DESCRIPTORS	Computer Uses in Education; Courseware; Distance Education; *Educational Media; *Educational Technology; Elementary Secondary Education; *Hypermedia; Material Development; *Multimedia Instruction; *Multimedia Materials; Postsecondary Education; *Telecommunications; World Wide Web

ABSTRACT

This proceeding presents 56 papers pertaining to the wide area of educational multimedia/hypermedia and telecommunications. The papers report on various stages of the development process, including the development and description of a concept, prototype development, prototype implementation and evaluation, and mainstream implementation. They cover a range of topics, including: (1) integrated World Wide Web (WWW) sites, e.g., courses on-line; (2) WWW delivery systems, e.g., WebCT, TeleTop; (3) WWW resources, e.g., Java Applets, assessment tools; (4) communications technologies, e.g., NetMeeting; (5) CD-ROM applications; (6) Novel environments; and (7) other, e.g., development processes, project management. Preface

Welcome to ED-MEDIA 99 in Seattle, USA. This year sees the conference back in the USA after two successful years in Calgary and Freiburg. ED-MEDIA 99 represents the 11th time this conference has run and this year's conference promises to be as successful as those which have preceded it.

The Conference is organised by the Association for the Advancement of Computing in Education (AACE) and over the years has developed a strong international following. The Conference has grown hand in hand with the emergence of new learning technologies and now represents the premier event for this field in the world. Each year sees an increasing number of delegates and participants and showcases the best efforts of the major advocates and researchers of learning technologies.

The strong international participation of the conference is demonstrated by the depth and breadth of submissions we have received this year for presentation at ED-MEDIA. We received over 600 proposals of full and short papers, workshops, tutorials and posters from nearly 50 different countries. Each proposal was generally reviewed by 3 referees from our panel of expert reviewers on the Program Committee. Those selected for presentation represent work of the highest quality. Our program of keynote and invited speakers once again reflects the international flavour of the programme, and we are confident that these people will inspire you by challenging your assumptions and extending your thinking.

In our roles as Program Chairs, we have been very interested to explore the types of presentations that people choose to make at ED-MEDIA. We are constantly looking for ways to bring new technologies into the mainstream of educational practices. Our reviews of the forms of research and content reflected overall in the ED-MEDIA programme makes interesting reading and provides some scope for reflection.

To aid us in this respect, we designed an analysis tool in the form of a matrix to enable us to classify the full papers, short papers and posters that were submitted to the Program Committee. The matrix considers on one axis the stage of the development process on which a paper reports. On this axis we see 4 main stages:

1. The development and description of a concept;
2. Prototype development;
3. Prototype implementation and evaluation
4. Mainstream implementation

The second axis of the matrix considers the domain of the technology. We chose to classify papers into the following categories:

1. Integrated WWW sites, eg. courses on-line
2. WWW Delivery systems, eg. WebCT, TeleTop
3. WWW resources, eg. Java Applets, assessment tools
4. Communications technologies, eg. NetMeeting
5. CD-ROM applications
6. Novel environments eg. VR
7. Others eg. development processes, project management

When submissions were classified using this schema, interesting patterns emerged. Our initial explorations indicated that the bulk of the research and development being undertaken is in Web-related areas and in particular in the development and evaluation of courses and programmes. Consider for example the results of using this schema to classify the papers considered for best paper awards at ED-MEDIA 99. These were the papers that achieved an average score of 4.5 or greater out of a maximum of 5 in the review process.

	concept	**prototype**	**evaluation**	**mainstream**
Integrated WWW sites	5	3	8	2
WWW delivery systems	2	1		
WWW resources	1	6	2	
Communications technologies			2	
CD-ROM applications			3	
Novel environ-ments eg. VR		1		
Other eg. project development	3		2	1

Classification of the papers considered for a Best Paper Award, ED-MEDIA 99

In terms of the stages of development, most papers tend to report prototype development and evaluation. There appear to be few ideas that go beyond this stage. Very few researchers are reporting on the mainstream use of their products and ideas. The work seems to be stopping at an early stage and not being taken to the final stage where it can really have an influence. We intend to explore these trends further and hope to be able to report back to you on our findings.

As Conference Co-Chairs we have been aided considerably by a number of volunteers and helpers who have given tirelessly of their time. In particular we must thank the Conference Steering Committee of Gary Marks, Ivan Tomek, Tom Reeves and Erik Duval who led and coordinated the conference this year. We would like to thank the Chairs of the various Program Committees, Niki Davis, Panels Chair; Sam Rebelsky, Workshops/Tutorials Chair; and Martyn Wild, Posters/Demos Chair. We would also like to thank the crew behind the scenes from AACE for their tireless efforts in coordinating and managing the huge number of administrative functions which a conference like this necessarily involves.

We look forward to meeting with you during the conference and trust that you will take the time to renew old acquaintances, meet new friends, be inspired by peers and take home some new ideas and activities to report back at ED-MEDIA 2000 in Montreal, June 26-July 1.

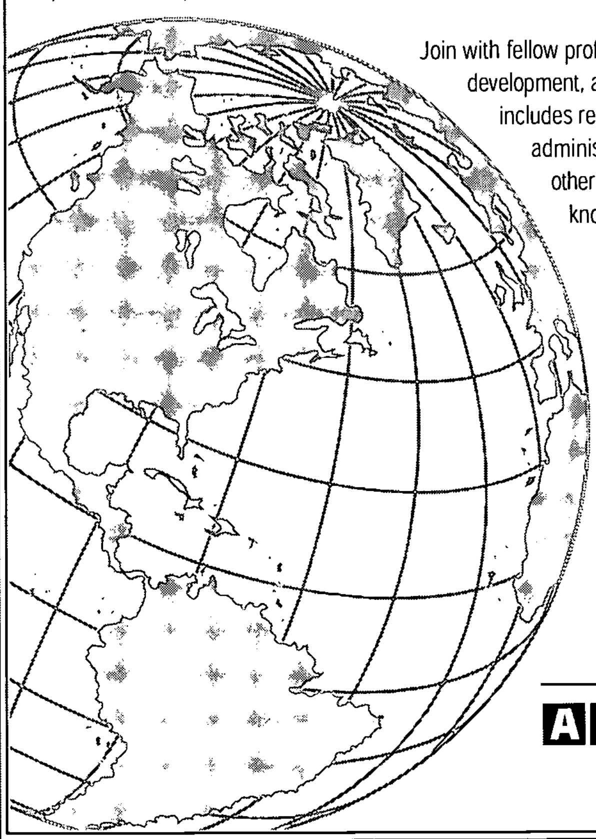
Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high-quality peer-reviewed publications, and conferences.



Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights

- *Gain professional recognition by participating in AACE sponsored international conferences*
- *Enhance your knowledge and professional skills through interaction with colleagues from around the world*
- *Learn from colleagues' research and studies by receiving AACE's well-respected journals and books*
- *Receive a subscription to the Professional Member periodical* Educational Technology Review
- *Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs*

Advancing Knowledge and Learning with Information Technology

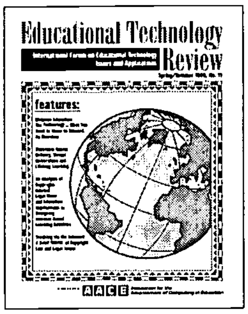
AACE Journals

Abstracts for all journal issues are available at www.aace.org/pubs

Educational Technology Review

International Forum on Educational Technology Issues & Applications
(ETR)

ISSN# 1065-6901

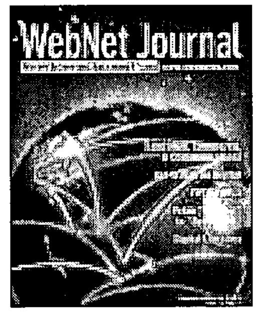


AACE's member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. It's purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. All AACE Professional and Student Members receive *ETR* as a benefit of membership.

WebNet Journal

Internet Technologies, Applications & Issues

ISSN# 1522-192X *Quarterly*

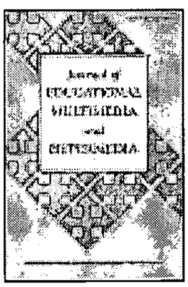


Focused on WWW, Internet, and Intranet-based technologies, applications, research, and issues, the *WebNet Journal* is intended to be an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

Journal of Educational Multimedia and Hypermedia

(JEMH)

ISSN# 1055-8896 *Quarterly*

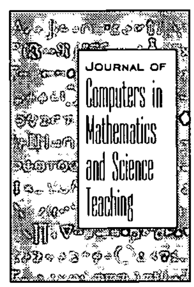


Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the *Journal* is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

Journal of Computers in Mathematics & Science Teaching

(JCMST)

ISSN# 0731-9258 *Quarterly*

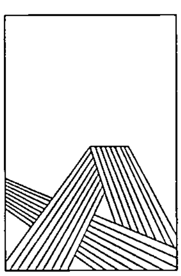


JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The *Journal* offers an in-depth forum for the interchange of information in the fields of science, mathematics, and computer science.

Journal of Interactive Learning Research

(JILR)

ISSN# 1093-023X *Quarterly*



The *Journals'* published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro- worlds, virtual reality based learning systems.

Journal of Technology and Teacher Education

(JTATE)

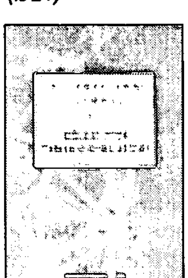
ISSN# 1059-7069 *Quarterly*

A forum for the exchange of knowledge about the use of information technology in teacher education. *Journal* content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

International Journal of Educational Telecommunications

(IJET)

ISSN# 1077-9124 *Quarterly*

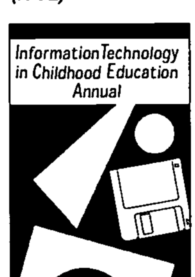


IJET serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Information Technology in Childhood Education Annual

(ITCE)

ISSN# 1043-1055



A primary information source and forum to report the research on and applications of using information technology in the education of children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.

AACE Conferences

Details for conferences are available at www.aace.org/conf

The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields; have an opportunity to participate in papers, panels, poster/demonstrations and workshops; and meet invited speakers.

ED-MEDIA 2000

World Conference on Educational Multimedia, Hypermedia & Telecommunications

JUNE 26-JULY 1, 2000 • MONTRÉAL, CANADA

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications

This 12th annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

WebNet 99

World Conference on the WWW and Internet

OCT. 30-NOV. 4, 1999 • SAN ANTONIO, TX USA

OCTOBER 25-30, 2000 • HONOLULU, HAWAII USA

WebNet - World Conference on the WWW & Internet

This annual conference enables the exchange of information in these major topics: Commercial, Business, Professional, and Community Applications; Education Applications; Electronic Publishing and Digital Libraries; Ergonomic, Interface, and Cognitive Issues; General Web Tools and Facilities; Personal Applications and Environments; Societal Issues, including Legal, Standards, and International Issues; and Web Technical Facilities.

International Conference on M/SET 2000

Mathematics/Science Education & Technology

FEBRUARY 5-8, 2000 • SAN DIEGO, CA USA

M/SET - International Conference on Mathematics/Science Education & Technology

The conference focuses upon information technology in mathematics, science and computer science education across all levels and settings, including elementary, secondary, college, and teacher education. Learn about the current research, development, classroom applications, issues, theory, and trends.

Society for Information Technology & Teacher Education 2000

11th International Conference

FEBRUARY 8-12, 2000 • SAN DIEGO, CA USA

SITE - Society for Information Technology and Teacher Education International Conference

This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences

ICCE - International Conference on Computers in Education

ICCE is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

NOVEMBER 4-7, 1999 • CHIBA, JAPAN

ICLS - International Conference on the Learning Sciences

ICLS, held biennially, is designed for researchers, developers, practitioners, consumers, and policy makers to share experiences and insights on fostering effective learning to serve real-world needs. Represented are a diverse group from the fields of cognitive science, multimedia, training, education, and artificial intelligence.

2001 • TAIWAN

Educational Reform by Information and Communications Technology: ICT Strategies for Educational Improvement-A Japanese Perspective

Takashi Sakamoto
Director-General
National Institute of Multimedia Education
Japan
sakamoto@nime.ac.jp

Abstract: In traditional education, students belong to only one school and passively learn from teachers through information transmission such as lectures and classroom demonstrations, along with a few opportunities for active participation. Traditional approaches to education are not effective enough to prepare citizens to cope with the complicated problems of the changing societies of the 21st century. Students need to develop the skills that will enable them to become lifelong learners.

Using information and communications technology, we could overcome borders of countries, universities, schools and academic subjects, and also barriers of even time and location. Each student could select the best course or even the best school or university in the world, according to his/her own interests, by means of internet, satellite and multimedia technology. Information and communications technology is reforming education. Recent examples of internet use in schools, satellite use in universities, new types of multimedia development will be described.

1. Culture Characterized by a Private Room and Culture Characterized by a Living Room

Some twenty years ago, when a British friend of mine and I were driving through an old neighborhood in London, he pointed toward the sky and said, "Look at the skyline over there. You can see small chimneys on the roof of each house. Four chimneys, six chimneys there s a roof with eight. Each one of them connects to a fireplace in a private room with a locked door. Most of these children have their own rooms. Many of them, boys and girls both, will leave their homes after high school and live independently in their own flats."

After this conversation, I began to pay closer attention to this ubiquitous element of so many Western skylines, although today, of course, more chimneys serve as a vent or decorative element than as an actual conduit for smoke.

Which brings me to the question: How are Japanese houses structured? We can begin by saying that Japanese homes have a completely different structure than their Western counterparts. A typical Japanese house features a central living room surrounded by a number of other, smaller rooms. These other rooms are partitioned by simple paper screens or papered sliding doors called fusuma. Because there are no locks or keys, anyone can open these partitions. Within the living room itself, this strategy of free-flowing division is often continued by means of free-standing panels or folding screens. In this sense, Japanese homes are extremely flexible and open. It is possible that this difference between Japanese and Western homes derived from climatic conditions. Western homes must bear the severe cold of winter, but Japanese homes must bear the heat and humidity of summer. But what I most want to emphasize here is that the respective openness and containment of the Japanese and Western architectural styles seems to have strongly influenced the way the members of these cultures think and behave.

In Europe, individuals are of primary importance. They join to form a group as equal participants. Brothers and sisters call each other by their first names. In one case, I even know of secondary school students who call their parents John and Mary. Parents, brothers, and sisters hold seemingly equal positions.

In Japan, on the other hand, younger brothers and sisters often call their elder brothers and sisters simply "brother" or "sister," rather than using their first names. Children almost never address their parents by their first names. When sitting around the fire, the head of the household sits in a central position, and the others hold their respective positions in the order of seniority, men and women. There has been a clear hierarchy among family members. In terms of privacy, even if children are given private rooms, their parents are able to open the paper screens or papered sliding doors at any time. The solidarity of the group is thus considered much more important than the exertion of one's individuality. In the center of the house is a living room with a fire. Private rooms, if they exist at all, are only temporary constructions. In Western homes, the living room is a place for communication where family members demonstrate their own individuality while respecting the individuality of the other members. Schools, which are designed as an extension of the home, are often equipped with a central open space. Just as at home, children realize their own individualities within this educational space, while remaining careful to respect the individualities of their peers. In the past, as an extension of the home-fire setting, schools in Japan were often called classroom kingdoms, with children studying together under a teacher who served as "king."

Today, however, with the exception of a number of large, country homes, a more west-European style of living prevails throughout Japan. Apartments increasingly consist of private rooms with a key. In this sense, people's life styles are steadily shifting to include an assertion of privacy.

A key signifies one's domination over what is locked. Without a key, no one can get into a domicile, or take anything out. In the past, then, a key was a security measure by which wealthy people protected their property. In an environment where people from different ethnic groups and social classes lived together, a key was a protective necessity. In earlier Japan, however, keys were largely superfluous. Villagers helped each other and treasured common property, private ownership of which was forbidden. Personal belongings were acknowledged by other group members and thus did not have to be locked up. This was the case in which group members are homogeneous.

In societies of this type, individuals obeyed the group to which they belonged. Dissenting viewpoints were unwelcome and were considered to disturb the collective harmony. This system worked quite well when the group leader was well-intentioned and capable. But in the absence of effective leadership, the results of this paradigm could be tragic. Then, group members who had very good ideas that might have improved the situation were hardly allowed to propose them, and people generally withheld their creative ideas for reform or their initiatives for problem solving.

This Japanese model of society tended to work best under peaceful conditions and with a group of reliable members from the same ethnic background. In the modern age, it has become increasingly difficult for a society to exist in such relative autonomy, and the necessity of contact with different cultural backgrounds has made a purely homogeneous group impossible.

In Western culture, individuals are not only permitted, but often encouraged to assert their own ideas. But their contemporaries must be persuaded of the logical efficacy of a particular idea before it will be implemented. Failure to persuade others can lead to the dissolution of a group. Thus a culture characterized by a "private room" mentality finds it difficult to maintain the group's common purposes and solidarity while simultaneously encouraging individuals to display their creativity and problem-solving abilities. On the other hand, a culture characterized by the "living room" paradigm is effective at engendering solidarity and sharing property, but less effective at maximizing the individual strengths of its members.

Education in the 21st Century will continue to develop along with internationalization, advances in science and information technology, and an increasing population of elderly and decreasing population of children. Cultures characterized by private rooms and those characterized by living rooms will meet more frequently everywhere. And the question of whether to adopt a "living room" culture while developing a "private room" culture, or to adopt a "private room" culture while developing a "living room" culture is now in the critical point.

Education in Europe and North America is shifting away from the "private room" model and placing new emphasis on characteristics of a "living room" culture, such as collective purpose and common standards. Conversely, education in Japan is shifting toward a new focus on respect for individuals, and in opening up the classroom "kingdom" in an attempt to communicate with different cultures while maintaining student individuality. In this way, both Europe/North America and Japan are attempting to recognize and assimilate the strengths of one another's systems.

Japanese education in the 21st Century will also attempt to further the open and flexible way of Japanese living so as to expand the "living room" culture from the home to the social unit, from the social unit to the nation, and from the nation to the world. It is important that this expansion also respects the independence of individual students by means of flexible temporary partitions made up of free-standing panels, folding screens, paper screens, and papered sliding doors, as well as by a "latch of the heart."

Learning to exploit advanced information and communications technologies is important whether the aim of education is to develop a cooperative mind with an emphasis on individuality, or an individualist mind with an emphasis on cooperation. It is important because such tools as multimedia content, home pages, databases, and network communications not only allow access to the inspired ideas of many individuals, but can also nonetheless be applied to achieving common goals.

2. Changes in Learning Styles

In the realm of 21st Century education, the learning styles of children everywhere will change.

Since antiquity, human beings have tended to acquire knowledge in a largely passive manner. That is, knowledge has been passed on from men of wisdom and authority. The Analects of Confucius and the sermons of Buddha and Christ are typical examples. People listened to the speeches of these seminal instructors in order to gain instruction for their lives. Even after the invention of the printing press, learning meant passive reading of the writings of knowledgeable and authoritative authors. In Japan, such wisdom was usually imparted in the course of repeated silent readings.

The introduction of radio and television did not change this model of passive learning. Even in school broadcasts, the University of the Air, and other types of distance education, the ordinary style of learning is to learn passively through a teacher's presentation and a textbook. Those who appear on these broadcasts are still men or women of wisdom and authority, and their students continue to be largely passive recipients.

Even this passive learning environment, however, sometimes involves more constructive activities in the form of submitting reports and taking examinations. And, with the growing emphasis being placed on searching skills and active learning, investigative and constructive activities have become important. This has resulted in a wide range applications, from scientific investigations or an observational diary, to a general emphasis particularly in elementary school on careful articulation of opinions.

This type of active learning will continue to expand along with the refinement of the various media which support it. One notable aspect of active learning concerns the selection of pertinent information. Recently, huge volumes of educational information have been made available to students, including textbooks, illustrated guides, newspapers, magazines, printed materials, web pages, and TV, radio, video, and computerized teaching materials. Learners must positively select the information appropriate for their learning. If learners take in information without a critical view, they will find themselves drowning in a sea of information. They must also compare, process, edit, and compile the selected information in order to produce a finished report or presentation. This process is an excellent example of learning through creating. Such engaged learning is critical, because learners understand content more deeply when creating something on their own.

Multimedia and the Internet are powerful instruments to support this process. Learners extract information from the web pages of universities, museums, companies, etc., or take digital-camera photos of their community, neighbors, or local parks, and then gather all this information into a computer, edit it, and complete a multimedia work. They can show the finished product to friends around the world via e-mail or a web page. But the opportunity for learning does not stop here. Friends and anonymous enthusiasts around the world are likely to respond to the student's work with questions, supplemental material, or corrections. And these responses will further motivate the child to reinvestigate, review and modify his or her works. This process for deepening the learning experience is not possible via conventional teaching methods.

What is particularly important is that new tools for expression, such as cameras, videos, word processors, and computers have appeared and spread. As a result, the communications world that once focused mainly on receiving information has now evolved into a world of transmission as well. Ordinary people can easily transmit words, voice, sound, still images, and moving video images. Today, business people routinely create and transmit information using multimedia tools and word processors. Even children can draw pictures on their computers and win competitions in contests with middle school students or older competitors. In one instance, a first grader in primary school created a multimedia work, stored it on a floppy disc, entered a contest, and won the Ministry of Education's Prize. And there is currently a primary-school boy who is creating "multimedia poems."

Originally, when people drew pictures, sang songs, played musical instruments, or recited sentences, they were transmitting messages in the same way that they communicated spoken words. Often, it was a process which required considerable time and effort. With a computer, however, one can draw pictures and compose music easily. The pictures drawn and music composed on a computer can be modified or duplicated an unlimited number of times. Mistakes can be instantly undone with the click of a mouse. In the case of real paintings or musical scores, however, because erasing is so difficult, the expression of radical new ideas is less likely. Also, with the current prevalence of word processors, an "information sending" society in which everyone can be a sender of information is rapidly approaching. Today, if a school is linked to a network, one individual can disseminate a message all over the world.

In this way, written media as a source of information has expanded to multimedia. We can selectively receive information from the media through reliable databases. We can also send multimedia information of our own. We are in the midst of a great change in the history of civilization.

In the 21st Century, the understanding, exploitation, creation, and transmission of multimedia information will become nothing special. Information integrating text, still images, moving video images, voice, and sound is expected to be routinely delivered on networks.

Learners in the coming advanced information society will have to possess not only the skills of reading, writing, and understanding information delivered from numerous media, including TV, but also the skills to retrieve and use multimedia information, and to create and transmit multimedia works.

In receiving information from the media, we must have the ability to distinguish authentic information from inauthentic or biased information, and we must be able to make this distinction independently, as individual agents. We also must be careful not to lose touch with the physical world around us through an excessive reliance on information. When sending information, we must be careful not to invade the privacy of others. We should not use or create biased or erroneous information. We must respect the intellectual property rights of information created by others. To act responsibly, learners must be aware of the importance of information for life in society.

3. Educational Reform by Information and Communications Technology

Information and communications technology are dramatically changing many aspects of education, including the essential functions, goals and contents of education, the methods, teaching materials, management, administration, and teacher education used to realize these goals, and the partnership between education and the local community.

- Essence of Education

Education has always had two major functions. The first is to hand on to successive generations the academic, cultural, technological, and traditional heritage of our ancestors. The second is to help foster desirable characteristics in the citizens of the next generation, and thus of the societies of the future. Elements to be fostered include creativity, imagination, the skills to express oneself, sensitivity, ethics, motivation, physical strength, coordination, collaboration, cooperation, and independence.

The essence of education has not changed even in the multimedia and Internet age. However, other aspects of education are likely to be affected by the requirements of particular times.

- Goals and Contents of Education

In the past, the goals of education have tended to focus on the first of the functions described above, the acquisition of knowledge as an inheritance from previous generations. Today, however, new emphasis is being placed on the second function, i.e., the evocation of student interest and motivation, and the fostering of intelligence, judgment, and self-expression. Stronger emphasis is being placed on developing the ability to take the initiative in creating a future society, than on inheriting past assets. In Japan, the goal of the new education is to foster a "zest for living."

The emergence of multimedia and the Internet has dramatically altered the goals of education. Knowledge and skills of information technology, an understanding of the role and importance of information technology in the society, and information ethics are new goals of education. And as the goals of education change, the educational contents change with them. To educate students to achieve an equal academic level nationwide requires consistent curricula throughout primary and secondary education.

- Methods of Education

The most drastic educational change resulting from the advent of multimedia and the Internet is in the educational methods themselves. Newly introduced teaching methods include individual learning that exploits multimedia instructional materials, creation of multimedia works (e.g., multimedia illustrated guides that integrate text, music and pictures), exchange of presentations with other children on the Internet, collection of necessary material from databases, global simultaneous computation of records, and classroom exchanges via satellite and telecommunication network.

- Instructional Materials

Multimedia instructional materials in the form of CD-ROM and DVD-ROM have been added to such conventional instructional materials as print media, models, slides, and OHP. Instructional materials are directly collected from various sources around the world via the Internet. Lists of links to instructional material sources are also available. In recent years, so-called tool software has been used widely. And application software itself designed to help children collect, process, edit, create, and transmit information is sometimes used as an instructional material.

- Facilities and Equipment

Equipment includes peripheral devices for computers and multimedia tools, network systems, and basic software. Facilities need to be expanded to install these devices and systems. In particular, recent years have seen the spread of communications satellites, videoconferencing systems, and high-speed communications networks.

- Management of Education

Because schools are connected to the whole world through networks, one can instantly gain access to worldwide education-related information. Distant schools and experts can carry out team teaching, and networks and communications satellites will help make conferences, meetings, and training courses more efficient.

- Administration of Education

The introduction of multimedia and the Internet is also changing the administration of education. This will mean changes in all aspects of education administration, including governmental policy making, budgeting, and dissemination activities to facilitate the exploitation of information technology for education.

- Teacher Education

Because multimedia and the Internet are new to the world of education, many teachers still have difficulty using them. Not surprisingly, multimedia and the Internet are recurrent themes at the training events, workshops, and academic meetings of teachers worldwide. Through such training, teachers will be able to acquire new abilities, including the skills to analyze and develop instructional materials and to use multimedia and the Internet.

- Partnership with the Local Community

By making multimedia equipment and the Internet available to the local community, schools can assert themselves as centers of culture and civilization in less developed regions. In developed regions, constant interactions between schools and the local community will be possible on networks.

4. Exploitation of the Internet for Education

It is interesting to speculate what might happen if cross-cultural communications continue to increase through the Internet and videoconferencing systems. With cameras and videocameras, children will be able to collect and edit the information surrounding them, e.g., information on nature, society, customs, languages, cultural heritage, and the people of their community, and use this information to create a multimedia work. They will then present their project on a home page or send it to friends in distant places via e-mail. Their friends will reciprocate with similar multimedia works. Children will ask questions about and exchange opinions on these works. Using this information, they will create better works and send them to friends in distant places. For example, children in snowy regions might tell children in the South Pacific about their own customs, practices, lives, and play in the snow-filled winter. Conversely, children in the South Pacific might share information about tropical foods and the habitats of tropical fish in a coral reef. Children in urban cities might admonish children in farming villages, "You should not use agrichemicals." Children in farming villages might counter them by saying, "We cannot produce good-looking agricultural products without agrichemicals. Will people in urban cities buy poorly shaped vegetables and fruits?" In this way children will understand that others may have different positions.

Utilizing the Internet in this way, children will be able to better understand their own cultures by cross-comparison with other cultures worldwide. They will begin to appreciate that acknowledging and respecting different cultures is integral to protecting and fostering their own. It may not be too much to hope that, as children continue to interact with different cultures on the Internet, some of the ethnic conflicts currently underway throughout the world will begin to disappear. In this way, the educational use of the Internet will truly be an effective means of engendering peace.

The so-called "100-School Networking Project" launched in FY (Fiscal Year) 1995 with the participation of 111 schools completed its tenure of two years. A new 100-School Networking Project is now in progress. Diversified activities are being carried out at schools and other educational organizations in and outside Japan. These activities include the gathering, transmission and exchange of information, collaborative learning and research, collaborative production, and network conferencing.

Furthermore, the "KONET Plan", designed to link 1,014 schools via the Internet and a videoconferencing system, has already been launched. Many activities such as interaction via e-mail, information gathering, and homepage creation are being conducted.

In addition to these projects, such areas as Gifu, Kochi, Saga and Osaka prefectures, and Mitaka City have actively been introducing the Internet. Non-profit institutions such as Media Kids have also contributed to increased internet use by students.

In FY 1997, classroom teaching, linking a classroom in a hospital and a master classroom in a school via optical communications, was started in order to teach, at a distance, children suffering from an illness.

The Ministry of Education has also selected 20 districts to study the effects of an information and communications network, designating six schools in each site. As part of the R&D project to study the use of advanced information and communications facilities for schools in rural areas, the Ministry linked schools in rural areas with schools in urban areas. These schools are connected via two sets of satellite communications systems, ten sets of optical communications, and 19 sets of digital communications networks. In many cases, children in rural areas benefit from acquiring vivid information from urban schools. It is expected that children in rural areas will, in turn, provide those in urban areas with information on their rich natural environment and traditional culture, thus contributing to each other's learning.

The FY 1998 supplementary budget included a plan to connect a total of 118 schools by optical communications. These schools comprise two schools from each of 47 prefectures and 12 cities designated by government ordinance. Approximately 1,100 schools in 30 local districts are also connected through either CATV, WLL (Wireless Local Loop), DSL (Digital Subscriber Line), or satellite internet communication technologies.

5. Effects of Information Technology on Education

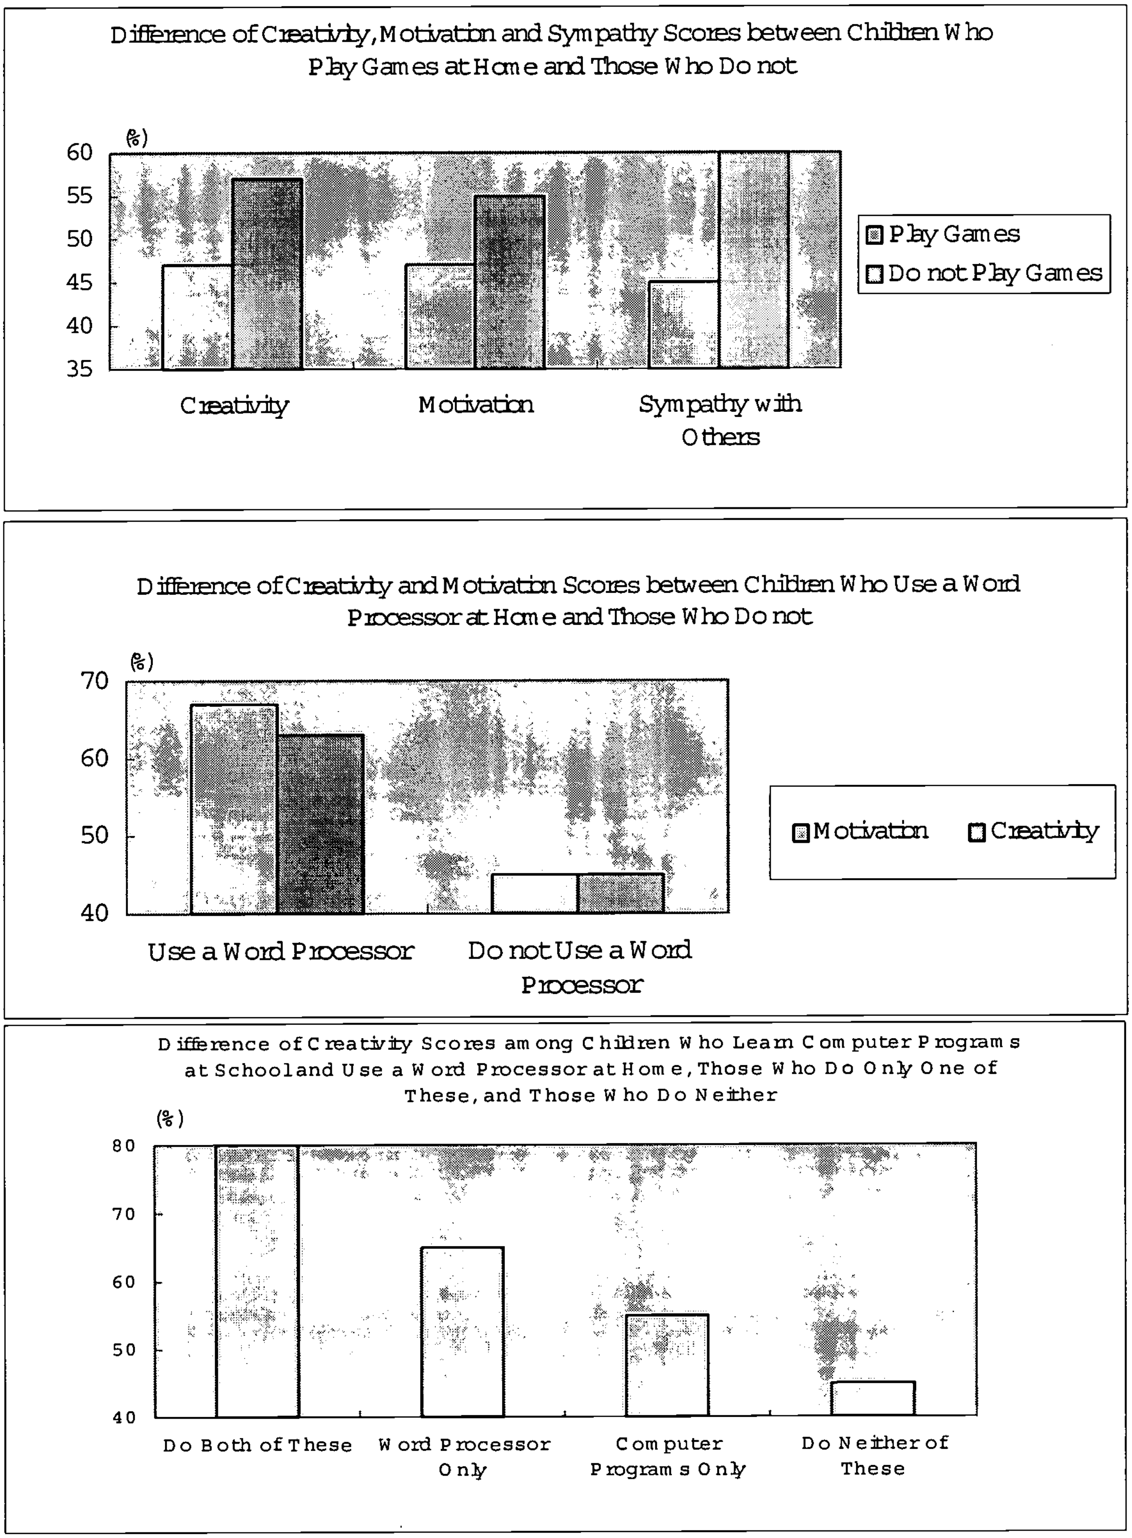
The research on the effects of computer-aided instruction (CAI) in enhancing educational experiences has been undertaken by many studies. In fact, as computers are increasingly used for problem-solving, material production, information retrieval and transmission, etc., their effectiveness is no longer in question. Computer-assisted graphs, composition, arrangement, drawings, and multimedia works are ubiquitous, and many of these projects have placed first in distinguished contests. Such prize-winning works could not have been created without computers.

Certainly, computers have made a substantial contribution to education, if for no other reason than because students cannot easily gather, retrieve, create, and transmit information without a computer or the Internet. But we must ask ourselves, do computers offer any benefits other than convenience? More specifically, do computers help develop children's ability to collect information, solve problems, edit existing material, create new things, think logically, and fully express what they think or feel? Now that the Internet and multimedia computers have been introduced to most schools, studies to answer these questions are extremely important.

For many years now, our group has been investigating the effects of computers and the Internet on education. The earlier outcome of our study showed that, as in Figure 1, fifth graders playing video games at home showed lower levels of creativity, motivation, and sympathy with others than those not playing games. In contrast, fifth graders using a word processor at home showed higher levels of creativity and motivation than those not using a word processor. The children who both learned computer programs at school and used a word processor at home showed higher levels of creativity than the children who did only one of these activities. Not surprisingly, those children who engaged in neither activity demonstrated the lowest creativity scores. In analyzing these results, it is noteworthy that the children who both played games and used a word processor at home showed high creativity scores. Our expectation was that children who participated in both these activities would demonstrate median-levels of creativity, intermediate between the low scores of those who only played video games and the high scores of those who only engaged in word processing. However, the children who did both showed the highest creativity scores. Although it is difficult to interpret this result conclusively, it seems reasonable that these children realized a synergistic effect between the constructive skills gained from word processing and the instantaneous judgment skills gained from playing video games.

In this study, creativity was assessed by means of questionnaires. We subsequently devised a test to measure thinking ability more accurately and conducted a six-month panel survey of the same subject group of fifth graders.

Figure 1. How does a computer affect the development of children's abilities?



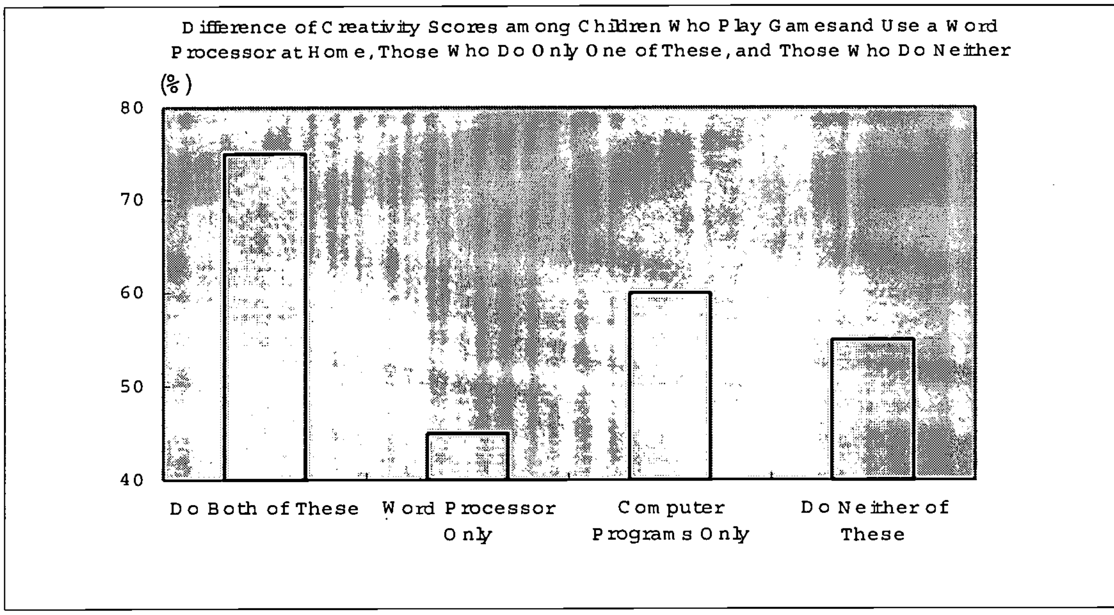


Figure 2 shows the results of the panel survey. Those fifth graders who took many computer lessons showed relatively higher scores in three of the five tests, i.e., the planning, deduction, and space cognition tests, than those who received fewer lessons. Six months later, however, when the same children were in sixth grade, those who received more computer lessons did relatively better in all five tests: planning, deduction, space cognition, induction and meta cognition. Thus, for the fifth graders, the results of the induction and meta cognition tests were not affected by the number of computer lessons taken. In fact, those fifth graders receiving fewer computer lessons actually showed the same or better scores for the two parameters. But by the sixth grade, the results of all five tests were dramatically improved by the use of more computer lessons.

We conducted another creativity test by using the commercial Guilford Test. This survey is a panel conducted at eight-month intervals. The Path analysis showed that computer use improves the deductive ability of elementary school boys. Unfortunately, the same effect was not obtained for junior high school students and elementary school girls. Rather, computer use lowered the creativity of elementary school boys. We may say that junior high school students and elementary school girls, who grow faster than boys, are too old to develop their inductive ability by use of computers. Because elementary school boys use computers based on certain patterns, they develop their deductive ability to apply their way of thinking to different cases. On the other hand, it was assumed that they were unable to develop creativity which required them to organize, edit, and reconstruct information by themselves.

We also conducted a similar panel to discuss whether computer use would affect children's motivation to learn and create at a later date. The panel was for fourth- and fifth-grade boys, and we found that those who originally possess creativity come to use computers more effectively, rather than that computer use develops creativity. This indicates that the use of computers is likely to widen the intellectual gap between those with higher creativity and those with less creativity. In this sense, a computer functions as a gap amplifier, not an equalizer.

We conducted another panel to investigate how the exploitation of the Internet influences children's information literacy. The panel showed that, for junior high school students, use of the Internet enhanced knowledge and skills relating to the Internet. In terms of information literacy, it was shown that the use of E-mail helps develop the skills of retrieving and selecting appropriate information.

We also conducted research activities from a slightly different perspective, which included work on the effect of MUD (Multi User Dungeon) on education. We found that when we let introversive students behave extroversive in the MUD, the introversive students looked at or spoke to strangers more frequently than those who were given a different computer task for the same number of hours. This study indicates that the experience of using a computer affects even the personality dimensions of the human being.

6. R&D Activities at NIME

NIME also conducts research into how information and communications technologies should be exploited to reform higher education.

To analyze and evaluate broadcast programs, we have developed a system that automatically produces a series of still images taken at specified time intervals from the scenes of a given program. We also produce 600 45-minute programs annually for the University of the Air at NIME studios. The patterns, photographs, illustrations, graphs, etc., which were used for these programs, are incorporated into a still image database.

A recent team investigated the physiologic effects of multimedia by taking measurements on the brain bloodstream and EEG. The results showed that certain acoustic waves of inaudibly high frequency positively influence human physiology. Based on this finding, an industry has released even CDs containing inaudible sound.

Other NIME activities include the use of DVD as a new medium to develop the world's first DVD video instructional material. At present, NIME is developing web-based DVD-ROM instructional materials. But the largest activity of NIME is to operate the Satellite Communications System (SCS), an Inter-university educational exchange system using a communications satellite.

7. Japanese Universities Linked in Space

In July of 1998, a meeting of the Committee for Implementing the Space Collaboration System (SCS) project was held. For the meeting, the National Institute of Multimedia Education (NIME) functioned as a HUB station and 76 VSATs in national universities across the nation from Hokkaido University to The University of Ryukyu were connected via a communications satellite with about five participants at each of the VSAT stations. I assume that approximately 400 people attended the meeting as a whole.

At present, 110 national universities and higher education institutions, and 10 private universities have VSAT stations. Some universities are provided with more than one VSAT station. For example, Kyoto University has four VSAT stations, The University of Tokyo, Hokkaido University, Tohoku University, Nagoya University, and Osaka University have three each.

VSAT stations are generally equipped with two large display screens: one showing the image of a communicating station and the other showing one's own image or the image of a third station now in contact. When a close-up of a speaker's face is shown on the screen, a slight time lag occurs between the movement of the mouth and the voice heard, which may be disconcerting to some people compared with an ordinary TV screen. However, as it is a negligible lag, one can get used to it soon.

An operating desk is equipped with simple terminal devices, which are easily operated by a teacher or an attendant. Every station can transmit images and host events such as lectures, guidance, and conferences as an organizer. An organizing university/institution plays the role of moderator and can call up a station onto the screen. When someone at a receiving station wants to express an opinion, that station just makes a request to speak by touching a panel. However, if that station is not called up by the organizer, its opinion is not heard by others. In this sense, the function of the organizer/moderator is very influential.

We are approaching an era in which undergraduate and postgraduate students select and take courses by their choice from among courses offered by universities through multimedia all across Japan. Those universities having many faculty members chosen by many undergraduate and postgraduate students all around Japan will gain a high repute. Those universities whose teachers are not chosen by other universities' students will be eclipsed as a result. An increasing number of undergraduate and postgraduate students now retrieve information from various sources around the world through the Internet for their studies. They become free from "passive learning" in which students passively osmose their professors' lectures. They search, create, and send out information on their own via networks, receive responses from people around the world, and thereby deepen the level of their studies further. This style of learning is beginning to develop as we enter the age of multimedia and distance education.

University reform has literally been initiated in space.

8. Significance of Exploiting Information Technology for Education

Systems Function

(1) Equalizer and Amplifier

Functionally, information technology provides everyone with an equal opportunity of education. On the one hand, information technology works as an equalizer because it enables everyone to obtain necessary information from all over the world. On the other hand, information technology works as an amplifier because people can collect a larger amount of information in less time by exploiting information technology, rather than by reading books as in the past. However, there is a potential danger that information technology might create a wide gap between those who can collect a large amount of information and those who cannot, and between those who learn fast and those who learn slowly.

(2) Generalization and Specialization

Information technology enables everyone to share information, thus contributing to the generalization of common education. Moreover, it facilitates the systematic collection of specialized information, thereby contributing to specialization of education.

(3) Diversification and Individualization

Information technology diversifies as well as individualizes education. It facilitates the collection of diversified information on law, economy, literature, science, medical science, art, and so on. It also enables learners to learn selectively and develop their own individuality.

Exploitation of Information

(4) Effective Exploitation of Information Sources

Each information source provides unique and distinctive information. Accessing such sources enables us to collect information which would previously have been very difficult to obtain. Schools and educational institutions provide local cultural information or specialized information.

(5) Approach to Excellence

A wide range of excellent information is available. If learners are selective enough, they can approach excellence.

