Occupational Aptitude Patterns (OAPs). An OAP may be defined as "The combination of aptitudes and minimum scores required to perform satisfactorily the major tasks of each occupation identified with each pattern". OAPs are the means by which individual aptitude scores are related to broad fields of work in which aptitudinal requirements are similar, even though the specific jobs may appear to be totally unrelated.

The OAPs, or groups of jobs, are numbered 1-66. The 66 OAPs cover 97% of the non-supervisory occupations listed in the Guide for Occupational Exploration (U.S. Department of Labor, 1979). The interpretation of OAP as High, Medium, or Low is as follows:

- HIGH**      The individual's scores equal or exceed those of workers judged to be satisfactory in the occupations. If also qualified on the basis of factors other than aptitudes, there is a good probability that he/she will do well on the job.
- MEDIUM**      The individual's scores are close to those of workers judged to be satisfactory in the occupations. However, the chances of doing well on the job are somewhat lower than that of persons in the "High" category.
- LOW**      The individual's scores are similar to or below those of workers found to be unsatisfactory in the occupation. Barring other factors, the probability of being satisfactory on the job is low, and he/she should be considered for other jobs which utilize stronger aptitudes.

It must be noted that since the OAP scores are not specifically determined, they should be considered as guidelines.

**GORT**

An additional measure of reading, the Gray Oral Reading Test was also administered. With this diagnostic measure various reading errors and speed of reading are evaluated. The difficulty of the reading passages utilized is a function of the difficulty of vocabulary, range and density of vocabulary, syllabic length of words, length and complexity of sentence structure, and maturity of concepts.

---

**HRNB.1**

A comprehensive neuropsychological evaluation was then undertaken utilizing the Halstead Reitan neuropsychological battery and ancillary procedures. Test data were analyzed using norms developed by Heaton, Grant and Matthews (1991) and permit demographic-corrected score conversion. This allows the individual's test performances to be compared with an appropriate normative peer group which is matched for gender, age, and level of education. In addition, the HRNB provides a number of means to differentiate the presence or absence of cerebral dysfunction involving "cutting-score" criteria. The Impairment Index, a ratio score derived from the number of scales above or below a critical score criterion indicative of brain damage offers a range of scores between 0 and 1.0. Scores below .4 are generally considered within normal limits.

---

**HRNB.2**

A comprehensive neuropsychological evaluation was then undertaken utilizing the Halstead Reitan neuropsychological battery and ancillary procedures. Test data were analyzed using norms developed by Heaton, Grant and Matthews (1991) and permit demographic-corrected score conversion. This allows the individual's test performances to be compared with an appropriate normative peer group which is matched for gender, age, and level of education. In addition, the HRNB provides a number of means to differentiate the presence or absence of cerebral dysfunction involving "cutting-score" criteria. The Impairment Index, a ratio score derived from the number of scales above or below a critical score criterion indicative of brain damage offers a range of scores between 0 and 1.0. Scores below .4 are generally considered within normal limits. A more refined methodology, the General Neuropsychological Deficit Score, involves the use of severity ratings in the differentiation of

the presence or absence of brain damage. Here, scores between 0-25 are considered fully normal and scores 26-40 indicative of mild neuropsychological impairment. Profile analysis available with the HRNB provides a means to associate the performance with specific functional or neuroanatomical correlates.

---

### **HRNB.TXT**

## **JORDAN**

The Jordan Left-Right Reversal Test is a norm referenced measure which assesses visual reversals of letters, numbers, and words in individuals from five years of age through adulthood. Obtained error scores are converted to percentile scores related to expected levels of performance.

---

## **LBNOR**

The derived profile was fully normal, suggesting no evidence of structurally based cerebral dysfunction. There were no focal or lateralizing signs of impairment and no indices suggestive of acute acquired cerebral dysfunction were discerned.

Briefly summarized, in the primary sensory-perceptual sphere, intact performance was seen in auditory, visual, and tactile-haptic processing. In terms of psychomotor performance, basic coordination and speed were intact. Augmentation of the battery in visuospatial and constructional skill domains revealed no particular problem area. Aphasia screening revealed no expressive or receptive language problems. Memory proficiency was fully normal.