(6) Elimination of Redundant Activities

At the same time that information technology enables one to gather broad information, it also allows one to quickly pinpoint and eliminate duplicated information. Thus concise information can be produced even in distributed, cooperative efforts.

(7) Publication of School Information

Schools can publicize their distinctive features worldwide via school home pages. This is expected to be far more effective, and more ecologically advisable, than distributing brochures within limited areas.

(8) The Ability to Search, Express, and Transmit Information

The repeated experiences of collecting, selecting, editing, creating, and transmitting information by use of information technology are expected to improve students' abilities to search for, express, and transmit information.

(9) Development of Information Literacy

Through the rich experiences of information handling, an information literacy can be developed.

Educational Systems

(10) Emergence of Distinctive Networked Educational Systems Open to Everyone

When all education-related facilities are connected worldwide through networks and provide unique information in the form of databases, home pages, or other means of direct transmission, the whole world will be incorporated into a single networked educational information system. Systems for admission, graduation or qualification acquisition will therefore become more flexible. A society where people are free to maximize their full capabilities for learning will be realized.

Now that the dissemination of information and communications technology enables people to gather information from, and send information to, locations all over the world, one needs to judge how much and what type of information are really necessary. To this end, information senders must make sure that their information is always correct, fair, unbiased, and previously unreported, and must respect the intellectual property rights of others. Information receivers, too, must select information which is correct, fair, unbiased, new, and reliable. And while ideally an international rule would be set to allow the transmission of only desirable information, in practice such a restriction is not feasible. Not only would such a law inevitably be broken, but its very existence would raise questions in regard to the freedom of communications.

It is therefore desirable that a reliable public organization consolidate information useful for education and provide links to such information sources. The services provided by such an organization could, at very least, help keep undesirable information out of the hands of children.

In this sense, such an organization could serve as both a global broker or an editor of excellence and wisdom. If organizations of this sort were established in many locations worldwide in order to moderate the transmission of global information, and if these organization were linked together to work as a team, a global educational information network could be built. Such a network would be connected to education-related home pages of governmental bodies, universities, schools, educational facilities, enterprises, and many other organizations around the world. In the hope of one day realizing such a vast educational resource, I encourage all such organizations to develop their own education-related home pages.

A Research Agenda for Interactive Learning in the New Millennium

Thomas C. Reeves
Department of Instructional Technology
The University of Georgia
604 Aderhold Hall,
Athens, GA 30602-7144 USA
<treeves@coe.uga.edu>

Abstract: During the past three decades, hundreds of research studies have been conducted to investigate interactive learning in a variety of forms ranging from the earliest days of mainframe-based computer-assisted instruction to contemporary multimedia learning environments accessible via the World Wide Web. In light of this body of research, some researchers believe that we are on the verge of developing a true instructional science whereas others conclude that we simply cannot pile up generalizations fast enough to adapt our interactive designs to the myriad variables inherent in human learning. In this paper, I summarize what we know and what we don't know about interactive learning, describe the strengths and weaknesses of various approaches to interactive learning research, and conclude by proposing a new developmental research agenda for the first decade of the new millennium.

Introduction

WHEN I heard the learn'd astronomer;
When the proofs, the figures, were ranged in columns before me;
When I was shown the charts and the diagrams, to add, divide, and measure them;
When I, sitting, heard the astronomer, where he lectured with much applause
in the lecture-room,
How soon, unaccountable, I became tired and sick;
Till rising and gliding out, I wander'd off by myself,
In the mystical moist night-air, and from time to time,
Look'd up in perfect silence at the stars.
Walt Whitman, Leaves of Grass.

Unlike Walt Whitman's "learn'd astronomer," I offer no proofs, no figures, and nary a chart in this paper. Instead, the paper primarily consists of a logical argument. I desire to persuade you with my argument, and although the phenomenon of interactive learning is hardly as wondrous as the stars, I hope to leave you with a greater appreciation for the importance and complexity of researching interactive learning. More specifically, I attempt to outline what we know about interactive learning as well as what we don't know, and to suggest some directions for a renewed research agenda in the early years of the new millennium. Before proceeding, however, I must reveal some of the biases I bring to this argument and also clarify what I mean by interactive learning.

Almost every field of inquiry today is beset with dichotomous controversies. Consider biology where one camp of scientists is laboring mightily to explain the nature of human behavior on the basis of genetic mapping whereas another camp argues that human behavior will ultimately be explained more completely by the effects of nurture and culture. If research on interactive learning can be regarded as a field (or at least a tiny plot) of inquiry, then it too has its controversies. One of the most obvious is between those who view this enterprise as a branch of science or technology and those who regard it as more akin to a type of craft or even art (Clark & Estes, 1998). I must confess that I have grown increasingly skeptical about the science of designing interactive learning and more attracted to the craft or art of this activity. However, my skepticism concerning learning sciences and educational technology does not preclude a strong commitment to developmental research and evaluation as necessary, but insufficient, methods for collecting information to guide the decisions that must be made when designing (crafting) interactive learning environments.

What is my definition of interactive learning? Burdened by a history of failed technology-based innovations (e.g., programmed instruction, teaching machines, and computer-assisted instruction), the latest buzzwords for interactive learning (e.g., interactive multimedia, the World Wide Web (WWW), and virtual reality) attract both ebullient enthusiasm (Perelman, 1992) and serious skepticism (Postman, 1995). Ultimately, all learning is interactive in the sense that learners interact with content to process, tasks to accomplish, and/or problems to solve. However, in this paper, I refer to a specific meaning of interactive learning as involving some sort of technological mediation between a teacher/designer and a learner. In my view, an interactive learning system requires an electronic device equipped with a microprocessor (e.g., a computer) and at least one human being (a learner). The adult school dropout developing basic literacy skills via a multimedia simulation, the high school student surfing the WWW for archival material about indigenous people to prepare a class presentation, and the three-year old practicing color-matching skills with Big Bird with a *Sesame Street* CD-ROM program are all engaged in interactive learning.

What We Know and Don't Know

There are two major approaches to using interactive learning systems and programs in education. (Although many of the ideas expressed in this paper may apply within training contexts, this paper will be limited to research from and implications for education.) First, people can learn "from" interactive learning systems and programs, and second, they can learn "with" interactive learning tools. Learning "from" interactive learning systems is often referred to in terms such as computer-based instruction or integrated learning systems (ILS). Learning "with" interactive software programs, on the other hand, is referred to in terms such as cognitive tools and constructivist learning environments.

The foundation for the use of interactive learning systems as "tutors" (the "from" approach) is "educational communications theory," or the deliberate and intentional act of communicating content to students with the assumption that they will learn something "from" these communications. The instructional processes inherent in the "from" approach to using interactive learning systems can be reduced to four simple steps:
1) exposing learners to messages encoded in media and delivered via an interactive technology,
2) assuming that learners perceive and encode these messages,
3) requiring a response to indicate that messages have been received, and
4) providing feedback as to the adequacy of the response.

The findings concerning the impact of interactive learning systems and programs can be summed up as:
- Computers as tutors have positive effects on learning as measured by standardized achievement tests, are more motivating for students, are accepted by more teachers than other technologies, and are widely supported by administrators, parents, politicians, and the public in general.
- Students are able to complete a given set of educational objectives in less time with CBI than needed in more traditional approaches.
- Limited research and evaluation studies indicate that integrated learning systems (ILS) are effective forms of CBI which are quite likely to play an even larger role in classrooms in the foreseeable future.
- Intelligent tutoring systems have not had significant impact on mainstream education because of technical difficulties inherent in building student models and facilitating human-like communications.
- Overall, the differences that have been found between interactive learning systems as tutors and human teachers have been modest and inconsistent. It appears that the larger value of these systems as tutors rests in their capacity to motivate students, increase equity of access, and reduce the time needed to accomplish a given set of objectives.

The foundation for the use of interactive learning systems as "cognitive tools" (the "with" approach) is "cognitive psychology." Computer-based cognitive tools have been intentionally adapted or developed to function as intellectual partners to enable and facilitate critical thinking and higher order learning.

Examples of cognitive tools include: databases, spreadsheets, semantic networks, expert systems, communications software such as teleconferencing programs, on-line collaborative knowledge construction environments, multimedia/ hypermedia construction software, and computer programming languages. In the cognitive tools approach, interactive tools are given directly to learners to use for representing and expressing what they know (Jonassen & Reeves, 1996). Learners themselves function as designers, using software programs as tools for analyzing the world, accessing and interpreting information, organizing their personal knowledge, and representing what they know to others.

The basic principles that guide the use of interactive software programs as cognitive tools for teaching and learning are:

- Cognitive tools will have their greatest effectiveness when they are applied within constructivist learning environments.
- Cognitive tools empower learners to design their own representations of knowledge rather than absorbing representations preconceived by others.
- Cognitive tools can be used to support the deep reflective thinking that is necessary for meaningful learning.
- Cognitive tools have two kinds of important cognitive effects, those which are *with* the technology in terms of intellectual partnerships and those that are *of* the technology in terms of the cognitive residue that remains after the tools are used.
- Cognitive tools enable mindful, challenging learning rather than the effortless learning promised but rarely realized by other instructional innovations.
- The source of the tasks or problems to which cognitive tools are applied should be learners, guided by teachers and other resources in the learning environment.
- Ideally, tasks or problems for the application of cognitive tools will be situated in realistic contexts with results that are personally meaningful for learners.
- Using multimedia construction programs as cognitive tools engages many skills in learners such as: project management skills, research skills, organization and representation skills, presentation skills, and reflection skills.
- Research concerning the effectiveness of constructivist learning environments such as microworlds, classroom-based learning environments, and virtual, collaborative environments show positive results across a wide range of indicators.

In summary, thirty years of educational research indicates that various interactive technologies are effective in education as phenomena to learn both "from" and "with." Historically, the learning "from" or tutorial approaches have received the most attention and funding, but the "with" or cognitive tool approaches are the focus of more interest and investment than ever before. Preliminary findings suggest that in the long run, constructivist approaches to applying media and technology may have more potential to enhance teaching and learning than instructivist models (Jonassen & Reeves, 1996). In other words, the real power of interactive learning to improve achievement and performance may only be realized when people actively use computers as cognitive tools rather than simply interact with them as tutors or data repositories.

At the same time, there is a paucity of empirical evidence that interactive learning technologies are any more effective than other instructional approaches. This is because most research studies confound media and methods. Sixteen years ago, Richard E. Clark ignited a debate about the impact of media and technology on learning with the provocative statement that "media do not influence learning under any conditions" (Clark, 1983, p. 445). He clarified this challenge by explaining that media and technology are merely vehicles that deliver instructional methods, and that it is instructional methods, the teaching tasks and student activities, that account for learning. Clark maintained that as vehicles, interactive technologies such as computer-based instruction do not influence student achievement any more than the truck that deliver groceries changes our nutrition. Clark (1994) concluded that media and technology could be used to make learning more efficient (enable students to learn faster), more economical (save costs), and/or more equitable (increase access for those with special needs).

Robert Kozma challenged Clark in the debate about the impact of media and technology on learning by arguing that Clark's separation of media and methods creates "an unnecessary and undesirable schism between the two" (Kozma, 1994, p. 16). He recommended that we move away from the questions about whether technologies impact learning to questions concerning the ways can we use the capabilities of interactive technology to influence learning for particular students with specific tasks in distinct contexts. Kozma recognized that although interactive technologies may be essentially delivery vehicles for pedagogical dimensions, some vehicles are better at enabling specific instructional designs than others.

Both Clark and Kozma present important ideas. It is evident that the instructional methods students experience and the tasks they perform matter most in learning. In addition, I maintain that the search for unique learning effects from particular interactive technologies is ultimately futile. After all, fifty years of media and technology comparison studies have indicated no significant differences in most instances. Whatever differences are found can usually be explained by differences in instructional design, novelty effects, or other factors. However, even though technologies may lack unique instructional effects, some educational objectives are more easily achieved with interactive learning than in other ways. Revealing effective implementations of interactive learning for various types of learners and discrete learning objectives and content is an important goal for educational researchers and evaluators.

A Renewed Research Agenda

The fact that educational research is not highly valued by educational practitioners is widely recognized. A large part of the problem can be attributed to the fact that the interests of academics who conduct research and those of administrators, teachers, students, parents, and others involved in the educational enterprise are often quite different. Tanner (1998) reminds us that educational research should be focused on the mission of enhancing educational opportunities and outcomes:

> *Unfortunately, much that is taken for social research serves no social purpose other than to embellish reputations in the citadels of academe and sometimes to even undermine the democratic public interest.... Early in this century, John Dewey warned that educational practices must be the source of the ultimate problems to be investigated if we are to build a science of education. We may draw from the behavioral sciences, but the behavioral sciences do not define the educational problems. The faculties of the professional schools draw on the basic sciences, but their mandate is mission-oriented, not disciplined centered. (p. 348-349)*

As noted in the previous section, research reveals that students learn both *from* and *with* interactive learning technology. Computer-based instruction and integrated learning systems have been demonstrated to be effective and efficient tutors, and there is considerable evidence that learners develop critical thinking skills as authors, designers, and constructors of multimedia or as active participants in constructivist learning environments. Unfortunately, the level of our knowledge about interactive learning is somewhat analogous to what health practitioners know about the functions of vitamins and herbs in supporting good health. There is general agreement within the healthcare professions that most vitamins and many herbs have health benefits, but there is considerable disagreement about the proper dosages, regimens, and protocols for using various products. Similarly, in education, while we can and do generally agree that interactive learning is good, we know very little about the most effective ways to implement interactive learning. In fact, the need for long-term, intensive research and evaluation studies focused on the mission of improving teaching and learning through interactive learning technology has never been greater. Both government and commercial interests are pushing interactive learning in various forms from preschool through lifelong learning, and major decisions are being made about these technologies based upon habit, intuition, prejudice, marketing, politics, greed, and ignorance rather than reliable and valid evidence provided by research and evaluation.

As we enter the new millennium, I maintain that our research and evaluation efforts should be primarily developmental in nature, i.e., focused on the invention and improvement of creative approaches to enhancing human communication, learning, and performance through the use of interactive learning technologies. The purpose of such inquiry should be to improve, not to prove. Further, developmental research and evaluation should not be limited to any one methodology. Any approach, quantitative, qualitative, critical, and/or mixed methods, is legitimate as long as the goal is to enhance education.

My recommendation to engage and invest in developmental research and evaluation overlaps somewhat with advice emanating from policy-makers in the USA where the Panel on Educational Technology of the President's Committee of Advisors on Science and Technology (1997) established three priorities for future research:

1. Basic research in various learning-related disciplines and fundamental work on various educationally relevant technologies.
2. Early-stage research aimed at developing new forms of educational software, content, and technology-enabled pedagogy.
3. Empirical studies designed to determine which approaches to the use of technology are in fact most effective. (p. 38)

The second of these priorities reflects my call for development research issued above. However, I believe that the President's Committee of Advisors on Science and Technology (1997) has placed too much faith in the ability of large-scale empirical studies to identify the most effective approaches to using interactive learning in schools. In the final analysis, the esoteric and complex nature of human learning may mean that there may be no generalizable "best" approach to using interactive learning technology in education. The most we may be able to hope for is more creative application and better informed practice.

Conclusion

Salomon (1991) describes the contrast between analytic and systemic approaches to research that transcends the "basic versus applied" or "quantitative versus qualitative" arguments that so often dominate debates about the relevancy of educational research. Salomon concludes that the analytic and systemic approaches are complementary, arguing that "the analytic approach capitalizes on precision while the systemic approach capitalizes on authenticity" (p. 16). Salomon's critique remains relevant because much of the research and evaluation of the effectiveness of CBI and other forms of interactive learning continues to be plagued by fundamental flaws that render much of this literature little more than pseudoscience (Reeves, 1993).

One reason for this deplorable state of affairs is that there has long been great disagreement about the purpose and value of educational research. For example, Nate Gage, a past president of the American Educational Research Association (AERA), has been a staunch defender of the notion that the goal of basic research in education is simply "more valid and more positive conclusions" (Farley, 1982, p. 12) whereas another past president of AERA, Robert Ebel, proclaimed:

....the value of basic research in education is severely limited, and here is the reason. The process of education is not a natural phenomenon of the kind that has sometimes rewarded scientific investigation. It is not one of the givens in our universe. It is man-made, designed to serve our needs. It is not governed by any natural laws. It is not in need of research to find out how *it works. It is in need of creative invention to* make *it work better. (Farley, 1982, p. 18, Ebel's italics).*

Should researchers and evaluators seek to establish immutable laws akin to those found in the harder sciences? Or should we be focused on finding out how to improve education with different types of students in specific places at particular times of their development? These questions reflect an on-going struggle between those who view our field as a science and those who regard it as a craft. The questions also reflect the so-called "paradigm wars" among educational researchers. Despite the increased acceptance in some educational circles of qualitative alternatives to the experimental methods that have dominated educational research in the past, there are signs that some powerful policy-makers are still pushing for more classically empirical approaches. The aforementioned Panel on Educational Technology of the President's Committee of Advisors on Science and Technology (1997) listed as one of its six major strategic recommendations that the government "initiate a major program of experimental research....to ensure both the efficacy and cost-effectiveness of technology use within our nation's schools" (p. 5). I contend that a wiser course would be to support more development research (aimed at making interactive learning work better) using a wider range of quantitative, qualitative, critical, and mixed methods and less empirical research (aimed at determining how interactive learning works) using experimental designs.

Acknowledgements

1. I would like to thank Betty Collis and Ron Oliver, the Co-Chairs of ED-MEDIA '99, for inviting me to present a keynote address at this important conference. If there is any merit in what I present, they deserve much of the credit for their advice and support in preparing this address. I take full responsibility for the faults that will inevitably be found.

2. This paper reflects my preliminary (and admittedly hurried) thinking about what I shall eventually present at the conference in Seattle. Please don't be surprised if I radically change the ideas presented in this paper when I actually give the keynote address. As Michelangelo said, "I am still learning."

INVITED SPEAKERS

Utilizing Disruptive Technologies in the University: Confessions of an Agent Provocateur

Terry Anderson, Ph.D.
Academic Technologies for Learning
University of Alberta, Canada
terry.anderson@ualberta.ca

Abstract: This paper overviews the programming and facilities at a large research University that is designed to assist faculty in maximizing their effective use of educational technologies. Different programs developed by a university-wide "new media center" are described and critiqued. The paper overviews the challenges that the University has in utilizing "disruptive technologies" and in developing models of enhanced teaching and learning that are cost and learning effective.

Introduction

This paper overviews the experiences and reflections of one employed by a major research university as a change agent, tasked with making sure the University does something about all this "education technology and distance education stuff"! In 1994 I was hired as one faculty member in a University with over 1800 full-time tenure-track academics charged to "change the world" - my only weapon a "title" - I was the Alternative Delivery Specialist. Fortunately, no one in 1994, nor today, knew what an alternative delivery specialist is supposed to do, leaving me with much freedom. In fact, the only ones who seemed to have a clear conception of what an alternative delivery specialist was, were obstetricians in the Faculty of Medicine who thought I represented yet another brand of mid-wife attempting to usurp their monopoly in the child birth business.

Five years later, some progress has been made and the sky has not fallen, the University has not gone bankrupt, has not been deserted by students, nor has it replaced all the instructors with teaching bots. Yet it is paradoxical that, as organizations based in information and knowledge acquisition and development, universities have not flourished in the so-called Age of Information. In fact I hear as much doom and gloom and regrets for the passing of the good old days as I hear optimistic excitement about the opportunities available to us at the start of a new millennium.

Why have information and communications technologies had so little impact on teaching and learning within the mainstream university? I believe that this is the case because, unlike the sustaining technologies used to support and enhance the *research* and *administrative* components of the University, *instructional* technologies are disruptive to the current culture and economics of higher education. Therefore, I believe that divergent strategies must be employed to ensure that the University adopts and exploits not only the sustaining technologies that will help us improve on our present practices, but also the disruptive technologies that will move us forward into the emerging new paradigm of instruction and learning in higher education.

In this paper I will trace the development of programs and staffing in a university "new media center" (http://www.atl.ualberta.ca) and try to identify those factors in programming that succeed in enticing faculty and administration to make both adaptive and proactive changes. Finally, I'll suggest strategies and means by which the central core of the academic community can be induced to use information and technology tools to protect and advance the fundamental values of the academic community.

Context and Challenges

Reid (1997) situates in time the information and communications context in which we live. Although universities were in the forefront of development of the Net in the "before commercialization" and "novelty" stages, we have been relatively less active as a presence in the "utility" stage and will be even less conspicuous in the "ubiquity" phase as commercial and public entertainment uses far eclipse our development and application endeavors on the Net. We are great inventors and tinkerers; our challenge is to leverage this tinkering into the core business of our academy. Greg Baroni, manager of KPMG's global education practice, states that "Universities are sitting at the gateway of the knowledge economy. The question is, will they leverage their intellectual capital or become a vestige of the past, talking about the way things used to be?" (from Woody,1998). There are many who think we do not have the drive, speed, or determination to recreate ourselves for a networked learning environment. I disagree. While we have many barriers to overcome, there are options open to us through which we can leverage and support our institutions and our faculty to overcome these barriers.

The list of challenges and threats to the modern University is large and growing -more students, widening disparity in prerequisite training and skills, increased demands for access and lifelong learning, increasing expectations from business, higher government expectations of reduced operating costs, productivity gaps - the list goes on and on. It has become apparent that the University cannot be all things to all people. Vest 1995 quotes an American university president's description of the modern research university as " Overextended, Under-focused; Overstressed, Under-funded " (Vest, in Clark 1995.p.146). These pressures result in a shortage of qualified academics willing to take on the challenge of leading our institutions at a time when that leadership is most needed, a tendency to develop a siege mentality, and a search for a technological quick fix to solve our complex problems.

When I talk to my colleagues on campus I have learned to expunge from my vocabulary words like market-share, customer and of course the *profit* word. But I hope you'll allow me to describe the market context for universities in Alberta, and, I suspect, similar market contexts in most of North America. In Alberta last year there was an increase of 4.8% in full-time undergraduate enrollments - and an increase of 10.3 % part time enrollments (Statistics Canada, Center for Educational Statistics, Nov. 10, 1998). Among the G8 industrialized countries, Canada enrolls the highest percentage of its citizens in higher education We have obviously moved from systems designed for the elite to mass systems of higher education for life-long learners.

In the USA, Clifford Aelman (1999) develops scenarios based upon increased numbers of high school graduates, increasing numbers of older, part time students, and increased participation by traditionally disadvantaged population groups, all of which translate to an increase in enrolment of between 23% and 40% during the next decade.

Our context, then, is not one of a great threat of having no students at the front door - quite the opposite, they will be lined up beating on that door. Our challenge is, while helping our institutions to increase capacity using traditional on-campus delivery systems, to get them to pay attention to opportunities to increase capacity through development of non-traditional and off campus programming. Why worry about students struggling to get in at the back door, when there are line ups at the front door?

A critical accomplishment of my first year at the University was the initial funding to establish a multi-media production studio. This facility was designed to assist faculty in developing innovative, technology based enhancements to their teaching. (see http://www.atl.ualberta.ca). It soon became apparent that we needed to develop a set of pedagogical, economic and technical models to guide the development of educational content and professional development programming in our unit..

Models of Courseware Development

There are at least 3 theories of educational software production. The first I'll call the *"drop off your ideas and come back in a few months and pick up the CD"* model. In this model academics are used as subject matter experts and the school or business lines up a team of experts including instructional designers, graphic artists, video producers and programmers. This is a model that commercial software houses use and with very few exceptions have been losing money at for the past 5 years. The production quality is generally excellent, some have even paid attention to pedagogical principles and to interface design. What the model fails to address is the customer - in this case the busy faculty member with the power to assign the purchase of the product to hundreds of undergraduates. This model strives to create such superior product that faculty will be compelled to assign it as compulsory tool in every class. But it doesn't address the issues of trailability, observability, and compatibility that are critical to adoption of any innovation (Rogers, 1995). How are professors to use a $80.00 CD when they already have a good text book, their lab or seminar topics all mapped out, and a niggling fear that if they do assign the CD only a handful of students will actually purchase it and worse maybe they will decide not to come to the lectures.

The second model was labeled by my friend Tony Bates from the University of British Columbia as the "*Lone Ranger and Tonto*" model. In this model a single faculty member, with a trusty graduate student, embarks solo on the development task. Single handedly, they master not only the content and instructional design of the discipline, but also the complete production process, including sales, marketing, finance and eventual retirement to a condo in Maui. We've played with this model and had some limited success. One faculty member developed a CD of rotateable, high resolution images of his mineral collection, which allows students to zoom in examine a host of minerals without having to touch or even breath on his lifelong rock collection. Unfortunately, he hasn't got the cash for the condo, yet as every potential publisher I introduce to him, walks away with at least an order of magnitude difference in assessment of the appropriate amount of royalty payments that should flow to the professor. Another relative success (morally if not economically) is the Healthy Student Shareware collection that we've developed. This is a serious of seven Authorware based tutorials on issues such as managing Stress, Nutrition, Booze and sexually transmitted diseases. We've installed these programs in kiosks around campus and given them away via FTP all across the world. This model can work, but requires a commitment, skill set and entrepreneurial bent that is only rarely found among academics.

The third model I'll call the "*teach 'em to fish model*" in which instructional and technical experts guide and assist faculty members with the special skills needed and through a scaffolding and training model, help faculty to create and maintain their own teaching resources. We implement this model through an annual competition for seats in our production studio. We pay for full course release for a faculty members and "immerse" them in the collaborative production of HTML, instructional design, www sites, Authorware tutorials, problem based learning scenarios and other innovative instructional approaches. We continue this program today because we see this as a necessary, long-term investment in our faculty.

Besides these differing models of content development, we've also developed various professional development programs during the past 5 years which I will classify according to those that have worked, those that have not and those we're not sure about.

Initiatives That Work

Partners Program This is our full teaching release, "come live in the production center" model of faculty development. The opportunity to work along side skilled peers and professional developers for an extended period of time is one of the few ways that we have seen truly transformative change in approaches to teaching and learning among our faculty. Although we realize that the long term answer to faculty empowerment, lies in the use and development of these tools, not in central development centers, but in the faculties, we also realize the benefits of immersion in a community of developers and the older tradition of providing a sanctuary for academics to develop their best work.

Training, Infrastructure and Empowerment System (TIES): Mike Szabo has led a two year project at our university that empowers task forces at the department level to create a vision and skillfully chart a plan of action for their faculty, while engaged in a learning process focussed not only on technical skill development, but also on the critical skills of change management (see http://www.quasar.ualberta.ca/DRMIKE/ties.html). Since the real business of the University -teaching and research happens at the departmental level, it is here that real change and innovation must be embraced. If the department based units ignore or oppose innovative developments then life at the University proceeds un-affected. "For change to take hold, one department and faculty after another needs itself to become an entrepreneurial unit, reaching more strongly to the outside with new programs and relationships and promoting third-stream incomes" (Clark,1997.p.7)

Decentralized, Discipline Related Support Centers: The support of faculty based development and support centers is a challenging task for the director of a centrally funded unit. However, I think the change process is so large, so complicated and in many ways specific to the context of the discipline that it is only when individual departments and faculties grapple with the issues themselves that real change happens. Our challenge is developing a central unit that coordinates, trains, and communicates amongst these units and maintains very specialized tools and expertise that can be used cost effectively to support these distributed development centers.

Student Guides And Tech Helpers: I don't think we have been as successful as we could have been in employing students as technical assistants, but I agree with Steve Gilbert (Gilbert, 1997) who writes that one of the few economical solutions to the "crisis of support" in technology assisted higher learning is in mobilizing our student body to provide assistance not only to other students but to faculty as well.

Pushed Mailing lists: The single most effective tool we have developed to engage and inform faculty has been our unmoderated Majordomo discussion list. We now have over 500 faculty on ATLNet, providing a forum for not only announcements but also for healthy debate and discussion. I've learned many lessons through management of this list including the need to limit membership to our faculty, to archive messages in WWW format (http://www.ualberta.ca/htbin/lwgate/atlnet/archives/) and unobtrusively regulate the traffic so as to reduce superfluous messages.

Things That Didn't Work Very Well

High Cost, Full Scale, Commercial Multimedia Content Development: We are in the midst of a very large scale multimedia development that is excellent technical and pedagogical product. However, I find it difficult to rationalize the inordinate amount of support that is required to sustain these developments. We have not been as successful as I would have liked in attracting support of major publishing houses. Despite Bill Gates assertion that "content is king" the core business of the University is in creating the context for learning, not in sustaining high risk, large scale content development. There may be "big money" in this type of development in the future, but it is too much like buying lottery tickets as a retirement planning scheme for my liking.

Lone Ranger Production Of Multi-Media Content: As I mentioned, we have had some pretty spectacular results from talented lone rangers (for example David Miall's excellent CD-ROM on Romanticism http://www.ualberta.ca/~dmiall/ROMCDINF.HTM) but this is model that only supports the early adopters, and we are after much more profound change within the academy then can be engineered through the heroic efforts of individual faculty members.

On-Going Professional Development Computer Conferences: I like computer conferencing for courses and short term virtual conferences, in fact I lay modest claim to having organized the first international virtual conference organized on the Internet in 1992 (Anderson and Mason,1994). However, the medium is inherently a pull technology, that relies on busy academics to make a special effort to adapt to and frequently logon to another environment. Our conferencing system, is full of conferences that petered out days or weeks after the enthusiastic startup by our training or development groups.

Production Of Print Based "Training Manuals": We joined in a consortium to produce a series of 27 training manuals for faculty development http://www.gmcc.ab.ca/users/imd/etpdp/sample/programmap.htm. The quality was high, the format professional - but our faculty just wasn't interested. We're now converting them to WWW however I still don't expect faculty to systematically go through the materials. At least on the WWW they will be available "just in time".

Individual Faculty Member Based Distance Education Initiatives I know this will sound very naive to distance educators, but in our desire to support the innovation of individual faculty, we have sometimes funded development of projects that died instantly when the individual faculty member got tired, retired, relocated or died. Education, and especially that designed for distance delivery requires a support system, starting at the chair and dean and moving right through to the registrar and all the way to the janitorial staff.

Forced Change: Ever tried to herd 3 cats - how about 1800? Enough said.

Ones I'm Not Sure About

Large Volume, Scattergun Staff Training Programs During the past term our staff hosted a training or professional development event every day (see http://www.atl.ualberta.ca/training/) Some were well attended, some weren't. We succeeded in burning out some staff members, attracting many of the same faces day after day, but made progress towards eliminating the two of the top eight barriers to adoption identified by faculty in our campus needs assessment survey (Anderson, Varnhagen and Campbell, 1998) – those being related to lack of knowledge and exposure to new instructional technologies.

WWW Contests We have run contests for the best web supported courses in a variety of categories during the past two years (see http://www.atl.ualberta.ca/cyc/home.cfm). We had over 70 entrants this year and gave away $8,000 in prizes, but I think we intimidated the majority faculty leaving the spoils of victory exclusively to the early adopters - no longer our major target group.

Strategic Planning And Long Term Technology Integration Plans I've spent far too many meetings this past year working on university and departmental Technology Integration Plans. I find it very difficult to develop plans that do not result in requests to the president for funding an order of magnitude or two above the capacity of the institution - thus creating documents with high potential for dust gathering. However, I remain convinced that planning that supports and allows for innovation is of critical importance to the evolving University.

I've tried to outline the challenges and accomplishments and failures of the past 5 years at our University and hope that you can draw some reflective parallels to your own context. I invite you to check out the URLs above to investigate any of these innovations in greater detail. I'd like to turn now to a bit more philosophical analysis of the change process.

The Teaching Professional

Many of you have probably read the article Digital Diploma Mills by David Noble (another powerful writer and Canadian scholar and academic most definitely, not in the tradition of Marshall McLuhan). Noble and others neo-Luddites lament the "commodification of knowledge" the displacement of control and ownership of intellectual property coupled with a supposed de-professionalism of academics as teachers. I'll return to the issue of economics later, but let me comment on academics as professional teachers. I'm not sure who first coined the axiom that "any teacher who can be replaced by a machine should be" but let me tell you that such cliches do not go over well in our Faculty Club. Many see machines as de-skilling professors and as I mentioned leading to the de-professionalisation of academics. What does it mean to be a professional? Applebaum & Lawton (1990) define a profession as having the following characteristics:

- Organized to serve a specialized body of knowledge in the interests of society
- A set of skills proficiencies, techniques and competencies
- Standards of excellence, self regulation, training of new members
- Established means of professional communications (journals and meetings)

Are professors at institutions of higher education professional teachers? Do professors at research universities maintain a "specialized body of knowledge in the interests of society" Of course they do, but it is the knowledge of a discipline, of research, of knowledge creation, it is not a specialized knowledge of teaching and learning. Do we have standards of excellence, training of new members, established means of professional communications? Again certainly within the discipline, but not with the profession of teaching.

I challenge you to undertake a piece of research when you get back to your campus. Go to your library catalog and do a search within any of the subject matter domains. Search for those periodicals, journals, meetings notes, training manuals or any other documentation supporting the development and growth, not of research within the discipline, but of research relating to the teaching of that discipline.

Let me tell you what I found from researching our own Faculty of Engineering, which is arguably one of Canada's finest faculties - based upon reputation, awards and success of graduates. This faculty has over 190 tenure or tenure track academics and over 4,000 students at undergraduate and graduate levels. I looked up how many Journals or periodicals we subscribed to that focused on the science, specialized knowledge, self regulation or training of faculty to the profession of engineering teachers. I found that there is a listing for *Engineering Education* the Journal of the American Society for Engineering Education. We have some volumes going back to 1898 in our holdings, but we dropped our subscription in 1991! We also have a few old volumes of the European Journal of Engineering Education but dropped the subscription in 1991 as well. Let's put this in perspective. Our same library catalog lists 207 periodical publications under chemical engineering and even 24 periodical titles under "low-temperature engineering". I realize that living in Northern Canada might justify a special interest in low-temperature engineering. But we subscribe to 24 periodicals on low-temperature engineering and not a single active subscription to the core business of the Engineering faculty - that of teaching and promoting learning - hardly professional.

What do I conclude? There is absolutely no danger, as Noble and others claim, that technology will deprofessionalize our teaching faculty. The fact is they are not professional teachers and probably never have been- professional researchers, scientists yes - but teachers no.

So what you might ask? It is interesting that Phoenix University, the fastest growing and I believe first University to be publicly traded on the Nasdec exchange, with 1997 profits to share holders of $33 million, boasts that none of their faculty (99.4% of whom are part time adjunct) are professional researchers - they are trained, guided and evaluated as professional teachers (Winston, 1999, p. 13). We boast that over 90% of our teaching are full time academics and researchers. Somewhat of a disconnect, I would say. Many of my colleagues argue that a research university doesn't need to worry about this, in that we focus on research, which defines our market niche. We are finding now in international education that we are competing with real professional teachers and researchers and I fear that our ability to compete will be compromised unless we find ways of rewarding faculty, within the research university, for expending the necessary energy and time to development excellence as professional teachers. Murry Turoff, one of the earliest developers of on-line courses, makes the case that ""Competition in education on an international and national basis will become the principle determinant of the success or failure of institutions in the next decade" (Turoff, 1999 p.30)

Why is it so difficult for us to embrace the technologies that are specifically designed to aid the core business of our Universities in teaching and learning? A key to understanding this is to differentiate these technologies between those that are sustaining and those that are disruptive of the social context in which our institutions were conceived and have evolved.

DISRUPTIVE AND SUSTAINING TECHNOLOGIES from (Archer, Garrison and Anderson, in press)

Universities currently enjoy a dominant position in the post-secondary education "industry." However, this "industry" is entering a period of rapid technological change – the sort of period in which the leading firms in an industry may rather suddenly be eclipsed by new players. In other words, the next few years could see a sudden change for the worse in universities' position in an educational marketplace being transformed by new technologies.

According to Christensen (1997), the main reason that successful and apparently well run organizations can and do flounder is that they fail to recognize the distinction between *sustaining* technologies and *disruptive* technologies. Sustaining technologies are those that improve the performance of established products. They are often developed by successful companies, the leaders in their fields, for and in close collaboration with their most important and lucrative clients. In other words, failures are often the result of successful firms' following the commendable business practice of listening closely to their customers.

In contrast to sustaining technologies, which improve the performance of established products, disruptive technologies often result in *worse product performance in the mainstream market*, at least in the short run. But they have other features that fringe (and generally new) customers value. Products based on disruptive technologies are typically cheaper, simpler, smaller, and, frequently, more convenient to use." Christensen, (p. xv) Generally disruptive technology based delivery systems are used to address new types or sectors of learners. Often professional development groups, or students not generally in a position to take advantage of residence based courses.

The innovator's task is to ensure that this innovation – the disruptive technology that doesn't make sense – is taken seriously within the company without putting at risk the needs of present customers who provide profit and growth. (p. xxiv) This requires that the development of niche markets that are protected from the demands and constraints of the main business activity of the day. It also requires a research and development capacity within the organization that can test, fail and recover very quickly from experimentation with the disruptive technology in small scale, but exemplar

So how should one direct the development focus and energy of a modern research university? In an interesting paper, Dan Surry (1997), differentiates between developers with a determinist philosophy related to technology and those who view development from an instrumentalist lens (Table 1.). Deterministic developers are convinced that technological change is inevitable and driven by the superior product and process that results in education from the use of new technologies. They focus on the product itself, seeking the "killer ap" that either increases speed, effectiveness or efficiency of the teaching/learning process. They see institutions as largely disorganized and ill-structured obstacles to the types of supportive environments necessary for faculty to develop and use technologies effectively. They seek to minimize the deterious effects of the context so as to allow the inherent technological superiority of the product to manifest itself.

PHILOSOPHY	GOAL Systematic Change (Macro)	Product Utilization (Micro)
Developer (Determinist)	Focus on the structure and establishment of a effective organizational framework	Focus on process of designing developing, and evaluating effective instructional products.
Adopter (Instrumentalist)	Focus on the social, political and professional environment in specific organizations	Focus on the needs and opinions of potential adopters and characteristics of the adoption site.

Table 1. Overview of Instructional Technology Diffusion Theories showing diffusion goal and philosophical view. From Surry (1997)

Instrumentalist developers on the other hand are philosophically focussed not on the technology, but rather on an analysis of the needs, opinions, characteristics of the actors within the adoption site. To instrumentalist agents, the power, advantage and efficacy of the tool is of much less importance than the match between the tool and the context within which it must operate. These developers realize that there are many innovations that will not and cannot succeed within the context because of the inherent conflict between attributes of the innovation and the environment in which they must operate. The long history of educational technology that have not been adopted convinces me that an instrumentalist approach is the one most likely to lead to systematic change.

Where we have failed to date in our attempt to develop a successful dynamist culture, within the academy, is not in constraining the freedom of faculty members to set their own teaching agendas, nor is it in actively discouraging innovation and adoption. Where we fail is in developing a culture that supports a ruthless evolutionary cultural of survivalism. Effective innovations are allowed to grow, but so are the ineffective. We have no "bottom line" to easily measure our quarterly performance and we steadfastly refuse to put our best minds towards the task of developing means and measures to evaluate the impact of our innovation on teaching and learning. This is a problem for both traditional and technology enhanced instruction. David Noble (1998) asks "if students are taking courses which are just experiments, and hence of unproven pedagogical value, should students be paying full tuition for them"? I would ask with equal stridency, "if students are taking course to which no empirical evaluation in regards to teaching or learning efficacy, nor any corporate or individual effort is expanded on research, development or enhancement of pedagogy, relevance or applicability has been undertaken for the past century, should they be paying full tuition either? Our challenge is to enhance our evaluation models and plans with every project so that if we fail - we do so cheaply and quickly. If we succeed, we can document the context and actions that precipitated that success.

More With More Model

All of this is background to my concluding remarks about how technology fits into the mix. The way it does not fit seems to be the way technology is advocated on many of our campuses - I call it the "More With More Model". It generally works as follows. Early adopters, visionaries, and missionaries like myself, plead with central administrators to give us more money, more technology, more teaching release time, more professional development, more student assistants, more technicians, more 'smart classrooms' and more tools and in return we will promise to deliver more high quality and more accessible education.

The University of Alberta currently spends over $1 million a year on our 30 public computer labs on campus and is still not meeting the demand for ubiquitous student access. We have a proposal before us to increase the number of smart classrooms on campus from 20 to 70 and keep them "evergreen" at a cost of $2million per year. However, 70 smart classrooms on our campus will hardly meet the ever increasing desire of our teaching staff to use even simple tools like Powerpoint presentations. Clearly, the current funding structure and model of teaching will not sustain a strategy based upon "more with more".

Polley McClure from the University of Virginnia published a simple formula to help us connect these variables. She notes that Productivity is a product of the amount of Learning and Access to the instruction, divided by the Cost to provide this education. P =(LXA)/C. *The More with More model* addresses only the Learning and increases the Cost. But in the end P, the productivity is constant or more likely to go down, unless we can very clearly demonstrate enhanced learning outcomes due to the use of technology. I believe that we will see very significant increases in learning, but they will be slow in arriving. Further, Thomas Russel shows us with the *No Significant Difference site*, http://teleeducation.nb.ca/nosignificantdifference/ that there are no guarantees that the use of any mediated form of delivery will, by itself, increase learning. The distributed nature of much networked based learning, begins to provide a small light at the end of the tunnel. Note that in the formula access is multiplied by learning - thus the effort in enhancing technology through distribution of our programming to new audiences through distributed education and by providing time shifted alternatives for on-campus students provide a means to improve upon the "more with more" model. To achieve the goal of increasing learning opportunities while containing costs, we have to be able to change major components of our teaching programs. We need to be able to develop appropriate combinations of independent study formats, industrialized learning systems and intense personal learning communities using both face-to-face and mediated instructional environments. The correct combination considers student learning and faculty teaching needs, but also is formulated with the costs and benefits of each adaptation are calculated as precisely as possible.

Conclusion

Universities cannot and should not extradite themselves from the rich political and social history nor from the rich cultural heritage of scholarship that we carry forward through the centuries. But neither have we the right, nor the means, to freeze the evolution of our institutions of higher learning. We are called as scientists, thinkers and teachers to empirically and philosophically test our assumptions and practice against the goals so nobly enshrined in our Latin mottoes and celebrated in the eye of our students and supporters.

We need to challenge our colleagues not in the techno-Babel of machine features or attributes that are outside of their perceived need or vocabulary. Rather we must challenge our colleagues and administration in the language of scholarship - of testing hypothesis, critically evaluating claims, substantiating our hunches and debating not only the results but also the costs of our innovations. We also need to seriously examine the values and commitments that should be driving us in a relentless search for better ways to teach and learn. These are lofty goals. Goals that will ensure the survival of the academy in a form that embraces any tool that provides long term assistance in the task of creating human beings wise enough to warrant the stewardship of this planet.

Posterel (1998) celebrates the freedom, the invigoration and motivation in play. And I'll conclude with a call for celebration of the opportunity provided to us to play in the emerging field of educational technology. My time as a change agent has been marked by a few successes, a number of things that might have happened, but didn't, and a growing list of things I really do want to get at. We are challenged by the opportunity to play in this field that is redefining the university but also the lives of each of us lucky enough to be actors on this stage. We are each entrusted with the honor and responsibility of carrying forward the traditions of scholarship, inquiry, reflection and teaching into the next century.

The Research Centre for Education and ICT
The Royal Danish School of Educational Studies (RDSES)
Emdrupvej 101
2400 Copenhagen NV, Denmark
http://www.copenhagen.dlh.dk/espdk

Abstract: Which official initiatives and which efforts are made regarding the implementation of ICT, including the use of telecommunication in the Danish school system? Taking the starting-point in different pedagogical scenarios we'll describe an approach to implementing ICT – specifically teleprojects carried out since 1987 within the framework of European Schools Project. Which educational materials have been produced to meet the need for and the demands from teachers entering transnational projects? How do we at RDSES meet the challenges in the use of ICT in in-service training, whether that be ordinary or distance learning courses? How do we collaborate between the European countries? Which initiatives are taken by the EU as far as the use of ICT and telecommunication in education?

Introduction

The authors work as senior consultants at RDSES 1). RDSES, which provides further education for teachers of the Folkeskole 2) and for lecturers at colleges of education, can trace its historical roots back to 1856. The graduate studies form part and parcel of the provision of further education for teachers. Alongside their teaching, the staff at the eight faculties and several centres - of which: 'Research Centre for Education and ICT' 3) is one - carry out research. In this way an essential part of the basis of the teaching in courses and graduate studies is brought into being. An increasing number of the research projects are carried out in co-operation with researchers abroad, many supported by e.g. the Nordic Council, EU, OECD.

Which challenges and barriers do teachers meet when they want to use telecommunication?

At a 'Council of Europe' Conference in Stockholm in 1993 colleagues from different European countries addressed us and the audience by giving brief accounts of the situation concerning telecommunication in their respective countries. Anne Villems from Estonia described her view as to which problems or barriers the teachers had to overcome:
'Hi,
Here is Anne Villems from Tartu, Estonia. This term we started with our own projects. As practice has shown it's extremely difficult for teachers: - to do too many things at a time, - to start participating in an international project, - to start to use computer and communication, - to connect projects with excisting curriculum, - to integrate activities with other subjects, - to use foreign languages, etc'.
The observations made very well expresses how teachers then and today are called to respond to new pedagogical, scientific and technological developments.

In a 'Communication Document' from a conference ' School Networks and Teachers Training', Athens, September 1998 6), the participants conclude: *'The rapid evolution of new technologies in combination with the continuous societal and economic changes pose the need for on-going teachers' professionlisation and updating'*. Conclusions similar to ours.

ICT in the Education System

Action Plan for 1998-2003 - The Danish Ministry of Education 1998 5)

In 1998 the Danish Ministry of Education published the combined strategies and action plan for ICT for the period 1998-2003. The plan describes five central areas: - the pupils and ICT, - the teachers and ICT, - the subjects and ICT, - equal and flexible access to lifelong education, - and coordination of ICT-based research and education. It's emphasized that *'It is not the objective to engage in massive investments in ICT in education just for the sake of ICT. ..ICT is to improve the teaching and learning process, and the students are to attain the basic ICT qualifications, which are necessary in the society of today and of the future'.*
Furthermore it's emphasized that: *All educational institutions are to be connected electronically in order to ensure access to knowledge and cooperation across the education sector. Moreover, Danish digital teaching materials are to be developed; materials which are based on Danish pedagogical principles.*

European Schools Project 7)

European Schools Project is a network organisation which supports a community of schools worldwide to explore applications of educational telematics. The ESP aims at improvement and innovation of educational activities and its organisation. It offers educational, organisational and technical support and provides opportunities for: - electronic communication between individuals, schools and educational networks, - the design, performance and evaluation of teleprojects, - the creation and usage of information resources, - to enhance better learning and teaching.
The first teleprojects, under the name 'Schools in Network' were launched at RDSES in 1987. In 1989 the project began to co-operate with ESP, initiated in 1988 by the University of Amsterdam, NL. The activities in ESP now include + 26 countries in Europe and beyond. Annual teachers' conferences take place in the participating countries - in 1998 in Copenhagen, Denmark, in 1999 in Tartu, Estonia 11) and in 2000 in Haugesund, Norway. Although the members of ESP are connected by telematics throughout the year, the participating teachers at the conferences find these to be an important forum for discussing pedagogical and didactical issues. The personal face-to-face contacts have also proved to be an important extra and very valuable element for designing successful curriculum collaborations.

Teleprojects

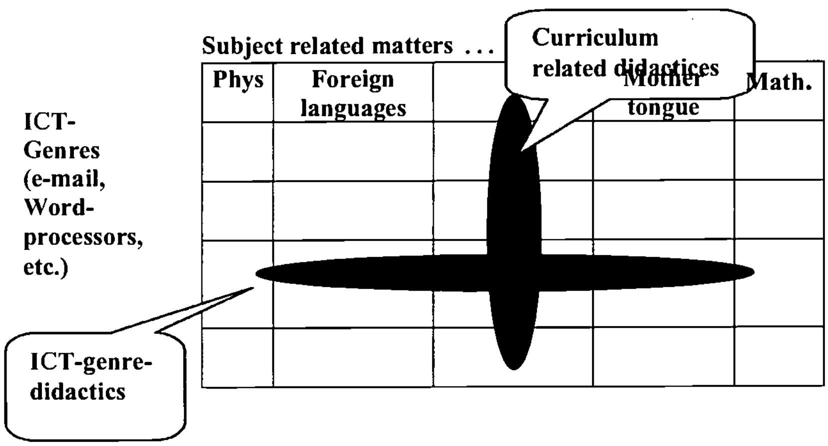
Teleprojects are co-operative distance learning projects in which telematics and foreign languages are communication tools. Teachers mutually determine a central topic of the curriculum around which students execute local (research) activities. Results are discussed and exchanged via Internet.
Materials to two of the many ESP-teleprojects, an environmental project Bionet 8) and a language teleproject The Image of the Other 9) can be found on the Internet.

The Image of the Other

'The Image' material, which is a result of collaboration between Danish and Dutch teachers, is meant for the teaching of English as a foreign (second) language for beginners (elementary stage). In this virtual classroom students and teachers experience, how they by using the foreign language and telecommunication as communication tools with their counterparts, acquire new knowledge and new understanding not only about their peers, but also about themselves, as "they are mirroring their own sitatuation in the others' ". The teachers have experienced how students improve their language skills, that the engagement in the project arise their cultural awareness as well as it is highly motivating and meaningful to take part in such a project. We thus observe a clear shift in education from teaching to learning, where the latter is strengthened and the education as such is enhanced. The Internet now thus gives all a chance - regardless of where you live - to have access to the same educational material.

Teachers' competences in ICT-genre didactics and curriculum related didactics

Teachers engaged in teleprojects all have had a traditional curriculum related didactical competence before they start. But many have lacked – at various degrees - the didactical competences related to each of the current ICT genres. It's of vital importance that a teacher before engaging in a teleproject masters both competences. Bent B. Andresen, director at the 'Research Centre for Education and ICT' at RDSES, has in the following model illustrated how the ICT-genre didactics and the subject related didactics complement each other. 10)



Teachers that acquire these ICT competences have, according to Bent B. Andresen, access to new pedagogical methods, whereas teachers who don't have these competences lack this freedom in their educational practice.

Importance of clearly formulated common objectives

Although teachers, may have access to the same material (e.g. the Image) some fail to describe the common objectives for their collaboration clearly. The emphasis could thus be put on the ICT-genres for one partner, whereas the curriculum related content was of major importance for the other. This invariably had an impact on the result of the collaboration and thereby an effect on the learning processes.

Why European in-service training courses?

ESP national co-ordinators for quite some time discussed the possibility of setting up European in-service training courses. Pedagogical, scientific and technological developments as well as the EU programme, Socrates, and similar programmes gave scope for implementing the ideas in the late nineties.
What we finally had were: - a common and far more user-friendly communication platform (i.e.www) - access to financial support from the EU, SOROS, Nordic Council of Ministers etc) to conduct in-service training courses - valuable pedagogical and organisational experience in the teleprojects as a basis for the contents of the courses - and a European team of moderators.

Co-ordination between international and national initiatives and in-service courses

The ESP co-operation and the courses running under the Socrates/ Comenius programme are most often bottom-up projects. It's vital that the courses match:
- national ICT initiatives, - national educational reforms for schools or for teacher education, - top-down European projects such as EUN (EUropean SchoolNet)

PIST

'The project makers - in-service training for educational key personnel on how to make educational projects, find partners and develop projects'.

The Norwegian and the Danish ESP-coordinators, together with a Scottish colleague ran two courses in 1997 and 1998 respectively with participants from 15 different European countries.
Experiences from these courses have resulted in a new Comenius course TRANSPRO with our Czech ESP-coordinator representing the fourth country in the collaboration. The TRANSPRO courses are planned to run in 2000.

The Nordic-Baltic Language Project

A project for teachers of foreign languages sponsored by the Nordic Council of Ministers and planned and coordinated - among others - by the Estonian, Danish, and Finnish ESP co-ordinators have run during the academic year of 1998 – 1999.
The aims of the introductory course to the transnational projects were to focus on:
- the cultural dimension in language teaching, - introduction to and designing of transnational projects based on: 'Das Bild der Anderen' (Material to be used in teleprojects in the German language) and 'The Image of the Other'- evaluation of the 15 teleprojects running during 1998-99.

Learning processes and didactics

We have learned that the following preconditions for successful in-service training in ICT should be born in mind, if you aim at running successful teleprojects: - emphasis should be placed on training processes rather than products/materials -A major priority should be the change of teachers' attitudes, since the teacher is the actual agent of innovation and change in schools, - Teacher training should be supported with the dissemination and analysis of models of 'good practice', which can be used as stimuli of discussion, reflection and change, - Teachers should be involved in evaluation of existing learning materials and this reflective/evaluative activity could form part of their training and professional development

National in-service training courses

The set up for in-service courses differ from country to country. Personally we have run an ODL course in introducing how to run teleprojects over the past 8 years with participants from both Denmark and the other Nordic countries. The Danish Ministry and others have introduced a large scale in-service training course on the use of ICT in all subjects - the so-called: 'ICT-licence' course – will be launched in the autumn of 1999.

Conclusion

Some of the observations and recommendations put forward at the Athens 6) state, what we already have experienced during the past decade or so that: *'There is obviously a trend towards 'process-oriented' pedagogy rather than 'product-oriented' or ' knowledge-centered' pedagogy.* We have to be aware that there is a shift *'from 'development of content' to 'development of practices' from text' to 'context'.... In other words, the teacher herself is called to reflect on, evaluate and participate in the development of training content and materials '6)* ICT forces us to accept a different concept of learning as well as the fact that the teacher's role is undergoing a change.
When looking upon Anne Villems's letter from 1993 we observe, that much has been accomplished during the past decade regarding teachers' pre-service and in-service training in ICT, nationally as well as internationally, but there is still a strong need for 'on-going teachers' professionlisation and updating'. As for examples of good practice much more ought to be accessable on the web. Further (action) research is needed regarding technological and educational issues also with much emphasis and stress on the evaluation of using ICT in order to ensure a high quality of the projects and thereby enhance education.

Reshaping Academic Practices through Multi and Hypermedia

Iliana Nikolova
Department of Information Technologies,
Faculty of Mathematics and Informatics,
University of Sofia
Bulgaria
iliana@fmi.uni-sofia.bg

Abstract: This paper focuses on the influences of multimedia and hypermedia technologies on the academic practices of a higher education unit. It traces the ways in which these technologies penetrate its research, development and teaching. Multifaceted uses of Web are illustrated: as environment for course design and delivery, as research project support environment, as product integrator, as facilitator of dissemination of research outcomes and support for their implementation. Examples of on-line courses, methodology and tools for Web-based course development, and specialized educational Web sites are presented. Pros and cons of this Web-orientated approach are discussed and current problems are identified. Multimedia developments for children – an authoring tool and applications, developed by a European consortium - are also reported. Finally, reflections on the overall dimension of change are made.

Introduction

We are witnesses and active participants in a vast process of globalization of education, educational communications and professional collaboration due to the remarkable developments in the area of distributed hypermedia systems and their applications. This tendency calls for adequate changes in the traditional activities of higher education institutions to effectively integrate these innovations. Challenged by the technology rich reality, many higher education units innovate their practices – either revolutionary restructure or evolutionary enrich and re-engineer (Collis 1997) a broad range of activities. This paper focuses on the impact of multimedia and hypermedia technologies on the academic practices of the Department of Information Technologies at the Faculty of Mathematics and Informatics, University of Sofia. First the ways in which these technologies penetrate research, development and teaching are traced. Then examples of on-line courses and methodology and tools for Web-based course design and delivery are presented. Next the utilization of Web as facilitator of dissemination of research outcomes and support for their implementation is discussed. Current multimedia developments – an authoring tool for children and applications, developed by a European consortium – are also reported. Finally, pros and cons of this hypermedia-orientated approach are discussed, problems are identified, and the dimension of the overall change is estimated.

"Webbing" Research, Development and Teaching: An Overview of Adopted Web Uses

I would define "academic practices" for our Department as including *teaching, research and development* and naturally embedding *communication and collaboration* – within the staff, with students, with other professionals. *Dissemination of research outcomes and implementation of our developments* supplement our activities as well. All components of our work have been significantly influenced by the developments in the networked multimedia and hypermedia. To understand *how*, let us start from the Department's Homepage (http://www-it.fmi.uni-sofia.bg/) which is in itself a small evidence of these influences – we are citizens of the cyberspace now.
Through the sections "About us" and "Staff" the Department's profile and each of us are now accessible on-line, which *eases our contacts with colleagues and students and helps expanding our local and international collaboration.*

"Teaching" is a major section here. The Department is responsible for the informatics part of the B.Sc. program "Mathematics and Informatics", which prepares teachers in mathematics and informatics. We also run an in-service teacher training center and offer two M.Sc programs: "Information and Communication Technologies" and "Artificial Intelligence", and run informatics courses for an MBA program. Information about these programs is now available on-line, and contacts with responsible persons are directly possible. This enhances the *efficiency of our information provision and two-way communication.* One major change, which will be discussed in more details later, is *the orientation to on-line teaching.* Most of the on-line courses offered by the Department are accessible from here too.

Another dimension of change refers to the *nature* of our teaching. Since 1984, when the unit was established, we have gone through different phases where different models of instruction have dominated. Almost skipping the typical for those days in Bulgaria highly structured, teacher-centered classroom instruction (relying mostly on the teachers and textbooks as sources of information), we went through less-guided, learner-centered, exploratory style instructional environments; arriving at constructivist principles and stimulating active learning (Campbell 1998). *Today our teaching, especially in the graduate courses, is flexible and highly individualized.* It widely embeds the project approach (Nikolova & Sendova 1995) and strongly relies on the "active learner" assumption and her/his access to information and knowledge, both locally and virtually. This wouldn't have been possible without technological facilitation: availability of multimedia learning environments, Web, Intranets, Internet tools for communication and collaboration. The changes in the nature of the teaching can be summarized as: *from teacher-centered to learner-centered pedagogy, from classroom-oriented to more individualized teaching, from tool-oriented (as far as computer use is concerned) to technology mediated teaching and learning.*

The "Research" section links to homepages of a number of national and international research projects. Within them Internet is used for *disseminating information* - to announce our research to others; *for communication among partners, sharing project resources and collaborative development of project outcomes* during the lifetime of the project (e.g. MATCh [1]: homepage, Workspace, Resource bank; MALL2000); *for sharing research outcomes and products with users* (VALUE, GEOMLAND). In this way *project participation and international collaboration are greatly facilitated.*

The "Activities" section links to Web pages of conferences, workshops and seminars organized by the Department. While for earlier conferences we used to only provide information, recent conference Web site embed more interactivity and allow on-line registration (e.g. EUROLOGO99), which is *a step towards a higher level of organization and time saving for participants and organizers.*

The "Student project" area is used to expose good master's projects and to store temporarily some students' course projects - for peers to view and share. This transparency of their work *creates additional motivation.*

The "Electronic Catalogues" section contains topics-oriented collections of references to on-line resources. They have been developed for students by students and serve as a virtual extension of the student's library. In this way *peer support is facilitated.*

Discussion

Building our Web presence was an early grass-root initiative of our Department. It was later promoted at administrative level and all departments are encouraged now "to go" on the University Web site. We are aware that there is much room for improvement and enrichment of our Web site, e.g. to build more interactivity and services, to more frequently update the information. Nevertheless and despite that being on the Web is trivial today for most academic units in the developed countries, we should acknowledge that this "small" step, facilitated by the utilization of hypermedia technologies, really made a difference in our professional lives.

---

[1] URLs are provided in the reference section as "on-line resources"

Teaching On-line

During the past few years there has been a definite tendency in the Department to integrate Web as a support tool in the teaching and learning process, to design Web-based courses (even for on-site students) and transfer existing courses, partly or fully, to the Web.

Why?

We went on-line for a number of reasons:
- we were challenged by some research projects, in which we participated, and gained initial experience from;
- this is an appropriate solution for our local environment, as a Web-based course provides the flexibility which our students need and we want to offer them;
- access to course resources and related international publications is easier for the students in this way (it may sound paradoxically, but it is true in our case, where new books in English hardly reach students' libraries)
- it extends the scope of our teaching geographically and in the number of students taught
- it eases the reuse of course materials
- it eases sharing courses and resources among staff

Some examples of On-line Courses

Most of the courses developed at the Department are supported by course Web sites, built around the virtual university and classroom metaphors (Nikolov & Nikolova 1996; Dicheva, Djakova & Bachvarova 1998). The site integrates course materials and links to on-line resources, possibilities for interaction between the instructor and students and among students themselves. Some course Web sites support group discussions through WWW boards, some allow on-line testing with automatic assessment. In most cases the courses are taught in a "simulated distance" mode – with some face-to-face sessions, but most of the students activities, assignments and communication are performed at student's convenience within a given period of time. The results are delivered to the instructor via e-mail or by uploading to the Web site. A few course examples are presented below.

Telematics and Distance Education

An elective graduate course from the "ICT" M.Sc. program (an early version of this course was the first experiment for teaching on-line in the Department). Developed as a self-initiative of the instructor, without any financial or administrative support. It was inspired by the course "Tele-learning" (Collis 1997) and is supported by a Web site (Fig. 1) which embeds course information and study materials, allows personal and group e-mailing and group discussion. The course is organized in units, each unit presuming self study of preparation material, face-to face session, off-class individual learning activities, and assignments submitted electronically. Feedback is provided either individually - by e-mail or face-to-face - or through a Web discussion board. All students develop course projects, individually or in groups of two. Project guidelines and support are provided through the Web site too.

Business English

Developed in the frames of a European project. The Web site (Fig. 2) is built around the virtual classroom metaphor (Stefanov, Dicheva, Nikolov & Djakova 1998): there are *walls* (for course description and syllabus), *message board* (for instructor's guidelines), *shelf* (for frequently used 'books'/sources), *corners* (for self-study activities), *gateways* (to the Post Office, Student Centre, Conference Centre, Video Centre, Library, and the Cafe). The units include pre-reading, reading and post-reading activities and interactive assignments.

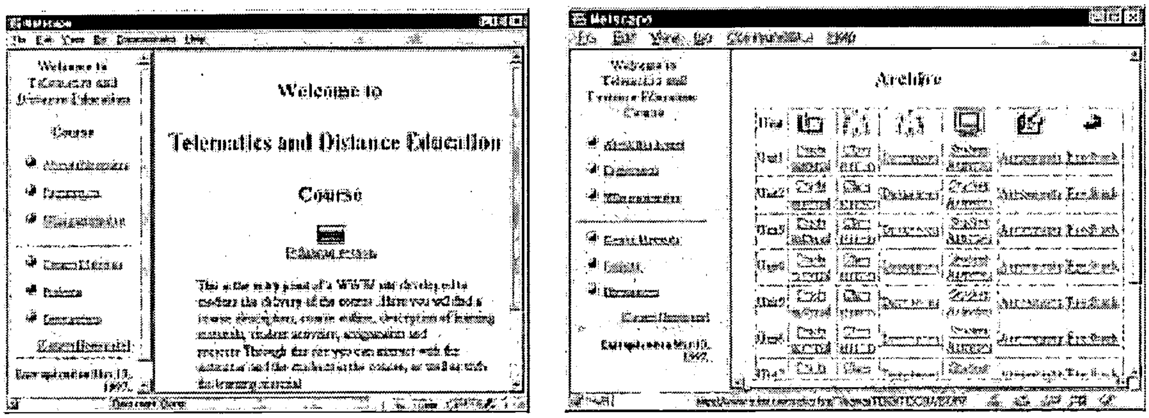

Figure 1: "Telematics and Distance Education" course

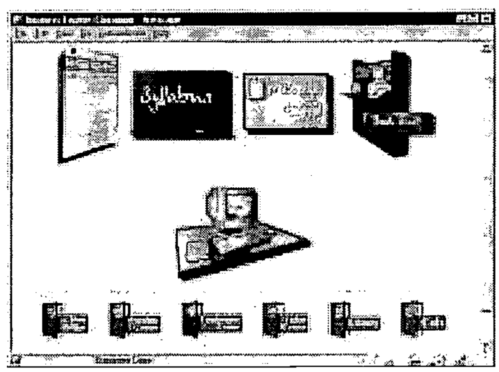

Figure 2: "Business English" course

Business on the Internet

Developed in the frames of a European project. Intended for graduate students in Economics and Business administration and clients from SME. Delivered through a virtual learning environment (Nikolov & Stefanov 1998) providing access to lectures and guest lectures, resource bank, tests and essays, group discussion.

Discussion

The experience gained so far has outlined both positive and negative aspects of Web-based teaching (Nikolova & Collis 1998; Dicheva, Djakova & Bachvarova 1998). According to students' views among the advantages are: *"flexible in space and time, which is very convenient; allows better concentration when studying on your own; allows your own pace through the course material, which enhances motivation; on-line, non-subjective testing; stimulates regular learning during the semester"*, while some drawbacks are: *"problems with speed of access and network stability - alternative ways of offering the course material, where possible, is desirable to minimize the on-line reading time; more intensive feedback from the instructor is necessary when the course is fully on-line"*.

One major specifics of the on-line courses is that they rely very much on the self-motivation and self-control of the learners, on the one hand, and appropriate technological infrastructure, on the other. Before a wider exploitation is considered, more in-depth evaluation is still needed and stronger administrative support is desired.

Methodology and Tools for Web-Based Course Design and Delivery

The Department has to deliver instruction in the field of ICT to different target groups – pre-service and in-service teachers, master students in ICT, AI and BA. The tendency to employ hypermedia technologies and the experience gained from the first Web-based courses called for a more general solution in order to offer more flexibility for the students while at the same time being more efficient in course design and development. A method for designing flexible instructional modules was developed (Nikolova 1996) to assist in designing modules, which are adaptable to different learner's needs and different delivery platforms. Later two software tools were developed to support the implementation of the method: Course Wizard - a desktop database-driven application, and Course Developer – a multi-user Web-integrated database-driven system. The method and the tools are briefly presented below.

The Method for Flexible Instructional Modules Development

The method is rooted in the theory of flexible learning (Van den Brande 1993; Collis, Vingerhoets & Moonen 1995). Flexibility is defined as offering the learner choices with respect to a number of flexibility dimensions, related to course time, content, entry requirements, instructional approaches and learning materials, delivery and logistics (Collis 1996). Telematics has an essential role to play when planning for more flexibility. For example, adding a *tele-learning* dimension to a traditional course, one can distinguish two further stages (Collis, 1996): *pedagogical enrichment* - when the components of the course and their balance are preserved, but the nature of activities changes due to the new possibilities offered by tele-learning; *pedagogical re-engineering* - when the course changes both in structure and nature of the activities.

The method is developed for an instructional provider (the Department, in our case) who, while given limited staff time and resources, has to design instruction for a range of learners' groups who share similar needs in a particular subject domain. It prescribes to construct a *generic module* which permits *adaptations* (variants for each group), the overall effort in terms of staff time and resources being less than when developing the variants separately. The method encourages team course design.

The main concepts employed by the method are: *generic module, adaptation* and *resource bank.* The *generic module* is designed for a particular subject domain and for a defined range of target groups. It is a *backbone* in terms of content, pedagogical profile and instructional materials. It is not a ready-to-use instructional module in itself, but a resource, which purpose is to facilitate the production of adaptations. An *adaptation* (Fig. 3) is a ready-to-use instructional module, which derives from the generic module and is designed for a particular target group. At certain moments more than one adaptation will exist around one generic module. The *resource bank* (Fig. 4) is a set of *resources* (stored in a database) which can be used to produce adaptations and to revise the generic module. Elements are added to the resource bank during the whole process of method application.

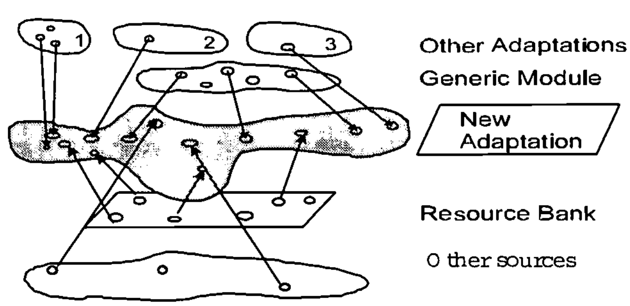

Figure 3: How an adaptation derives

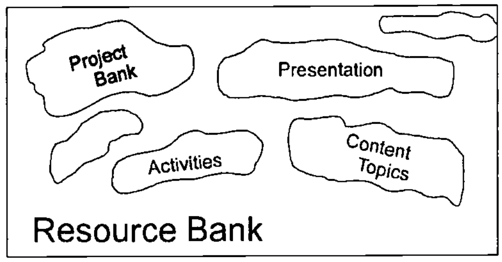

Figure 4: A Resource Bank

The Course Model

A course is a set of units. Each unit can have its own structure (Fig. 5), which is a subset of a predefined component set (default pedagogical profile). The latter includes: lecture or demonstration, communication b/n instructor and learner, group discussions, individual study and preparing exercises, individual or group project, student's testing, feedback from the instructor (Collis 1997). To each component one or more instructional materials can be assigned. The instructional materials are part of the resource bank and are stored in the course database. The database also stores information (as links) about the structure of the course and its units.

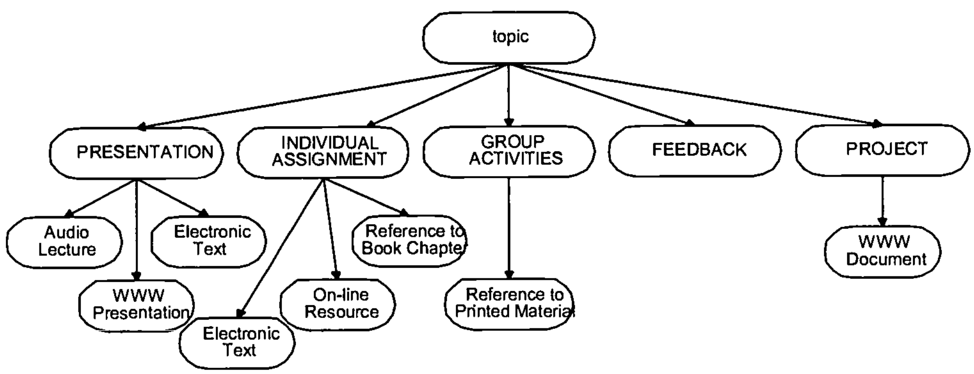

Figure 5: Sample unit structure

Course Wizard: A Desktop Program for Course Design and Course Web Site Generation

Course Wizard is a desktop application (Nikolova & Pelovski 1998), which leads the designer through the process of building a generic module and/or an adaptation. Throughout this process the course database is created - the designer provides course information, schedule and structure, assigns materials. Then the course Web site is automatically generated by using an existing template and asking the designer to specify additional information to customise the layout (Fig. 6). The Web site of the "Telematics and Distance Education" course (Fig. 1) is an illustration of the result. Course Wizard eases the multiple uses and updates of a course. The program is implemented in Borland Delphi and uses Borland Interbase Server.

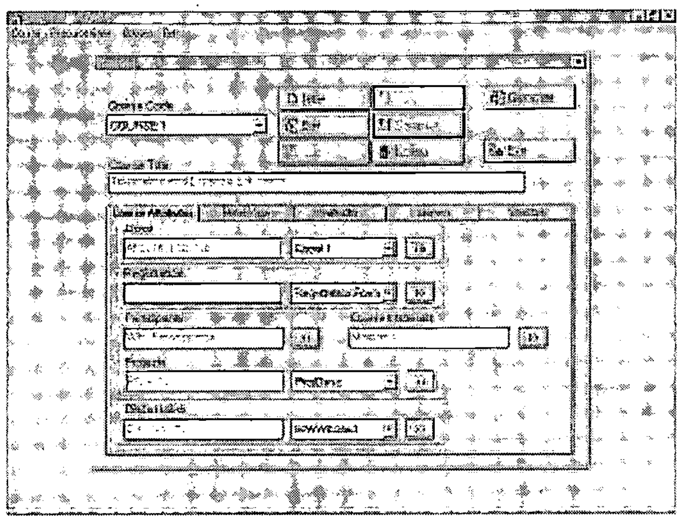

Figure 6: Course Wizard: Specifying the course homepage

Course Developer: A Web-based Course Support System

Course Developer (Nikolova, Boyanov & Dimitrov 1999) is an ancestor of Course Wizard in terms that it supports the design of courses of the above model and generates a Web site to mediate the course delivery. It has additional features and functionality though, which make it a powerful course support system. It has a Web interface (Fig. 7) and enables team development/update of a course over the network. It allows different types of users - administrator, designer, tutor, student and guest - with different access permissions. Supports not only the process of course design and development, but also course delivery by offering registration of tutors and students, access to course materials, internal course mail, discussion center and information on student progress and tutor's tasks. A module for automatic test generation and student assessment is also available. Course Developer is a Web-integrated, database-driven system, which uses dynamic pages based on the ASP technology.

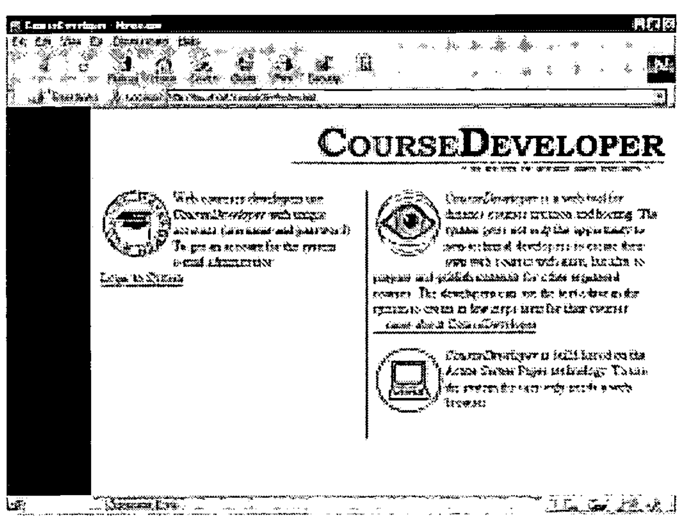

Figure 7: Course Developer's homepage

Discussion

Web-based course environments require powerful infrastructure and are expensive to produce. Many professional systems for Web-based course support exist nowadays (http://www.online.uillinois.edu/oakley/): Mallard, CyberProf, Web Course in a Box, TopClass, WebCT, Lotus Learning Space and many more. Our Course Developer system is a result of the research effort of a small group of people and was developed with almost no financial support. In this sense it can hardly compete with the above systems. The advantages are that it is tailor-made – it closely fits our needs, and the work on it allowed us to not only be users, but also engineers of such environment, which has an added value for better understanding the anatomy of the process, tools and outcomes. If we move to a large-scale on-line teaching, we will probably choose companies' products, but the experience gained will still be valuable and helpful.

Sharing Research and Development Outcomes and Providing Support to Users

A significant part of the Department's research and development outcomes is directly useful for schools and teachers, but there is neither appropriate infrastructure, nor organizational and administrative support for bringing it to them. It is quite cumbersome to manage the flow of individual and group requests coming from all over the country, organize in-service teacher training and follow-up activities, as a voluntary supplement to one's regular activities. Still we continue doing it as teachers inquire us and we feel we can help. But it is very important to be able to do it with minimum time, effort and distraction from our direct work. Some examples of employing the Web to ease the transition from research labs to potential users are presented below.

VALUE – A Virtual Almanac for Logo Users and Educators

The project "Learning by developing with Comenius Logo", initiated by the Teacher Training Center run by the Department, aims to bring the spirit of Logo and Logo educational philosophy to the Bulgarian schools (Nikolova 1997). Comenius Logo (Blaho & Kalas 1998) - an attractive and sophisticated environment with considerable conceptual and operational power - was chosen as software platform. We adapted the system to the Bulgarian language, developed Bulgarian on-line help, and a whole range of reference, teaching and learning materials (lessons, problems, projects, microworlds) for teachers and students. In this sense the project is a good example for initiating and supporting educational innovations (Fullan 1991). We used the Web as a supplementary channel for delivering our production to users, getting feedback and establishing collaboration with motivated teachers. VALUE: A Virtual Almanac for Logo Users and Educators was created (Nikolova & Ginkulova 1998). We integrated there the developed materials and embedded communication and discussion (Conference Room metaphor), event announcement (Message Board), building virtual Logo community (Guest Book metaphor). For easier orientation within the site a *site map* (Fig. 8) is available. A lot of users benefit from VALUE, which lowers significantly our load and contributes to the effectiveness of the implementation process.

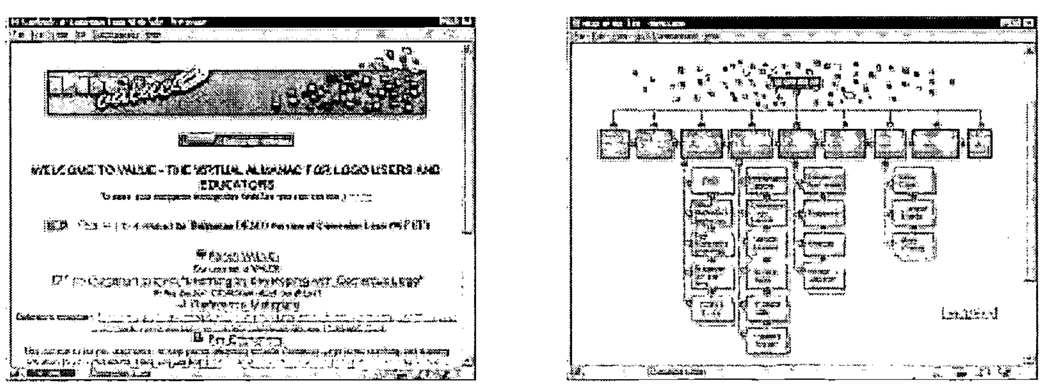

Figure 8: VALUE: Homepage and Site map

GEOMLAND – A Laboratory for Mathematics Explorations in Logo Style

GEOMLAND (Sendov & Sendova 1997) is a powerful Logo style learning environment for mathematics explorations, developed at the Department. Its dissemination and school implementation is accompanied with similar problems as the ones mentioned above. A recently developed Web site (Fig. 9) makes it convenient to provide users with what they need – the software is downloadable from there, research and methodology papers, demonstrations and examples are available. The time spent until recently on personally advising users, providing information and demonstration for them can be now allocated to other tasks.

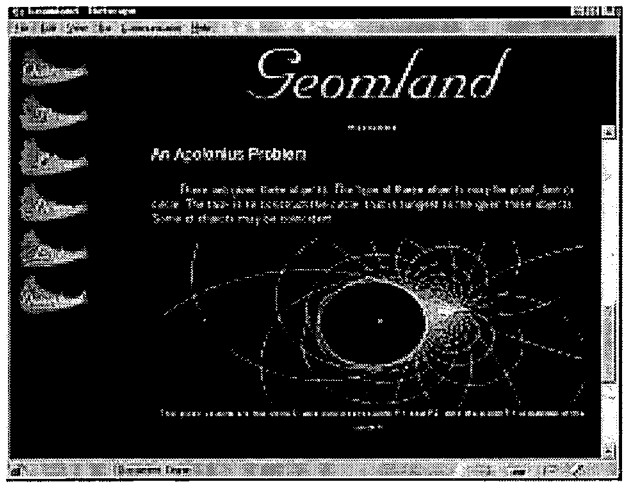

Figure 9: A GEOMLAND Web page

School Resource Bank – A Subject-Oriented Web Resource Catalog

Our students make field-oriented Web searches and develop useful collections of annotated on-line resources. One example is the School Resource Bank (Fig. 10), which is a subject-oriented educational catalog. It is included in the Department's Web site and offered also to the Bulgarian I*EARN section for use by schools with Internet access.

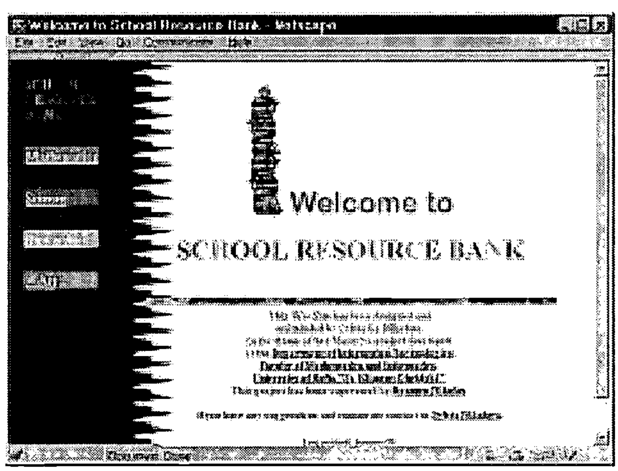

Figure 10: School Resource Bank

Discussion

Maintaining educational Web sites does not only save time and help reach more users. Feedback from users is facilitated, two-way communication channel and mutual collaboration are established. Another positive effect is, that offering meaningful material and helpful interactions to teachers in such a way, they get used to using Internet for educational resources and motivated to make their own Web developments.

MATCh: A Multimedia Authoring Tool for Children

A recent European project with partners form Slovakia, Hungary, Holland, UK, Greece and Bulgaria was devoted to developing an environment for multimedia authoring for children (Triantafilou et al 1997).

MATCh Overview

The system employs the constructivist learning philosophy and supports creative thinking and expression by means of multimedia technologies. It consists of five tools – Frame, Sound, Animation, Story and Web editors. In the Story editor the user can create applications (stories) by combining multimedia resources – either already available or self-produced by the Frame, Sound and Animation editors. The Story editor can be entered at three levels (Fig. 11): *beginner's, intermediate, advanced*, and two modes: *run* (to play a story) and *edit* (to create a story). The Web editor can export (with some restrictions) a story into a Web presentation. During the school testing the environment was well accepted by the teachers and students and proved to be an appropriate component of today's technology rich classroom. Especially the Story editor, with the ease of use and attractiveness of the final result, was valued as a motivating and rich context for active learning and creative expression. An important requirement for the effective use of the system is the availability of rich libraries of multimedia resources for the children to start.

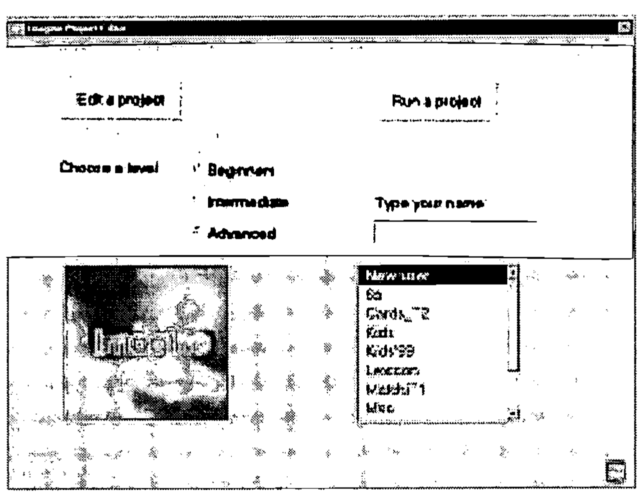

Figure 11: Story Editor: Entry Screen

Applications Developed by the Bulgarian Team

Several MATCh applications were developed to demonstrate the power of the environment and serve as system testbeds. Some of them are quite complex and have an educational value on their own.

Multimedia Screen Cards

A *multimedia screen card* is a moving, speaking, singing card, the user can play with (click on certain elements to make something happen), print, modify, export into a Web page. Each card has its own scenario, i.e. is a short multimedia story. The application faces children with most popular European traditions and festivals and with personal occasions, when people interact with each other by sending greetings, expressing good wishes or appologies. It tends to stimulate children for a more social style of behavior and interaction by using new means of expression - multimedia technologies. Sixteen sample cards for different occasions were developed (for Christmas, St. Valentine's Day, Easter, Mother's Day, Birthday, GetWell, Apology, etc.) and built into a consistent Screen Card World with a well designed visual navigation. The user is taken by hand by the main character, the Duck, who tells a story about each occasion (Fig. 12). Then the sample cards for this occasion can be played with (fig. 13). Not only can the child enjoy the Screen Cards World – its cognitive value, intriguity, variety, brightness, dynamics and interactivity. There is more: she can use the rich collection of resources developed for this application – actors, images, sounds, music, recorded speech, backgrounds – and combine them in her own way, thus designing her own cards and multimedia stories.

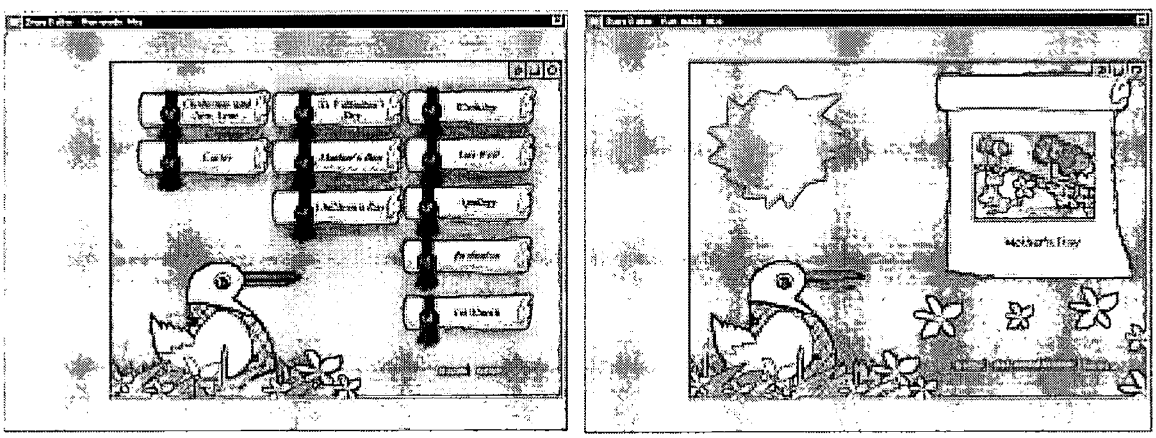

Figure 12: Multimedia Screen Cards application

Figure 13: Playing sample cards: "Apology" and "Get Well"

Save the Animals

This application illustrates the possibility to design multimedia games with Match. It is a story where the child plays the role of a Zoo Detective, trying to help an animal in danger (Fig. 14). The application has a modular structure and allows modification and extension. A rich collection of resources was developed for it: animated actors and animals, media files and backgrounds.

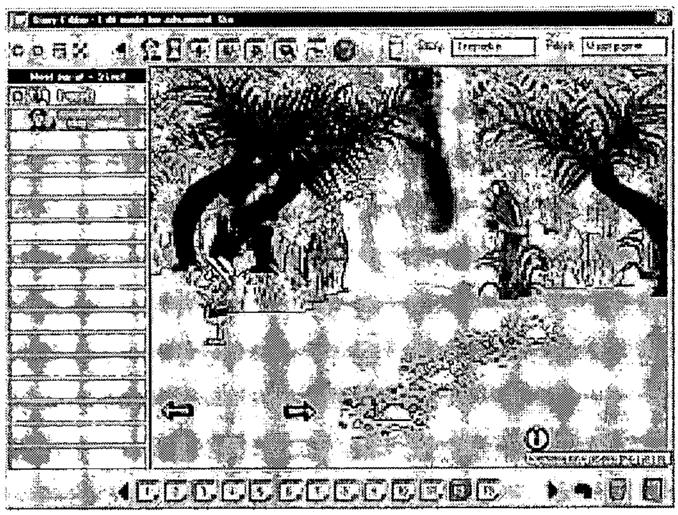

Figure 14: Save the Animals (Editing a page of the story)

Children's Projects

While testing the system and applications in school, children made their own production with MATCh – individual screen cards and class projects: "Meet our class" (Fig. 15) and "Class album". This work kept them very much involved. An interest to different types of information was provoked and children were motivated to learn more about using and processing texts, pictures, movements, sounds and music.

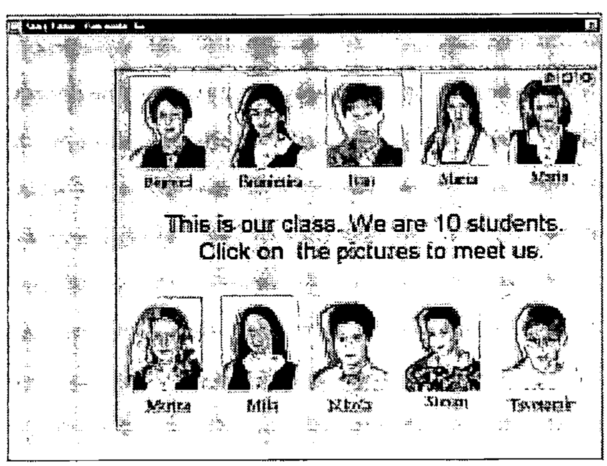

Figure 15: Meet Our Class project

Discussion

Why multimedia authoring for children? To provoke children's thinking, imagination, expression, active learning (Druin & Solomin 96). To enable children taste the process of creating multimedia and personalize the basic concepts of the multimedia world surrounding them. To create a context, in which each child can contribute to an enjoyable collaborative activity with what s/he is talented for – choosing/creating/mixing music, telling a story, creating an interesting scenario, drawing, producing animation, designing interface. There are various roles as various the children's preferences can be.

Reflections

The dimension of change illustrated by the above is not only a technological one. It is much broader, concerns attitudes and culture and refers to both professional and personal level. The overall tendency of virtualization and globalization of our professional lives is sometimes in conflict with the intuitive reaction to defend ourselves from an intra-personal Internet invasion. On the other hand, armed with the modern technologies, we were able to establish a meaningful context for challenging and rewarding professional activities within an environment, which is still suffering from social, economic and organizational deficiencies.

Acknowledgements

The multimedia developments reported in this paper have been done with the financial support of the EC INCO-COPERNICUS MATCh project.

The author would like to specially acknowledge the ultimate role of Dr. Roumen Nikolov, Head of Department of Information Technologies for the achievements presented in this paper. The overall development of the Department as a modern academic unit would not be possible without his broad vision, innovative spirit and constant efforts to implement visions into practice.

FULL PAPERS

Evaluation of Effective Interventions to Solve the Drop out Problem in Adult Distance Education

ychyung@boisestate.edu

Abstract: Described in this paper is a case study of evaluation conducted in the instructional & performance technology (IPT) department at Boise State University (BSU). The IPT department offers a distance education (DE) option in its Master's degree program. This case study describes the effective interventions that the educational organization used to reduce the drop out rate. The drop out rate during 1989 and 1996 was 44%. The IPT DE program designed and implemented interventions to reduce the drop out rate during the three semesters in 1997. Within a year, they found that significantly positive results were obtained from their interventions. The purpose of this paper is to help audience understand how to design, implement, and evaluate interventions to reduce high dropout rates. Several instructional design models and an evaluation model such as the ARCS model, the Organizational Element Model (OEM), and Kirkpatrick's evaluation model are discussed in the paper.