---

## **LINGUIST.TXT**

### Linguistic Faculties:

There were no specific dysphasic features apparent in our assessment of receptive and expressive language. Articulation and speech prosody were normal. There were some errors noteworthy in the pragmatic usage of language (grammar and syntax), but these were not uncharacteristic of the type seen in patients with limited literacy skills.

---

**LNNB.TXT**

The neuropsychological portion of the examination was conducted via the administration of the Luria-Nebraska and ancillary procedures. The Luria-Nebraska Battery provides an age and education adjusted profile of performance across fourteen domains deemed relevant to the assessment of higher cortical functioning. No focal or lateralizing signs of specific cerebral dysfunction were identified.

**M**  
**M**

**MBTI**

The Myers-Briggs Type Indicator (MBTI) is a personality survey which is primarily concerned with identifying the basic preferences of people in regard to perception, judgement, incorporating information, and making decisions.

There are two opposite preferences for each of the four scales reported by the MBTI. It is important to realize that everyone uses both of the opposite preferences at different times, but not both at once, and in most cases, not with equal confidence. The four scales and preferences are briefly defined below.

EI scale: Where does one prefer to focus his/her attention?  
**Extroversion (E)** - focus on the outer world of people and things.  
**Introversion (I)** - focus on one's inner world.

SN scale: How does one acquire information, or find out about things?  
**Sensing (S)** - focus on the realities of a situation, work with known facts.  
**Intuition (N)** - focus on meanings, relationships, and possibilities that go beyond the information from one's senses.

TF scale: How does one make decisions?  
**Thinking (T)** - objectively, on the basis of cause and effect, by impersonally analyzing the evidence.  
**Feeling (F)** - subjectively, on the basis of person-centered and personal values.

JP- scale: How does one orient the outer world?  
**Judging (J)** - like to live in a planned, orderly way, wanting to regulate life and control it.  
**Perceiving (P)** - like to live in a flexible, spontaneous way, gathering information and keeping options open, seeking to understand life rather than control it.

\_\_\_\_\_ indicated preferences for the following type:

\_\_\_\_\_’s preferences on the MBTI are \_\_\_\_\_ with his/her preferences on the COPEs. Enclosed with this report is a more extensive interpretive aid on the MBTI and \_\_\_\_\_ preferences. \_\_\_\_\_ types do best in careers needing \_\_\_\_\_, \_\_\_\_\_, and \_\_\_\_\_. Examples include: \_\_\_\_\_.

## MCFI-II.TXT

The MCFI-II, a multi-axial inventory measure comprised of twenty clinical scales, was designed to distinguish the more enduring personality characteristics of patients (Axis II) from the acute clinical disorders categorized under Axis I as well as measure the severity of clinical syndromes present. Cutting scores are used to make decisions concerning primary behavior disorders or syndrome diagnoses and elevations among subsets of scales can provide information regarding level of impairment, severity, and chronicity of the disorder.

## MDRS-N-S

### MDRS-N-S

The Mattis Dementia Rating Scale (DRS) screens five major domains of cognitive function, yielding composite scores for each of the subtests as well as a total test score. The subject’s scores/performances on each of these variables can then be compared to peer reference data available for normal controls and those who carry diagnoses of Senile Dementia of the Alzheimer’s-type (SDAT). The data obtained with \_\_\_\_\_ is noteworthy on several counts, and these will be explored from general through specific levels of interpretation.

A composite test score of \_\_\_\_\_ was obtained, (placing below the actuarial cut-off score of 123) suggesting that a diagnosis of dementia may apply. What is most interesting, however, is to review the strengths and weaknesses across the subtests and contrast these with existing normative data.

	NORMAL CONTROL			SDAT NORMS

DRS Total		137.3	6.9

**MMPI.INV**

An attempt was made to potentially contribute to diagnostic formulations regarding this individual's psychiatric status by administering an abbreviated version of the Minnesota Multiphasic Personality Inventory. In short, the MMPI profile was not viewed as valid for interpretive purposes. The item endorsement pattern suggested an extreme overstatement of unusual symptoms, feelings, and/or experiences. The magnitude of disturbance implicated through the responses was so severe that the likelihood that this represents bonafide psychopathology is very slim. Such an overstatement of psychologic distress may be the result of multiple situations or dynamics. For some individuals, it is possible that the test queries were misunderstood or that they were careless in responding to render a somewhat haphazard item endorsement. For others, such an extreme portrayal may represent a plea for psychological help. Finally, the possibility of malingering must be considered if there is reason to believe that secondary gains could be derived from such severe emotional disturbance.