1. Introduction

1.1 Adult Education

The U.S. Department of Education defines adult education as the teaching of adults via any education activities, except full-time enrollment in higher education credential programs. According to the Digest Education Statistics published by the U.S. Department of Education (1997), the number of adult education participants among 117,826,000 employed persons during 1996-1997 was 59,734,000.

What motivates adults to be involved in continuous formal education? Houle (1971) conducted a qualitative study from which he identified three types of adult learners: goal-oriented participants, activity-oriented participants, and learning-oriented participants (cited in McCreary, 1990). Verduin and Clark (1991) categorized three main types of adult education programs: adult basic education (ABE) programs (to acquire ABE), leisure and enrichment education programs (to increase enrichment in adult life), and career education programs (to prepare or upgrade their job-related knowledge and skills). Examples of adult education activities include part-time college attendance, classes or seminars given by employers, classes taken for adult literacy purposes, adult basic education or English as a second language, or courses for recreation and enjoyment.

1.2 Adult Distance Education

Distance education is defined as "any formal approach to learning in which a majority of the instruction occurs while educator and learner are at a distance from one another" (Verduin & Clark, 1991, p.8). Distance education, due to its time and geographic flexibility, has appealed to working adult learners who work full-time yet want to seek for continuous education. Many adult learners attempt to achieve their goal of adult learning via distance learning options. Distance education institutions use various distant learning technologies such as audio and video conferencing devices, the Internet, or computer-mediated communication systems.

According to a survey conducted by National Center for Education Statistics in 1995, out of about 14.3 million students enrolled in higher education institutions in fall 1994, about 758,640 adult students formally enrolled in distance education courses in academic year 1994-95. Eighty one percent of institutions reported that they offered courses designed for undergraduate students; thirty four percent for graduated students; and thirteen percent for professional continuing education. Among the distance education institutions, thirty nine percent of them targeted professionals who were seeking recertification, and 49 percent targeted other workers who looked for skill-updating or retraining as potential audiences.

1.3 Adult Distance Education in Boise State University

The Instructional & Performance Technology (IPT) Department at Boise State University offers a Master's degree program via distance education (DE). The IPT-DE program is intended to prepare adult students at distance for careers in the areas of instructional design, job performance improvement, human resources, organizational redesign, training, and training management. The majority of students attend the IPT's distance program not only to earn a master's degree in IPT but also to upgrade their professional knowledge and skills. The majority of the adult distance learners who enroll in the IPT-DE program are classified as goal-oriented and learning-oriented learners. The asynchronous computer-mediated communication (CMC) environment that the IPT-DE program provides in the DE classes has been helping the adult learners engage in interactive and dynamic discussions among the participants and achieve their goals of higher education through the collaborative learning experiences.

2. A Problem in Adult Distance Education

Although distance education has appealed to working adult students who work full-time and seek for continuous education as part-time students and allow them to attempt to achieve their goal of adult learning via DE options, a problem in DE has been a high turnover in enrollment. Retention of DE students is usually lower than retention of on-campus students (Verduin & Clark, 1991). Reasons for dropouts are found to be various. Adult DE students tend to drop out of DE programs when they perceive that their interests and course structure are not matched (Fenner, 1998), that they are not confident enough in learning processes (Chacon-Duque, 1987), and/or that they have achieved what they wanted (Holmberg, 1989 cited in Verduin & Clark, 1991).

The dropout problem in DE programs was found in the IPT-DE program at Boise State University as well. Between the fall semester of 1989 and the fall semester of 1996, 44% of DE students dropped out of the IPT-DE program by their third course (Fenner, 1998).

3. Systemic and Systematic Interventions

In order to solve the dropout problem, it is important to approach to a solution in a systemic and systematical way. It is critical to conduct a careful analysis on the causes to the problem first, then to seek for the most appropriate solutions to the problem, to implement the solutions, and evaluate the effectiveness of the solutions. The ARCS model, the Organizational Element Model (OEM), and Kirkpatrick's evaluation model guide such processes.

First, according to Keller's ARCS model (Keller, 1987), there are four factors that influence the degree of learners' motivation to learn: Attention, relevance, confidence, and satisfaction. Learners lose their motivation to learn and quit learning, especially when they do not perceive the instruction as interesting or relevant to their goal. They also lose motivation to learn when they are not confident in learning processes, and/or they are not satisfied with the instructional processes. Therefore, it is critical to design DE instruction based on the ARCS model in order to prevent dropouts.

According to the OEM (Kaufman & Thiagarajan, 1987), there are four elements in a results chain: Organizational inputs, processes, products, and outputs. Effective instructional *inputs* and *processes*, possibly designed based on the ARCS model and delivered by an educational organization, will result in successful learning outcomes, which is one of the educational organization's *products*. Learners who experience successful learning outcomes will more likely continue to be motivated to learn; that is, there will be a high retention rate in enrollment, which is one of the educational organization's positive *outputs*.

In order to evaluate the effectiveness of the educational organization's inputs and processes, products, and outputs, Kirkpatrick's model of evaluating training programs can be used (Kirkpatrick, 1996). The level 1 evaluation is to measure learners' reaction to the educational organization's instructional *inputs and processes*. Since the instruction was designed based on the ARCS model, it is appropriate to evaluate learners' reaction to the instruction based on the four ARCS elements. That is, measured are learners' perceptions on their attention levels during the instruction, relevancy of the instruction to their interests, confidence levels in learning, and satisfaction levels toward the instruction as well as the instructor. The level 2 evaluation is to measure the educational organization's *product*: i.e., the learning outcomes. The level 3 evaluation is to measure the educational organization's *output*: i.e., whether the dropout rate has decreased or not. A summary of the systemic and systematic interventions and evaluations of the effectiveness of the interventions conducted by the IPT-DE program at BSU is illustrated in Figure 1.

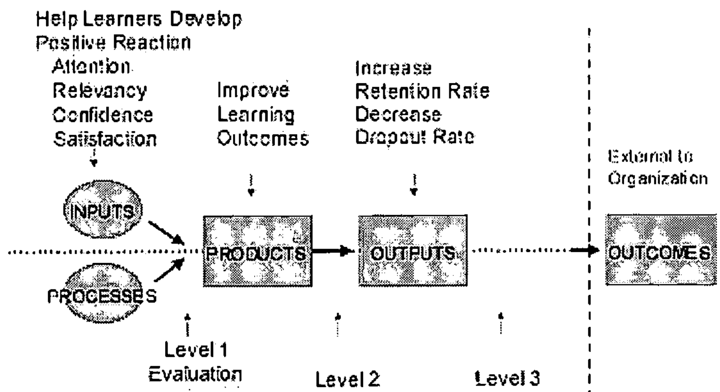

Figure 1. Systemic and Systematic Interventions and Evaluations

4. Cause Analysis

In order to find out the causes of the dropout problem, the IPT-DE associate program developer conducted interviews with the students who dropped out of the program as well as those who were continuing the program between 1989 and 1996. From the interviews, it was concluded that their satisfaction levels during the first or second courses were the major factor that determined their decisions to continue or not to continue the program. Forty two percent of the students who dropped out of the program expressed 'dissatisfaction with the learning environment' as a reason for their dropout. More specific reasons for dropouts included:

- discrepancies between their professional or personal interests and the course structure
- low confidence levels in distance learning
- doubts in successful online communication
- incompetence in using the DE software as an effective learning tool
- feelings of being overwhelmed by the advanced knowledge and overloaded information
- de-personalized learning environment.

5. Intervention Plan

From the cause analysis, it was obvious that a solution to the dropout problem must be to help new distance students be satisfied with instruction and improve their performance as well as their confidence levels during the first and second courses. During three semesters (spring, summer, and fall) in 1997, the IPT-DE program addressed how to design instruction to be more *attractive* enough to keep new DE students motivated in learning, to be more *relevant* to their professional interests, and to increase individual students' *confidence* and *satisfaction* levels toward the instruction. The ARCS model and the OEM were used to guide the instructional design and developmental processes. Especially the instructor of the first DE course aimed to help her students develop self-regulated learning skills in the DE environment. In doing so, she used various *instructional* strategies, including:

- to administrate a pre-knowledge assessment to measure students' previous knowledge levels at the first week of the semester
- to interact with individual students as much as possible and encourage them to interact with each other as well
- use all types of data presented by individual students in order to know the students better
- to break down the instruction into small weekly modules and help them master each module at a time

- to inform students of the goals and objectives of the weekly instruction and encourage them to self-evaluate their weekly learning process as well as weekly learning outcomes
- to provide students with clear criteria of expected performance levels
- to provide specific help to the students who have low pre-knowledge levels and provide more challenging work to the students with high pre-knowledge levels
- to deliver instruction via multiple media such as PowerPoint slide show, the WWW, and an electronic bulletin board when appropriate
- to provide meaningful examples and analogies to help students learn new concepts
- to modify instruction based on students' background when it is possible and appropriate in order to help them see the instruction relevant to their professional and personal interests
- to conduct formative evaluations during the semester in order to obtain information about the effectiveness of the interventions and individual students' perceptions toward instruction
- to monitor individual students' performance and provide *immediate*, *frequent*, *regular (weekly),* and *personalized* feedback
- to give positive reinforcement to students when they collaboratively work toward achieving the instructional objectives

In addition to the instructional strategies presented above, another important intervention is an *administrative* strategy - *personalized advisement throughout the program.* Prior to the registration, the DE associate program developer and the faculty members provided advisement to individual DE students, especially regarding the most appropriate sequence of courses for them to take. It is in order to prevent the DE students from taking advanced courses too early and having unnecessary experiences of failure or to help them take courses that are more relevant to their professional and personal interests.

6. Evaluation of Reaction, Learning Outcomes, and Dropout Rate

6.1. Reaction (Level 1)

At the end of each of the three semesters in 1997, a course evaluation questionnaire was administered to measure students' reaction to the quality of the course and the instructor. The response scale used was A: Outstanding, B: Very Good, C: OK, D: Improvement Needed, and E: Unsatisfactory. As coding their responses, the number one was assigned to a response to 'A'; 2 to 'B'; 3 to 'C'; 4 to 'D'; and 5 to 'E'. The data of average scores revealed that students were more satisfied with the quality of the course as well as the quality of the instructor as the implementation of interventions became matured semester after semester (see Table 1).

Semester	Attention	Relevance	Confidence	Satisfaction toward Course & Instructor
Spring, 1997	M = 1.41	M = 1.92	M = 1.83	M = 1.92 & 1.42
Summer, 1997	M = 1.17	M = 1.63	M = 1.75	M = 1.50 & 1.00
Fall, 1997	M = 1.25	M = 1.47	M = 1.56	M = 1.31 & 1.06

Table 1. Level 1 Evaluation: Attention, Relevance, Confidence, and Satisfaction Levels

6.2. Learning Outcomes (Level 2)

In each of the three semesters in 1997, a pretest and a posttest were administered to measure and compare between the pre-knowledge levels and the learning outcomes. All t-tests revealed that the posttest scores were significantly different from the pretest scores (see Table 2).

Semester	Means (Learning Outcomes)	t-test results
Spring, 1997	M (pre) = 24.58, M (post) = 36.83	t (11) = -20.61, p < .01
Summer, 1997	M (pre) = 25.59, M (post) = 34.78	t (16) = -7.64, p < .01
Fall, 1997	M (pre) = 25.38, M (post) = 34.81	t (15) = -9.25, p < .01

Table 2. Average Pretest and Posttest Scores and t-test Results

6.3. Dropout Rate (Level 3 and 4)

Between the fall semester of 1989 and the fall semester of 1996, the average dropout rate by the third course was 44%. In other words, 44% of DE students dropped out of the program by their third course. At the end of 1997, a year after the interventions were implemented, the dropout rate decreased down to 22% (Fenner, 1998). Twenty-two percentage of the dropout rate from 44% is a significant decrease.

Among those who dropped out of the program, three students dropped out after the first week of the course due to hardware and software incompatibility problems. Six students cited that they decided not to continue the program because their professional goals and the degree program did not match. Other reasons cited were a health problem and time constraint.

7. Conclusions and Educational Implications

This case study revealed how systemic and systematic ID models such as the OEM and the ARCS model, and Kirkpatrick's evaluation model guided throughout the processes of solving the dropout problem in the IPT distance education program at Boise State University. The impact was significantly positive in terms of the benefits to the educational organization itself as well as to the learners themselves. Due to the educational organization's efforts of designing and implementing effective interventions based on the OEM framework and the ARCS model, the DE students perceived the delivered instruction as more interesting and relevant to their professional and personal goals. They were confident in learning and satisfied with the distance learning environment. Due to the effective instructional inputs and processes, DE students achieved significant learning outcomes. Due to the positive reaction to the instructional inputs, learning processes, and successful learning outcomes, they more likely decided to continue to learn via distance education. As a result, the educational organization significantly decreased the previous dropout rate. It is cost-efficient to decrease dropout rates to maintain the number of enrollment, instead of trying to recruit new students. This case study revealed how effective *means* lead to desirable ends within an educational organization.

Abstract: The increasing utilization of the World Wide Web in higher education allows instructors to re examine pedagogical strategies and explore ways of taking advantage of the Web's potential to provide for learning experiences that go beyond that possible in the traditional classroom environment. Assumptions on how this enhances the learning experience for students require examination. This paper discusses a study which examines, among other issues, student perceptions of the learning experience when asynchronous, Web-based, collaborative tutorial activities are utilized within an undergraduate health education subject. Analysis of the study data demonstrates that students' perceptions of the effectiveness of the Web-based tutorials lie in their appreciation of opportunities for flexibility, reflection, and self-directed investigation within the learning environment.

Introduction

The increasing utilization of the World Wide Web in higher education allows instructors to re examine pedagogical strategies and explore ways of taking advantage of the Web's potential to provide for learning experiences that go beyond that possible in the traditional classroom environment. Our assumptions on how this enhances the learning experience for students require examination.

In an effort to investigate the use of Web-based instruction in the delivery of health education at the undergraduate level, the Faculty of Education at the University of Wollongong implemented Web-based learning activities as part of the tutorial component within its Health and Health Behaviour subject (a core subject for students enrolled in a pre-service teaching Bachelor of Physical and Health Education degree program). This study examined, among other issues, the perceptions of the learning experience for students engaging in these Web-based collaborative tutorial activities.

This paper discusses the design and development of a Web-based learning environment with embedded collaborative tutorial activities; methodology and implementation process, and preliminary findings of student perceptions of the Web-based learning experience.

Theoretical Background

Important components of the learning process are discourse and learner interaction. Duffy and Cunningham (1996) define learning as a "social, communicative, and discursive process, inexorably grounded in talk" (p. 181). Dialogue and discourse encourages the higher order thinking skills of cognitive conflict and resolution in providing context and a mechanism for explanation, justification and reason (Oliver, Omari & Herrington, 1997). Learners' interactions with instructors and other learners "give them perspective, place them within a community of learning, and contribute to their mastery of concepts and skills" (Price & Petre, 1997, p. 869).

This essential component of learner interaction and discussion in the learning process focused our attention on learner discourse through collaborative activities. The questions that guided the study included:

- How do learners participate in and contribute to collaborative health education learning activities within the class and Web environments?
- What knowledge, attitude and behaviour change occurs when students engage in collaborative health education learning activities within class and Web environments?
- What are learners' perceptions of the effectiveness of class and Web environments for health education?

Learning Environment Design and Development

Phase one of the study involved the development and formative evaluation of collaborative learning activities and a prototype Web learning environment.

For the purposes of investigating the impact of implementation of Web-based learning within the subject, six online learning activities were developed. During the first half of session, concurrent class and online tutorials focused on issues related to HIV/AIDS.

The literature suggests the pedagogical benefits of asynchronous communication includes the opportunity for learner reflection, self directed learning, and learner participation in topic negotiation and communications control (i.e., subject matter discussed, number of topics discussed, and, the speed at which communication about topics occurs) (Laurillard 1993; Romiszowski & Mason, 1996). With this in mind, Web-based learning activities were designed for asynchronous participation.

All Web-based and class-based learning activities were structured to allow for small group discussion and collaboration. The general format for the structure of each learning activity was to provide a stimulus to discussion in small groups (e.g., a survey to be answered, questions to be considered, etc.) with each group arriving at some consensus or shared understanding that could be communicated to the larger class during the subsequent lecture. In Duffy and Cunningham's (1996) terms, the learning strategy involves a problem which provides stimulus for an authentic activity where knowledge is developed through working on the problem.

Once the learning activities were designed, the Web learning environment was designed and developed. A guiding factor in the design of the Web-based learning environment was consideration of the computer and Web experience of the students enrolled in the subject. Based on history with similar cohorts, it was expected that there would be a range of computer experience among the students with the majority having little experience with computers. Additionally, it was expected that there would be a range of Web use experience with the majority of the students having either none or little experience in using the Web. Brown and Thompson (1997) argue that "interface design must provide ease of navigation, a sense of human interaction, helpfulness and responsiveness to the needs of learners studying in an information rich, self-directed medium." (p. 78) As such, particular attention was paid to constructing a Web environment with a simple structure with embedded communication tools that were easy to use.

The Web site structure included four main components: (1) the subject outline which provided information such as the rationale, objectives, content, presentation, assessment, and participation expectations for the subject; (2) the subject schedule which provided, in table format, the week-by-week timetable of lecture topics and tutorial activities; (3) resources and Web links which included links to a number of Australian and international Web sites related to the topics covered in the subject; and, most importantly, (4) the Activity Centre which facilitated the learning activities for the students who were participating in Web-based tutorials.

The Activity Centre was designed using a structure based on the suggestion that Web-based learning environments should put minimal cognitive load on the student and that templates be utilized in screen design which "promotes understanding by allowing the reader to focus on new information rather than devoting time and energy to variations of format" (El-Tigi and Maribe Branch, 1997, p.25).

The initial structure of each activity consisted of two or three Web pages. The Things To Do page outlined the activity and provided stimulus to the group discussion. Examples of discussion stimuli utilized in the learning activities included: a questionnaire (e.g., In what situations can HIV be transmitted?) to be answered and discussed by the group and a narrative that provided an example for groups to develop their own story (e.g., for risk factors of HIV/AIDS). In cases where an online questionnaire provided stimuli to the collaborative learning activity, results of the individual group members were provided on a separate, Results, page. This facilitated the sharing of ideas among group members and provided a basis for their discussion. The Discussion Area for each activity was designed to be the focal learning area. The comments submitted to this page were viewable only by group members and were displayed in chronological order on the page.

Formative Evaluation

The formative evaluation of the learning environment, with embedded activities, involved a multi-faceted approach including: review by experts in the areas of health education and instructional technology; review by instructional technology postgraduate students; and testing by undergraduate teacher trainees.

After using the Web site, the health education and instructional technology experts were interviewed and instructional technology postgraduate students were surveyed regarding: Web environment interface issues; clarity and quality of information and external links; and, perceived pedagogical effectiveness of the learning activities. Undergraduate students were asked to fill out a one-page survey of questions regarding Web site interface issues and usability.

The Web learning environment was revised, based on analysis of the data collected during the formative evaluation, with the majority of changes to the Web site focused on the individual learning activities within the Activity Centre. Specific reviewer suggestions to describe learning activities and tasks in more detail resulted in a clarification of the structure of each learning activity and thus, a proliferation of pages for each activity.

In the revised version of the learning environment, each learning activity was associated with five main areas. The This Week's Task Into page introduced the student to the activity, related the activity to the specific lecture, provided additional conceptual information and stimulus into the group activity by asking the student to respond to some initial, topical questions. Once the student submitted their response to these initial questions, they were automatically moved to the Group Tasks page. Here, the student could read a detailed description of the group task for that particular learning activity. The student also had the opportunity to view their responses and the responses of the other members in their group to the initial, topical questions by accessing the Individual Responses page. The earlier version of the Discussion Area was maintained, however, based on reviewers suggestions, an abbreviated list of the group tasks was added to the top of the page. A Submit Page form was also added, to the structure of each activity, as the area in which the group submitted their final product. All five areas of the individual activities were available to the student at all times (i.e., students are not forced to follow a particular page sequence when engaging in the activity).

Study Methodology and Implementation Process

The study was implemented in July 1998 within the Health and Health Behaviour subject. Sixty-two students were enrolled in the subject with the majority of students (57) registered in their first year of the Faculty's Bachelor of Education in Physical and Health Education degree program. The subject was conducted over a 14 week schedule.

During implementation of the study, a crossover factorial design was utilized where students were randomly assigned into two tutorial groups and each group then randomly assigned to one of two learning environments (class or Web) for the first half of session. In the second half of session, groups crossed over to engage in their tutorials within the alternate learning environment. Both tutorial groups were further, randomly, divided into working groups (seven working groups in each of the two tutorial groups) consisting of four or five students.

All tutorial sessions (conducted either in the class or in the Web-based environment) were associated with an assessable activity task for which each working group was required to submit a final group product prior to the next lecture.

During the first week of session, students were advised of the subject Web site and its location (http://www.immll.uow.edu.au/UG/EDUP144/). At that point, all students could access the subject information and resources but could not access the Activity Centre where Web-based tutorials were located.

The first Web-based tutorials were implemented in the fourth week of session while the second set of

Web-based tutorials were implemented in the eleventh week of session. This time frame allowed students to develop a working relationship with their tutorial work group; become accustomed to the process of completing and submitting their group work within the weekly time frame; and, complete three weeks of Web skilling exercises within a Information Technology subject. During the week prior to commencing Web-based tutorials, students were provided with a brief presentation as an introduction to the Web site and the structure of the learning activities. At this time, students were also given an individual username and password to access the Activity Centre.

Pre-tests and post-tests for knowledge, attitude, and behaviour related to the health topics covered by the learning activities (HIV/AIDS and nutrition), and computer literacy and computer comfort, as well as a post-test which included items related to perception of the learning environments were administered to students. The collaborative learning activities were recorded (via audio tape and electronic Web logs).

Once learning activities were complete, a representative of each working group was chosen, at random, and asked to engage in an in-depth interview regarding their experience and perceptions of the class and Web learning environments. Specifically, the interview sessions gathered information from the students regarding: how their group process was managed during weeks when tutorials were held in the classroom and when they were conducted within the Web-learning environment; their perceptions of engaging in group-based tutorials within the Web learning environment in general and the individual learning activities specifically; their perceptions of the effectiveness of the Web-based tutorials compared to class-based tutorials in terms of their own learning; and, their experience in terms of group interaction in both the Web and classroom environments.

Findings

An analysis of the in-depth interviews conducted with students who engaged in the Web-based learning environment during the first half of session (seven students representing each of seven tutorial working groups) is presented as preliminary findings.

All students expressed positive opinions on their experience of engaging in the Web-based tutorials. While one student had previously experienced a subject which was supported with Web-based learning materials, none of the students had previously engaged in collaborative group learning activities using the Web. They felt it was a "novelty"; a "...buzz to sit down and talk to three other people in different places"; and that "... it intrigued you because it was new and because it was different." All the students mentioned the benefit of the "convenience" and "flexibility" of engaging in the Web-based tutorials.

Most students (six of seven) felt that the Web-based tutorials were more effective in terms of facilitating their own learning than the classroom-based tutorials. Some suggested that this was due to the fact that, in the Web environment, they had time to research the information (either in texts or via external Web sites) and reflect on the group task. One student's explanation of the experience is indicative of that expressed by many of her peers, "... when you're all rushed, you won't concentrate . But ,when you've got time for it, you can sit down, think about it . A couple of times I'd go off and read some books that I had at home to help me a bit and make me think more about the answer. Then I could come back to it whereas, when you are in the class you've got to know straight away, right there. I mean, I'd go onto the Internet and try to find some information to give me some ideas and then I'd go back on and write my answers... so I thought that was good."

Each student was asked to comment on and compare the participation and interaction among their work group members in both the class-based and the Web-based tutorials. Only two students reported that, during class-based weeks, their group actually worked on the entire task as a whole group. The other five students reported that their group tended to separate the task into small parts and assign those parts to individuals. Then, one member of the group would be responsible for pulling together the individual parts into a final product.

This did not seem to be the case for the weeks in which the tutorials were conducted in the Web-based environment. All students noted that, during these weeks, all group members contributed by completing the individual introduction page and interacting within the Discussion Area on all aspects of the task. To complete the group Submit Page, three of the seven students noted that their group met around one computer and completed the page together. The other four students noted that their group delegated the responsibility of synthesizing the group discussion to one group member.

In comparing the nature of the interactions that took place in the two environments, most students (five out of seven) felt that more detailed contributions were made within the Web-based environment. One student noted that, "I think it makes you express what you think more because you're not talking. When we would meet to talk... one person would say what they think then the others would just say, 'yeah, I agree'." Another student felt this detailed contribution in the Web-based tutorials was due do the fact that the Web takes away the pressure of the face-to-face environment, "Some people would be sort of afraid to come out and say things. But on the Web, people aren't directly looking at you and you're not the focus of attention. On the Web, in great detail, you can tell someone about something. But in the classroom you don't tend to go into a lot of detail... I think for people who are reluctant to let everything out in the classroom, [the Web] is a really good opportunity, you don't have any pressure on you."

This student went on to explain that she noticed a difference in her own contribution, "I think I contributed a lot more on the Web than I do in the classroom, I tend to sit back and listen and just throw something in every now and then... In the classroom, if you've got very talkative people in your group, chances that you'll sit back and let them run the show. But when you're on the Web you're free to make a huge contribution if you want to, so you write as much as you want ... you say a lot more on the Web than you would in the class."

When asked what, if anything, the classroom tutorials provide that was unavailable in the asynchronous Web-based environment, some students mentioned the ability to ask questions of the tutor or another student "there and then".

The students were asked to think about their own skills in using computers and the Web and the appropriateness of the introduction to the Web-based environment which they had received. Four of the seven students interviewed said that they felt competent about using computers and the Web prior to engaging in the Web tutorials. These students noted that the brief introduction to the Web site was enough to get them started on the Web-based tutorials. They all felt that the structure of the Web-based tutorials was very easy to understand.
The other three students who were novice computer and Web users also felt that the structure of the Web environment was very easy to understand and that they were adequately equipped by the prior Web skilling exercises in the Information Technology subject to be able to engage in their Web-based tutorials. These students felt that the experience of engaging in the Web-based tutorials not only increased their computer and Web skills, but also allowed them to feel more "relaxed" using the technology. One of the students expressed her feelings in this way, "I was a bit nervous, I mean, I know computers are going to be important so I've wanted to do it, but I haven't had the confidence... actually using them for something constructive, I've got the confidence now... a big positive."

Students commented that felt they would benefit from suggestions on how to better manage the group process when engaging in Web-based, asynchronous tutorials. Some students mentioned instances when they were unsure when their work group members would be logging on to the Web site or how the final group product was going to be organized. However, it is interesting to note that many students also reported that they experienced similar process issues in the class-based tutorials.

Discussion

Analysis of this sample of data demonstrated a degree of perceived effectiveness for the implementation of the Web-based collaborative learning activities within an undergraduate health education subject.

The majority of students perceived Web-based tutorials to be more effective for learning than class-based tutorials. They suggested that contributing factors to their learning process in the asynchronous Web-based environment was the opportunity to research information using print and electronic resources and reflect on their ideas and the contributions of their work group peers. This supported the literature (Laurillard 1993; Romiszowski & Mason, 1996) on the pedagogical benefits of learner reflection and self-direction afforded by asynchronous learning environments .

The students' perceived that the quantity and quality of participation and interaction among their work group was higher in the Web-based environment. This reinforced the literature on computer-mediated communications (CMC) which suggests that collaborations within this environment can be more powerful than face-to-face encounters (Romiszowski & Mason, 1996).

Full quantitative and qualitative measurement of the effectiveness of the of the Web-based tutorials in terms of learning will be substantiated with comparisons of the pre and post knowledge, attitude and behaviour tests and with in-depth content and discourse analysis of the recorded learner interactions in both class and Web environments.

Final analysis of the data from the study are expected to provide a fuller understanding of: effective Web-based teaching and learning strategies for health education at the tertiary level; the efficacy of the World Wide Web in delivering health education; how discourse-based knowledge construction and attitude development is supported in a Web-based learning environment; and, design issues for Web-based learning environments.

Abstract: Computer-Supported Cooperative Learning (CSCL) is a research area that studies how technology can support the learning processes promoted through collaborative efforts among students working in a given task. The objective of this work is to trace a profile with the main issues related to CSCL environments. For this, a framework is proposed to organize these issues, and a report is made, including available environments and their classification in agreement with the framework.

1. Introduction

Cooperative learning is a technique with which students are supported in learning process, working together with other students and the teacher. Cooperative learning should be based on: (1) individual responsibility for the information gathered; (2) positive interdependence, so that the students feel that nobody will be well succeeded , unless everybody is; (3) better form of understanding a given material; (4) development of interpersonal skills, which will be necessary in future life; (5) development of skills to analyze the dynamics of a group and to work about problems; (6) a way to increase involvement of students in proposed activities; and (7) an interesting and entertaining focus.

Computer-supported cooperative learning (CSCL) aims to effort the learning process, using systems that implement a cooperation environment playing an active role in analysis and control of it. The collaborative technologies allow production of shared knowledge and new community practices. Several subjects of educational and technological order, related to each other, are involved in the construction and implementation of such environments. For example, to determine the kind of communication technology to be used in an environment will depend on the educational objectives pointed by the learning theory adopted by it. So, the set of features of an environment will establish its application and effectiveness.

In this context, a framework for CSCL environments' analysis appears as important conceptual maps, supplying guidelines for research and development. However, available frameworks are incomplete and do not consider important dimensions of this kind of environment. The present work gathers the main aspects of CSCL environments and proposes a framework for its classification.

2. Issues Related to Computer-Supported Cooperative Learning

In this section, we discuss the most important issues that should be observed in CSCL environments.

✓ **Learning Theories** - One of the most important factors that regulates the collaboration is the learning theory on which the cooperative interaction will be based. The learning theories aim to recognize the dynamics involved in the acts of teaching and learning, and try to explain the relationship between the pre-existent knowledge and the new knowledge. Learning is not supposed to be just intelligence and knowledge construction, but basically personal identification and relationship through the interaction with other people. CSCL environments should provide both dimensions and bring other pertinent factors in the human mediation through the technology. Several theories contribute to the understanding of cooperative learning. These theories have in common the assumption that individuals are active agents in the search and knowledge construction within a significant context. In Table 1, the main characteristics of learning theories related to cooperation, are summarized.

Learning Theories	Characteristics
Genetic Epistemology of Piaget	Central point: cognitive structures of the individual. Development facilitated by the offer of challenges. Social interaction and interchanges among individuals stimulate the process of knowledge acquisition.
Constructivist Theory of Bruner	Leaner is active in the process of knowledge acquisition. Determination of more effective sequences of material presentation. Contemporary theory: to create closer learning communities of collaborative practice in the real world. (Kearsley, 1998)
Partner-cultural Theory of Vygotsky	Cognitive development is limited to a certain potential for each range of ages (Proximal Zone of Development). Complete cognitive development requests social interaction.
Problem Based Learning/ Anchored Instruction	Learning begins with a problem to be solved (anchor or focus). Centered in the apprentice and the context.
Distributed Cognition	Interaction among individuals, environment and cultural engines. Reciprocal Teaching. Important role of the technology.
Theory of the Cognitive Flexibility	Knowledge restructuring as answer to context demands. Re-visitations to the instructional material. (Spiro at al., 1992) Activities should contain multiple representations of the content. Sources of interconnected and distributed knowledge.
Situated Cognition	Learning happens in function of the activity, context and culture of the social environment in which is inserted. Social interaction and collaboration are critical components for learning (community of practice). (Lave, 1988)
Self regulated Learning / Metacognition	Control and monitor of the own cognition by the individual. Self-observation, self-judgment, self-reaction.

Table 1: Learning Theories

✓**Models of Cooperation or Kinds of Tasks for Cooperative Learning** - The computational support in learning process can be used to treat the cooperation in different kinds of tasks. These tasks are one of the factors that will determine the cooperation model proposed by the Environment, and they can be enumerated independently of the subject domain that is being taught. Kumar identifies three kinds of cooperative tasks: concepts learning, problems solving and projects' development (Kumar, 1996). Besides these kinds, an environment can be based on Forums of Discussions, where the subjects refer to the participants' behavior, such as, "When do the students read notes?", "When do they write notes?", "What is the participation level in the class?".

✓**Domains** - Cooperative learning is generally more effective in domains where people are engaged in skills' acquisition, categorization, group planning and tasks that request construction of collective memory (Kumar, 1996). Studies proposing cooperative learning to help students to understand complex subjects in specific domain's environments (e.g., scientific thought) present good results. In procedural tasks that do not involve deep understanding, becomes more difficult to observe the occurrence of conceptual changes, suggesting that there are "more" and "minus" shared domains.

✓**Technologies** - Two kinds of technologies can be used in cooperative learning environment: asynchronous and synchronous communication. The use of one or other or of their combination will determine the interaction degree. The need of different communication possibilities will depend on the model proposed by the environment.

Interaction degrees can be small (there is a low degree of interaction among involved participants. For example, interaction happens only in the information sharing activities); medium (the interaction degree is a bit bigger, but it is already far from the effects of face-to-face interactions. For example: interaction happens when people use e-mail for communication); and big (involved people need to know more deeply the other participants and with this purpose they do social changes. For example, interaction happens when people use synchronous video-conferencing).

✓**Activities of Cooperative Work** - Depending on the learning environment proposal, it can support a wide range of activities, such as: coordination of activities; negotiation and decision making; representation of group knowledge; sharing of a database (group memory); perception of the presence and the other participants' actions (awareness).

✓**Role Assignment** - Some systems explicitly assign different roles for the users, which will have distinct rights and specific tasks to carry on in the learning process. For example, teacher/tutor role and student/learner role.

✓**Implementation/Platform** - The platform and resources used in a system development define for example, its type of users.

3. Framework for Study of CSCL Environments

Starting from the discussed issues, a framework is proposed for the study and classification of CSCL environments.

Issues	Possibilities
Theory of Learning	Genetic Epistemology of Piaget Constructivist Theory of Bruner Partner-cultural Theory of Vygotsky Problem Based Learning/Anchored Instruction Distributed Cognition Theory of the Cognitive Flexibility Situated Cognition Self-regulated Learning / Metacognition
Model of Cooperation or Kind of Task	concepts learning problem solution project development knowledge construction forum of discussions
Domain	development of the scientific critical thought ecological models scientific texts non specific domain
Kind of Interaction	asynchronous synchronous
Quality or Degree of Interaction	small medium big
Activities of Cooperative Work	coordination of activities negotiation and decision making knowledge representation group memory awareness
Role Assignment	teacher/instructor student/learner
Implementation/Platforms	UNIX Windows NT Macintosh WWW

Table 2: Framework for Study of CSCL Environments

4. Computer-Supported Cooperative Learning Environments: Brief State-of-the-Art

A study of available Computer-Supported Cooperative Learning Environments took place, aiming to classify them according to the proposed framework.

4.1. N.I.C.E.: Narrative, Immersive, Constructionist/Collaborative Environments

NICE's objective is the construction of virtual learning environments for children, based on narrative theories, construcionism and collaboration. The system was projected to be executed in CAVE, which is a virtual reality environment, room-sized where several people can move freely, both physic and virtually (Roussos at al., 1997). A theoretical framework that combines ideas of the constructivist learning theory, narrative techniques and collaboration provides the basis for it. Considering the theory of Piaget and in the ideas of Dewey, the constructivism is related to the ways that students acquire knowledge by participating in activities or tasks where they are stimulated to build, to manipulate, and to explore objects.

In N.I.C.E., it is possible to accomplish virtual construction blocks which contain characteristics that physical toys or learning tools do not have: the children can catch heavy or big objects, transfer them to another children remotely located, combine them in new objects, or simply observe modifications in their attributes as time goes by. All objects and representations are VRML models, that can be moved, increased or decreased by the children in real time.

One of the construction activity products in NICE is the narrative: both the composed stories and those created by the children who participated in an interaction with the system (Roussos at al., 1997). All the actions that took place within the environment are added to a continually composed story, even when they do not represent children's interactions. The sequence of the story goes through a parser, that changes some words for their iconic representations and publishes it in a WWW page. The collaboration in NICE is emphasized by the interaction of virtual communities (students geographically separated) and physic ones (students in the same physical space), and it could involve verbalization, collective decisions, conflicts resolution, reciprocal teaching (all facilitated by virtual reality techniques). NICE's main objectives are learning from multiple perspectives; learning how to collaborate with other people; learning by controlling and exploring active variables of the environment; programming for demonstration; exploration of structures of stories; and creation of a final product.

4.2. CSILE: Computer-Supported Intentional Learning Environments

CSILE is a collective database that supports students' ideas in textual or graphic format, available for all the participants. In this multimedia set, the students generate nodes with ideas, or part of important information to a topic in study. The data are indexed and organized in such a way that can be accessed through a series of channels, allowing students that are studying a topic in a certain domain, to access information related to it but presented in another domain. The students produce information, formulate subjects, provide feedback and evaluation, and organize the knowledge in the database. According to Gay (1996), CSILE is based on three research lines: intentional learning (attempt to actively reach an objective, different from simply try to do school activities); specialization process (process of progressive problems solution, moving besides the current competence limits); and restructuring of Schools as communities of knowledge construction. The emphasis of CSILE is in the cooperative learning, in spite of the teacher's responsibility for this experience. The teacher and all the students can monitor the learning of the other ones, answer the ideas of the other ones, request information, and make comments.

4.3. CLARE: Collaborative Learning And Research Environment

CLARE is a distributed learning environment supported by computer, where the objective is to facilitate learning through the collaborative knowledge construction. For this, CLARE provides a semi-formal representation language called RESRA and an explicit process model called SECAI (Wan and Johnson, 1994). RESRA (Representational Schema of Research Artifacts) is a semi-structured knowledge representation language specifically projected to facilitate collaborative learning of scientific texts. Wan and Johnson (1994) describes the three premises in which RESRA language is based: (1)the human knowledge can be represented in terms of a small number of primitive nodes and links; (2)the use of these primitives to characterize scientific artifact and subsequent activities in group is significant to learning process, because the learners should make themselves many deep level questions (such as, what hypothesis is being made?, With regard to what problem?, Is this theme a hypothesis or a theory?); and (3)different learners should generate different representations based on the same artifact, and comparing these representations, the similarities and differences in these points of view can be discerned. A map of the knowledge structure reflecting students mental model about the author's of the text intention will be build. SECAI (Summarization, Evaluation, Comparison, Argumentation, and Integration) defines an explicit model for a collaborative scientific texts learning process (Wan and Johnson, 1994). Metaphorically, collaborative learning with SECAI "pulls" the learners from the external, isolated and individual position to the intern perspective, integrated and collaborative in an artifact. As the learners go by the proposed activities in the SECAI model, the level of collaboration grows and at the same time a knowledge base is formed.

4.4. CaMILE: Collaborative and Multimedia Interactive Learning Environment

CaMILE supports asynchronous collaboration on then Web with the objective of fostering learning. It is situated in the CSCL approach described by Guzdial (1997) - analysis in a high level of aggregation: forums of discussions with multiple groups or a whole class. All the accesses to the system are accomplished through a Web browser that accesses a single server. System interface is based on forms, and it is the same for all the users.
The discussions in CaMILE are contextualized as in a newsgroup, even so, the context is persistent, and it is always available for the users, not "disappearing" after the visualization. Similar to CSILE, CaMILE provides a facility in which the students are requested to identify the kind of collaboration they are presenting (e.g., a subject, a new idea, a refutation, etc.) and productive initial sentences are suggested to be used in each one of these kinds of notes. The notes in CaMILE can contain everything that a Web page can contain. In agreement with Guzdial, an important difference between newsgroups and CaMILE is that this environment supports anchored collaboration, which means that each individual note can only be referenced through a Web browser (Guzdial, 1997). So, the notes direct addresses allow that Web pages contain hyperlinks for a discussion context CaMILE. The anchors function as indexes and remainders of what students discussed on a certain context.

4.5. Belvedere

Belvedere helps learners in critical discussion of scientific theories, based on the collaborative paradigm. It can be summarized as a groupware for the construction of logical and rhetorical relationships' representations in a debate, using an interface that looks like a graphic editor. Belvedere provides the students with concrete forms of representing abstract components and relationships between theories and arguments. Ideas and relationships are represented as objects that can be pointed, tied up to other objects and discussed. Belvedere can be used by students that are physically close to each other working simultaneously (synchronous); students sharing arguments in different times (asynchronous); and students working simultaneously, but remotely located to each other. According to Suthers (1996), the environment combines three approaches for learning: collaborative learning, guided learning, and problem based learning. Each one of these aspects is covered by a category of educational software within the environment: groupware for learning; intelligent tutor; and simulation. The software provides argument diagrams that dispose different geometric forms for different kinds of arguments and their components, with positive and negative links, multiple forms of connections, and possibilities of attaches to accommodate complex arguments. Belvedere also provides means for authoring knowledge on-line. This work can be accessed and copied by all the students. The environment was extended to serve as a WWW browser, allowing authors to use existent HTML tools.

5. Classification of the Environments

The analyzed environments were classified in agreement with the proposed framework.

Issues Environments	NICE	CSILE	CLARE	CaMILE	Belvedere
Theory of Learning	Constructivism Theory of Piaget	Constructivism	Constructivism	It is not explicit in references.	Problem Based Learning
Model of Cooperation or Kind of Tasks	Project development Knowledge Construction through	Knowledge construction	Knowledge construction through SECAI	Forum of discussions	Knowledge construction. Problem solving

	narrative of stories		model		Concepts learning
Domain	Ecological Model	Not specific	Scientific texts	Not specific	Discussion of scientific theories
Kinds of Interaction	Synchronous and Asynchronous	Asynchronous	Synchronous and Asynchronous	Asynchronous	Synchronous and Asynchronous
Quality/Degree of Interaction	Big	Medium	Big	Small	Big
Activities of Cooperative Work	Decisions Making Representation of knowledge Group memory Awareness	Representation of knowledge Group memory	Representation of knowledge Group memory	Group memory Awareness	Representation of knowledge Group memory Awareness
Role Assignment	None	None	None	None	None
Platforms	Virtual Reality CAVE Environment	Macintosh, UNIX	UNIX / X-Windows	WWW	WWW

Table 3: Classification of CSCL Environments according to Framework

From the above Table, we can stand out some observations:

- Most of the environments privilege the collaborative construction of some kind of knowledge, being based on theories of learning.
- The environments that develop elaborated models allow interactions of higher degree and combine another research areas' technique.
- The group memory and knowledge representation are present features in most of the systems.

6. Conclusions and Future Perspectives

Computer-supported cooperative learning is a relatively recent area of researches and there are not still complete theoretical frameworks that describe and structure its whole dimensions. In this paper, a framework that organizes the main aspects related to CSCL environments was discussed, in order to facilitate the study and analysis of them. It also aims to give directions for new environments building.

The work is inserted in the context of a wider study on CSCL area, whose objective is to define a more general framework embracing, besides the classification of learning environments, other themes related such as: software environments for development of cooperative learning applications; distance education, and computer-supported cooperative learning in organizations.

Computer-Mediated Communication and Foreign Language Learning via Telecommunication Technology

Amy S.C. Leh
Department of Science, Mathematics, and Technology Education
College of Education
California State University at San Bernardino
San Bernardino, CA 92407
aleh@csusb.edu

Abstract: This study investigated (1) the difference of language performance and confidence of the participants who used computer-mediated communication (CMC) and who did not, (2) the content and appropriateness of CMC in distant learning, (3) the opinions of students and the instructor towards the use of CMC in instruction, and (4) the problems the participants encountered in the use of CMC. The participants were college students in the USA learning Spanish and communicating with college students in Mexico via e-mail for ten weeks. Data collection included scores of cloze tests, written reports, and oral examinations. Data also consisted of e-mail messages, survey, and interviews. The study revealed that CMC was beneficial for distant learning and that the students and the instructor were in favor of the use of CMC in instruction. A follow-up study was conducted one year after the initial study was completed. The results of the follow-up study supported the findings.

Introduction

Recent developments in electronic technologies have dramatically altered global communication. The technologies have changed how people communicate and also influenced how they learn. The Internet, which transcends international boundaries, allows people to communicate with audiences afar within a short time. It also allows everyone on the globe to join one big learning environment. E-mail, a computer-mediated communication (CMC) technology that relies on the Internet, has become the most common and the least expensive way to communicate and learn at a distance.

Is CMC appropriate for learning? Should educators encourage the use of CMC in instruction? Before answering these questions, one needs to understand the nature of CMC and social presence. Most CMC today is based on text and lacks nonverbal cues, such as facial expressions and gestures. Text-only e-mail communication is an example of CMC where the reader can not access the sender's emotions unless the sender expresses them in the text. Social presence is the degree to which a person feels "socially present" in a mediated situation. People feel intimate and share more if they feel socially present. However, when social presence is lacking, people recognize the impersonal environment and share less. Social presence is an important factor in distant learning and one of the four theoretical constructs in distance education (McIsaac & Gunawardena, 1996). Many scholars have addressed the topics of CMC and social presence. Two perspectives have emerged in the literature of CMC.

One perspective is that the lack of social cues in CMC is problematic. Rice (1984) and Trevino, Lengel, and Daft (1987) noted that the absence of social cues affected users' perception of communication context and constrained users' interpretation of messages. Many scholars noted that it is less appropriate to use CMC for personalized interactions which are needed in resolving disagreement, getting to know someone, or negotiation (Hiltz, Johnson, & Agle, 1978; Rice & Case, 1983; Rice, 1984; Steinfield, 1986). An argument can be made that since interactions are crucial to the learning process, CMC is inappropriate for learning. Research studies provide more specific information about the topic. According to Short, Williams, and Christie's (1976) study, when fewer nonverbal codes were available in a medium, the users paid less attention to the presence of other social participants. Hackman and Walker (1990) studied students in an interactive television setting, and they found that cues given to students such as encouraging gestures, smiles, and praise were social factors that enhanced students' learning. Without such cues, CMC can be "less friendly, emotional, or personal and more businesslike, or task-oriented" than other communication media (Rice & Love, 1987, p. 88). Appelbaum and Enomoto's (1995) study revealed that individual differences could not be highlighted via CMC. Ruberg, Moore, and Taylor (1996) noted that CMC limited student participation and interaction. Because of CMC's nature, researchers have determined that CMC is not appropriate for communication and learning.

The other perspective that emerges from the literature is that CMC is appropriate for learning. Gunawardena (1995) stressed that although CMC contained few social context cues, it could be perceived as interactive, active, interesting, and stimulating by participants. She suggested that student perceptions of the social qualities of a medium depended upon the social presence created by the instructors (or the moderators) and the on-line community. Many scholars have described advantages of using CMC in education. They noted that CMC users adapted to the medium and developed "on-line communities" (Hiltz & Turoff, 1978; Kerr & Hiltz, 1982) and that CMC messages were friendly and personal. An argument can be made that since CMC messages are personal and foster interactions which are crucial to the learning process, CMC is appropriate for learning. Some studies provide insight into the underlying process for CMC in education. Hiltz and Turoff's (1978) study presented cases where friendship and warm relations developed. Rice and Love (1987) found a significantly greater percentage of socioemotional content in a computer "bulletin board" than had been previously reported in experimental findings. Steinfield (1986) found that the need for communication across locations was associated positively with CMC messages. Johansen, DeGrasses, and Wilson (1978) reported that messages among participants on a network reflected participants' interests and attitudes and that network communication turned into friendships over time. Foulger (1990) reported that experienced computer users rated several text-based media, such as e-mail, as "rich" media. Ruberg, Moore, and Taylor (1996) found that CMC encouraged discussion among students. A study by Olaniran, Savage, and Sorenson (1996) indicated that students generated more ideas using CMC. Anderson and Kanuka (1997) concluded that CMC was beneficial for communication.

In summary, the literature provides support for two perspectives: that the lack of social cues of CMC is problematic and that CMC messages are personal and foster interactions. The former have not supported the appropriateness of CMC in communication and learning while the latter have. The study presented in this article extends our knowledge of CMC appropriateness in a distance learning environment by examining foreign language learners and by involving two nations. This study investigated (1) the difference of language performance and confidence of the participants who used CMC and who did not, (2) the content and appropriateness of CMC in distant learning, (3) the opinions of students and the instructor towards the use of CMC in instruction, and (4) the problems the participants encountered in the use of CMC.

The Study

Student Samples

The participants were United States (US) students who were enrolled in a fifth-semester Spanish Conversation and Composition course offered by the Department of Languages and Literatures at a large public university. Students in two classes participated in the study. They were taught by the same instructor on the same days. One class learned and used e-mail during the semester, and the other one did not.

The e-mail group communicated with students in Mexico via e-mail. The e-mail communication was conducted in Spanish and lasted for 10 weeks. A total of 18 US students were involved in the CMC and each had two Mexican pen-pals. They were encouraged but not required to communicate with their pen-pals.

The pen-pals were Mexican students taking a university mathematics class in Instituto Tecnologico y de Estudios Superiores de Monterrey in Mexico. The Mexican professor encouraged the students to communicate with the students in the United States of American (USA) and to find out how students in the USA learn mathematics.

Research Questions

This study asks the following questions:

1. Does the reading, writing, and speaking performance of the students using e-mail in class differ from the performance of those students not using e-mail in class?
2. Does the confidence of the students using e-mail in class differ from the confidence of those students not using e-mail in class?
3. What does the content of the students' e-mail messages involve?
4. What are the opinions of the students and instructor about using e-mail in foreign language learning?
5. What problems do students encounter during communication with their pen-pals via e-mail?

Procedures

At the beginning of the semester, the researcher explained the project to the students of the e-mail group, introduced the possible use of e-mail in foreign language learning, and expressed the hope that the students would choose to participate. The subjects were told that they were not required to participate in the study. If they decided to get involved in it, they had the freedom to stop it at any time. They had the choice of writing a lot using their e-mail accounts, or writing little, or even not writing at all. Students were told that they would write their e-mail outside of class so that the writing would not take up any class time. If they decided not to write, it would not affect their course grade.

To encourage the students to write more, the instructor agreed to give extra points up to ten percent of the total score for participating. The extra points were based on the number of the e-mail messages sent to the pen-pals and the amount written in the e-mails. To get extra points, the students were told that they should send copies of their e-mail messages to the researcher. After the explanations, all students volunteered and signed the consent letter. They filled in a demographic data sheet and an attitude survey form, and they participated in a cloze test.

The researchers repeated similar procedures to the non-e-mail group. The students also signed the consent letter, filled in the demographic data sheet and the attitude survey form, and took the cloze test. Since they did not use e-mail, their extra points were based on the number of articles they read outside of class and the amount of summaries they wrote.

Throughout the semester, both the e-mail and non-e-mail classes received the same encouragement from their instructor to conduct the out-of-class work for extra points. The project lasted for ten weeks.

At the end of the semester, the students in both the e-mail and non-e-mail classes answered the same cloze test and the attitude survey as at the beginning of the project. The e-mail group filled in an additional questionnaire to share their opinions about using e-mail in their classroom. They were informed that a telephone interview would be conducted to clarify the responses on the questionnaire. During the following days, all subjects were interviewed.

After the final examinations, the instructor provided the researcher with scores of both classes, including scores of all written reports and two oral examinations. Finally, the instructor was interviewed to share his opinions about the use of e-mail in his class.

Data Analysis

Both quantitative and qualitative research methods were used to analyze the data. The data analysis consisted of three major parts.

The first part is to answer the first two research questions. It included the use of statistical analysis to compare the language performance and confidence of the students of the e-mail group with those characteristics of the non-e-mail group. Both pre-e-mail and post-e-mail scores were obtained. Pre-e-mail scores included scores of the cloze test administered at the beginning of the research study, the first three written reports, and the first oral examination. Post-e-mail scores consisted of scores of the cloze test administered at the end of the research study, the final three written reports, and the final oral examination. A t-test was first used to evaluate whether the pre-e-mail scores of one group were significantly different from those scores of the other group. If there was no significant difference, a t-test was used to compare the post-e-mail scores of the two groups. If there was a significant difference, an Analysis of Variance (ANOVA) was conducted.

Due to the lack of a reliable language test, the evaluation of language performance of this study was based on the scores of the cloze test (reading), the students' written reports (writing), and the oral examinations (speaking). The cloze test consisted of paragraphs requiring students to fill in twenty key words. A total of 100 points were available. The reliability of the cloze test was checked by consulting with two Spanish experts. The students' writing and oral skills were graded by their instructor who used grading criteria agreed upon by all the instructors teaching the Spanish course and by the coordinator of the course. Because the instructors were Spanish experts, the reliability of those language scores was high.

The analysis of the students' confidence was based on the attitude survey. It consisted of 10 questions asking students to rate their confidence on their Spanish language skills and their knowledge of Spanish cultures. For each individual, the rating from each question was summed together into a total rating ranging from 5 to 50. The mean of the rating numbers of the e-mail group was compared with the mean of the non-e-mail group. The reliability of the attitude survey was checked by consulting with three reputable researchers. The internal reliability of the attitude survey was also checked by SAS. The Cronbach Coefficient alpha value of the attitude survey of the e-mail group before the e-mail communication was 0.95, and the alpha value after the communication was 0.93.

The values for the non-e-mail groups were 0.85 and 0.81. The values were high, and the items of the survey were reliable.

The second part is to answer the third research question. It involved the use of qualitative research methods to analyze the e-mail messages. The content topics in the e-mail messages were coded and categorized according to topics in the previous literature (Barson et al., 1993; Cononelos & Oliva, 1993; Kern, 1995). Topics in the literature included culture (e.g., values, beliefs), language itself (grammar, syntax), course management (due date, assignment), social activity (planning for a movie, a party), and so forth. In the process of coding and analyzing, other topics emerged, too. Further, the e-mail messages were analyzed in depth. The messages which were warm and friendly and which fostered learning and communication were coded and collected into specific folders.

The third part is to answer the fourth and fifth research questions. It consisted of reviewing and analyzing the data collected by survey questionnaires and interviews conducted in the e-mail group. The survey consisted of 10 questions with a scaling from one to five and three essay questions. The survey was designed to find the participants' opinions towards the use of e-mail in the study. The internal reliability of the questionnaire was checked by SAS. The Cronbach Coefficient alpha value was 0.82. This value was fairly high, and the items of the questionnaire were reliable. Interviews were conducted to clarify any ambiguous information.

Results

The quantitative results of the study indicated that there was no significant difference on reading, writing, and speaking performance between the two groups. The students' confidence of one group also did not significantly differ from that of the other group.

The qualitative results of the study revealed that CMC provided the participants with good language learning environment, motivated the learners, fostered learning, and encouraged communication. The content of the e-mail messages consisted of discussions about cultures (e.g. values, customs, and life styles) and Spanish language use, such as syntax and semantics. As several CMC researchers mentioned, many e-mail messages of the study also revealed that the participants developed on-line communities. Their messages were warm and friendly, and the participants became friends via CMC.

The results of the survey and the interviews indicated that the students in the e-mail group and the instructor were in favor of using e-mail in language learning. The students had strong desire of using CMC while the research study was conducted and after the study was completed as well. Many e-mail messages at the end of the semester appeared to be discussions about how to continue the CMC. The students unanimously supported the use of e-mail in foreign language learning and thought that e-mail was a good addition to their class.

Problems occurring during the semester were systematically recorded by the researcher. Some problems were successfully handled by the researcher and the professor in Mexico; for example, (1) the students' initial mail was returned as undeliverable and (2) some students did not receive their pen-pals' responses. Problems addressed in the study can be of interest to researchers or practitioners who wish to conduct similar projects. The following problems surfaced, for example, (1) several students had limited access to a computer, (2) some pen-pals lacked commitment of writing, and (3) the students could not use foreign characters in their e-mail system.

The Follow-Up Study

The follow-up study was conducted one year after the initial study. E-mail was sent to each of the students in the e-mail group. The students were asked to answer the following questions: (1) Did the student continue writing to the pen-pals after the research project was completed? (2) Was the student still communicating with the pen-pals via e-mail? and (3) How did the project affect the student over time? Four students answered the questions by e-mail, and ten students answered the same questions through the phone. Four students could not be located.

One third (four students) of the participants involved in the follow-up study said that they have continued writing to their pen-pals after the project was over. The communication lasted for a few weeks for two of the students and lasted for three months for one student. The fourth student was still communicating with her pen-pal when the follow-up study was conducted. Other students did not continue writing to their pen-pals because they were too busy to write or because their pen-pals did not reply.

All of the students reiterated that using e-mail in foreign language learning was a great idea and should be integrated into instruction. Several students reported that the project has positively affected them. Three students described exactly how the project influenced them.

One of the students mentioned that although his experience with his pen-pals in the Spanish class was "short lived," the project motivated him to make friends with people in Brazil and helped him to "remain in touch with the culture there." Another student stated that his pen-pals in the class were not "very responsive." However, he found other pen-pals and was writing to them weekly. He said, "Your study got me interested in writing to people, and I have found several lists [newsgroups] of Spanish pen-pals on the Internet." Another student mentioned that she was helping her daughter's school to connect with people in Mexico. She said that, without the experience with the research project, she could not help the school.

Conclusion

The research study revealed that e-mail (CMC) is beneficial for learning and communication. Although the participants lacked social cues, such as gestures, the participants developed on-line community for communication. The students used CMC to discuss cultural issues and language use with their pen-pals (Spanish native speakers) at a distance. CMC provided the participants with good environment for friendship, learning, and communication. The students and the instructor who participated in the study were in favor of the use of e-mail. The students had strong desire to use CMC not only while the research study was conducted but also after the study was completed. They unanimously agreed that CMC was a good addition to foreign language learning.

The results of the follow-up study, conducted one year after the research study, revealed the consistent positive opinions of the participants towards the use of CMC. They addressed again that CMC is beneficial for foreign language learning and should be integrated into foreign language instruction.

Abstract: This paper, based on the first author's Ph.D. dissertation describes an experimental system for authoring and delivering tutorials on the web under the assumption that the system should deliver the latest versions of the selected documents, even when they are not controlled by the tutorial author. The great richness of materials available on the web encourages reuse of web documents in tutorials. However, the dynamic, sometimes chaotic nature of the World Wide Web poses a new challenge for tutorials that depend on links to various people's or institutions' web pages. Therefore our system includes provisions for anticipation of various kinds of changes to documents or their availability. At time of tutorial delivery, our system validates web documents by evaluating differences between document profiles stored at authoring time and new profiles based on the current versions. If appropriately constructed, the tutorials can then adapt to the changed circumstances of availability or reliability.

Introduction

Motivation

The educational potential for the Internet has aspects that can be categorized under several headings: online library services and reference material, communication and conferencing, and online tutorials and courseware. These functions are interrelated and can easily be combined. For example, tutorials can make use of online reference material by including links to it. The Internet enhances opportunities for authors to reach distant and diverse audiences, and it makes it easy to combine and integrate resources found on the World Wide Web into tutorials.

This paper explores some of the issues involved in authoring and delivering tutorials via the World Wide Web that reuse documents found on the web. The World Wide Web is somewhat chaotic: web sites come, go, and evolve. Documents referred to in tutorials may change. The student's access to various web pages may not always be timely. One solution to these difficulties would be to encapsulate all documents used in a tutorial on a CD-ROM and distribute the tutorial on CD-ROM. This solution is appropriate for many situations, but it has some disadvantages. The encapsulated documents may become obsolete or if not obsolete then inferior to improved versions that get posted by their creators. There may also be legal restrictions placed upon the use of the documents that forbid their copying and distribution on CD-ROM. Finally, distribution by CD-ROM may not be as convenient as just-in-time downloading. Therefore it is sometimes appropriate to adopt the following assumption: documents referenced in the tutorial should be the latest available versions and should be retrieved when needed, without copying other than the normal caching performed by the browser and network relay sites. We call this the *current-documents assumption.* The current-documents assumption together with ubiquitous reuse of documents is the primary consideration that changes the nature of Web-based tutorial authoring from conventional tutorial authoring.

After we describe our experimental tutorial system, Wtutor, we discuss one of the technical problems that arise in web-based tutorials with the current-documents assumption: ascertaining to a reasonable degree of certainty that the information contained in a current document is consistent enough with that of the original document (the document at the same URL at the time of authoring) that the tutorial will not suffer any loss of effectiveness. We call this the validation problem. We provide a solution to this problem and describe our experience with the experimental system.

Related Work

Tutorial systems for reuse of World Wide Web documents have been created by several groups. The primary concern among these efforts has been providing means for navigating through the web of documents. The "Walden's Paths" system is one such program using this approach (Shipman et al. 1996). It uses a proxy server and CGI scripts to translate requests for tutorial documents into requests for documents from the World Wide Web. Paths are stored as linear lists of URLs. The path server not only fetches the documents from the web but also modifies them before they are displayed by the user's browser. The modifications include the insertion of new navigation links that, when activated, take the user one or more steps forward or backward along the path. A related system is Footsteps (Nicol et al. 1996). This system also uses CGI scripts to request and then modify incoming documents; however, rather than offering links to several documents along the path in the vicinity of the current document, Footsteps provides a link to an index to all of the documents in the path.

Another tutorial system for the web is Brio (Roscheisen et al. 1995). The BRIO system makes use of special documents called annotations. The tutorial author creates one annotation for each web document and specifies a connection structure by linking annotation documents to each other. A special browser is used that provides two panes for the user: one shows a list of links to annotated documents in the tutorial. The other shows the documents with their corresponding annotations superimposed.

These systems provide facilities for gluing web documents together into tutorials. However, they do not provide any support for meeting the challenges of the dynamic nature of the World Wide Web.

The Wtutor System

Our experimental system for delivering web-based tutorials is called Wtutor (Johnson 1997). Its two fundamental components are a tutorial control program and a modified web browser. The tutorial control program is written in Common Lisp. It holds a representation of the tutorial in terms of URLs and how they relate to one another as parts of the tutorial. The control program receives messages from the browser and also instructs the browser to load particular web documents. The modified browser serves as the interface between the student and the tutorial material as well as an interface between the student and the control program.

Each tutorial is represented using a structure we call the tutorial map. The map consists of a set of URLs (World Wide Web document addresses the adhering to the Uniform Resource Locator syntax), together with information about the relationships among the documents for purposes of the tutorial. Documents are ordered and can have alternatives specified. The author of a Wtutor tutorial can specify that URLs belong to groups of URLs. The groups can be used as elements of precedence relationships, implicitly specifying alternatives. The groups can also be labelled as "concurrent," meaning that all URLs in the group should be displayed simultaneously in different portions of the screen. For example, this permits commentary written by the tutorial author to appear in synchrony with a "reused" web document from a third-party web site. Tutorial maps represent the allowable flows of visitation through the portion of the World Wide Web of interest to the tutorial. They also contain information that supports effective validation of the documents used in the tutorial

The Validation Problem

As we have already discussed, the validation problem refers to the challenge of making sure that URLs included in the tutorial continue to serve their purposes in the tutorial even though the documents they point to may have been removed or may have been changed by their authors. Given the dynamic nature of the web, this is an important consideration in reusing web documents under the current-documents assumption that students see only documents just downloaded from their original sites.

Documents placed on the World Wide Web typically undergo changes after the times they are first posted. Sometimes these changes are trivial–minor adjustments to formatting or the correction of a few spelling errors. In other cases, significant portions of text are added or removed. Sometimes document are removed either because they were parts of temporary web sites (e.g., college student web pages that get removed when the student graduates) or because they were found to violate some copyright. In many and perhaps most cases, documents remain on the web and remain effective for their use in a tutorial. However, the challenge is to have a means for the tutorial delivery system to automatically make a reasonably reliable judgment about whether a document is still effective for the tutorial's purpose.

Approach to Validation

There are many ways in which a tutorial system could anticipate the kinds of changes listed above and respond to them. The simplest way would be to store a complete copy of the original document. This would allow comparisons to be done with existing tools such as *diff*, which could provide a detailed list of the physical changes to the document. Given the list of physical changes, it would still be necessary to infer the significance of the changes.

This approach has the disadvantage of consuming large quantities of storage space and consuming large amounts of bandwidth either at tutorial map retrieval time or at document validation time. A tutorial could easily contain hundreds of megabytes of data, which would have to be either stored on the student's local storage medium or on a central storage medium. The space requirements could be partially mitigated by the use of compression techniques on the document text, but this would still lead to significant space and transmission requirements. What is needed is a document signature that significantly reduces storage requirements while still providing enough information about the document that useful comparisons can be made.

Rather than storing copies of the tutorial documents, Wtutor creates digital signatures of each document when the document is first added to the tutorial and stores these signatures. When a reader is taking a tutorial, Wtutor retrieves the current versions of the tutorial documents, calculates the current signature and then compares the stored signature to the current to infer the level of change in the document.

Wtutor signatures

Wtutor takes advantage of the structural information provided in HTML documents to extract meaningful document signatures. In Wtutor, document signatures are composed of three elements: the checksums of the paragraphs of the document, the headings of the document, and any keywords the tutorial author chooses to specify. A sample signature is shown in (Fig. 1). Before extracting the signature, Wtutor normalizes the document by converting all the text to lower case and reducing each contiguous group of whitespace characters to single space characters.

URL	http://www.cs.washington.edu/research/metip/tutor.form.image.html
Paragraphs	(19316 47247 21696 47247 21696 33122 37527 38582)
Headings	(quantization sampling rate applying linear filters tutorial image request form)
Keywords	(NIL)

Figure 1 Sample Wtutor Signature

Other possibilities were considered for inclusion in the signature, such as the title of the document or the links contained within the document. The paragraph checksums, headings, and keywords were chosen as the elements that best provide information about the document.

Wtutor signature comparison method

Wtutor stores document signatures in the tutorial map. The tutorial author can run a procedure at any time to update the signature of any URLs in the tutorial map. When a student is using the tutorial, Wtutor validates each URL by comparing the digital signature stored in the map with the document's current digital signature. The comparison yields a numeric distance value, which indicates how much the document has changed.

For each element of the signature, Wtutor infers whether there have been additions, changes, or deletions. Once the number of changes, additions, and deletions in each category have been determined, they are combined according to the function in (Fig. 2). To allow for documents of different lengths, the function normalizes by the number of items of each type within the original document. This normalization recognizes that the scale of changes matters—adding five paragraphs to a document that originally had two paragraphs is generally much more significant than adding five paragraphs to a document that originally had fifty paragraphs.

dist = checksum dist + heading dist + keyword dist

checksum dist = checksum weighting factor *
(#chgs * chg_weight + #adds * add_weight + #deletes * del_weight) / #checksums

heading dist = heading weighting factor *
(#chgs * chg_weight + #adds * add_weight + #deletes * del_weight) / #headings

keyword dist = keyword weighting factor *
#deletes * del_weight / #keywords

Figure 2 Document signature distance function

The distance function also recognizes that some types of differences can be more significant than others by including a weighting factor for each type of difference. For example, it is probably more significant if a heading has been deleted from a document (implying that some segment of information is no longer provided by the document) than if a heading has been added (additional information is generally not a bad thing, unless so much is added that the original content is overwhelmed by the new).

The distance function also allows for the different elements of the signature to be weighted differently. A tutorial author may feel that the headings of a document are more significant than the paragraph checksums, since the headings provide more of an indication of the semantic content of the document. Another tutorial author may feel that no changes of any sort should be allowed, and choose to weight all elements equally. The Wtutor distance function provides the author the flexibility of choosing these weights.

Once the distance for a document has been calculated, Wtutor compares that distance to two defined levels: a warning level and a reject level. If the distance from the original signature to the current signature is less than the warning level, the document is simply displayed to the student. If the distance is greater than the warning level but less than the reject level, the document is displayed and a warning message is provided to the student indicating that the document has changed since its inclusion in the tutorial. If the distance is greater than the reject level, Wtutor first checks whether the document has an alternative. If an alternative has been specified in the tutorial map, that document is retrieved and displayed instead of the rejected document. If there is no alternative document, the rejected document is displayed to the student along with a message that warns the student that the document has changed significantly and may not be appropriate for the tutorial.

Testing the Validation Technique

The default values used in Wtutor for weighting the different types of changes in document signatures were selected after a set of testing with a small set of selected documents found on the World Wide Web. A set of artificial changes was applied to each of these documents, and then the signature comparison algorithm was used to compare the before and after versions of each document. Once the default weights had been determined and the warning and reject levels had been established, the validation technique was tested on examples of real changes to existing documents found on the World Wide Web.

Document life cycle

The first test case is a Web page describing Wtutor. There were five different versions of this document. The initial version (version 0) was a brief (72-line) description of Wtutor. Version 1 is essentially the same document, with a bit of rewording done. Version 2 adds introductory paragraphs to version 1. Version 3 is a User's Guide to Wtutor, which includes most of the material in version 2. This document was significantly larger than the earlier versions. Finally, version 4 of the document goes back to version 2, but adds links to sections of the User's Guide to Wtutor.

The distance measures for each of the versions of the Wtutor document are shown in (Tab. 1). These distance measures are the result of comparing the signatures of the versions to the signature of version 0. The distance measures do not exceed the warning level for versions 1, 2 and 4. This is a desirable result, as the changes in these versions are minor and do not significantly change the semantic content of the document. Version 3 exceeds the reject level. Again, this is a desirable result. While the semantic content of the earlier versions is included in version 3, the document contains so much more material that it is not really comparable to the other versions.

Version	Distance	Description
0	0.000	Original version; brief description of Wtutor
1	0.145	Slight rewording of version 0
2	0.209	Addition of introductory material to version 1
3	2.718	User's Guide to Wtutor
4	0.245	Back to version 2, with addition of links to User's Guide

Table 1 Distance measures for versions of Wtutor document

Sample tutorial

The second case in which Web documents were tracked over time was a sample tutorial about Dr. Martin Luther King. Although the tutorial was created primarily as an illustration of Wtutor's capabilities, it also served as a good test of the validation approach, because several of the documents that were selected for inclusion in the tutorial changed after the tutorial was originally created.

About a month after the creation of the tutorial, a running of the validation report for the tutorial showed the chronology document as having a distance measure of 0.007. This small distance is well below the warning level, so it did not have an impact on the tutorial. Upon investigation, the reason for the distance was found to be a correction of one of the dates in the chronology.

Two weeks later, another running of the validation report showed very large distance measures for several documents. All the documents from one site had distances in the 1.9-2.3 range, well above the reject level. Further investigation revealed that the owner of the documents had moved to a different site. The original site provided a note that the documents had moved, but did not provide direct links to the new locations. This required updating the tutorial map to point to the new locations for the documents.

In both of these cases, the validation method worked as desired. In the first case, the change to the document was recognized as small enough that the student was not even informed of the difference. In the second case, Wtutor recognized that the documents returned by the original server were not at all what the tutorial author wanted and notified the student of that fact. Without the validation, the student would not necessarily known that the documents returned were not what the tutorial author intended.

Two weeks later, a running of the validation report showed one document with a distance measure of 0.62, again above the reject level. Upon inspection, the document was found to have been updated by the owner. In the course of correcting several typos in the document, the author had significantly reformatted the document. In this case, the validation method returned a "false positive". The text portion of the document had not changed significantly, but the differences in markup were interpreted by the signature comparison as significant document changes. A student going through the tutorial would have received a warning message that the document might no longer be appropriate for the tutorial, but the document would still have been displayed to the student.

Author volunteered examples

In the final case of tracked Web documents, Web document authors were solicited via Usenet postings for participation in the experiment. Prospective participants were asked if they had Web documents that they were planning to update. Dr. Hubert Partl of the Universitaet fuer Bodenkultur in Vienna, Austria volunteered to participate and provided a list of the URLs for his documents. Dr. Partl's documents make up an HTML handbook.

A tutorial map that contained each of the URLs was created and document signatures were taken. Copies of each document were saved at the same time as the document signatures were taken so that actual changes to the documents could be tracked. During a six month study, periodic validation reports were taken to test whether the documents had changed since the initial document signatures were taken. At the same time as the validation reports were done the current versions of the documents were retrieved and compared to the original copies, so that the actual changes could be reviewed and the appropriateness of the resulting distance measure could be evaluated. The URLs for the volunteered set of documents are listed in (Tab. 2), along with two distance measures for each document. The intermediate distances are from compares done about two months into the measurement period; the final distances are from the compares done at the end of the measurement period.

URL	Intermediate Distance	Final Distance
http://www.boku.ac.at/htmleinf/hein.html	0.22	0.39
http://www.boku.ac.at/htmleinf/hein1.html	0.30	0.44
http://www.boku.ac.at/htmleinf/hein2.html	0.28	0.50
http://www.boku.ac.at/htmleinf/hein3.html	0.21	0.29
http://www.boku.ac.at/htmleinf/hein4.html	0.10	0.43
http://www.boku.ac.at/htmleinf/hein5.html	0.27	0.44
http://www.boku.ac.at/htmleinf/hein6.html	0.18	0.21

Table 2 Volunteered WWW document distance measures

How well do these distance measures reflect the changes that were made to the documents during the measurement period? The first observation is that only one version of the documents exceeds the default rejection level. This is a desirable result, as most of the changes to the documents fell into the categories of markup changes, spelling changes or corrections, rewordings for clarity, or minor additions. For most of the documents, the final versions exceed the warning level. This is primarily due to the number of minor changes that were made to these documents. The final version of hein2.html just reaches the reject level. The reason that this document exceeds the reject level is that it includes some deletions of headings and paragraphs.

The distance measures for the intermediate and final versions of these documents seem appropriate for the differences between these versions and the original versions of the documents. Overall, the Wtutor approach to validating documents provides a useful method of verifying that documents still fit within the tutorial.

Abstract: Rapid advances in information technology and telecommunications (IT and T) are impacting on a changing world in which boundaries, whether they are at local, national and international levels are now less clearly marked. The so-called information superhighway is reaching and linking many regional, rural and remote communities so that the world itself has become a small global village. This leads to the assumption that the power of information technology and telecommunications is inescapable and unresistable. A logical response to a changing and challenging world is to prepare "global villagers" for acculturation into a new IT and T discourse community. However, potential IT and T users are human not virtual beings and fear, anxiety, confusion, resistance and inspiration are part of the acculturation process towards an IT and T discourse community. In this paper the concepts of acculturation and discourse community are discussed and applied to IT and T discourse generally and educational multimedia in particular. A paradigm shift is occurring in education with the introduction of IT and T, and strategies have to be developed to facilitate acculturation of new users to this paradigm to prevent hostility and rejection of the advantages they bring to regional, rural and remote communities. Three aspects of acculturation in education are presented and discussed. The implementation of acculturation in the context of IT and T is explored through a description of the provision of rural health education and training opportunities in the small Island State of Tasmania.

Acculturation as A Psychological Process

Mead in Williams (1972) defined socialisation as "a process by which human children born potentially human, are able to function within the societies in which they are born". However, socialisation is a rather broad concept. Williams (1972) discussed the fine distinction between socialisation and acculturation, arguing that the former refers to the process of transmitting human culture whereas the latter is the process of transmitting a particular culture. However, in an interactive world in which people of different cultures are engaged inter culturally, the question of cultural identity needs to be addressed. In an intercultural interaction, acculturation is a significant phenomenon. It is a process in which people of a different culture have adapted the new culture (Brown 1994). It is not a smooth process with feelings of confusion, resistance, and reluctance and sometimes suffering evident at all stages.

In education, acculturation takes place when learners from a different culture learn a new language or face a new educational paradigm that requires a partial or whole orientation to a new cultural discourse and become members of its discourse community. The acculturation process normally consists of the following stages, cognitively and affectively:

- *Conflict:* This is a shock stage as a new culture is rejected as a whole, due to negative attitudes towards the new culture.
- *Confusion:* This is the time when negative attitudes toward the new culture are challenged by other people or events, or when the new culture becomes a part of that person's life.
- *Exploration:* Accidentally or intentionally, a few 'things' about the new culture are discovered.
- *Familiarisation:* Learning more about the new culture in order to function well in it.
- *Acceptance:* The new culture has been accepted. The crisis has disappeared.

These stages are not necessarily sequential.

Acculturation in an IT and T Discourse Community

Swales (1990) presented six defining characteristics that are necessary for identifying a group of individuals as a discourse community:

- A discourse community has a broadly agreed set of common public goals that may be formally inscribed in documents or be more tacit.
- A discourse community has mechanisms of intercommunication among its members. The participatory mechanisms will vary according to the community: meetings, telecommunications, correspondence, newsletters, conversations etc.
- A discourse community uses its participatory mechanisms primarily provide to information and feedback.
- A discourse community utilises and in turn possesses one or more genres in the communicative furtherance of its aims. A discourse community has developed and continues to develop discoursal expectations. These may involve appropriateness of topics, the form, function and positioning of discoursal elements, and the roles texts play in the operation of the discourse community. In so far as genres are how things get done, when language is used to accomplish them, these discoursal expectations are created by the genres that articulate the operations of the discourse community.
- In addition to owning genres, a discourse community has acquired some specific texts. This specialisation may involve using lexical items known to the wider speech communities in special and technical ways, as in information technology discourse communities, or using highly technical terminology as in medical communities.
- A discourse community has a threshold level of members with a suitable degree of relevant content and discoursal expertise.

Swales' concept of discourse community can be applied to IT and T discourse. It is argued that IT and T does not exist in a cultural vacuum. It has become "a cult with its own esoteric language and rites, 'in' groups and 'out' groups, and above all faith in the intrinsic value of electronic communications" (Moran 1997). Aoki, Fase & Stowe (1998) introduced the term 'virtual micro culture' as a unique group dynamics, which arises as a result of frequent interaction and collaboration toward a common goal. It has its own culture and anyone who is exposed to it will go through a 'socialisation experience', namely acculturation. The stages described above reflect well the acculturation process experienced by its users when IT and T are introduced.

A review of the literature on the role of educational multimedia in the past decade supports the view that acculturation is a powerful phenomenon inherent in various experiences involving educational multimedia. While the business world has embraced IT and T wholeheartedly, educators, in comparison, have been rather slow in accepting them in teaching and learning. In some cases technological resistance occurs due to passive or active resistance to adopting technology (Allen 1997). Though the concepts 'teleteaching', 'virtual classroom', 'Internet-based teaching' have been introduced during the past decade and occur in various curriculum discussions, in reality the full adoption of IT and T into practice is still a long way off. Teaching is still conducted in a predominantly non-virtual context, in which the traditional resources are teachers, books and blackboards (or overhead projectors). But, significantly, there has been a mixture of feelings such as hostility, rejection, fear, and confusion among educators in relation to the use of IT and T in teaching and learning. According to a study by Holt & Thompson (1996), old attitudes, held by long-time serving staff, limited vision of what was possible in the flexible learning mode. To facilitate the experience of acculturation, it is desirable to start with a relatively clean cultural slate than to inherit a fully mature, but unreceptive culture.

There are three aspects of acculturation in education. Firstly, IT and T experts are contributing factors to the negative attitudes among IT and T prospective users. The worst case is when such experts hold the assumptions that IT and T is the magic solution to education and that teachers are secondary in the teaching and learning process. IT and T are therefore the magic wand, which can effectively replace teachers. The curriculum concept 'learner-centred' is sometimes confusing in the sense that it mis-signals a shift of significance from teacher as a primary source and learners as a secondary source. In other words, some may interpret learner-centred curriculum as role-oriented rather than process-oriented. This creates a misconception that IT and T can replace the teacher. However, if 'learner-centred' is interpreted as 'learning-centred', the emphasis is not on the comparison (whether implicit or explicit) of students' and teachers' roles, but on the process of learning itself. In this way, IT and T can play a significant role in improving learning in general and in enhancing positive attitudes towards IT and T in particular.

Secondly, a paradigm shift is occurring in education. According to Roberts (1997) this is "the rejection of one set of values and ideas about education and the adoption of a new set with regards to what constitutes effective pedagogy". This paradigm shift is occurring worldwide but faster in some parts than others depending on the availability of resources, existing infrastructure and the stage of development reached.

A new paradigm should not be regarded as old wine in a new bottle as it is not only the technology that counts but a new spirit with a new discourse community that has emerged. Therefore strategies have to be planned carefully to facilitate acculturation of current and prospective users to a new educational paradigm created by IT and T. Otherwise the acculturation experiences can be painful and sometimes destructive. As a result, hostility can be seen in headlines in the media such as 'students damaged computers

It is important to involve users in the curriculum-decision making process in their acculturation into an unknown or less familiar territory. In the past, IT educators have tried to reverse the direction of discourses by placing IT in the discourse of education rather than placing education in the discourse of IT. For instance, Moos' work has influenced the development and use of instruments to assess the qualities of the classroom learning environment from the perspective of the learner (Waldrip & Fisher 1997). Though IT and T can create a perfect virtual learning environment, learners should not be treated as virtual beings. They bring to a virtual class and the acculturation process their personal, social and cultural backgrounds, which shape their learning styles, educational attitudes, and interpersonal relationship.

Thirdly, there should be a good harmony between learning IT, learning about IT and learning through IT. Otherwise, the perception of IT and T in the curriculum will be challenged.

Stage 1: *Learning IT:*
This is a hands-on practical knowledge about IT and T such as word-processing, emailing, Web-navigation, scanning.

Stage 2: *Learning about IT:*
This involves concepts and issues relating to IT and T such as interactivity, ethical consideration, security etc.

Stage 3: *Learning through IT:*
This involves literature search, conferencing with teachers and peers, publishing etc.

These three aspects should not be treated in a linear progression. In other words, the syllabus should not proceed rigidly from stages 1 to 2 and 3. In an interactive dynamic learning process, users may start with their need to share with others their views on certain issues (learning through IT). Then they proceed with how to use the Web for interacting with others (learning IT). While doing this, they are aware of the use and limitations of the Internet (learning about IT).

Rural Health Education: an Example of Acculturation

We have discussed the concept of acculturation in relation to the culture of IT and T. Now the focus is on the implementation of acculturation in the context of IT and T and rural health education in Tasmania.

Thomson and Walker (1997) demonstrated the role of communications technology in health care provision through identification of various communications techniques and analysis of these in relation to health care delivery and health professional education. They showed how communications technology provides a logical link between education and health care delivery by acting as a tool for change to the knowledge, skills and attitudes of health care professionals towards rural health.

Walker (1998a) noted that the level, quality and cost of telecommunications infrastructure for rural and remote populations in Australia is being addressed via the Regional Telecommunications Infrastructure Fund (RTIF), known as 'Networking the Nation'. The aim is to reduce the gaps in the quality and cost of telecommunications services between metropolitan and rural Australia. She also explained how the Commonwealth Government in Australia is establishing and funding a number of university departments of rural health. In Tasmania, Australia's small, rural island state, a University Department of Rural Health was set up in late 1997. It acts as a catalyst for the development of a comprehensive and co-ordinated approach to rural health education, training and research across the State and across the range of relevant disciplines and professions. The aim of the Department is to provide access to education, training and support opportunities for rural health workers and trainees through an open and flexible learning framework supported by an IT and T base. It is built on a principle of partnership with health service providers and communities and is part of Tasmania's developing Telehealth Network to provide access to health services and rural health education services using technology as a tool. The Department has implemented a series of strategies to enhance the implementation of information technology and telecommunications in rural health. A top priority is acculturation into the new IT and T discourse community.

People who are involved in rural health care are drawn from:

- health professionals, directly responsible for patient care e.g., doctors, nurses, dentists, pharmacists, radiologists, pathologists and technicians;
- administrative and support staff involved in health care administration e.g., business managers, service development managers, patient information management officers and corporate strategists.

Increasingly, many of these people do not work in rural areas but are based in urban-based large hospital environments. Through Telehealth, services are provided at a distance and rural, locally based health care providers have a vital role to play in ensuring successful delivery of services and enhanced health outcomes. However, most health care workers do not have a sound understanding of the fundamentals of Telehealth and the use of IT and T for education purposes (Hasman & Albert 1997). Many exhibit feelings of hostility, rejection, fear and confusion in relation to use of IT & T in health care provision and access to education and training opportunities. This, in tune, reflects negatively on consumers of rural health services. It makes it difficult for practitioners to make decisions about the usefulness of applications and to express their needs in terms that can be understood by informaticians and IT and T personnel. Education and training in the place and use of IT & T is needed at a variety of educational levels, in different modes, for various professions in health care and with different types of specialisation.

In Tasmania, the Department of Rural Health and the State Department of Health and Human Services have embarked on a collaborative project. This will see the progressive roll out of Telehealth and IT and T education and training to meet an increasing demand for information management and the use of information and telecommunications technologies to enhance health services, to access education and training, and to assist in the acculturation process.

A major objective is to assist the change process to a health information management and information technology and telecommunications environment through training, including the use of IT and T to deliver training that is customised to workplace needs. It requires strategic planning across a range of services and collaboration in use of shared resources. It requires training that is based on the recognition of the role that acculturation plays in a new discourse community (Walker 1998b).

At the same time, the University Department of Rural Health is establishing a network of Rural Health Teaching Sites (RHTS) in collaboration with the Telehealth Network. The Department is facilitating rural health education and training programs for undergraduates (medical, nursing pharmacy and allied health students) in targeted rural areas and is building on the intellectual capital of these rural areas by providing on-going teaching, research and service development support to resident health care workers. Each Site has a defined catchment area and provides accommodation and learning facilities with computing, fax, internet access, audio and videoconferencing. An important part of the program is provision of training in the use of the technologies.

The three aspects relating to the role of IT and T have been taken into consideration: Learning IT, Learning about IT and learning through IT. Through the RHTS rural users have sound and reliable access to IT and T. Teleteaching and teleinteraction, with awareness and sensitivity to rural health issues and rural users, have been carefully planned and introduced. The Department's IT strategies have targeted rural health workers who have been disadvantaged by their isolation from the IT and T discourse community in rural health. For example, the Australian Physiotherapists' North-East Journal club runs internet access lunch time get-togethers to share the meaning making process about IT and T with local health staff and students. This event is organised and co-ordinated by the University Department of Rural Health. Without this effort acculturation into the IT and T discourse community will never take place.

Conclusion

IT and T is permeating deeply into various aspects of society. The IT-based superhighway is travelling to many remote parts of the world and has brought with it the technological power to make human communication dynamically interactive and effective. It has certainly brought people in the world much closer. However, the power of IT and T is often viewed without taking into consideration the potential conflict between IT culture and the acculturation experienced by those who are introduced to it. While IT and T can create many virtual experiences, we must remember that potential IT and T users are human not virtual beings and fear, anxiety, confusion, resistance and inspiration are part of the acculturation process towards an IT and T discourse community.

IMPROVING TEACHING BY TELECOMMUNICATIONS MEDIA: EMPHASISING PEDAGOGY RATHER THAN TECHNOLOGY

Peter Jamieson
Centre for Higher Education Development,
Monash University, Australia.
<peter.jamieson@adm.monash.edu.au>

Abstract:
This paper reports the findings of a study of how university teachers approach teaching with one form of telecommunications media – cross-campus video conferencing. Typically, the assumption underlying training for teachers in the use of telecommunications media is that teaching will improve as a result of improved use of the technology. However, this study reveals that factors other than the role of the technology are crucial in determining the way teachers conduct their teaching. The study shows that a more pedagogically-oriented understanding of teaching with telecommunications media is needed to inform faculty development programs intended to improve teachers' approaches to teaching. The findings of this study have direct implications for the use of other forms of educational telecommunications media in university and other educational settings.

No medium, however useful, can solve educational problems. Media cannot alter the way teachers understand teaching (Ramsden, 1992, p. 161).

Introduction

The shift towards more *student-centred*, *open* and *flexible* approaches in university education, with their consequent reduction in on-campus attendance, is largely based on the capacity of telecommunications media to provide for various forms of real-time and delayed interaction (Mason, 1994). In light of this development, institutions face the significant task of supporting on-campus teachers experienced in face-to-face delivery in the development of effective approaches to teaching with one or more forms of telecommunications media.

The research reported in this paper was undertaken to inform the design of faculty development programs relating to teaching conducted by one form of telecommunications media – cross-campus video conferencing. Typically, telecommunications media are used to break down the classroom-student nexus by reducing contiguous teaching and learning situations (e.g. online courses).

However, cross-campus video conferencing teaching stands apart from most other uses of telecommunications media in a fundamental way and presents teachers with an enormous conundrum. As with on-campus education, it consists of a scheduled class in a fixed classroom location and involves group-based learning. The arrangement of the facilities and technology most commonly presumes a teacher-led lesson where the control of the technical facilities is placed at the teacher's disposal at the front of the classroom. Yet, this situation combines the teacher-student arrangement and synchronous interaction of the regular classroom with the teacher-student separation characteristic of distance education. Generally, it involves a group of students in attendance at the same site as the teacher forming a regular face-to-face class whilst the teacher is also physically separated from the other student group(s) gathered at a similar classroom facility. As in traditional distance education, often the teacher may have no direct, personal contact with any of the distant students throughout the duration of the course.

The literature on teaching by video conferencing has largely emphasised the primary role of the technology in the teaching process. The key assumption made by researchers and authors of training manuals alike is that the technology is at the core of teaching in these situations. From this perspective, teaching (and learning) will be improved by enhancing the teacher's skill in working with the technology (Cyrs, 1989; Ostendorf, 1995). Schiller and Mitchell (1993) claim that video conferencing 'requires a different teaching methodology from any that lecturers have used previously' (p 50). Overall, the emphasis in the literature and guides on how to teach by video conferencing is on *how* teaching happens.

Does a focus on the technology and how it is used result in the most effective approaches to teaching ? Is the technology the critical element of teaching by video conferencing? The present study is concerned with the way teachers understand teaching, in other words the meaning it has for them, when it takes places in the cross-campus video conferencing setting. It commences from the assumption that how teachers make sense of the context within which they act is integrally linked to how they approach their teaching.

Considerable research has been conducted into university teaching and learning over the past three decades (Entwistle & Ramsden, 1983; Marton et al., 1997). One of the key ideas to emerge from this research is that the *content* of student learning (*what* is taught) logically precedes the method of teaching content (*how* it is taught) (Ramsden, 1992). In other words, without a content to teach, there is no teaching method. From this perspective, at the core of the teaching process, including when it involves the use of any form of telecommunications media, is the way the students are brought into engagement with the specific content of their learning by the teacher. The teacher's critical role concerns the way in which the content is represented to the students, and how they structure the student learning experience. Previous research into teaching with telecommunications media has paid little or no attention to these elements by narrowly conceptualising the teacher as the user of a technology through which the teaching is conducted.

Providing an overview of the pedagogically-focused research, Ramsden (1992) says effective university teachers:

- engage the student at the appropriate level of their understanding;
- focus on key concepts, and students' misunderstandings of them, rather than covering the ground;
- enthuse students to make the material being taught interesting and stimulating;
- explain the material in simple, concise ways;
- use methods and set tasks which require students to learn actively and collaboratively;
- provide high-quality feedback on student work; and
- use valid assessment methods.