**MMSMB.TXT**

Personality assessment was conducted via use of the Minnesota Multiphasic Personality Inventory - II (MMPI-II), the Millon Clinical Multiaxial Inventory - II (MCMI-II), the SCL-90-R, the Multidimensional Self-Esteem Inventory (MSEI), and the Beck Depression Inventory (BDI).

**NELSON.TAB**

	<u>Standard</u>	<u>Percentile</u>

**OUTDOOR**

**Outdoor** occupations involve activities performed primarily out of doors. They include the growing and tending of plants and animals and the cultivation and gathering of crops and natural resources in the areas of agriculture and nature as in forestry, park service, fishing and mining. Sample occupations include Nursery Laborer, Soil Conservationist, and Park Ranger.

---

**OUTDOOR.AGR**

**OUTDOOR, Agribusiness** occupations involve activities performed primarily out-of-doors which are concerned with the growing, tending and harvesting of plants and animals for human consumption. Sample occupations include Dairy Technologist, Farmer, Horticulturist, Soil Conservationist, and Range Manager.

---

**OUTDOOR.NAT**

**OUTDOOR, Nature** occupations involve activities performed primarily out-of-doors which are concerned with the protection, accumulation and harvesting of natural resources. Sample occupations include Derrick Operator, Fish and Game Warden, Forester, Oceanographer and Ecologist.

---

**PERFORM**

## PERFORM

**PERFORMANCE SUBTEST DESCRIPTIVES FOR:**

**PICTURE COMPLETION  
PICTURE ARRANGEMENT  
BLOCK DESIGN  
DIGIT SYMBOL  
OBJECT ASSEMBLY**

**PC**

a measure of concentration and the ability to differentiate essential from nonessential details

**PA**

the ability to interpret social situations and nonverbal reasoning ability

**BD**

a measure of visual-motor coordination and spatial visualization

**DS**

a measure of speed of mental operations and visual-motor coordination

**OA**

visual motor coordination and perceptual organizational ability

**RHEMSOC.SYN**

Perceptual deficits associated with a right hemisphere syndrome may render the individual at further disadvantage in the realm of social understanding and behavior. Cognitive/perceptual deficits may result in deficiencies in the ability to interpret/understand nonverbal sources of communication (such as subtle facial expressions, body postures, various gestures, etc.). Consequentially, this individual may be at further risk for misinterpreting or failing to interpret relevant elements in social situations as well as the environment at large. Subtle interpersonal nuances pertinent for effective relating skills may not be present (such as appreciating the others' personal space; perceiving appropriateness in timing and length of dialogue). Additionally, poor social reception may be related to these variables as well as the somewhat unusual prosody of speech.

The individual's inefficacy in "sizing up" situations (both socially and personally), may result in reliance upon very concrete and routinized self-monitoring skills. The consequences could be manifested in ways such as poor management of personal affairs, inadequate maintenance of impulse controls, and the limited capacity/potential for changing maladaptive behaviors.

**S-B1.TAB**

The Stanford-Binet Intelligence Scale: Fourth Edition was utilized to assess general intellectual functioning. Presented below are the Standard Age Scores (SAS's) that were derived for each general domain and the Test Composite Score, all of which are based on a mean of 100 and Standard Deviation of 16.

Verbal Reasoning SAS  
 Abstract/Visual Reasoning SAS  
 Quantitative Reasoning SAS  
 Short-Term Memory SAS

Further analysis of cognitive strengths and weaknesses within each of the general domains is available through review of performance levels across the various subtests of the Stanford-Binet: Fourth Revision all of which have a mean of 50 and a Standard Deviation of 8.

**Verbal Reasoning Subtests**

Vocabulary  
Comprehension  
Absurdities  
Verbal Relations

**Abstract/Visual Reasoning Subtests**

Pattern Analysis  
Copying  
Matrices  
Paper Folding and Cutting

**Quantitative Reasoning Subtests**

Quantitative  
Number Series  
Equation Building

**Short-Term Memory Subtests**

Bead Memory  
Memory for Sentences  
Memory for Digits  
Memory for Objects

---

**SCIENCE.LIF**

**SCIENCE, Medical- Life** occupations involve activities concerned with the conducting of research and the accumulation and application of systemized knowledge in medicine and the biological and life sciences. Sample occupations include Anesthesiologist, Pharmacologist, Psychiatrist, Geneticist, and Biomedical Engineer.