Researching teachers' experience of teaching by video conferencing

One of the most influential approaches to research into teaching and learning in higher education has been undertaken within phenomenography. This qualitative approach to research developed in Sweden in the early 1970s and grew out of a concern with the relationship between the ways in which students approached learning and the learning outcome. Phenomenography assumes that the world, or aspects of it, do not exist in isolation from the individual experiencing it. Rather, the only world that can be known to the individual (and the researcher) is an experienced, and therefore an interpreted, world. Phenomenographic studies focus on individuals' descriptions of their experiences of a specific phenomenon. The aim is to describe the qualitatively distinct ways in which a phenomenon has been experienced or understood (phenomenography uses these terms interchangably) by a particular group of people.

Phenomenography contends that some ways of understanding a phenomenon, or aspects of the world, are more sophisticated than others; and for this reason it has been used overwhelmingly in educational studies. In more than two decades, phenomenography has developed a rich heritage of studies primarily concerned with aspects of student learning and, more recently, teachers' approaches to teaching (Marton & Saljo, 1976; Trigwell & Prosser, 1997).

From the phenomenographic perspective, teachers do not simply teach differently by cross-campus video conferencing. Rather, teachers *experience* or *understand* the phenomenon of teaching by cross-campus video conferencing in fundamentally different ways. The variation in how teachers approach their teaching, in other words which aspects of the situation they are most concerned with, reflects the different ways they *experience* or *understand* teaching in that situation. With phenomenographic data drawn from empirical research, it is possible to conduct faculty development programs which aim to shift an individual teacher's *experience* or *understanding* of the phenomenon of teaching by cross-campus video conferencing to one which is more pedagogically sound.

The present study

The present study was concerned with the teachers' perspectives of their experience of teaching by video conferencing. It aimed to identify which aspects of the teaching process teachers were most concerned with, and which most affected teachers' approaches to teaching, in the cross-campus video conferencing classroom situation. The study asked the question: How do teachers experience, and make sense of, teaching by video conferencing? It involved ten examples of university teaching by cross-campus video conferencing and included twenty-three teachers.

The study was based primarily on open-ended, semi-structured interviews. Teachers were interviewed prior to a specific class. Based on the view of teaching underpinning this study, the interviews initially centred on the content to be taught, how the teachers intended students to learn that content, whether their teaching by video conferencing differed to teaching in the regular classroom and, if so, how? These aspects of the teaching (and learning) process were not conceptually separated from the teacher's use of the technology, but were seen to provide the rationale for its use. The class was subsequently observed, and a post-class interview was conducted to discuss what had occurred.

What is at the core of teaching by cross-campus video conferencing?

The teachers in the present study focused on a number of critical elements of the teaching process when teaching by cross-campus video conferencing. In contrast with the research literature's fixation on the technology, the study showed that teachers had a primary focus on one of three broad, distinct aspects, with critical distinctions in each category. They were:

The teaching environment.

Several teachers were predominantly concerned with the physical context of the video conferencing classroom, including the technology, the method of communication between linked sites, and the arrangement between, and the governance of, the physically separated classrooms.

Given its critical role, it is not surprising that the technology was the primary concern for some teachers. From the phenomenographic perspective of this study, these teachers can be said to have the least sophisticated understanding of teaching by cross-campus video conferencing. They were preoccupied with the affect of the technology on their own role as teacher. Any difficulties found in the teaching environment were viewed in terms of the inconvenience caused to the teacher, rather than in terms of the impact on student learning. In particular, the teachers felt a massive dependence on the technology which related to the reliability of its operation, rather than how teachers would use it. Prior to each lesson teachers were uncertain whether or not the class would be convened until the video conferencing technology established the link between distant sites.

Furthermore, some teachers' understandings of what constituted the technology extended to the technical support staff who were the embodiment of the teachers' dependency. Teachers felt that they had little or no control over the operation, maintenance and update of technical facilities. Unlike the regular classroom, where the teachers felt they had considerable autonomy over their teaching, the video conferencing classroom was predominantly the domain of the technical support staff where teachers were relegated to a secondary role. On another level, the teaching and learning environment was also formed by the medium of communication provided by video conferencing. Some teachers spoke of the barrier it created for communicating between participants compared with the regular classroom; particularly the difficulty in reading facial expressions and problems in hearing student responses.

A further problem related to the two or more classroom sites joined electronically and the problems teachers faced in managing student activity and measuring student responses to set tasks undertaken at distant locations.

How does a focus on the teaching environment affect a teacher's approach to teaching? Because of the comparative complexity of the video conferencing classroom and its impact on their own role, these teachers had an extremely negative view of teaching by video conferencing. The teachers adopted a very didactic, information-delivery approach which relegated students to passive transcribers of a presentation made by the teacher at the front of the classroom. The students in these classes were presented with no opportunity to influence any aspect of the teaching and learning process.

Importantly, these teachers treated the physically separated student groups as distinct classes joined electronically, rather than as a single, unified class. As a consequence, those student groups remote from the teaching site received relatively less attention from the teacher and were reduced to distant observers of a process which centred on the teacher's immediate physical location.

Teachers in this category made no attempt to work collaboratively with teaching colleagues in the design or delivery of their teaching programs. Instead, the teaching input was largely governed by each teacher's physical location and can best be described as sequential, with various teachers making individual contributions to specific sections of the program. Equally, these teachers made no effort to co-operate with technical support staff to ensure a more effective use of the facilities.

The teaching process.

Teachers in this category had a more sophisticated view of teaching by cross-campus video conferencing than those with a focus on the *teaching environment.* They were primarily concerned with their own role as teacher in the video conferencing classroom. These teachers either focused on replicating their previous teaching practice in the regular classroom in the new situation; or were intent on improving their current practice to become better video conferencing teachers.

Although they were not concerned with the impact of the environment on their own performance, they remained fixed on what they would do as teachers in the situation, rather than the implications this may have for the quality of the student learning experience. Teachers with this focus did not make a direct link between the teaching process and student learning.

How does a focus on the teaching process affect a teacher's approach to teaching? Some teachers in this category simply attempted to transfer previous classroom teaching practice into the video conferencing environment. They saw the context as one which accommodated their existing practice. However, in doing so the teachers failed to take into account the specificity of the circumstances (ie. multiple student groups; more than one teacher; different requirements for responding to distant students; the impact of the telecommunications media on interaction) due to their concern with their own teaching role.

Other teachers in this category did make adjustments for peripheral elements of the new environment (ie. changing forms of text and graphics to comply with presentation methods). However, in these instances the changes were similarly driven by a primary concern with their own teaching role, rather than the potential to enhance student learning. Although in relative terms they worked in closer co-operation with teaching colleagues, these teachers did not seek to maximise the potential for working collaboratively with other teachers who were also engaged in the subject, or with technical support staff.

Student learning.

From the perspective underpinning this study, a *student learning* focus is the most sophisticated and preferred way of experiencing or understanding teaching by cross-campus video conferencing. In this category, teachers were overwhelmingly concerned with the student learning experience, rather than environmental factors, or their own role as teacher. In addition, some teachers saw in the new situation the prospect for improving student learning by enhancing the technical system, or by incorporating video conferencing to enable additional chances for student interaction and participation.

How does a learning focus affect a teacher's approach to teaching? Teachers with a *learning* focus placed the student learning experience at the heart of their practice. The video conferencing classroom became a setting in which they aimed to actively involve students in their own learning. Teachers with this focus viewed the situation very positively, and sought the advantages it offered to students. Their teaching was conducted as facilitation, in which their role was to maintain momentum in a class which was driven overwhelmingly by the students' contributions and interests. As a result, these teachers recognised the value of close collaboration in the teaching process through which students would gain access to a wider range of expertise and knowledge regardless of their physical proximity to an individual teacher.

Teachers with a *learning* focus were aware that the situation of multiple student groups provided an opportunity to engage students in ways which would enhance the learning experience of the total group. Most importantly, teachers with a *learning* focus were the only ones to encourage and expect students to operate the technology of video conferencing, thereby further reducing the role of the teacher in that classroom setting. These teachers emphasised what student would do in the context, rather than their own operational or presentational skills, and worked closely with technical support staff to ensure the most efficient and effective environment for students.

Implications for improving teaching by cross-campus video conferencing

The concept of what teaching is in the video conferencing classroom needs to be seen by researchers and faculty developers as a pedagogical process rather than a technical one. Faculty development programs relating to telecommunications media have concentrated on improving teachers' operational and presentational skills for one simple reason: it has been assumed that this is the most important and distinctive feature of teaching in these contexts. The findings of this study give cause to reconsider the design of faculty development programs relating to teaching by video conferencing, and the principal assumption underlying such programs.

Teaching by video conferencing should not be conceived primarily as the act of using a telecommunications medium effectively. Although teacher proficiency with the technology will assist student learning, the teacher's response to other key aspects of the teaching process has a much greater impact on their approach to teaching. Where the technology *is* the primary concern, this study shows that teachers' understanding of the technology is much more complex than the literature generally acknowledges (ie. it creates the method and form of interaction).

Clearly, some ways of seeing the act of teaching by video conferencing are more preferable than others. From a broad phenomenographic perspective, faculty development programs should be based upon the present findings that teachers have a range of primary concerns, or ways of experiencing teaching by video conferencing. The aim of faculty development programs firstly, should be to establish how individual teachers understand teaching in that context, rather than assume that the technology is the predominant concern for all. Then, teachers should be made aware how other teachers in the program understand teaching by video conferencing, thereby introducing each teacher to the range of understandings, and the implications for how teachers approach their teaching. Ultimately, the intention should be to shift the teacher's understanding to a more sophisticated one. Faculty development programs should aim to produce a student learning focus where the teacher is fundamentally directed to how students will be brought into engagement with the lesson content in the relative complexity of the video conferencing classroom. Faculty development programs should also address several of the key issues to emerge from the present study which are directly related to how teachers approach teaching by video conferencing. For instance, there is a clear need to promote a view of the separate student groups as a single, unified class. Such an approach emphasises the value of the group-based learning experience, which is the essence of the video conferencing classroom, where the aim should be to generate interaction between all students. In group-based learning contexts, interaction should be the intention, and the group members viewed as sources of knowledge and experience to be utilised for the common good.

Finally, the study demonstrates that teachers need to work collaboratively in the design and teaching of a program, with all teachers assuming responsibility for the learning of the whole student group. Faculty development programs should directly address the concept and process of *team teaching* rather than assuming that collections of teaching colleagues will necessarily work effectively. In order to have the greatest impact of student learning, faculty development programs should be directed at course or subject teams rather than individual teachers. The concept of collaboration should also extend to the role of technical support staff who have a major role in assisting teachers to function effectively in the video conferencing classroom, and who should be regarded as members of the teaching team in development programs.

In broader terms, the approach to conceptualising and researching teaching by video conferencing reported in this paper also has major implications for other forms of telecommunications media as well as other educational sectors.

Abstract: The purpose of this research was to assess the impact of a school district technology initiative on the adoption of computer technology as an innovation for teaching and learning. A review of the literature suggests that instructional technology is not widely implemented in the educational setting. The Board of Trustees of a large school board in Western Canada operated a district Technology Incentive Program (TIP) from 1996 to 1999. This study assessed the impact of the first year of TIP. The data were collected through quantitative and qualitative methodologies. The results showed that there was an increase in TIP participants' perception of the level of expertise in using a computer and usage of computers for teaching and non-teaching purposes. Results were discussed in terms of theories of change and innovation.

Introduction

The purpose of this research project was to: (a) examine the effects of the Technology Incentive Program (TIP) on selected aspects of the implementation of computer technology by teachers, and (b) make recommendations to school districts to encourage teachers in adopting computer technology.

In Western Canada, one large school district initiated a multi-year Technology Incentive Program during the school year 1996-1997, for teachers who were novice users of computer technology, to gain experience in using computers. The Board of Trustees approved a three year district project which provided teachers with computers and in-service training to encourage them to adopt computer technology in teaching.

With the advance of computer technology, educators are feeling pressure to use computers in the classrooms. Some parents are demanding changes in the curriculum. They want computer technology to be integrated into the curriculum so that their children will be ready to meet the challenges of an information society once they graduate. Means and Olson, (1994), Szabo & Schwarz (1997), and the U.S. Congress, (1995) have shown that, although computers are generally available in schools, a substantial number of teachers are either not using computers as tools for teaching, or the use of computers is at low level (e.g., word processing). Some school districts are looking for ways to support teachers so they will adopt computer technology into the instructional process.

Research Question

This study was designed to address the question: What impact did the first year TIP have on teachers with regard to computer usage? The research question was broken down into ten sub-questions so that the impact of the first year of the TIP could be examined in detail.

Sub-questions dealt with (a) changes in skill and knowledge in computer usage, (b) usage of computers for teaching, (c) usage of computers for non-teaching purposes, (d) the impact of having a computer for one year, (e) teachers' attitude towards computers, (f) TIP participants' purchase of computer as result of the TIP, (g) the TIP training program, (h) interest shown in computer-related activities, (i) other factors which influence the use of computers, and (j) computer usage and teachers' perception of what they need.

Review of the Literature

The review of the literature shows that the implementation of computer technology should be looked at as an embedded innovation problem within the process of change. Research is needed in the adoption and implementation of computer technology and on the impact of computer technology programs at district and local levels. The review and research drew heavily from the work on change and innovation of Fullan (1991, 1992), Rogers (1995) and Szabo (1996).

Study Methods

Data were gathered from a survey of TIP participants for an ex post facto study. To add depth of understanding to the study, seven TIP participants were also interviewed.

Sample of Study

The target population consisted of teachers who were novice-users of computer technology and would volunteer to participate in programs similar to the TIP. The accessible population was comprised of: (a) teachers who participated in the TIP in a large school district in Western Canada, in 1996/1997 and (b) teachers who applied for the program but were not selected (non-TIP).

There were 148 (64%) TIP teachers and 20 (14%) non-TIP teachers who responded to the survey. Seven TIP participants were chosen, based on grade levels taught to gain an insight into the impact of the TIP at the different grade levels, to be interviewed.

The impact of the program was defined by the (a) change of perception of teachers in the skill and knowledge or level of expertise with computer usage, (b) change in the number of hours of computer use for teaching purposes, (c) change in the number of hours of computer usage for non-teaching purposes, and (d) attitude toward the use of computers shown by surveyed teachers .

Hypotheses

It was hypothesized that TIP participants exhibit a difference before and after the TIP, with regard to (a) their perception of their skill and knowledge in using a computer, (b) the number of hours in computer usage for teaching purposes, and (c) the number of hours in computer usage for purposes other than teaching.

It was hypothesized that Non-TIP teachers exhibit a difference before and after TIP, with regard to (a) their perceptions in the level of knowledge and skill in using a computer, (b) the number of hours they used the computer for teaching purposes, and (c) the number of hours they used the computer for purposes other than teaching.

The Technology Incentive Program

In July, 1996, a large school board in Western Canada approved $753,000 to operate a TIP in which 230 teachers were given a computer and software productivity suite for their personal use for one year and approximately three weeks and four Saturday sessions of training in its use. Due to the funding limit, the administrator of the school was asked by the district to nominate some of the teachers who volunteered for the program. Of the 371 novice computer users nominated by their schools, 230 were successful in applying for the program.

The summer workshops included sessions on: (a) unpacking and setting up the computer system, (b) the operating systems of either Windows 95™, with MS Office™ or Macintosh™ system 7.5, with ClarisWorks™, (c) how to use word processing software; (d) electronic presentation; (e) CD-ROM resources such as Encarta and Canadian Encyclopedia, and (f) the Internet. Saturday workshops were offered in language arts, mathematics, science, and social studies to teachers in Divisions One and Two (grades one to six). Workshops on word processing across the curriculum, spreadsheets, database were offered to teachers of Divisions Three and Four (grades seven to twelve).

Data Analysis

Response Summary

Five TIP teachers were not accessible due to moving or leaves of absence. Of the 150 surveys returned by the TIP teachers, 148 (64%) were usable for data analysis. Of the 21 surveys returned by non-TIP teachers, 20 of them (14%) were usable for data analysis. The majority (76%) of the TIP participants were female and that 69% of the TIP participants were elementary teachers (43% taught in Division One and 26% in Division Two).

Analysis of Data

A comparison of the data was made by using paired t tests on *the level of expertise with regard to computer technology* the TIP participants perceived they had, before and after the TIP training. Comparison of the data was also made by using paired tests on *the number of hours the TIP participants used computers*, for teaching and non-teaching purposes, before and after the TIP training. The same procedure was used for the both TIP and non-TIP participants. A comparison across TIP and non-TIP teachers was not made due to the vastly different sample sizes.

Presentation of Findings: Survey of TIP Participants

Results for TIP Participants: Level of Expertise and Computer Usage

Results of t tests showed that the TIP seems to have made a significant impact on the participants with regard to their self-reported knowledge and skill in using a computer. The TIP also seemed to have made a significant impact on the participants with regard to the use of computers for teaching and non-teaching purposes.

Results for TIP Participants: Attitude and Confidence in Computer Usage

The TIP participants reported being more confident in using a computer. They also reported being more proficient in using a computer and exhibited a more favorable attitude toward computer technology for teaching and learning. An overwhelming majority of TIP participants held the opinion that computers should be used for learning (89%) and that the computer is an effective tool for teaching and learning (92%). However, only half of the teachers agreed that they were confident with using computer technology in delivering instruction.

Impact of TIP Training Program and Interest in Computer-related Activities (TIP Participants)

The TIP was reported to have made positive impact on its participants regarding the use of the Internet, clip art and word processing. It neither made a great impact on integrating computer with content area nor with the computer applications of spreadsheets, data bases or transferring data between applications. The TIP appears to have increased participation in computer related activities such as reading books, articles or magazines, and attending conferences on computer technology. As well, the TIP computer, a component of the TIP program, appears to have influenced some participants toward the purchase of a computer.

Factors of Usage (Other Than TIP) for TIP Participants

When asked about influential factors other than the TIP, TIP participants identified a necessity to learn to use computers for report card purposes and needs of students along with help from family, colleagues and friends and having access to computers in school or classroom.

Perceived Needs of Teachers (TIP Participants)

Participants in the TIP indicated requirements for (a) people support, (b) help in applying technology in classroom, (c) access to hardware and technical support, (d) training strategies, and (e) school and administrative support.

Summation of Discussion of Data from TIP Participants

Findings from Quantitative Data

The findings of the impact of the TIP were generally compatible with the theories of change and innovations as suggested by the review of literature. Teachers adapted to the process of change in their early attempts to adopt computer technology as an innovation as a result of the impact of the training from the TIP. However, there are many other factors in a complex social structure, such as a school district, which affect the change process. While it was not possible to completely isolate the effects of the TIP from this milieu of complexity, the TIP seems to have had a not insignificant impact.

Findings From Interview Data

Interviewees had different reasons for their participation in the TIP. Overcoming of the fear of technology, a change to a positive attitude towards using technology and an increase in teachers' use of computers were some of the significant outcomes of the TIP. Teachers perceived that they need help in the implementation of technology with curriculum. The interviewees identified barriers which prevented them from the successful implementation of computer technology in their classrooms. In general, the findings support the conclusions made by Szabo and Schwarz (1997) which stated that in addition to training, teachers require a broad range of support (infrastructure) and the ability to adopt the innovation to unique needs (a form of empowerment) (Tyack & Cuban, 1995).

Discussion of Results of Non-TIP Group

Non-TIP teachers reported increases in knowledge and skill in using a computer for personal and teaching purposes. They seemed to have gained more confidence in using computer technology and acquired a more favourable attitude towards computer technology for teaching and learning.

Non-TIP teachers appeared to participate in computer related activities such as reading books, articles or magazines, and attending conferences on computer technology. They also seemed to have increased the usage of word processing. However, they did not seem to show much increase in their use of the multimedia software and the application programs of transferring data between applications, spreadsheet or database.

The non-TIP group identified usage of computer for report card as one of the factors which increased computer usage. They identified lack of time as a reason for prevented them from increasing their use of computers.

Non-TIP teachers reported that, in order to increase the use of computers with their students, they needed (a) people support, (b) help in applying technology in classroom, (c) access to hardware and technical support, (e) training strategies, and (f) easier scheduling of facilities.

Summation of Discussion of Findings of Data From Non-TIP Teachers

Of the 21 surveys returned by non-TIP teachers, 20 of them (14%) were usable for data analysis. Since the sample of Non-TIP teachers was low, it cannot be assumed that the sample of the twenty teachers is representative of the Non-TIP population of teachers. Therefore, the comparison of the two group of teachers, TIP and Non-TIP teachers, was not made. The validity of the findings of the Non-TIP group is also questionable, due to the small sample.

There are several factors to suggest the gains made by the non-TIP teachers. A close examination of the returned surveys from the Non-TIP respondents revealed that three of the respondents received training, support and had access to hardware similar to what the TIP participants had received. These three Non-TIP respondents constituted to 15% of the sample for the Non-TIP group. The fact that the three teachers were given all the support they needed could be a confounding factor because of the 'rippling effect' of the TIP program.

Since principals knew about the existence of the TIP program, they might be trying hard to keep up with what was happening in the district by giving teachers who volunteered for TIP but were rejected by TIP as much support as they could afford to give. This could very well have been a confounding factor to the findings of the Non-TIP group.

There are several factors to suggest the gains made by the non-TIP teachers. Since the non-TIP group originally volunteered for participation in TIP, their motivation to adopt computers as an innovation was likely as high as the TIP participants. The concomitant popularity of the Internet might have been a catalyst in causing the non-TIP teachers to try to learn more about computers on their own. The fact that over one third of the teachers identified the usage of computers for report cards showed that there was a need for the non-TIP teachers to adapt to the changing process of using computer technology in their classrooms. Another possible factor is the fact that money and training were committed, which was likely interpreted as a signal of the importance of technology to the senior administrators (Szabo, 1996). This is in stark contrast to a common reaction of "There's not enough money in the budget for computers."

All the above mentioned factors combine to suggest why the non-TIP group seemed to have gained confidence in skill and knowledge in their ability to use the computer and have shown a tendency to adopt computer technology as an innovation for teaching and learning.

Conclusion and Recommendations

This study was concerned with the research question, "What impact did the TIP have on teachers with regard to computer usage?" The TIP impacted teachers' usage of computers in a significant way because it addressed the needs of the teachers in the implementation of computer technology by supporting them in their adaptation to the process of change. The TIP was the beginning of a process in which teachers began the adoption of computer technology in their classrooms. An analysis of the TIP, from findings of quantitative and qualitative data of this study, showed that the main reason for the success of the TIP was that the implementation of computer technology was looked at as an embedded innovation problem in which teachers had to be adapting to the process of change. Teachers were involved with the change process. They knew what the innovation was. Their training, organization and resource needs were beginning to be met within the TIP. They were given the time to try the innovation for a one year period so they could make informed decisions as to whether to adopt or reject the innovation. More teacher input into decisions about the content of the inservice program for the inservice sessions would be helpful for future programs modeled on the TIP.

As TIP participants demonstrated the characteristics of adopters of the innovations of computer technology for teaching and learning, the challenge of institutionalization lies ahead for the school district which initiated the TIP. As recommended by Fullan (1992), the ultimate adoption of an innovation for implementation was the institutionalization of the innovation. Institutionalization of an innovation is a process in which the innovation is fully implemented by members of the group with support from the institution or community in which the members are involved. The major contribution of the TIP was the impetus which initiated the implementation of computer technology as an educational innovation in a large school district.

Recommendations

Szabo (1996) proposed a model which begins with a vision from the senior administrative level, followed by the development, training and support of strategically placed leadership teams who are empowered to make the vision a reality in their own schools. Szabo's model could be considered for the implementation of computer technology in the classroom.

From a case study of implementation of new educational technologies in Ontario schools, Fullan (1992) suggested that teachers' requirement for organizational, resource and training support must be met in order for them to successfully implement technology as an educational innovation. In conclusion, the first Technology Incentive Program, though significant in its impact as to the influence it had on teachers with regard to their computer usage, is but a first step in the right direction. The school district must accept the challenge of supporting teachers with the further implementation of computer technology by helping to institutionalize the new technology for the school system.

Significance of the Study

The significance of this study lies in (a) its contribution to classroom practice by gathering data on how teachers attempted to implement computer technology in their classrooms within the TIP, and (b) its contribution to theory by relating a district initiative technology program with the theories of change and innovation in education.

Abstract: This study presents the rationale, model and results of the first year of operation of an operational change model based in innovation. The change model focuses upon professional development of faculty in the area of alternative delivery systems. The two main components of TIES are the development of and commitment to a vision for change using alternative delivery systems and a leadership team training approach whereby faculties may interpret and develop the vision according to their own unique needs and goals. Results of the first year of operation in terms of vision development and leadership team training and support are presented.

Overview

The philosophy of TIES is that the process of change is equally or more important than training or resources to faculty use of alternative delivery systems. While numerous theories of change have been put forth in the literature, there are few working examples of comprehensive application of the principles which derive from the theories.

The purpose of TIES was to design and test a system for change in a university environment. The system is based upon 1) innovation change theory, 2) a workable, not just theoretical approach, 3) content taught is alternative delivery systems, 4) change methodology, 5) both top-down and bottom-up operation, 6) professional development and 7) empowerment through leadership training.

There are two major intended goals of TIES. The first is that the chief academic officers identify a vision for alternative delivery systems of instruction for the university, publish that vision widely, and demonstrate their commitment to it in a clear and convincing fashion. Secondly, departments within the university create leadership task forces to interpret the vision for their unit and prepare colleagues to implement the shared vision.

TIES was devised in 1996 by the Project Director during a sabbatical leave and through LEE funding, implementation began in 1997. The first description of TIES was presented at an International Conference in 1996 and can be viewed at http://www.atl.ualberta.ca/papers/change/tie.html/ and Appendix A. Note that all appendices can be viewed at http://www.quasar.ualberta.ca/edmedia/TIES/TIES_Report.html

Deliverables

The first deliverable is an outline of a Visioning workshop for Chief Academic Officers (CAO)s of an institution. This describes what will transpire in a workshop to create a vision for the institution (Appendix B). The second deliverable is a workshop outline for the training of TIES Leadership Task Forces (TLTF)s (Appendix C). The third deliverable is a set of TIES training modules in Web-Based Instruction (WBI) format. The list of modules is located in Appendix D. A sample module (L7: Dealing with Mental Models) has been provided in Appendix E. All modules are available at http://www.quasar.ualberta.ca/edmedia/TIES/Ties_home.html/

Project Planning and Implementation

Problems/Issues

The driving force behind TIES stems from the conviction that bringing people to actually change their practices with respect to new teaching approaches is extremely difficult. Critics of education, of which there is no short supply, often contend that:

- students are poorly prepared (for the work force),
- education has become bureaucratized, politicized and centralized,
- the current classroom-instructor based model and old learning theories are more consistent with preparing students for the industrial model of work, rather than for work in the information age,
- education is slow to change,
- school districts undertake innovation under circumstances of unclear goals, unpredictable technology, and uncertainty in general (Morris, 1997).

There are major advantages and disadvantages to Instructional Technology (Appendix F). The University has a rich history in computer-based instruction and the environment for Alternative Delivery Systems (ADS) there is described in Appendix G. Furthermore, ADS is an innovation. It cannot be understood or made to happen without a strong understanding of what an innovation is or is not. See Appendix H for pertinent findings from educational innovation.

Assumptions of TIES

Almost every system rests upon a set of assumptions which, if not met, may render the system inoperable before it begins. The assumptions of TIES are as follows.

- ADS is stimulated MORE by a strong vision, the willingness to share that vision, and an unequivocal commitment to that vision, THAN by policies and procedures (which should follow). Normal pressures for institutional reorganization, such as falling student numbers, competetion, and customer dissatifaction are not yet apparent in Alberta where expansion needs are being met using old models.
- Emphasis is placed FIRST on realistic goals of improving formal learning, such as increased achievement, decreased learning time, increased accessibility to instruction or cost control, and SECOND on the use of the technology of ADS.
- To succeed in reforming an institution, implementation of ADS must be widespread and pervasive throughout the institution and not confined to the small percentage of 'early adopters.'
- ADS requires ownership (commitment, not just compliance) by those who will ultimately implement it. This is the "Empowerment" phenomenon.
- ADS cannot be implemented in a shotgun approach. It must be strategically leveraged. This does not mean there is one correct model or plan--thus the emphasis on departmental teams making local decisions within the University.
- Implementation of ADS requires sacrifices at all levels of the institution. The sacrifices should not fall unevenly on specific groups or individuals. This was problematic in that the University of Alberta is currently recovering from a 21+% reduction in government funding.
- No one can predict the future, especially in the highly changing area of instructional technology. The best way to predict the future is to invent it though experimentation, keeping the good ideas and shelving those that don't work.
- The three sequential stages of innovation are play, use, and creativity. Support for and evaluation of ADS needs to be different for each of these three stages.

Phases

Phase I: Vision Building

The ultimate goal of Phase I is the creation, dissemination support building for a vision of what the instructional program of the institution will look like in the future; a vision generated by the Chief Academic Officers (CAOs).

A retreat involving the CAOs and key support staff who would be provided with stimuli, resources and a mechanism to capture and edit their deliberations was chosen (Appendix B). At the retreat, CAOs would be presented with examples of the use and impact of IT from within the institution as well as a sampling of the best practices from around the world.

Next comes a brainstorming session to create the University of Alberta Vision for Alternative Delivery Systems. The basic question to stimulate these outcomes is: "Suppose it is now 10 years into the future and your vision has succeeded beyond your wildest expectations. If you were to walk around the campus, city, and province, what evidence would you see of the success of this vision?"

Finally, discussion focuses on "What are the major barriers that stand between us and the accomplishing this vision?" This session encourages the CAOs to identify ways these barriers could be overcome. After a suitable time, it is expected that the CAOs publicly present the results of their deliberations with emphasis upon the vision and presenting a convincing case for their commitment to having it become a reality.

Phase II: Identification of Departments

Deans of faculties and chairs of departments were approached to describe the vision of the institution and the role of the TIES Leadership Task Force (TLTF) to meet that vision, and extend an invitation to participate. The authors identified six departments that appeared to be prepared to participate and in which there were active colleagues from previous work in ADS. One had other more pressing agenda items and declined to pursue the option further. Deans and Chairs were informed that the funding would provide $7,500 for each team and requested to provide additional resources in support of the work of each team.

Phase III: Development of TIES Workshop and Modules

The modules to be created had to provide basic instruction in ADS and change methodology, model ADS, and incorporate adult learning strategies (andragogy). The driving philosophy behind TIES is to make certain all TLTF members have a basic competence in the following areas of ADS: presentation and interactive digital technology, professional development, leadership, curriculum and instruction, evaluation, and related issues (See Appendix D) for a list of the 38 modules by topic.

In keeping with adult learning principles, it was recognized that 1) not all participants would need to study all the modules, 2) there was not enough workshop time to complete all modules needed by each individual, 3) some selection was needed by individuals, and 4) learning rates would require an allowance for self-pacing, all modules were developed in an individualized, self-paced web-delivered instructional format, complete with diagnostic and prescriptive self-assessment tools. The workshop also had the goal of building a team orientation to complete the workshop tasks and the activities of the coming year

Phase IV: TLTF Training

The workshop was conducted during a four day break in the second term of the academic year.

Phase V: Follow Up Support

TLTFs were informed that the training team would be available to assist in whatever way possible during the coming 12 month period. The support provides and models the importance of on-going, local and just-in-time support. A Web conference site was set up to facilitate communication within and between teams and trainers.

Evaluation Results

Phase I: Vision Building

Initially a retreat to develop a vision could not be scheduled. There was some difference of opinion as to whether the vision should be developed by the CAOs themselves (the author's opinion) or should be developed by key people in the university and presented to the CAOs for their approval.

During a retreat with CAOs, limited progress was made toward the goals of examining current noteworthy applications, creating a vision for the university, and identifying the key barriers and their solutions to making the vision happen. One key outcome was to begin a dialogue on the role of ADS with the deans of the university. Another outcome was the development of an updated version of the institution's technology integration plan (Learning First, 1998). However, this document and subsequent versions at the

University and Faculty levels do not possess the essential vision component. It appears that using a vision model does not mesh well with current adminstrative planning models.

Phase II: Identification of Departments

After extensive discussion and probing, five teams from across the university agreed to participate in the year long program, starting with an intensive workshop.

One Dean had begun work on a technology integration plan and invited the author to discuss TIES and asked to nominate a TLTF (TLTF B). Due to the small size of the departments in this faculty, they requested to participate as a faculty level team rather than as a department level team.

TLTF C was formed from an instructional technology team which had already been created and was grappling with how to proceed. Their plan was to convert a large undergraduate course to ADS-based instruction and use that to encourage departmental colleagues to become involved. This team had the most questions to ask about TIES and the author met with them repeatedly and answered numerous questions in person and electronically.

Discussion with another faculty resulted in the formation of TLTF D at the faculty level since the departments were quite small. The Dean was enthusiastic and involved a faculty member who was heavily involved in developing IT course materials.

When a presentation on TIES was made to the Associate Dean of another faculty, the enthusiasm was quite high and a meeting with the Dean was quickly arranged, followed by a presentation to the Dean's Council. TLTF E was formed from this faculty and once again, it was a faculty-wide endeavor as the departments involved are small and engage in many joint projects.

Due to the complexity of the TIES and its innovative nature (attempting to deal with change and reform rather than simply training or resources), an extensive schedule of meetings, discussion, writing, explanation, answering questions and negotiation had to be carried out

Phase III: Development of TIES Workshop and Modules

Content: The driving philosophy behind the TIES training program is to make sure all TLTF members attain a basic competency in several different areas of ADS and change. In the area of ADS, modules were designed to deal with digital presentation technology (7), digital interactive technology (5) and distance delivery (3).

In response to instructors' requirements to know how to apply IT to courses and curricula, a set of modules on curriculum and instruction (6) and evaluating students (4) were developed.

On the assumption that teaching bright, articulate, and motivated instructors to develop ADS is relatively easy but motivating people to change behaviors is considerably more complex, a series of eight modules designed to promote leadership skills aimed at resistors was developed. The content of the modules draws heavily from the work on change of Senge, Kotter, and Covey among others, and their writings were employed in the learning activities.

Finally, a series of 5 modules on key related topics (e.g., professional development, copyright, and effectiveness of IT) were created. These modules are open for viewing at the TIES web site listed at the end of this article.

Methodology to Acquire Content : Each module was designed to be completed in a self-paced format with several optional objectives and linked activities to choose from. Each module has its own self-assessment pre and posttest, the expected objectives, and learning activities to meet those objectives. In keeping with the team-building theme, several modules required completion by either the departmental team or a cross-team but small group. In order to make the instruction available on an extensive basis, i.e., beyond the workshop, the modules were created in a web-based instruction format. A diagnostic pretest, covering all 38 modules, was developed using the preassessment items from the modules

Methodology to Foster Team-Building : Professors may or may not have experience in substantial team efforts, in spite of the fact they may have worked together in the same department for substantial lengths of time. Activities were included which were aimed specifically at dealing with cooperative efforts with respect to providing leadership. These were couched in the context of ADS.

Phase IV: TLTF Training

The TLTF training took place during a 4 day school break in February 1998. The entire TLTF C participated, including the department chair and a faculty member who was officially on sabbatical leave. TLTF A, on the other hand, was a no-show. No one from the team participated and the chair did not offer the courtesy of contacting the workshop coordinators that they had decided not to participate, although one participant had indicated a conflict due to a conference scheduled the same time

TLTF B consisted of a single individual who had recently returned from his faculty from several years at another institution. This individual was well-versed in the WWW component of IT, keenly interested in the promoting IT in general and had strong support from the dean.

TLTF D did not translate the specified team structure into reality. It consisted of one full time faculty member who was actively developing a WBI course for the faculty, three part time sessional instructors, and no faculty administrators. TLTF E was also at the faculty level and consisted of a seasoned IT person, also just returned from a sabbatical leave, an Associate Dean, and a sessional instructor. They also participated in the entire workshop and began to develop ideas for working with their faculty colleagues.

During the six months following the training of TLTFs, the teams returned to their respective academic homes to 1) increase personal use of alternative delivery technology, 2) identify and meet training needs of colleagues in the home academic unit, 3) provide or arrange for support for colleagues in the unit and 4) develop a long range plan for the home academic unit which would begin to address the future direction and requirements for alternative delivery systems. The latter activity was particularly timely as the university administration, with stimulation from ADEM, requested a "Technology Integration Plan" from each Faculty.

Evaluation Results

TLTF "A"

It is not clear why this task force did not bother to attend the workshop or to inform workshop leaders of this decision. One member previously indicated inability to attend due to a conflict with a previously scheduled conference. Perhaps the lack of interest in ADS evidenced by the lack of a clear vision statement for ADS by either the university or the dean sent a signal. Perhaps a clear understanding of TIES and its goals and objectives was not conveyed to those involved.

TLTF "B"

Team "B" consisted of a single individual from a faculty whose Dean had previously and in several ways expressed a strong interest in ADS. They too chose to participate as a faculty rather than department due to small size. The individual participated extensively and expressed appreciation for the empowerment philosophy of TIES, having recently come from an environment where technology had been ruthlessly enforced on a faculty with major negative implications. After the workshop, the Dean reassigned this individual to a full time ADS coordinator who then formed an ADS team that embarked upon developing and implementing a long-range technology integration plan for the Faculty.

TLTF "C"

This team came the closest to meeting the TLTF selection criteria: several key opinion leaders, the department chair, and several members already active in ADS. Before agreeing to participate, they asked many important questions about the workshop and commitment expected. They participated actively during the workshop and by its end had developed the structure of a long range technology integration plan. At the time of this writing, the Project Director has not had the opportunity to interview the team for more specific details of their progress.

TLTF "D"

TLTF D was driven by a single individual, rather than a team. Steve (not his real name) identified a need for training his colleagues in the basic use of computers and contracted two individuals to create training materials in these areas which would meet the unique needs of this Faculty.

Steve personally conducted several two day workshops and provided personal support to colleagues. The major activity that consumed Steve's time, in addition to carrying an above average (for the University) teaching load, was the development of a web-based course.

The experience of TLTF D is highly representative of the individual entrepreneur approach to change (see Team Section of this report above). Note that no administrators or other faculty opinion leaders (beside Steve) participated in TIES training week. It might be concluded that the experience of TLTF D was solid, positive, but quite limited in the scope and depth of addressing alternative delivery systems in the unit. It depended upon the good will of Steve. However, Steve observed that his work in alternative delivery, particularly in the development of a web course was cited as a positive factor in his receipt of tenure.

TLTF "E"

TLTF "E" participated as a faculty, rather than as a department. Historically, this faculty had recently been reorganized through a merger of disparate departments that did not possess a great deal of affinity with one another. This task force came close to meeting the selection expectations, with an Associate Dean and several key opinion leaders. It also included several sessional instructors and research personnel. Their participation in the workshop was quite strong and they too began to develop their technology integration plan. Subsequent to the workshop, this team developed and submitted its TIP to the faculty as a whole, developed several successful ADS funding proposals, hired a course developer and hired an instructional designer. They have also begun discussions with other units on campus regarding joint professional development masters degrees to be delivered by ADS.

Lessons Learned or Revisited

- TIES is relatively successful in meeting its goals, given the limitation the several of its critical assumptions were not met.
- People are interested in quick and easy solutions to complex problems which involve change, reform, or different ways of operating.
- Communicating the requirements for change is extremely difficult, both in the reason change is needed and how change can be effectively implemented.
- The concept of making the necessary commitments to build internal expertise to provide leadership through a task force does not fit within the normal operational mandate of educational institutions. Task forces are rarely explicit about professional development, don't understand the need for commitment by senior leaders, and are often viewed as 'the solution' rather than as a means to the solution.
- The effects of the absence of a strong vision from chief academic officers and other administrators ADS appears to have been substantiated.
- The importance of the entrepreneur or keeper of the dream to the functioning of the TLTF has been substantiated.

Webcasting the First U.S.-China Internet-Based Telemedicine Consultation

Michael Fuchs, Web Projects Manager,
Stanford University School of Medicine Information Technologies
<fuchs@stanford.edu>
<http://fuchs.stanford.edu/work/>

Abstract: On June 26-27, 1998, doctors at UCSF Stanford Health Care consulted via the Internet with pediatricians at Xi'an Medical University Hospital in Xi'an, China, on the cases of two critically ill children. Stanford Medical Information Technologies (medIT), in cooperation with Sun Microsystems and others, developed an architecture that allowed the doctors to use Internet video, audio, whiteboard, and browser applications to confer and review the medical cases; and to webcast the entire session across the Internet via RealMedia. Secretary of State Madeleine Albright and other ranking members of the Clinton Delegation to China attended the session.

Introduction

Background: Internet-based telemedicine, though in its early stages of development, is of great importance in less-developed countries, where advanced medical facilities and expertise are concentrated in major cities, and inaccessible to large segments of the population who reside in outlying areas. Telemedicine systems can allow practitioners in regional and rural hospitals and clinics to draw on the resources of major medical centers. Many hospitals in China, such as Peking Union Medical College Hospital, have acquired video-based teleconferencing systems and are delivering telemedical services. These services are far too expensive for the use of the average Chinese citizen. Internet-based consultation systems have been used to distribute telemedicine at extremely low cost. In the spring of 1995, the case of a patient with heavy metal poisoning was sent from Beijing to the U.S. Respondents around the world sent suggestions for treatment over the Internet by e-mail. However, text-based e-mail does not provide the capability for radiological imaging, transmission of sound files (such as the output of a stethoscope), and in particular the real-time direct interaction of medical colleagues, which is seen to be crucial in facilitating consultation. The Internet now holds the promise of providing this type of interaction at much lower cost than proprietary videoconferencing systems.

Goals of the Demonstration: The high-end telemedical technology systems that are being used in the U.S., U.K., and Israel, cannot be deployed widely in China, or operated on a routine, day-to-day basis. What are needed are low-end systems that match the capacities of existing network infrastructure and computers, such as the Internet-based applications that were demonstrated at Xi'an Medical University and UCSF Stanford during this demonstration. The challenge is to deliver benefits of modern medicine to locations that are last in line to receive them, using applications that will work reliably and on a day-to-day basis in the most difficult environments. Making use of the publicity surrounding the Clinton visit to China, it was hoped that a convincing demonstration of real-time Internet-based telemedical consultation (the first of its kind) would pave the way and lead to future advances.

The Event: On June 26-27, 1998, doctors at Xi'an Medical University (western China) and at UCSF Stanford Health Care (California, USA) participated in the first real-time medical consultation between China and the United States over the Internet, on behalf of two critically ill children. The demonstration, which coincided with President Clinton's visit to China, was designed to highlight U.S.-China cooperation in medicine and technology and underscore the role that telemedicine can play in improving patient care. The consultation used Internet technology, which allows for real-time communication and sharing of information, including images of the participants, photographs, medical records and other graphics, and voice communications. The nonprofit organization Bridge to Asia conceived and organized the demonstration, which was hosted by UCSF Stanford Health Care. The technology was installed and managed by Stanford medIT (in the U.S.), and engineers from XMU (in China), with support from Sun Microsystems.

Participants: In China, the event was presided over by Secretary of State Madeleine Albright and Secretary of Commerce William Daley, both of whom addressed the audiences in California and Xi'an with speeches praising the technological cooperation and emphasizing the importance of medical, educational, and cultural exchanges between the U.S. and China. "This is indeed a very impressive set-up and an impressive achievement, and as we inaugurate this link between Xi'an and The Stanford Medical Center, we use technology the way it should be used–to save and improve people's lives," said Albright. "It is a sign of how quickly the newest information technology is coming to China and how far reaching its effects will be."

The other U.S. dignitaries were Senators John D. Rockefeller, Daniel Akaka, and Max Baucus; and Representatives Edward J. Markey, John Dingell, and Lee Hamilton.

The UCSF/Stanford physicians providing the consultation were Dr. Daniel Bernstein, Chief of Pediatric Cardiology and Associate Professor of Pediatrics, Stanford; Dr. David Stevenson, Neonatologist, Stanford; Dr. Joseph Kitterman, Professor of Pediatrics and Neonatologist, UCSF; and Dr. David Teitel, Professor of Pediatrics and Chief of Pediatric Cardiology, UCSF. Said Dr. Teitel, on the subject of telemedicine, "I think it's clear that patients gain a tremendous amount when physicians are able to communicate and share critical diagnostic information and images in real time."

The Patients: The doctors discussed treatment for what had been diagnosed as viral myuocarditis, an inflammation of the muscular walls of the heart, in a 12-year-old girl who had been suffering from shortness of breath, fatigue, and abnormal heart rhythms. They also reviewed treatment for a male infant who was born by Cesarean section on June 13 and was suffering from brain damage due to a lack of oxygen and decreased blood flow at birth.

Technology and Architecture

Overview: There were two technological challenges to the telemedicine demonstration. One was facilitating the actual conference, with video, audio, shared whiteboard, and image viewers (for radiological images)–ideally using lightweight and widely available applications. The second was capturing all of the audio and video, digitizing it into RealMedia, and streaming it out live, so people world-wide could witness the event online. The final architecture was a bit complex, but very robust and functional. Two Sun workstations were installed on each end, running a suite of freeware Internet conferencing applications, browsers, image viewers, and supporting software. The full video output from one of the conference workstations was captured with a high-end scan converter and streamed into an onsite PC running Windows 95 and RealPublisher; this machine converted the video (and audio, captured from a conference phone) into RealMedia, which it streamed across the local network to another PC (in the next building) running RealServer. From there, the audio/video stream was sent out over the Internet. The video feed was also sent to a large display device in the U.S. conference room, for the edification of live participants as well as captured directly by the various camera crews in attendance for broadcast on news programs.

The Complete Architecture of the Setup on the U.S. End

Hardware & Software (for the videoconference): On each side, two Sun Ultra 5s (one with 24-bit graphics capability), both running SunOS 5.6, were utilized for the conferencing applications. Sun desktop cameras and microphones, as well as standard VHS video camcorders, were used for audio and video capture. The workstations on both ends ran a suite of TCP/IP conferencing applications from Berkeley Labs: vic (video), vat (audio), and wb (shared whiteboard space). [Documentation available at <http://www-nrg.ee.lbl.gov/>.] All machines ran the Sun HotJava web browser and the RealPlayer streaming media player from RealNetworks. Unix talk was utilized for some technical interchange.

Hardware & Software (for the webcast): A HyperConverter 1024 Scan Converter was used to capture the full video feed from the main conferencing workstation. [Information on this product available at <http://www.pcvideo.com/1280ds.htm>.] A high-end table-top conference phone, with direct RCA audio out, was ultimately brought in for the audio portion. (The TCP/IP-based audioconference link was judged too spotty (see below) for use in the actual event, and was supplanted by telephony.) A Windows 95 box onsite ran the RealPublisher 5.0 software to capture, and convert in real time, the audio and video streams. These streams were run across the LAN to a Windows NT server running RealServer 5.0, with a 100-stream license, and out to the Internet. A link to this RealMedia stream was provided on the official web site. [Information on RealPublisher and RealServer available at <http://www.real.com/>.]

Network: The machines on the Stanford end were connected via 10 megabit ethernet to the SUNet backbone, and through BBNPlanet to the Internet. In Xi'an, the machines were connected to CMINET (the Chinese Medical Information Network) to CERNNET (the principle backbone in China) to the Internet. Two satellite hops and a microwave link were involved in getting Internet traffic from the U.S. to Xi'an (in rural western China).

Hurdles

Infrastructure: One of the catch phrases of the event was was to show "the Internet in China as it is, not as we wish it to be." In numerous tests over a period of several weeks leading up to the event, attempts were made to secure, and make best use of, bandwidth into Xi'an Medical University. It was particularly critical to experience some success in our testing, as a number of the "dry run" sessions were attended (frequently without advance warning) by members of the U.S. State Department advance team; their impressions would dictate whether this consultation was included on the schedules of the visiting U.S. delegation. During one State Department visit, a camera went out; during another, one of the workstations in China crashed and wouldn't come back up. These situations were handled smoothly on a case-by-case basis. But, overall, experiences of limited bandwidth, packet loss, and low video frame rates were acute in numerous tests. Compression of the video was optimized, but it was ultimately decided that the spottiness of the audio stream would be too frustrating for the dignitaries, and (to a lesser extent) the physicians. As a result, we reluctantly decided to use a telephone conference call for the audio portion of the live event.

The total bandwidth into XMU was extremely limited, so some steps were taken in advance to address this. The microwave link from Xi'an to Beijing was overheating in the sun during the day, so the dish was upgraded a few days before the event. Preparations were also made to cut off all other Internet traffic from XMU during the period of the demonstration. Additionally, during testing the night before, we experienced interference in the video stream from China which was unrelated to the Internet transport. We determined that this was caused by on-off cycling of air conditioning units at XMU; consequently, people at XMU were cut off from their climate control (as well as the Internet) for a short time.

The Internet-based video, shared whiteboard, and shared image viewing eventually went over extremely well. Although video-taped welcomes and introductions were not shipped to China in time for the event, digitized RealMedia versions of these materials were transferred electronically, an unexpected coup for the Internet.

Architecture for the webcast: One of the main architectural challenges was how to capture various video sources (two conferencing windows, the whiteboard, images in a browser, etc.), as well as audio (complicated by the use of telephony), and convert it all into one audio/video stream for RealCasting. Several strategies were considered, but ultimately we concluded we had to pull the full video feed from the main workstation (on its way to the monitor). The HyperConverter 1024 scan converter, with its 13W3 Sun video connector, solved that problem for a relatively modest price ($1,395). The direct RCA audio out on the conference phone solved our problem of capturing both ends of the dialogue. The scan converter and the phone were both run directly to the PC running RealPublisher, resulting in a very good quality RealMedia stream.

U.S. vs. China: Time zone, language, and cultural differences were issues to be dealt with--but none proved serious. Most of the live tests were conducted in the evening on the U.S West Coast, to coincide with morning in Xi'an. The great majority of the Chinese technicians and physicians had a very good command of English--though on some occasions it was helpful to have a bilingual participant who was familiar with medical terminology (James Bair, the Director of International Medical Services for UCSF Stanford Health Care). Finally, the cultural differences were inconsequential, and the engineers definitely spoke the same language.

Results

On the evening of the event, introductory comments were made by Secretaries Albright and Daley, and the Internet link was established. The U.S. physicians consulted, in pairs, on the two different cases (neonatology and pediatric cardiology) for about two hours. They viewed CT and lung x-ray images in an image viewer and browser, asked questions, and provided opinions to their colleagues in China. They also exchanged e-mail addresses (using the whiteboard application) to facilitate follow-up.

Several multimedia materials (a welcome and introduction of the physicians, a video tour of pediatric facilities at UCSF/Stanford) were prepared but not used in the actual event (they are available on the site). The live webcast of the actual event was not ultimately approved by the People's Republic of China, or the U.S. State Department, a mildly disappointing turn of events. The initial consultation and preparatory session of the night before *was* successfully webcast, proving the viability of the architecture. But the main event, with the dignitaries, was blacked out from the Net, though not from traditional media.

The event received coverage from the New York Times, the L.A. Times, the San Jose Mercury News, the China Press, and Sing Tao Daily; as well as CNN International and San Francisco area local broadcast news.

The Main Screen of the Event. Counterclockwise from top left: the consulting physicians in the U.S.; a chest x-ray of the infant; a web browser with a screen from the official site; in China, Secretary of State Madeleine Albright using the system (assisted by Robert Yung, CTO Sun Microsystems Asia).

The Web Site

A complete informational site was created in conjunction with the event. Information, images, multimedia, and future plans continue to be available on the web at <http://telemed.stanford.edu/telemed/>.

Becoming a Student in an Asynchronous, Computer-Mediated Classroom

Donald J. Winiecki, Ed.D.

Abstract: Graduate instruction is traditionally delivered in face-to-face classrooms in university settings. However, with the decentralizing of corporations and workforces in the late 20th century, potential students have been distributed far from traditional academic centers. Distance education is a viable option for these persons. Asynchronous learning networks (ALNs) are an increasingly available option for distance education. However, ALN environments impose unusual constraints on the way individuals perceive themselves, their fellow students and their teacher, and how they interact as students and teachers. The transition from face-to-face classroom to ALN classroom is, therefore, tricky for students and teachers alike. This paper describes characteristics of competent students in a face to face classroom and then contrasts them with problems typically experienced by students in an ALN. Solutions for these problems are described and used to create a model of instruction for helping students become competent and collaborative learners in an ALN.

Introduction

Graduate instruction is traditionally delivered in face-to-face classrooms in university settings. However, with the decentralizing of corporations and workforces in the late 20th century, potential students have been distributed far from traditional academic centers. Faced with this situation, persons wishing to pursue continuing professional education have been forced to choose between employment and leaving a job to attend school full-time.
Distance education has emerged as a viable option for these students. Instead of moving to the education, a student can have educational opportunities sent to himself or herself. Students can enroll in courses, participate in them, and graduate with degrees without every actually "being with" their instructors or classmates.

Many delivery options exist for distance education. For example, correspondence courses, compressed video or satellite television and computer based asynchronous learning networks (ALNs) are common distance education delivery systems. ALNs have the advantage of permitting students to participate in educational experiences in a "time shifted" environment. In other words, because students and teacher are not required to meet at the same time, ALNs permit students from different time zones, and with different work schedules to interact in the same "classroom."

The skill of being a competent classroom student is a status and skill learned implicitly over many years of experience in traditional face·to face classrooms. However, ALNs impose unusual constraints on the way individuals perceive themselves, their fellow students and their teacher, and how they interact as students and teachers. The transition from face-to-face classroom instruction to ALN instruction is, therefore, tricky for students and teachers (Harasim, Hiltz, Teles & Turoff, 1995).

A Theoretical Model of the Competent Classroom Student

Hymes (1974) indicates that there are several skill-sets required for competent interaction. First is a mastery of the behavioral elements of interaction. Second is a mastery of the linguistic components of interaction, and third is skill at mixing the first two – knowing how to behave in interaction, and saying appropriate things at the right times. Hymes (ibid.) indicates that this third skill is what makes a person a functional and contributing member of a culture or community. However, before this skill may be practiced, the first and second elements must be mastered. Each of the three interaction skills is necessary for competent classroom interaction, but none is sufficient for competent classroom interaction.

Hymes' (ibid.) constructs are intended to describe competent members of interactive social communities. However, his three-part model is readily applicable to classroom settings – whether they are instantiated in traditional face-to-face classrooms, or asynchronous classrooms. This is especially true in highly interactive, or cooperative classrooms. Highly interactive classrooms are sometimes very desirable, for example in a design-based engineering classroom where ideas and technologies are discovered, tested and refined. In fact, Salomon (1993) and Schrage (1990) explicate that interactive or cooperative communities provide a richer environment in which to share and develop ideas and engage in learning, than do more didactic instructional environments. When members of a classroom possess and practice all three of Hymes constructs, cooperative learning communities can exist and thrive.

The Task of Becoming an Asynchronous Student

Problems. Distance education in general, and ALNs in particular permit access to educational opportunities to persons who might not otherwise have it. However, there are several roadblocks to competent classroom membership in the ALN classroom. The first can occur immediately upon entry to the distance education environment and is associated with using the technological tools of the distance classroom.

In the asynchronous classroom, students normally use some form of E-mail to send comments to classmates and the teacher, and to receive messages from them. If a student is unfamiliar with the particular communications tool being used in class, he or she lacks the first of Hymes' constructs. There is a paradox associated with this problem. In order to be a contributing member of the classroom, a student must have mastered the tools being used to interact, and the ways they may be used. However, the novice ALN student must know how to use the communication tools before interaction becomes possible.

The second roadblock is related to the first. It is not enough to simply "know how" to use the required communication technologies. The student must also know when to use these tools in a way that will facilitate the learning process. For example, a student may know how to send and receive classroom messages (fulfilling part of Hymes' first competency construct), but if he or she does nót know and practice the skill of filing messages in a way that facilitates retrieval (for example, by a keyword, or in a particular folder arrangement) – and then use their system to organize efficient study of the material, learning may not be accomplished.

The third roadblock to competent classroom membership effects the second of Hymes' interactive skills, mastery of the linguistic components of interaction. While most students attending a distance class will be capable speakers of the language used in class (for example, spoken and written English), speaking and writing in the distance classroom is subtly, but importantly, different then what is familiar in a face to face classroom. For example, in a traditional face to face classroom, interactants make use of many non-language signals to create messages and to interpret and understand what is going on. For example, voice inflections, facial expressions, hand motions, linguistic devices (for example, sarcasm), etc., are used by speakers to embellish their messages. Once these paralinguistic devices are known and understood, they also assist listeners in understanding the message as intended. However, because the primary communication channel in the asynchronous classroom is written text, none of these para-linguistic devices may be used in their conventional form. However, because they are so common in face to face classroom interaction, it is very common for novice asynchronous students to use sarcasm, a cliché, or "insider knowledge," to embellish a written comment. However, without the benefit of familiar paralinguistic signals, these comments are often misunderstood – and may result in unintentional insult or embarrassment. Together, these three roadblocks may create an incorrigible problem for students in an asynchronous classroom. Therefore, interactive learning communities may never develop.

Solutions. It has been observed, however, that when the instructor and students foster an open and interdependent exchange of instructional and social dialog in the asynchronous distance education classroom, students can simultaneously overcome both of these roadblocks (Winiecki, 1997). This process is similar to that described by Wittgenstein's "language games" (1958). Sociolinguists have argued that language games facilitate the development of pidgin languages and eventually permit individuals with vastly different backgrounds and languages to develop a mutually acceptable language. "Language games" are characterized by episodes of showing what is being spoken of, speaking of it, and negotiating understanding of a task that involves it, at the same time. The goal is to communicate not only the concepts being discussed, but also to negotiate a mutually understandable and acceptable way of communicating about it, at the same time.

For example, the following conversation occurred between two, first-semester graduate students in the ALN course, "Introduction to Instructional & Performance Technology," offered the Instructional & Performance Technology department of Boise State University's College of Engineering.

[start of transcript segment]

Rebecca (9/28/97, 9:20PM): I can't find last week's assignment! I remember reading it, but now

Instructor (9/29/97, 8:15AM): Hi Becky. You should be able to find it in your database of messages. Go into your database, and search for all messages sent on September 22nd. It will be easy to pick out of that list.

Rebecca (9/30/97, 6:23PM): What database! I don't have any database – all I see is a bunch of messages from everyone to everyone!! Nobody seems to be talking about the same thing!!! This is very confusing!!!!

George (9/30/97, 7:44PM): Hey Rebecca, did you follow the setup instructions in the computer conferencing guide? It's really easy and it tells you all about creating and using your messages database.

Rebecca (9/30/97, 8:03PM): It might be easy for you!!!!! I tried to follow those instructions but I can't understand them – I must not be computer literate enough to understand it all. Will you send me the assignment?!

Instructor (10/01/97, 8:27AM): Hi Becky, I'll send you the assignment again, but we've got to get your messages database set up. Try this: From the "message packets" screen, click the "Import" button, and then answer "Yes" when the software asks you if you "want to import all messages." The software will then build your messages database (you'll see a scrolling list of every message you've ever received, as it is inserted into the database). When it's done you'll see a new icon titled "Messages database." You'll be able to search through this to find any message.

Rebecca (10/01/97, 7:10PM): Thanks for your help, but how do I know which screen is the "message packets" screen?!

George (10/02/97, 8:44AM): Oh, sorry about that... The "message packets" screen is the one with the gray background, and has a list of many message "packets" in a blue rectangle.

Rebecca (10/02/97, 7:37PM): Hey! I just did it – and now I've got a messages database. Should I keep all of the other files that are listed on this "message packets" screen?

George (10/03/97, 8:48PM): Super! It's a real feeling of accomplishment when you prove to your computer who's boss – isn't it!? I remember when I got my first BASIC program to run. I felt like jumping up and "high-fiving" everybody!

Rebecca (10/03/97, 9:15PM): Hey! You must be some kind of computer expert – writing programs and all! ...

[end of transcript segment]

In this interchange, Rebecca was unable to understand the language contained in a booklet that described how to perform some task in the communications software. Another student and the instructor attempted to communicate with her but found that she was not able to interpret their language either. George then engaged in a "language game" with her (shown as boldface in the transcript, above) complete with descriptive references to the software screens and how she should proceed. This language game was used between the students to negotiate what "database," and "message packets screen" meant before they could actually solve Rebecca's problem.

Rebecca's inability to solve the problem is not unusual. There are as many "Rebecca" students as there are "George" students. Technical documentation is not enough to support all ALN students. Occasionally, it is necessary to engage in an interactive "language game" to find out what is not understood, and how to solve the problem. In some instances telephone calls between students or between the instructor and students are necessary, to work beyond problems – especially if the difficulties prevent asynchronous interactions.

Ability to control communications software is only a small part of interacting and learning in an ALN. Hymes reminds us that it is also necessary to know how to communicate to other learners. Students in an ALN classroom are very familiar with classroom interactions – they have all been students in conventional, face-to-face classrooms in the past. However, "talking" in an asynchronous classroom as if it were a face-to-face classroom can lead to unexpected results, as can be seen in the following transcript.

[start of transcript segment]

Anna (10/12/97, 9:08PM): Hey, Wanda – old girl! How did your performance appraisal interview go at work yesterday?

Wanda (10/14/97, 7:23PM): Anna, I know we've been working on a group project this week, but I don't know how to understand your comment from last Sunday. Have I been too slow to finish my part of the project?

Anna (10/14/97, 8:10PM): Wanda, I had to go back to my message from Sunday to find out what I said. I apologize, I didn't mean to imply that you're moving slowly on the project (or anything for that matter). I was just teasing a little bit because we seem to be doing so well as a group.

[end of transcript segment]

In this dialog, Anna appears to have been offended by Wanda referring to her as "old girl!" After these comments, Anna and Wanda appeared to remain somewhat uncomfortable with each other and their groupwork and classroom interaction suffered. A telephone interview by the researcher, with both Anna and Wanda disclosed that this incident was troubling to both of them, and that neither was able to "forget about it." However, following this experience, both Wanda and Anna reported that they were much more careful about how they worded messages to classmates.

Nevertheless, sometimes it will facilitate interaction if the "speaker" and "listeners" in an ALN are able to discern the attitude with which a certain comment is being voiced. For example, sarcasm and hyperbole are important linguistic mechanisms with which to highlight misperceptions in a Socratic dialog. In some situations, comedy relief can be used to change the course of a discussion or to defuse tensions in a prolonged discourse. However, as displayed above, all of these linguistic techniques are easily misunderstood if the "listeners" are not savvy to the "speaker's" intention. On the other hand, these techniques lose their impact if the speaker is too obvious in "telegraphing" his or her plan.

Interactants in online "chat" groups, MOOs, and MUDS (multiplayer, computer-based role playing games) have developed a technique that increases the possibility that these linguistic techniques will be recognized appropriately, but that does not reduce their potential impact. This technique is called "emoting" and is accomplished by embedding posture or attitudinal information in a message (Turkle, 1995). Similar techniques have been called "embodied actions" by other researchers (Jarmon, 1995).

For example, to display embarrassment, and a childhood innocence, a message sender might write:

<Don looks at his feet, and toes the sand> Gosh...

To display an almost fanatical devotion to an idea being discussed, the researcher once typed the following message:

<Don stands on his desk, faces East, thrusts his right fist into the air and shouts> Long live B. F. Skinner!

To exhibit approval for a student's effort, but also to encourage him to press on despite persistent difficulties, the researcher once wrote:

<Don emerges from a mist, and whispers in a solemn voice> use the force, Aaron.

Interestingly, the technique of "emoting" was spontaneously adopted by several of the researcher's students in their own messaging. Through telephone interviews with these students, I learned that my "emoting" comments elicited laughter, reflection and surprise – but in all cases, the students described that the use of "emotes" led to a much faster, and deeper understanding of the comment than they felt could have been realized otherwise.

Serendipitous Side Effects

The social processes and the cooperative development of technical skills and communication techniques described above has also had the serendipitous side effect of engendering a cooperative and interdependent learning culture among students (Winiecki, 1997). Soon after the emergence of "language games" and "emoting," students increased their mutual problem solving and help seeking activities. They became much less reliant on the teacher as a source of answers, and more reliant on each other and their individual areas of expertise, as the following set of messages displays.

[start of transcript segment]

Rebecca (11/12/97, 12:14AM): George, I haven't been able to figure out what Gagne is talking about in chapter 4. Have you been able to make sense of it?

George (11/13/97, 7:18PM): Hi Becky, I've been away on a business trip and haven't had time to reread the chapter. But if I remember correctly, he was trying to classify the different kinds of things that people usually have to learn. I understood verbal, psychomotor and concrete concepts, but I don't think I really know what he means by defined concepts or rules. Is this where you're getting stuck also?

Rebecca (11/13/97, 7:45PM): Yes, George, I'm "not getting" what he means by "defined concept." Every time I think that I understand, I go back and read pages 59 – 61 and I start doubting myself again.

Aaron (11/13/97, 8:27PM): Rebecca and George, I think I've got an example of the difference between a concrete concept and a defined concept...

George (11/13/97, 8:36PM): Hi Aaron. Your example got me thinking. Do you suppose that ...

Rebecca (11/13/97, 9:17PM): Hmmm <rebecca scratches her head, and looks confused>, I'm still not sure – but I think that I'm getting closer to knowing what this stuff means. I don't know what I'd do without you guys. Here it is almost 9:30 on a Thursday night and we're still working on this stuff. Do you think we'll figure it out before the test next week?

[end of transcript segment]

Aaron, George and Rebecca appeared to be the most active cohort in the class. Their interactions spanned both curricular and personal matters. On several occasions, Rebecca referred to future interactions with her classmates. For example, as the semester neared its end, she sent a message to the class: "when we graduate, we're going to have to have a big party together!"

Since the semester when these transcripts were captured, Rebecca, Aaron and George have not taken another ALN course together. However, they still correspond in a public area of the ALN, called (aptly enough), the "Student Union." Their messages still refer to their experiences as classmates and they still task about taking other courses together. The experiences they shared were instrumental in facilitating an ongoing, and an interdependent learning relationship.

Conclusion

This paper describes tacit practices that are necessary for the successful accomplishment of "competent studentship" in a face-to-face classroom. It then described how these same practices are sometimes difficult to realize in asynchronous learning networks (ALNs). Finally, methods for aiding the ALN student to accomplish these tacit practices are described, and examples were given. While the concepts and techniques described in this paper are remarkably "unremarkable," their mundane appearance belies their importance in educational interactions.

The Effects of Expert Stories on Sixth Grade Students' Achievement and Problem Solving in Hypermedia-supported Authentic Learning Environments(HALE)

Douglas C. Williams, University of Texas at Austin, Department of Curriculum & Instruction, USA, dcw@mail.utexas.edu

Abstract: An issue concerning school-based learning is the difficulty many students experience in applying what they have learned to everyday situations. Authentic learning environments such as problem-based learning have been proposed as a way to provide students an opportunity to engage in authentic activities in authentic contexts. This research study examines the effects of expert stories on students' achievement and problem solving. Two sixth grade science classes were randomly assigned to the treatment conditions in which the learning environment provided support in the form of expert stories or expert non-stories. Measures of factual knowledge recall, near and far transfer were administered. On the measure of factual knowledge recall, no significant difference was found between the story and non-story conditions. However, when asked to solve near transfer and far transfer problems, students in the story treatment did significantly better than students in the non-story condition. This finding suggests that expert stories can scaffold student learning. In particular, it appears that expert stories may help students transfer learning to novel situations.

1. Research Framework

An issue concerning school-based learning is the difficulty many students experience in applying what they have learned in school to everyday situations. Many schools are concerned with the transfer of abstract, decontextualized concepts (Brown, Collins, & Duguid 1989). Increasing amounts of research indicate that the inability of students to apply concepts learned in formal contexts is due to the abstraction and decontextualization of learning (Cognition and Technology Group at Vanderbilt 1992). Spiro and Jehng (Spiro & Jehng 1990) argue that the decontextualization of knowledge creates inflexible understandings. But it is not the abstraction of knowledge as such that distracts learners, but that the abstractions are not illuminated with examples in context. Understanding is a product of the context and activity (McLellan 1993).

Context provides a framework which guides and supports the learner. The context naturally structures knowledge in a way that suggests its proper use. Traditional instructional design attempts to simplify learning by dividing the content into components and teaching them separately. This reductionsist approach most likely will result in students resorting to rote memorization rather than engaging in meaningful learning. In contrast, situated cognition argues that learning is simplified by embedding concepts in the context in which they will be used (Brown & Duguid 1993). The context provides the much-needed support when working at the edge of one's ability. Yet authentic context alone is not enough to support student learning. Situated cognition argues that learners must engage in authentic tasks as well (Winn 1993). Authentic activities are the ordinary practices of the experts in that domain (Brown et al. 1989). The learning activity is an integral part of what is learned. One activity in which all domains engage is the solving of problems. Experts utilize tools to support problem-solving in context. Active use of a culture's tools provide learners the opportunity to view knowledge from the experts' perspective (Brown et al. 1989). Active learning in the context of a domain's culture allows the gradual "fleshing out" of concepts over time.

There has been a growing body of research on authentic and situated learning environments utilizing the problem-based approach to learning (Spiro & Jehng 1990). Problem-based learning (PBL) emphasizes solving authentic problems in authentic contexts. It is an approach where students are given a problem, replete with all the complexities typically found in real world situations, and work collaboratively to develop a solution. Problem-based learning provides students an opportunity to develop skills in problem definition and problem solving, to reflect on their own learning, and develop a deep understanding of the content domain (Lajoie 1993) (Jacobson & Spiro 1995). This approach was developed in the fifties for medical education, and has since been used in various subject areas such as business, law, education, architecture and engineering. Most recently, there is a growing interest among educators to use problem-based learning in the K-12 setting, and a growing need for problem-based educational software to facilitate the development of higher order thinking skills via technology.

Though literature supports the efficacy of problem-based learning environments, little research exists which investigates the types of tools or features that are effective in supporting students working in PBL environments. Many researchers have found that providing tools for students to use while working in a learning environment can result in positive learning outcomes (Lajoie 1993).

With an increased awareness of the efficacy of learning in context, there is a renewed interest in the use of stories as an information resource (Bell, Gold, & Kaplan 1998) (Burke 1993). Students are familiar with the narrative format, therefore stories are a useful vehicle for providing information (Edelson 1993). Stories are usually memorable since they provide rich detail within a specific context (Schank 1990). Stories of an expert's experiences can provide valuable insight into the application of knowledge in varied contexts (Danzig 1997). These stories can also provide a considerable amount of information about the teller's beliefs (Burke). All of these factors indicate that stories may be a useful mechanism for providing information to students when engaging in authentic problem solving.

In order to design an effective computer-supported PBL learning environment, it is important to understand how student learning can be supported. It is, therefore, the purpose of this study to examine how the use of first person narratives related by experts affect student learning while immersed in a problem-based learning environment.

2. Research Questions

This study investigates the effects of expert stories on middle school students' learning of science concepts. Specifically, the study asked the following questions: (1) How do expert stories affect students' acquisition of astronomy concepts? and (2) How do expert stories affect students' ability to transfer learning?

3. Design of Study

3.1 Sample

The participants of the study (N = 101) were students enrolled in sixth grade science at a middle school located in a medium-sized city in the southwestern United States. Four intact classes participated in the study. The participants in the study consisted of 73% white, 17% Hispanic American, 7% African American, and 2% Asian American students. The age of the students ranged from 12 - 14 years. There were approximately an equal number of male and female students.

3.2 Treatment

For this research, a hypermedia-supported authentic learning environment (HALE) was developed in the content area of astronomy. The learning goals of the HALE were for students to be able to:

- Plan and implement procedures for solving complex problems
- Identify relevant information needed in solving a complex problem
- Identify the characteristics of objects in our solar system

- Describe components that comprise probes used for astronomical research
- Rationalize the design of a probe in regards to it's intended mission
- Analyze data and draw conclusions from astronomical data

Two versions of the HALE were developed corresponding to the two treatment conditions: stories and non-stories. All versions of the program contain the same content and tools differing only in the implementation of the information provided by the expert tool. The *Stories* version has an expert tool containing short first person narratives (video) related by an expert. The *Non-stories* version provides the same content as the *Stories* version, except the expert relates factual information with no story elements.

3.3 Dependent Measures

Of primary interest in this study is how expert stories affect student learning. Therefore, measures of knowledge recall and transfer were administered. In addition to knowledge recall and transfer measures, interviews were conducted with the participants and the classroom teacher. The triangulation of the quantitative and qualitative data sources will help to answer the research questions with richer and more detailed information.

3.3.1 Recall Measure

The recall measure evaluated the amount of declarative knowledge students have concerning the astronomy concepts being taught in the study. The measure consists of multiple choice and fill-in-the-blank items. A panel of reviewers were asked to verify the validity of the measure. Items were revised until agreement was reached. The recall instrument was administered as a pretest, posttest, and retention measure. Due to the factual and objective nature of the measure, it was scored by the principal investigator. The recall measure was used to gauge the degree to which students acquire an understanding of astronomy.

3.3.2 Transfer Measures

As noted in the literature review section, students are often unable to apply what they have learned in problem solving situations. The review of literature put forth that this is due to the decontextulization of learning. Therefore, in order to evaluate student learning it is not sufficient to only measure acquisition of concepts. But one must also measure the ability to apply that knowledge in context. Hence, near and far transfer measures have been included in the design of this research.

3.3.2.1 Description of Near Transfer Measure

In order to evaluate to what degree students are able to apply their knowledge in solving problems similar to the one received in the treatment, participants were given a scenario in textual form describing a problem similar to the one received during the study. The near transfer measure was given as a posttest and used to provide information on the effects of the expert stories on student learning. After reading the problem scenario, participants were asked to provide the following information:

1. Hypothesis of a solution to the problem.
2. Rationale for hypothesis which includes supporting information learned while using the environment.
3. Indication of other information that would need to be gathered to support the answer.
4. Description of which scientific tools could be used to gather information to test the hypothesis.

3.3.2.2 Description of Far Transfer Measure

In order to evaluate to what degree students are able to apply their knowledge in solving problems that they have not encountered before, students were asked to solve a problem unlike those encountered during the treatment. The far transfer measure was given as a posttest and used to gauge the degree to which students are able to apply what they have learned to a novel situation. After reading the problem scenario, participants were asked to provide the following information:

1. Hypothesis of a solution to the problem.
2. Rationale for hypothesis which includes supporting information learned while using the learning environment.
3. Indication of other information that would need to be gathered to test/support the hypothesis.
4. Description of which scientific tools could be used to gather information to test/support the hypothesis

3.3.2.3 Scoring of Near and Far Transfer Measures

Since scoring the near and far transfer measures is subjective in nature, responses from the near and far transfer measures were evaluated by three trained graders who will be blind to the subjects' treatment conditions. Due to the large number of responses to evaluate, the responses will be randomly divided between the three graders. In order to ensure interrater reliability, each grader was given an additional 20% of the essays from each of the other two graders. These additional essays were randomly selected, scored, and compared with the scores from all graders. Each essay was scored in the following manner:

1. A score from 0 to 15 was given for the essay on the following criteria: (a) Quality/plausibility of the hypothesis and supporting rationale, (b) Level of incorporation of details and facts in the essay, (c) Thoroughness of analysis of needed information to support answer, (d) Number of tools cited and the appropriate use of them, (e) overall originality of ideas, (f) overall quality of the essay.
2. Scores from each of the criteria were collapsed into one overall score for the response.

3.4 Procedures

Four intact classes were randomly assigned to either the *Stories* condition or the *Non-stories* condition resulting in two classes in each. Because the treatment was included as a part of the regular science class, complete random assignment was not possible in this case. The assignment resulted in 49 students in the *Stories* condition and 52 students in the *Non-stories* condition. Within each class, students worked in heterogeneous groups of 3-4 students created by the classroom teacher. Students were presented with information about the nature of the learning environment. They were informed that at the end of the activity they would be asked for input concerning the aspects of the environment they found useful and those they did not. Prior to treatment, students were asked to complete the recall measure. After all groups had completed the activity, participants were asked to complete the recall measure, near transfer measure, and far transfer measure. Three weeks after the completion of the study, the recall measure was administered once again to all of the participants to collect retention data.

4. Analysis, Results and Discussion

In order to examine the effects of expert stories on students' declarative knowledge (research question one), a simple ANOVA with repeated measure was conducted using the data collection points pre, post, and retention on the factual knowledge measure with the treatment conditions as factors. The results show there was no significant effect for data collection point on achievement from pre-treatment to post-treatment to retention when considering the interaction between the treatment condition and the measure: $F(2,94) = 1.34$, $p = .266$ (STORY MEAN $_{pre}$ = 6.96; STORY MEAN $_{post}$ = 8.22; STORY MEAN $_{retention}$ = 7.87; NON-STORY MEAN $_{pre}$ = 5.96; NON-STORY MEAN $_{post}$ = 7.27; NON-STORY MEAN $_{retention}$ = 8.12). That is, students who received expert stories performed similarly to students who received expert non-stories on the measure of factual knowledge.

The unexpected lack of a significant difference between the story and non-story treatment conditions may be attributed to a number of factors. The HALE used for this research had many features to support student learning. The only apparent variation between the two treatment conditions was that the story treatment received expert support in the form of stories while the non-story condition received the same information, but in a format that was not a story. Since the environment was designed with many features to support authentic context and activity, the additional support provided by expert stories may not have been strong enough to make a difference in student's declarative knowledge. Especially since both treatments conditions received the support "just-in-time". In other words, other features in the learning environment may have supported students in the non-story condition. Similarly, stories and non-stories provide the same factual information differing only in the presentation. Therefore, acquisition of factual knowledge may not have been influenced since the factual content was equivalent in the two treatment conditions.

In order to measure the effects of expert stories on near transfer (research question two), a simple ANOVA was calculated with story/non-story conditions as a between-subjects independent variable and the near transfer measure as the dependent variable (post-treatment only). The results indicate there was a significant difference between the treatment groups: $F(1,52) = 6.37$, $p = .015$ ($MEAN_{story} = 10.6$; $MEAN_{non\text{-}story} = 6.9$). That is to say, students who received the expert stories performed significantly better in solving a near transfer problem than students which received non-stories. In order to explore the effects of the expert stories on far transfer (research question two), a simple ANOVA was calculated with story/non-story conditions as a between-subjects independent variable and the far transfer measure as the dependent variable. The results show a significant difference between the story and non-story treatments: $F(1,52) = 4.6$, $p = .037$ ($MEAN_{story} = 7.8$; $MEAN_{non\text{-}story} = 6.1$). In other words, students who received the expert stories performed significantly better in solving a far transfer problem than students who received non-stories.

These findings support the hypothesized benefits of situated cognition in a number of respects. Recall that situated cognition argues that it is essential that learning occur in an authentic context, that students engage in authentic activities, and that students learn about the culture of the knowledge domain (Brown, Collins, Duguid 1989) (Choi & Hannafin 1995) (McLellan 1993). The ability of students to solve complex problems is often cited as one of the most important goals of education. However, traditional methods of teaching often fall short of this elusive goal. Students frequently have difficulty solving such problems and often need support. This research hypothesized that expert stories might help scaffold student problem solving. Data collected for this research indicate that students who received expert stories did significantly better on solving near and far transfer problems than students who received the same information but not in story form.

It can be argued that stories can help provide a meaningful context for student learning through the rich detail included in them. Stories are also capable of illustrating knowledge in context, hence making learning more meaningful. It appears that the authentic context supported by expert stories can facilitate students' ability to transfer learning to new situations. Research by the Cognition and Technology Group (Cognition and Technology Group at Vanderbilt 1992) supports this finding that providing an interesting relevant context for problem solving can facilitate transfer to new problem solving situations. Other implementations of learning environments which emphasize the importance of providing a rich context for problem solving such as Schank's goal-based scenarios (Schank & Edelson 1990) and Spiro's cognitive-flexibility hypertexts (Spiro & Jehng 1990) (Jacobson & Spiro 1995) further support this finding.

Stories can also support student engagement in authentic activities. Scientists often share information in the form of stories. The listening to stories is itself an authentic activity. Mentors often share stories with apprentices in order to illustrate some point. Both theory and practice can be shown by the use of expert stories (Danzig 1997). Hence, the stories help students engage in authentic activities thereby facilitating better performance on problem solving. Research on anchored instruction and problem-based learning support this finding that engaging in authentic activities can facilitate transfer of learning to new problem solving situations (Cognition and Technology Group at Vanderbilt 1992).

4. Conclusions

As problem-based learning becomes more popular, instructional designers must find new ways to utilize technology in order to support problem-based learning. For this research an innovative problem-based learning environment was created which provided the context for learning and authentic activities for students to engage. Just as a mentor provides stories to an apprentice while working in context, this software attempted to provide stories to students as they were working. Constructivism and situated cognition provide a useful framework for realizing that it is not enough to rely on the affordances of media, but that the media must be utilized to facilitate the engagement of students in meaningful activities. In order to make learning meaningful, students should be placed in learning situations which allow them to engage in the same types of activities experts would in a context that is rich and interesting. Hypermedia-supported authentic learning environments (HALE) can be designed to accomplish this goal. HALEs bring together the valuable elements of hypermedia (i.e. audio, video, animation, non-linear access to information) and problem-based learning environments (authentic context and authentic activities) to create rich contexts for learning.

The confluence of hypermedia technology, constructivism, situated cognition, and problem-based learning provide an opportunity for instructional designers to create authentic learning environments. Hypermedia-supported authentic learning environments can extend beyond the school walls by providing a series of authentic experiences which can direct students along the path of life-long learning (Dewey 1938).

Combining Social Networks and Collaborative Learning in Distributed Organizations

Hiroaki OGATA and Yoneo YANO
Department of Information Science and Intelligent Systems
Faculty of Engineering, Tokushima University, Japan
E-mail: {ogata, yano}@is.tokushima-u.ac.jp
URL: http://www-yano.is.tokushima-u.ac.jp/ogata/

Abstract: The exploration of social networks is essential to find capable collaborators who can help problem-solving and to augment cooperation between users. This paper describes PeCo-Mediator-II for seeking for a collaborator with the chain of personal connections (PeCo) in distributed organizations. Moreover, this system helps gathering, exploring, and visualizing social networks. The experimental results show that the system facilitates that learners encounter collaborators and develop a new helpful relationship beyond the classroom.

Introduction

Recently, opportunities for communication and collaboration via computer networks have immensely been increased in networked organizations (Sproull and Kiesler, 1991). A fundamental problem is how to encounter people who can help problem-solving. We are focusing on the problem of discovering such people through social networks. Social networks are at least as important as the official organizational structures for tasks ranging from immediate, local problem solving (e.g., fixing a piece of equipment), to primary work functions, such as creating collaborative groups (Kautz et al., 1997).

In CSCW (Computer Supported Cooperative Work), researchers are interested in the role of social networks between organizational members. Clement stated that users developed informal collaborative networks to know how to use a new software (Clement, 1990). Then, private networks are important for workers to solve problems by providing helpful information. A number of studies have shown that one of the most effective channels for gathering information and expertise within on an organization is its informal networks of collaborators, colleagues and friends. The networks of helping relationships are called "*Help Network*"(Eveland et al., 1994). However, the networks are not collected and generally follow work group alignments rather than technical specialization. Therefore, it is significant to use members' interpersonal connections effectively in their activities.

In CSCL (Computer Supported Collaborative Learning), one common component of collaborative learning is the "*informal peer-help networks*". This notion is compatible with Wenger's communities of learners (Wenger, 1996), where people who share learning goals within an authentic learning environment can develop ties that reinforce learning outcomes. From this viewpoint, Greer et al. (1998) proposed PHelpS (Peer Help System) that supports workers as they perform their tasks, offers assistance in finding peer helpers when required, and mediates communication on task-related topics. On the other hand, our approach focuses on how a system can support both storing and exploring "*Personal Connection*" (***PeCo***) in a collaborative learning environment.

W propose PeCo-Mediator-II (Ogata et al., 1996a; Ogata et al., 1998) for gathering, seeking, and visualizing social networks in a networked organization. PeCo-Mediator-II is a distributed system with a personal database (PeCo-Collector) and a software agent (PeCo-Agent). Every user has the two softwares on the respective site. PeCo-Collector incrementally gathers information on its user's acquaintances and the relationships through watching the exchanges of e-mail. PeCo-Agent moves to colleagues' sites and negotiates with other agents and users to find collaborators. Although the users of both NetNews and e-mail lists are passive to find answers, our system can actively discover collaborators with the chain of personal connection from the user and the collaborators.

Overview of PeCo-Mediator-II

Our initial system called PeCo-Mediator (Ogata et al., 1995) is a groupware that allows sharing of PeCo in a group and to search for connections between the user and targets. The users need to share PeCo with the common database of PeCo-Mediator. Although the system was very available in some small groups, it was reluctant in terms of users offering their private information like PeCo into the common database. Also, it is hard for the users to entry personal data of their friends.

When a computer network connects people or organizations, it is a social network. Just as a computer network is a set of machines connected by a set of cables, a social network is a set of people connected by a set of social relationships, such as friendship, co-working, or information exchange (Garton et al., 1997). Computer Mediated Communication (CMC) systems also reduce the transaction costs of initiating and maintaining interpersonal ties (Pickering and King, 1992). Weak ties created by CMC expand the channels of information sources for the individual and have potential for strong ties.

PeCo-Mediator-II is combined PeCo-Mediator and on-line social networks. It consists of the two systems; PeCo-Collector and PeCo-Agent (see Figure 1). Every organizational member has the two softwares on the respective site. PeCo-Collector gathers information on its user's acquaintances and the relationships through watching the exchanges of e-mail. PeCo-Agent moves between members' sites to find a partner in the community. The user's PeCo is a starting point for the exploration. The user's acquaintance acts as a liaison between the user and the partner in this situation. In this figure, user X requests user Y to help the problem solving, and user Y introduces user Z. After that, user Z can help user X by request.

The characteristics of this system are:

1) Accumulation of on-line and off-line social networks: Mainly, our system deals with PeCo based on the exchange of e-mail. PeCo-Mediator-II automatically stores relationships based on e-mail tags (Ogata et al., 1996). In addition, the user can provide on-line relationships; e.g., based on the exchange of name-cards.
2) Measurement of PeCo strength: The strength of PeCo is estimated with the frequency of e-mail exchange. This degree is very useful for deciding the receivers of the request (Ogata et al., 1996).
3) Privacy protection: PeCo-Mediator-II manages individual ties with a distributed personal database in the user's own site. Personal data is safer in a personal database than in a common database. Therefore, it is easy for this system to protect user's privacy and to be accepted in a large-scale organization.
4) Compatibility: The architecture of PeCo-Mediator-II is compatible with existing e-mail mechanisms. Compatibility reduces user overhead in taking advantage of the e-mail tools.
5) Scalability: Even if the number of users increase, this system can work robustly because of an agent based distributed system architecture.
6) Parallel exploration assisted by agents: PeCo-Agent supports the user to search for a collaborator through social networks while negotiating with other users and PeCo-Agents. Moreover, the user can visually understand the current status of the exploration and easily control that process.
7) Mitigation of collaborators' overload: The questions are possibly concentrated on a part of users (experts). This system provides a common database of answers and navigates the questions with strategies on educating the secondary collaborators and on spreading the answers.

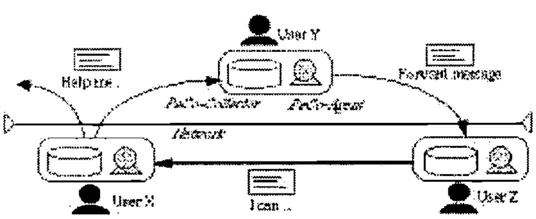

Figure 1. Overview of PeCo-Mediator-II.

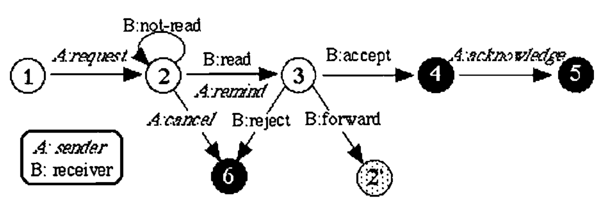

Figure 2. Data diagram of exploring social networks.

Exploration Model of Social Networks

PeCo Exploration Diagram

Figure 2 shows the data diagram of exploring social networks. User A is a sender of e-mail and user B is its receiver. Each node denotes the state during the exploration, and it moves to the next state if the user acts on the activity of the arc. The starting point is the state one and the ending point is the state four, five and six. The state 2' shows the exploration is continued from the state 2 after changing the receiver. The sender has three options: request, cancel and remind. The receiver has five options: read, not-read, accept, forward, and reject. For example, if user A sends a request to user B, the receiver either reads it or does not read it. If user B does not read it, user A may remind user B to read it. If user B reads it, s/he either accepts the request, rejects it, or forwards it to his/her friends. Until someone accepts the request or user A cancels it, the exploration of social networks is continued. Finally, user A acknowledges to user B.

Table 1. Taxonomy of users with the exploration history.

User type	Condition
Collaborator	*accept* > α and *accept* > *reject* and *accept* > *forward* and *accept* > *request*
Mediator	*forward* > α and *forward* > *reject* and *forward* > *accept*
Requestor	*reqeust* > α and *request* > *accept* and *request* > *forward*
Non-collaborator	*reject* > α and *reject* > *accept* and *reject* > *forward*
Semi-collaborator	*receive_accept* > α and *receive_accept* > *accept*

(Italic word shows the number of the action. α is a constant given by the user.)

Taxonomy of Users

Based on the above history, we divide users into the five types (see table 1):

1) Collaborator: The collaborator is a user who usually accepts the request during this system use. The collaborator is often an expert about the request.
2) Semi-collaborator: The semi-collaborator is a user who potentially has the capability for cooperation about the request. We assume that a semi-collaborator receives the answer from others rather than accepting requests.
3) Mediator: The Mediator is the user who usually forwards the request to his/her friends.
4) Requestor: The requestor is a user who asks a question and s/he becomes a stating point of exploration of social networks.
5) Non-collaborator: The non-collaborator is a user who almost rejects the request.
6) Unknown user: If a user has never received or sent a request, the user is unknown for the system.

PeCo-Agent understands the users' capability through watching the exchanges of questions and answers. We represent the capability of the user and his/her acquaintances with the keywords in the e-mail. For example, a friend is a collaborator about C programming language although the friend is a non-collaborator about Tcl/Tk.

Supporting PeCo Exploration with History

PeCo-Agent helps a user in the following situation:

1) Request support: When the user decides a receiver of the request, this system shows the user the following information about the receiver:
   a) User's type (a collaborator, semi-collaborator, mediator, requestor, non-collaborator, or unknown user): If the receiver is a collaborator, the user may find the answer easily.
   b) Strength of relationship: If the connection between the user and the receiver is strong, it is easy to ask for cooperation.
   c) The number of requests left unattended: If the receiver has many requests, his/her answer may be late.
   d) System usage: If the receiver uses this system at that time, the user can obtain the response as soon as possible.
2) Acceptance support: If the user accepts a request, the system provides the reply of the request to the user. The user edits the past results to answer it.
3) Forward support: PeCo-Agent shows the user the possible acquaintances that can help the user with the results of the past exploration. If the user has a friend who is a collaborator, semi-collaborator or mediator, PeCo-Agent recommends them as the receiver.
4) Reject support: PeCo-Agent automatically rejects the request, if the relationship strength between the user and the request sender is lower than the given value by the user.