---

**SCIENCE.PHY**

**SCIENCE, Physical** occupations involve activities concerned with the planning and conducting of research and the accumulation and application of systemized knowledge of the physical world in the earth sciences. Sample occupations include Chemist, Physicist, Pharmacist, Geologist and Research Dietician.

---

**SCIENCE.PRO**

**Professional Science** occupations involve responsibility for the planning and conducting of research and the accumulation and application of systematized knowledge in related branches of mathematical, medical, life and physical sciences. Sample occupations include Actuary, Chemist, Pharmacologist, and Programmer.

---

**SCIENCE.SKL**

**Skilled Science** occupations involve observation and classification of facts in assisting in laboratory research and it's application in the fields of medicine and life and physical sciences. Sample occupations include Surgical Technician, Dental Assistant, Hygienist, Pharmacy Helper, and Meter Reader.

---

**SCII**

A second measure of occupational interest was utilized to further explore \_\_\_\_\_'s career interests. The Strong-Campbell Interest Inventory (SCII) yields systematic information about patterns in one's vocational interests and how these patterns compare with those of successful people in many occupations. Results are based on interests, not aptitudes or abilities. Indicated likes and dislikes are analyzed in three main ways: 1) "General Occupational Themes" for similarity to six important overall patterns; 2) "Basic Interest Scales", for similarity to 23 clusters of specific activities; and 3) "Occupational Scales", for similarity to the interests of men and woman successfully employed in 106 occupations.

Found below is \_\_\_\_\_'s profile on the General Occupational Themes of the SCII. The range of scores is roughly from 30 to 70, with the average person scoring 50.

<u>GENERAL OCCUPATIONAL THEME</u>	<u>SCORE</u>	<u>RANGE</u>
Realistic		
Investigative		
Artistic		
Social		
Enterprising		
Conventional		

Of the 23 Basic Interest Scales of the SCII, \_\_\_\_\_'s interest reached average or higher on the following scales:

<u>BASIC INTEREST SCALE</u>	<u>SCORE</u>	<u>RANGE</u>

\_\_\_\_\_’s responses were very similar or similar to those of persons working in occupations corresponding to \_\_\_\_\_ of the 106 Occupational Scales of the SCII.

There are two Special Scales on the SCII designed to yield additional insight into interests and expectations. The Academic Comfort Scale differentiates between people who enjoy being in an academic setting and those who do not. Persons with low scores (below 40) often are inclined to view education as a necessary hurdle for entry into a career, whereas persons with high scores (above 50) typically seek out academic courses. \_\_\_\_\_ score of \_\_\_\_\_ on this scale indicated a \_\_\_\_\_ inclination/disinclination toward formal academic coursework. The Introversion-Extroversion Scale is associated with a preference for working with things or ideas (scores above 55) or with people (scores below 45). \_\_\_\_\_ score of \_\_\_\_\_ on this scale indicates a \_\_\_\_\_ preference for working \_\_\_\_\_.

Enclosed with this report is \_\_\_\_\_ comprehensive SCII Profile Report and further interpretive information.

## **SCL.90**

The SCL-90-R is a 90-item self-report symptom inventory which yields a profile based upon nine primary symptom dimensions labeled Somatization, Obsessive-compulsive, Interpersonal sensitivity, Depression, Anxiety, Hostility, Phobic Anxiety, Paranoid Ideation, and Psychoticism.

## **SENSORY.TXT**

### Sensory-Perceptual Faculties:

In terms of basic tactile-haptic skills, there was no evidence of impairment in the ability to discriminate stimuli delivered to the skin. Finger localization, point and pressure sensitivity, and two-point discrimination were readily demonstrated. As soon as a symbolic demand became associated with the interpretation of tactile stimuli (drawing shapes or alphanumeric symbols on the skin or discriminating objects placed in the hand) performance

became obviously less efficient.

In the auditory modality, there was no evidence of any loss in primary acoustical or phonemic discrimination skills. With increasing complexity of auditory stimuli, however, especially the processing of lengthy spans of sequential auditory information, performance immediately faltered. We emphasize that we were not impressed with evidence of "attentional impairment". Rather, there appears to be evidence of central information processing difficulties. This individual appears limited in the amount and complexity of information which can be acted upon and sequentially processed.

---

### **SERVICE.INS**

**SERVICE, Instructional** occupations involve activities concerned with the instruction of techniques in interpersonal relations especially in caring for the personal needs and welfare of others in the field of education. Sample occupations include Teacher, Coach, and Director of Student Affairs.

---

### **SERVICE.PRO**

**Professional Service** occupations include positions of high responsibility in caring for the personal needs and welfare of others in fields of social service, health and education. Sample occupations include Teacher, Counselor, and Nurse/Physician.

---

### **SERVICE.SKL**

**Skilled Service** occupations involve providing services to persons and catering to the tastes, desire and welfare of others in fields of personal service, social and health related services, and protection and transportation. Sample occupations include Housekeeping, Home Health Aide, and Security Guard.

---

### **SERVICE.SOC**

**SERVICE, Social-Health** occupations involve activities concerned with interpersonal relations in caring for the personal needs and welfare of others in fields of social service and health. Sample occupations include Nurse, Counselor, Speech Pathologist, Probation Officer, and Recreational Therapist.

---

**SPEECH.TXT**

Expressive speech evidences an articulation disorder as well as an unusual tonal quality and flow. These deficits are not, however, conceptualized as classic "left hemisphere" language problems but rather, components of the suspected right hemisphere syndrome. The same motor lags creating slowing and incoordination in the contralateral hand could also result in the developmental articulation problems evidence. The demonstrated prosodic abnormalities are equally interesting and impressive within the conceptualized formulation of right hemisphere dysfunction. Specifically, this is described in the literature as frequently associated with right hemisphere pathology since prosody relies upon affective expression and rhythmic appreciation. There is a body of literature to support that mediation of both may integrally involve right more than left hemisphere regions.

---

**SR1**

\_\_\_\_\_ was given information regarding services available from the Office of Vocational Rehabilitation (OVR) and was instructed to contact OVR directly if OVR fails to contact him/her within three weeks of hospital discharge.

---

**SR2**

No follow-up is planned in NARS at this time as outpatient treatment will be non-catchment at WPIC as per Institute policy.

---

**SR3**

\_\_\_\_\_ would be a good candidate for vocational skill training. Any training program under consideration should be evaluated in terms of necessary reading skills. \_\_\_\_\_ would probably do best in jobs/training that emphasize hands-on rather than textbook learning.

---

**SR4**

\_\_\_\_\_ could benefit from job seeking skills training, support and assistance.

---

**SR5**

\_\_\_\_\_ is a good candidate for job placement assistance.

---

**SR6**

\_\_\_\_\_ will be receiving outpatient treatment through \_\_\_\_\_, therefore, no follow-up is planned in NARS at this time.

---

**SR7**

\_\_\_\_\_ is seen in the NARS clinic twice per month on an outpatient basis. He/she has been referred to the Office of Vocational Rehabilitation (OVR) and liaison services will continue.

---

**SR8**

As the patient has expressed an interest in attending college, consideration should be given to California University of Pennsylvania's specialized programs for students with learning disabilities, which include summer programs for high school juniors and seniors, as well as an Associate Degree program.

---

**SR9**

Consideration may also be given to the specialized instruction and "survival skills" training for the learning disabled available through the Association for Learning Disabilities.

---

**SR10**

\_\_\_\_\_ should be referred to the Office of Vocational Rehabilitation (OVR) in order to establish eligibility and to facilitate further vocational counseling and subsequent financial sponsorship in programming.

---

**SR11**

It is recommended that \_\_\_\_\_ continue to explore the nature of careers of interest as well as various related college programs of study and curriculum choices.

---

**SR12**

\_\_\_\_\_ could gain exposure and practical experience through informational/site interviews, and working as a volunteer or part-time in a \_\_\_\_\_ setting.

---

**SR13**

\_\_\_\_\_ may benefit from experiencing one or two courses representative of the core curriculum of high interest careers. These could be taken on a non-credit/"leisure learning" basis or for credit.

---

**SR14**

The patient may wish to consider Community College of Allegheny County's (CCAC) Learning Disabled "Block" Program, in which students with learning disabilities take classes in remedial math, English, and reading, as well as word processing, study and survival skills, and career development.

---

**SR15**