Reducing the overload of collaborators

Collaborators are often burdened with the requests from others. To mitigate that, we propose educating semi-collaborators in this system. If semi-collaborators are educated and reach a level of collaborators, the number of collaborators increases. Therefore, PeCo-Agent recommends a collaborator to send the request to semi-collaborators and reduces the overload of collaborators. The collaborator sends the answer to the requester after checking and correcting the answer from the semi-collaborators. Next time, PeCo-Agent recommends that the requester sends the request directly to the semi-collaborator. After that, the semi-collaborator becomes a new collaborator and the requester becomes a new semi-collaborator. Moreover, the free rider issue (Salomon, 1992), which is a user who obtains information without giving any, might be settled also.

Implementation

System Configuration

We developed a prototype system on a workstation with Tcl/Tk (Ousterhoult, 1994).

(1) PeCo-Collector: This system has two components: data management and E-mail handler. All the data is managed by TRIAS (Triple Associative System) and the e-mail tool is TkMH based on MH (Peek, 1994).

(2) PeCo-Agent: The characteristics of PeCo-Agent are:

1) To represent capability of users with keywords about e-mails;
2) To obtain the capability of users from the user and other agent;
3) To move around the Internet and communicate with other users and agents;
4) To find the candidates of partners concurrently.

In PeCo-Mediator-II, a user communicates and negotiates with others through e-mail. In the same way, PeCo-Agent communicates with other agents with structured e-mail (Malone, 1986). Keywords are extracted with Chasen (Matsumoto, 1997) that is a Japanese morphological analysis tool. PeCo-Agent calculates the similarity between the given question and the stored questions by matching nouns elicited from Chasen filter.

Interface

Figure 3 shows the interaction after "aiso" asks a question to his PeCo-Agent. In the window (A) "aiso" writes the request message. In the window (B), the user sets time out for seeking social networks, the minimum strength of PeCo and the maximum steps between "aiso" and the receiver. PeCo-Agent finishes the exploration according to this setting. In the window (C), PeCo-Agent assists "aiso" to decide who is the better receiver of his acquaintances and the user agent provides information about the candidates of the receivers. The window (D) displays the list of the requests that the user has sent. The window (E) shows the flow of the exploration from he user graphically. This tree is the result of traveling with the connections of "aiso". The icons except "aiso" denote the candidates of partners. The shorter the distance between two icons, the stronger the relationship they have. While the dotted line denotes the receiver has not read the message yet, the solid line shows the receiver has already read it. The black icon means the user has rejected the request. The node icon shows the user has forwarded the message to his/her friends. The leaf and white icon means the user has accepted the cooperation. In this figure, "mendori" refused aiso's request, and "ogata", "abe", and "kawasaki" agreed to his request. "akagi" has not read the message yet. If the user reminds the reply to the request from this window, PeCo-Agent of "akagi" tells him to read the message. From this result, "aiso" is the most familiar to "goji" and can easily access the collaborator "ogata" through the mediation of "goji".

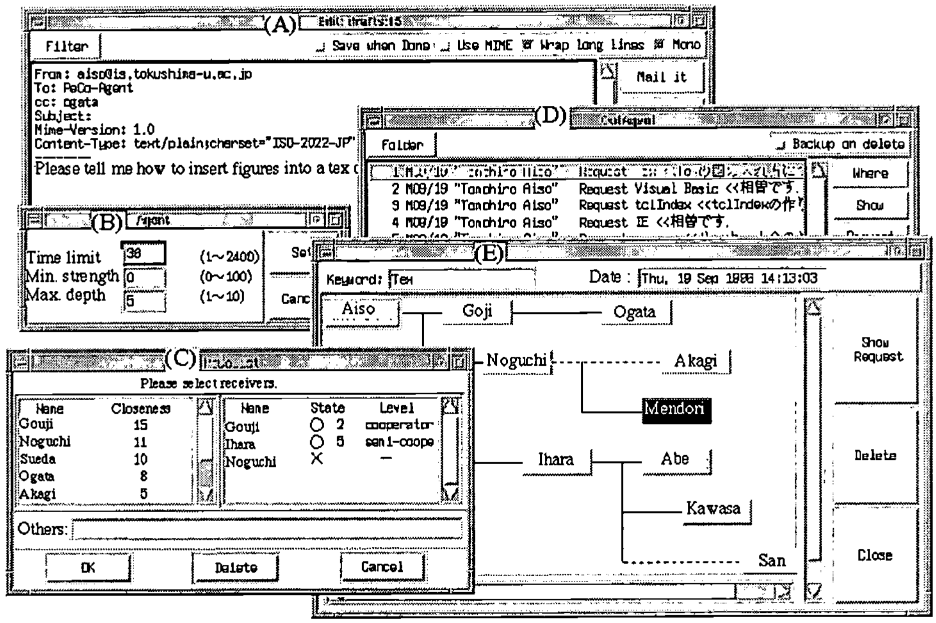

Figure 3: Screen shot of PeCo exploration with PeCo-Mediator-II.

Experimental Use

Users and Tasks

In this experiment, we arranged 13 master course students (group A) and 94 undergraduate students (group B) who had no relationship with the members of group A at the first stage of the experiment. Only one person, teacher VI, knows all the members of group A and B. They used the prototype system during nine weeks in a class of programming language C. We divided nine weeks into three terms. Teacher VI gave group B some homework every week, for example, making a program of data sorting.

Term 1: In the first three weeks, the system gathered their usual ties. Each group member communicated among the internal group members without the contact of the other group.

Term 2: We allowed group A and B to communicate and collaborate with each other to solve problems. The users solved the given problems through this system without supporting PeCo exploration with history.

Term 3: In this period, we evaluated the function for supporting PeCo exploration with the history that was stored in the term 2.

Experimental Results

Figure 4 shows the social networks between the users after six weeks from the beginning of this experiment. While the user of group A is indicated by a circle, the user of group B is shown by a square. The thick arrows denote the requested messages from the sender to the receiver. The thin arrows represent the forwarded messages over one time. The weight of the arrow shows how many times e-mail was exchanged from the sender to the receiver. The user VI was a central person and acted as a liaison between group A and B. As shown in this figure, group A and B learned to communicate with each other through the introduction of user VI, although they did not have connections beyond the group. Moreover, most of the requests from group B concentrated on user VI and III, and the collaborators were almost fixed at six persons of group A. In this case, there was no collaborator in group B.

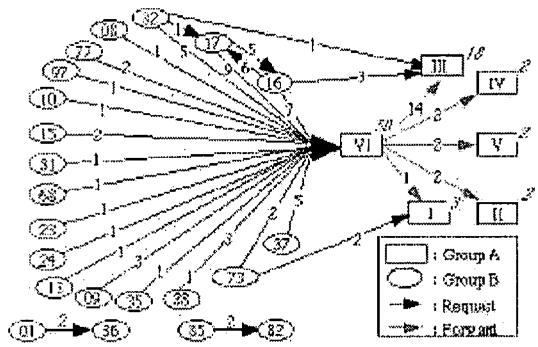

Figure 4. Network forming in the term 2.

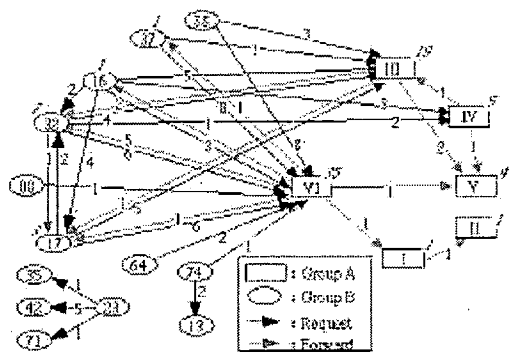

Figure 5. Network forming in the term 3.

In the previous experiment (Ogata et al., 1998), we compared this system with e-mail, mailing list and NetNews during four weeks. This experiment was executed in the same class. Both mailing list and NetNews were not often used for getting answer, because the student hesitated to ask a question. On the other hand, both this system and e-mail were frequently used. In this case, social networks were stable because direct and explicit relationships were used to get collaborative help. Likewise, (Yamakami, 1995) describes the interaction patterns of e-mail and bulletin board are stable from the long-term usage observation.

Figure 5 depicts the message flow in the term 3. Some of group B became collaborators because our system lead the users to reduce the incipient collaborators' load. For example, the system recommended user VI to forward the request from user 32 to user 17 who was a semi-collaborator. After that, user 32 directly requested user 17 to cooperate with problem solving.

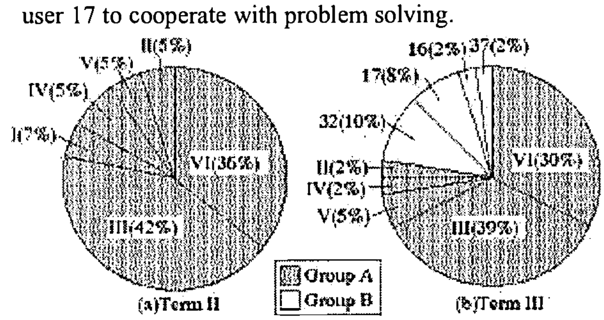

Figure 6. Rate of collaborators in the term 3.

Figure 6 shows the comparison of the collaborators in the term 2 and 3. In term 2, the user VI and II accounted for 78% of all collaborators, and there was no collaborator in group B. In term 3, the cooperation rate of the user VI and III decreased 69% and some of group B became collaborators. This experimental result seems to show that the facility of this system is available to prevent the collaborators from being fixed and to facilitate mutual cooperation. In the term 3, the users provide their knowledge into the shared repository.

Conclusion

This paper proposed PeCo-Mediator-II as a support to find capable collaborators with the chain of personal connections in a collaborative learning environment. This system helps gathering, seeking, and visualizing social networks of organizational members. PeCo-Mediator-II is an agent-based system to deal with e-mail. This system consists of PeCo-Collector as a personal database and PeCo-Agent as a user's assistant. PeCo-Mediator-II was experimentally tested and evaluated in a C programming language course. The results showed the system could help the user to encounter a collaborator and developed the new relationship with the collaborator.

Abstract: The design, development, implementation, and evaluation of Web-based courseware for teaching and learning are important issues in higher education. However, available evidence suggests evaluation of much courseware is minimal.

This paper reports a meta-analysis of the adoption, usage, and implementation of a generic, customisable, online survey / evaluation software tool—Learning Evaluation Online (LEO). A customisable evaluation tool derived from the need to:

- customise each survey to suit each particular project,
- collect data from widely geographically separated evaluators, and
- decrease the time and expense of data collection and evaluation.

LEO was also designed to be customisable by individuals with minimal computing experience. Templates for basic evaluation question types are provided. The use of LEO was logged by the LEO software engine and our LEO-on-LEO survey. An analysis of the quantitative and qualitative data generated is presented together with recommendations for improving implementation of similar tools.

Introduction

In the recent past, the evaluation of courseware has often occurred when the project is nearing the end of the software development. However, this is changing as the perception of the value of formative evaluation has improved (Barker, 1995; Beattie, 1994). Laurillard (1994, p. 287) suggested that "formative evaluation has a vital role to play in the progress of multimedia because it is the means by which we build up our knowledge of what the medium can do".

Learning Evaluation Online (LEO) was originally developed as a survey / evaluation tool in response to a need for an asynchronous Web-based evaluation mechanism, that could be easily modified to suit a variety of potential respondents (e.g., peers, students, multimedia developers, interface designers, etc.), and courseware from various content domains. We also wanted to decrease the time and expense of data collection and evaluation. Other systems have been reported (Recker & Greenwood, 1997). However these systems lacked the ability to be used easily by non-programmers. A system such as LEO had the potential to make evaluation of courseware less problematic—in terms of programming, deployment, and adaptation for a range of evaluation or survey needs.

The LEO software environment is a template using the first author's OXYGEN (Object eXtensible analYsis and Generation of Education coNtent) software engine. The authoring capability of the OXYGEN software engine is extremely flexible, making it very adaptable for a wide variety of potential for uses, and users. Initially, LEO was developed to meet the needs of evaluating interactive Web-based learning tools then under development at

Multimedia Education Unit, at the University of Melbourne (Kennedy & Fritze, 1998; Kennedy, Ip, Eizenberg, & Adams, 1998). LEO has a number of purpose built features that support:

- the creation of the survey objectives as a hyperlink,
- the entry of the purpose of the survey,
- the generation of common demographic details, and
- seven different pre-defined question styles, including Likert scales, true/false items, free text responses and a custom style.

A more complete description of the basic functionality of LEO may be found in (Kennedy & Ip, 1998).

A Generic Survey Tool versus a Specific Measuring Instrument

LEO was designed to meet a specific need—evaluation of Web-based courseware. However, it is a tool, not an instrument. Most published survey or evaluation instruments are in paper form (e.g., the Course Experience Questionnaire (Ramsden, 1991)). An instrument is designed to measure specific parameters and therefore requires validity and reliability studies. Any survey developed with LEO would have to be rigorously analysed and validated to ensure reliability and validity.

However, LEO has been implemented as a generic tool, making little (if any) assumptions about the objective of any particular survey or the information the survey author may be seeking. No specific items have been defined except a limited number relating to the demographic details of the respondents—those too have been customised in response to requests from survey authors. In summary, LEO is a tool that provides:

- ease of question authoring (we believed),
- a simple method of deployment to potential respondents, and
- a mechanism for the survey author to retrieve the data and export it to a statistical package for further analysis.

In this paper, we shall use the term "lecturer" to refer to the survey author. The authors of this paper have used LEO to formatively evaluate two Web-based interactive learning tools (Kennedy & Fritze, 1998; Kennedy *et al.*, 1998). However, the wider use of LEO by academics may also provide insights into the uptake of generic software tools of this type in higher education.

We hypothesised that the value of LEO to the wider academic community would be:

- its ease of authoring,
- customisability by the lecturer,
- short developmental time between authoring and actual delivery of the survey, and
- the return of any data generated in electronic form.

We shall report on these factors in later sections of this paper, Both qualitative and quantitative data was generated by a LEO survey (using LEO, of course) and further quantitative data captured by the usage log of LEO (the actual content of each survey is confidential).

Using LEO

LEO is entirely web-based. The LEO web site (http://www2.meu.unimelb.edu.au/OXYGEN/LEO/), asks potential users to fill in a simple web-based form with the user's name and email address, and proceed to the authoring environment . An email is returned to the lecturer to her or his email address with:

- the assigned survey ID;
- a password, and the name of survey author—required to author the survey and later to collect survey data;
- the uniform resource locator (URL) to which the respondents may be directed;
- a URL for collecting survey data in table form, and
- a URL for collecting survey data in comma delimited form.

In addition to the password generated (provided automatically by the LEO system), one more level of security can be obtained by using a random letter user name.

Authoring a LEO survey or questionnaire

Once the survey author has entered the LEO authoring environment with their password the lecturer may choose to enter the following information:

- a title for the survey,
- a brief introduction to describe the purpose of the survey for potential respondents,
- the objectives of the survey, which will be available to the respondents as a hypertext link,
- the demographic details the lecturer wishes to collect, and
- the first survey item.

After clicking on the *Submit* button, the lecturer will be prompted to provide subsequent items. The question style of each item is chosen from a list. The process continues until the *Finish* button is clicked. In order to facilitate more complex formatting (for authors who require it), all data entry fields are html (hypertext markup language) active. Text with html tags may be entered directly into the data entry fields (e.g., <B>My survey</B> would result in **My survey** in bold). In Figure 1 (Fig. 1) the basic question entry template is shown with a bipolar Likert style question as the selection in the popup menu used to decide the question type.

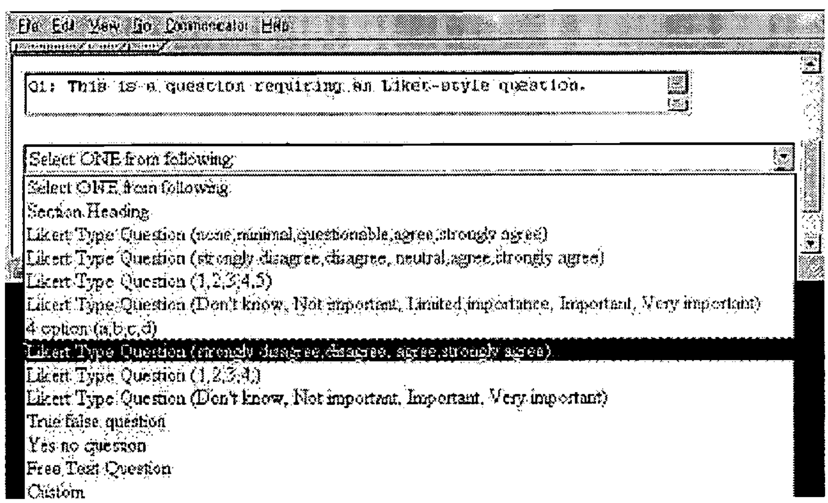

Figure 1: Choosing a question template with LEO

Survey delivery

The LEO system incorporates a database to store the data generated by the survey. Respondents access a LEO survey by clicking on a hypertext link in a web-page. The LEO server creates the survey in a window in the html browser of the respondent. This process enables lecturers to create an online survey without the need for programming skills, knowledge of html, or server management experience. The LEO project web site is currently hosted by the experimental web server at MEU, the University of Melbourne and is available 24 hours 7 days a week, the database being backed up daily at about midnight, Melbourne time.

Results retrieval

The lecturer accesses the results of a survey in the form of a html table or comma delimited text file. The comma delimited text files can be imported to most statistic packages and/or a spreadsheet with minimal difficulty.

LEO on LEO

We have created a LEO survey on our project web site to evaluate the authoring process and the use of the tool. The stated purpose of LEO-on-LEO survey is to, improve the functionality of LEO, determine the uses to which LEO is being put, determine the potential requirements for more pre-defined question styles for survey authors, and improve the performance aspects of LEO (e.g., time for the survey to load to the respondent's browser, or response to a survey submission).

Evaluation of LEO

The data we are able to generate from LEO users are:

- who and how many surveys have been constructed by individual users (from name and email address);
- the number of respondents who complete each survey;
- the time period over which the survey operates;
- the number of surveys that are constructed as part of the learning process of generating a LEO survey;
- the lead time between survey creation and data collection; and
- feedback from the LEO-on-LEO survey.

From the usage log, we found that between March, 1998 and October, 1998, LEO has collected 20780 data points from 599 respondents with the 235 potential surveys created. However this data includes the demonstration surveys we did for academics, and some test surveys generated during minor modifications of the functionality of LEO. In fact, the first author has created 56 surveys and only two are in real use. The second author has created 43 surveys with 4 in actual use. One of the 235 surveys is the LEO on LEO survey mentioned above.

The log shows that there were 75 users other than the authors. From the email addresses supplied, there are 3 users from outside Australia. Demonstrations of LEO in the United Kingdom, Sweden and Germany during 1998 on computers with Macintosh and PC operating systems did not result in any significant time delays in comparison to surveys developed and deployed locally. Of the 75 individuals who investigated LEO, 26 individuals created two or more surveys (excluding the authors of this paper). In our experience most people accessing the LEO site did so to have a brief look at the tool. At the time of writing, only one lecturer (beside the authors) has produced more than one survey for active use.

The time between the creation of the survey and the first use of the survey varied from 2 minutes to 63 days. Generally, the longer the time delay, the more likely the survey was intended to be used for genuine data collection.

Out of the 235 potential surveys, only 30 surveys have more than 2 respondents. Table 1 shows the distribution of respondents to the number of surveys that have that number of respondents. This data suggests that academics are interested in a LEO-like tool. However, in many cases they were not yet in the position to use LEO. Typically, developing online courseware requires a significant lead time and many academics indicated they would be using LEO in the future, once the courseware had been developed. Indicative of the process of creating an active survey are the surveys with the larger response rates (58, 63, and 112 respondents). These surveys required 2, 7, and 3 attempts respectively. Some of the surveys are still generating data (Feb. 1999). The lecturer who required 7 attempts customised the survey substantially using the html facility of the LEO template.

This data confirms that LEO is easy to learn using the templates provided, but customising any particular survey (using html) will require a greater investment in time. From initial data we estimate the learning curve to be about 3 to 5 attempts in order to get a survey into a format satisfactory to the lecturer. We have no evidence to indicate which is the limiting factor—authoring using the LEO templates, or constructing the survey.

Respondents	Surveys	Remarks
2	5	Most likely, these are test surveys.

52	2	
58	1	
63	1	
112	1	An survey in the medical faculty (by the second author)

Table 1: Number of respondents and survey numbers

Informal discussions and feedback from the LEO on LEO survey have indicated that few survey authors access the FAQs in order to find out the best way to approach the task. Most seem to prefer to try it and see. From our LEO on LEO survey, one lecturer commented that she was:

> Rather fussy about layout and (the lecturer) wanted the survey to look as good as a paper one would be.

The lead time (the time of first registering for a survey and the time the first response was collected) ranges from 8 minutes to 147 days. Generally, surveys with a short lead time (in the order of minutes) are test surveys. The 147-day lead time survey was later identified (by the course advisor) to be a well planned formative evaluation for a new web-based course at The University of Melbourne.

The LEO on LEO survey only generated 7 respondents (a disappointing result—not unlike the problems with paper-based evaluations, not all potential respondents complete the survey). Two respondents used LEO for formative evaluation, one for a questionnaire to obtain contributions from students and teachers to facilitate the construction of a resource database, two for formative and summative evaluation, one for evaluation of student use of a new anatomy CD-ROM and one as end-of-course evaluation. Comments supporting LEO and the LEO authoring interface included the simplicity of the authoring interface, ease and speed of deployment of the survey, and ease with which surveys for a range of potential respondents may be constructed. Actual comments from the LEO on LEO survey include:

> That it is Web deliverable, relatively easy to use once you've got the hang of it and quick. I could never have got a paper survey out in such a short time.
>
> Once you know how to use it, putting a survey online is so quick.
>
> It's easy for a non-computer person to handle.

The lecturers identified the following weaknesses of the current implementation, including:

- a need of more Likert tags (the descriptors used to discriminate the level of response);
- limited editing capability of items of the survey once submitted
- no choice of background graphics at present; and
- the need to manually modify the data collected before exporting to a spreadsheet.

Future Directions

In seven months of operation, LEO collected over 20,000 pieces of data for 75 users from a range of different surveys. It has been extremely reliable. We estimate that LEO has saved over 100 hours of transcription time, postage, and maybe a tree. Lecturers recognise the value of access to a tool such as LEO and we expect many more users next semester, once the online courseware currently under development are in use. There are a number of areas in which the current iteration will be improved. We are working in the following areas:

- more templates variations to cater to broader needs,
- more secure means of delivering the survey,
- faster response from the underlying OXYGEN engine,
- exporting the survey data into Excel spreadsheet with built-in frequency counts, barchart generation and cross-tabulation for preliminary data analysis (almost complete at the time of writing).

The experience with LEO provides evidence that designing online tools that are generic rather than prescribed, customisable rather than fixed, and easily adapted by non-programmers, overcomes some of the issues of the 'not invented here syndrome' prevalent in much software use (Australian Vice Chancellors' Committee, 1996). One of the most satisfying outcomes our evaluation of LEO has been the discovery that lecturers are using the tool in ways we didn't imagine.

Abstract: This paper describes the transformation of a multimedia program, designed to teach research skills to business students, from one based on an 'instructivist' model to one underpinned with a constructivist philosophy. The revised program uses the theory of situated learning as a framework for the instructional design, and introduces elements such as authentic context, an authentic activity, collaboration, and opportunities for articulation and reflection, into the learning environment.

Introduction

Over the past decade or more, there has been a substantial theoretical shift from a 'behavioral to cognitive to constructivist' learning perspectives amongst educators (Ertmer & Newby, 1993, p. 50; Jonassen, 1991; von Glasersfeld, 1995). Little credence is now given to learning theories that propose that learning is no more than the transmission of a body of knowledge from teacher to student. No matter how much teaching methods in the classroom have changed, the theoretical foundations of interactive multimedia programs are frequently found to be based on behavioral traditions inherited from educational technology. As Jonassen puts it: 'The roots of behaviorism extend deeply into IST [instructional systems technology] practice' (Jonassen, 1991, p. 6). It is possible, even today, to find many examples of multimedia learning environments which use the same instructional design as the early programmed instruction texts of the 50s.

It is one such multimedia program which we describe in this paper—a program firmly in the behaviourist mould, which attempted to take the subject of research methodology and transmit that knowledge in a linear fashion through eight modules and 26 lessons. The program was based on a pedagogical philosophy described by Reeves and others (Reeves, 1993; Duffy and Jonassen, 1991) as 'instructivist' where little emphasis is placed on the learner 'who is the passive recipient of instruction' (Reeves, 1993, p. 4). The program had been under construction for about two years, and had already swallowed up a substantial amount of funding. The Faculty was committed to the program's completion. But we both envisaged a far better way to create a learning environment to teach research methodology. We planned to design a constructivist shell to provide a meaning to the lessons that comprised the original program.

Some educators, such as Squires (1996) have spoken of programs designed from a constructivist philosophy being used in very non-constructivist settings. Young, Nastasi and Braunhardt (1996) relate their experience of implementing 'a constructivist design in a constructivist manner' (p. 121). Clearly, the software itself is but one aspect of an interrelating group of influences which may determine whether learning is successful. Our plan was to incorporate a 'non-constructivist design' into a learning environment based upon a constructivist philosophy.

An Instructivist Learning Tool

The original program comprised a multimedia package for teaching statistics and research methods in a business degree, traditionally taught by lectures and tutorials. As in many similar courses, mastering the theory took most of the time, leaving little room to explain its application and the practicalities of using it in business. A first attempt to improve the course recognized the power of multimedia to present technical material in a self-paced format (Figure 1), using multiple choice or other closed format exercises to help students test their understanding at each stage. This approach was based on the typical transmission model of learning, made interesting with multimedia features like graphics, animations, and interactive exercises. However, unlike a lecture, students could also repeat sections of the course until the concepts were mastered.

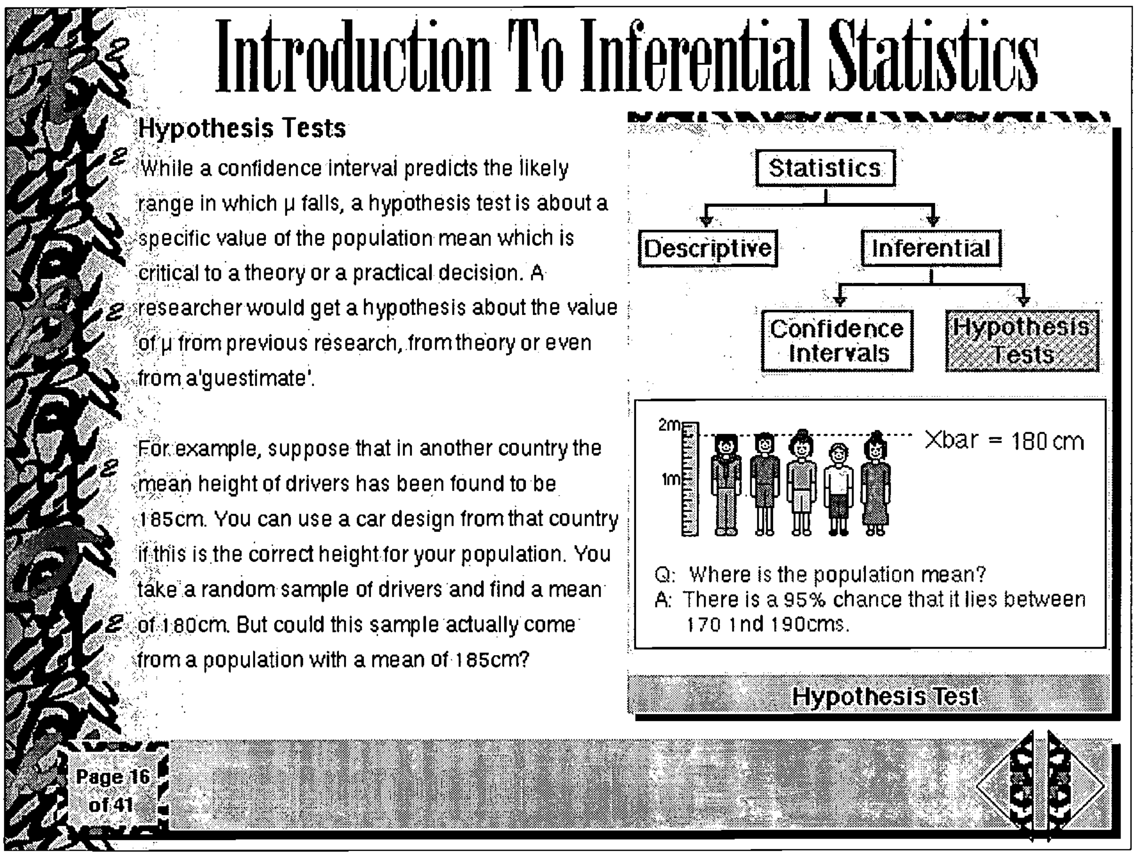

Figure 1: Instruction screen

The resulting 'electronic textbook' had some advantages over traditional lectures and tutorials, but pilot testing showed it did not really solve a major problem of the course: that the technical material was boring when studied in isolation from its application. Students lacking work experience could not make the connection, and business students are renown for their resistance to teaching that is not apparently relevant. The attractions of self-pacing, constant feedback and animations were acknowledged, but the trial revealed no improvement in students' motivation to work through the many steps needed to understand the material. In hindsight, self-pacing and constant feedback can be seen as *reducing* the quality of teaching: students could not turn off when the material was difficult, nor use their considerable skills at answering tutorial questions with very partial knowledge. A solution designed to increase learner control worked on one level, but had the reverse effect on another and was actually judged worse or no better than traditional methods. The following sections describe the philosophy we adopted and how we designed a more constructivist learning environment to incorporate this original program.

Situated Learning

In designing our 'constructivist shell', we wanted to provide a real-life context and meaning to the learning that the students were required to do as they worked with the program. In so doing, we drew heavily on situated learning theory (Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991; McLellan, 1996) which emphasises the notion that the learning process cannot be divorced from the context of the problem, and that the learner will use information and clues from the situation rather than apply formally taught problem-solving techniques. Resnick (1987) contends that school and university learning is fundamentally different to everyday, practical learning in that it provides too little engagement with genuine situations, and too much emphasis on theoretical perspectives. Above all, we wanted the learning environment to more closely resemble the way learning occurs in real life than it does in formal school and university settings.

From the literature on situated learning, it was possible to produce a list of nine critical criteria (Herrington & Oliver, 1995) that could be used to guide the design and development of the interactive multimedia which was to comprise the constructivist shell. The program needed to provide:

1. *Authentic context that reflects the way the knowledge will be used in real life*

The program needed to be able to encompass a physical environment which reflected the way the knowledge would ultimately be used, and a large number of resources to enable sustained examination from a number of different perspectives (Brown et al., 1989; Honebein, Duffy, & Fishman, 1993). The context chosen was a large research company, with all its resources and infrastructure, where the students gain temporary employment.

2. *Authentic activities*

The learning environment needed to provide ill-defined activities that have real-world relevance, and which present a single complex task to be completed over a sustained period of time (Bransford, Vye, Kinzer, & Risko, 1990; Brown et al., 1989). The authentic activities in the program include three research 'jobs' on the students' desk when they start work, each of which require 2-4 weeks of a semester to complete.

3. *Access to expert performances and the modelling of processes*

In order for the learning environment to provide expert performances, the program needed to provide access to expert thinking and the modelling of processes (Brown et al., 1989; Collins, Brown, & Newman, 1989; Lave & Wenger, 1991). The program provides examples of completed research projects to enable students to examine professional research reports.

4. *Multiple roles and perspectives*

In order for students to be able to investigate the learning environment from more than a single perspective, the program needed to provide different perspectives on the topics from various points of view (Collins et al., 1989; Honebein et al., 1993; Spiro, Feltovich, Jacobson, & Coulson, 1991). In each of the research scenarios, the students need to interview a number of different employees within organisations to obtain information, and to consult a variety of other resources.

5. *Reflection*

In order to provide opportunities for students to reflect on their learning, the program needed to provide both an authentic context and non-linear navigation to enable them to return to any element of the program (Boud, Keogh, & Walker, 1985; Collins & Brown, 1988; Kemmis, 1985). Unlike the original research methodology program, which followed a linear form, the new shell enabled students to navigate at will within the resource.

6. *Collaborative construction of knowledge*

The learning environment needed to provide the opportunity for students to collaborate, and while this could not be incorporated within the software itself, it is recommended that students work on the program in small groups to enable them to problem-solve together (Brown et al., 1989; Collins et al., 1989; Hooper, 1992).

7. *Articulation*

The learning environment needed to ensure that students were free to discuss the task as they use the program to enable them to learn to speak the language of the discipline and community of practice (Collins et al., 1989;

Lave & Wenger, 1991). Unlike the original program which was designed for individual students working silently on their own, the new learning environment encouraged the students to articulate their growing understanding of the research methodology with their partners.

8. *Coaching and scaffolding*

The learning environment needed to ensure that the teacher was available to provide required coaching and scaffolding for students as they used the program (Collins et al., 1989; Greenfield, 1984).

9. *Authentic assessment*

In order to provide assessment of student learning compatible with the situated learning model, the program needed to provide assessment that was seamlessly integrated with the activity (Linn, Baker, & Dunbar, 1991; Reeves & Okey, 1996; Wiggins, 1993). Students are assessed on the research report that is the purpose of their work at the research agency, rather than on the separate quizzes and tests of the original program.

A Functional Learning Tool

While this constructivist style of multimedia is not as simple to create as the instructivist electronic textbook, it has many advantages: it shows the relevance of theory to application; learning of theory is driven by the need to use it, rather than an artificially imposed pedagogical framework; and field experiences closer to professional realities than simplified student projects can be simulated. The context is modeled on the experience of a student employed as an apprentice in a summer job with *Acumen Research* to undertake research for a client, a large bank. In their office at *Acumen* (Figure 2) are various resources, including information on office procedures (principally on navigating in the simulation) and a folder containing information on the project.

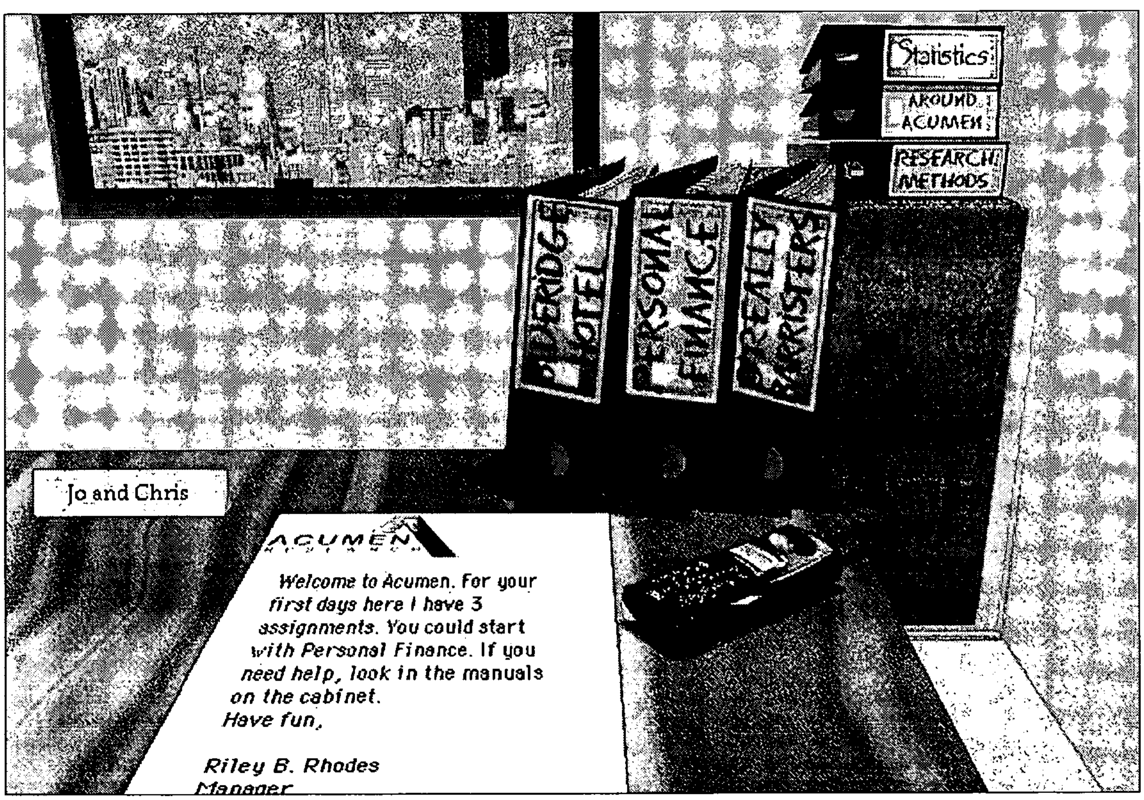

Figure 2: The office at Acumen

The books on research and statistics are the electronic texts described earlier: students do not now have to use them except as they need to supplement learning from other sources to complete the project. Two general resources available throughout the simulation are a phone that provides context sensitive help (e.g., hints on what to do next), and a notepad primarily for taking notes or storing information. No instructions on using the program are needed as navigation involves only clicking on objects or people to perform activities as they would be done in the real situation. After familiarizing themselves with the resources, students are directed to the client's office. There they meet the manager commissioning the research and have a preliminary 'discussion' on the nature of the problem as he sees it. This involves a statement by the manager, followed by the opportunity to choose questions from a list in the notebook (the manager's statement and responses are video clips). Students are expected to choose questions with some thought to the situation: there is not time to answer all questions, and some are largely irrelevant to the problem. Students work in pairs, and are encouraged to discuss their choices.

The manager subsequently invites the student to discuss the project with a senior staff. They learn in these discussions that the problem has other angles and must be reframed to meet the needs of the various organizational members. Apprentices are told beforehand that, as in the real world, there may be no one right way of construing the problem, but that some views may be more politically important than others. These are often unexpected and interesting issues to students, and not readily available in the traditional teaching approach. After constructing their version of the problem, students design a questionnaire by selecting questions from a large bank of items used in previous surveys. Next, they choose the sampling design from a set of alternatives; tradeoffs between scientific accuracy and costs invite students to see theoretical principles in the context of real world constraints. On finishing the research design tasks, students receive their data, which has been 'collected' by a group of telephone surveyors employed by the research agency. Finally, the data are downloaded, analyzed in a standard statistics package, and written up. The report can be evaluated by the lecturer, authentically, in the same way its real-world counterpart would be.

Behavioral to Constructivist

In designing a constructivist shell for a behavioral interactive multimedia program, we deliberately sought to adopt an approach which saw learning as an active process rather than the result of a transmission of knowledge from program to student. The tasks that were designed for the program were global, complex and sustained, rather than clearly defined tasks and subtasks, neatly broken up into lessons and modules. These tasks were placed within a full and authentic context rather than fragmented tasks and pre-determined instructional sequences. The new program required and encouraged students to explore the learning environment, rather than be captive to the presentation of a number of linear lessons. It presented a complexity which required more reflective thought than the step-by step lessons of the original program. Students were required to select relevant data and material from a wealth of sources, rather than try to absorb a pre-determined and well-defined body of knowledge. In so doing, they were required to reflect about their path rather than progress automatically through it. The interface of the new program used an ecological approach (Pejtersen, 1993) which presented real world metaphors and objects rather than buttons as navigational devices. Students would need to associate the meaning of an object with its destination rather than click upon the ubiquitous forward and back arrows of the original program.

In its implementation, the learning environment moved from a purely individual and solitary pursuit to a collaborative one, supported by a teacher who could provide coaching and scaffolding at appropriate times. Assessment of learning became integrated, authentic and inseparable from the activities themselves, as opposed to the separate tests and quizzes designed to assess decontextualised packets of learning.

In the real world, unlike the classroom, practitioners actively construct their understanding of a problem, and design a sequence of problem-solving steps based on both the textbook principles *and* contextual factors. The program described here provides an understanding of how the theory behind research functions in the face of ambiguous and contradictory information, practical limits on time and budget, and social agendas. In so doing, it provides students with a learning environment no longer based on the instructivist models of the 50s, but one firmly grounded in recent theory and research.

A Web-based Virtual Education System for Tele-training Courses

S. Sioutas, J. Tsaknakis, A. Tsakalidis, B. Vassiliadis
Computer Engineering and Informatics Department
University of Patras
and
Computer Technology Institute,
Greece

Abstract: The need for a higher integration of training and work is becoming increasingly apparent in countries such as Greece where the costs for higher education have lead to a permanent development process of the educational culture. In this paper we describe our ongoing work on an educational system which properly exploits the recent advances in information & communication technologies and addresses efficiently the above need. This effort aims to the development of the necessary infrastructure and services in order to establish a complete "Virtual Education System" offering tele-training services based on WWW technology.

Introduction

Internet has became an integrated set of inter-networking resources and services based on open, de facto standards and offered by an array of competing providers in a commercial environment now exhibiting many of the features of a commodity market. The World Wide Web (Web) and its attendant browsers, with their origins also in the research and academic communities, catapulted the Internet to its current revolutionary status as an educational phenomenon [Bertrand et al. 1995].

Today, training in Greece is characterised by classroom seminars where computer technology (multimedia systems) is used occasionally. But the latest progress in the field of computer networks has not been taken into account yet. Many educational institutions own World Wide Web servers thus providing information on their interest areas, their achievements and goals. In the Internet, a large number of digital libraries containing a wide amount of knowledge are able to provide information but they are not oriented for on-line training. Moreover, in the last few years, Greek universities offer off-line tele-training via the Web.

The Virtual Education System described in this paper is an on-line, web based educational platform which aims to enable the user to exploit the capabilities and tools offered today due to the progress of computer science, in order to:

- access multimedia information about relevant educational subjects
- communicate with other users sharing the same interests and exchange ideas end knowledge
- develop new skills
- keep in touch with the recent advances that affect working methods

The system addresses the need of restructuring traditional vocational training concepts in order to support current educational requirements such as effective integration of work & training, flexibility, in place-training needs and wide exchange of experience and problem solving methodologies.

In this work we present the overall architecture of the system which currently exists as a prototype. The paper is organised as follows: section 2 describes the main objectives of the system. Section 3 presents certain issues that are posed when developing distance education systems over the Internet. Section 4 presents the general architecture and the technological aspects of the system and finally, section 5 discusses future directions.

Main Objectives of the Proposed System

The educational concept of the system is characterised by the transformation of theory into practice. The course modules are separate entities, and play the role of plug-ins to the system. The Virtual Education System plays the role of a customised borwser and collaboration tool, which fully facilitate the Greek language providing a simple and friendly user interface [Tritsch 1995]. This feature allows even novice users to operate complex services (like video conferencing) with little effort.

Each course module deals with a specific subject (e.g. computer science or algebra) and is constructed using special WYSIWYG authoring tools. This way, the training material is system independent and every educational author can construct his own courses. The only limitation is that certain lesson architecture rules should be followed in order for the module under construction to be compatible/readble by the system. Each subject is not taught point by point but as an integral whole and through action oriented methods. This serves to promote the process of "natural learning" working in teams and projects and is oriented on future personnel development conceptions [Goldberg 1996].

The users can communicate over virtual education centres with tutors, experts as well as other users (see figure 1). The design of these virtual systems has the aim to link all functions under a uniform surface. All functions can be used single or combined which means that they can be used for:

- communication
- learning
- any combination of the above

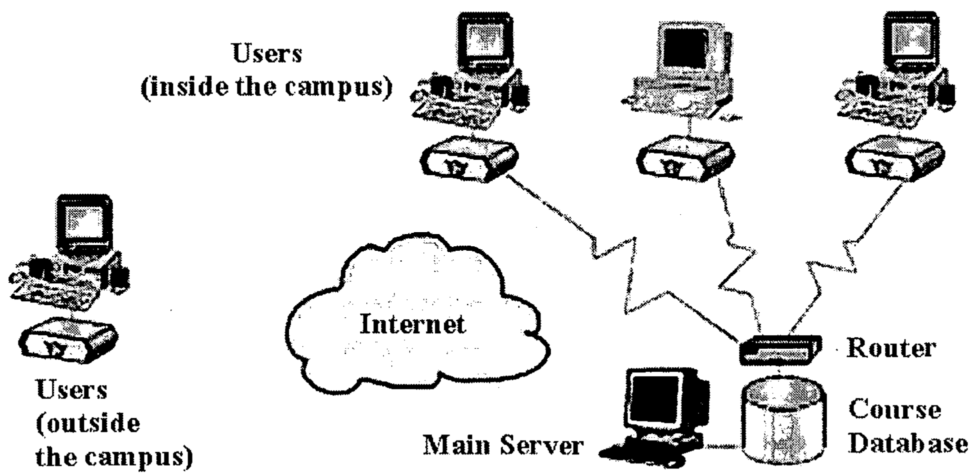

Figure 1. The topology of the system.

The Virtual Educational System will use all recent advances in the fields of information & communication technologies, in order to achieve:

- *Integration of working and training*. The process of learning will change in accordance to the developments of work processes. Working and learning will be more and more linked together so that the education and working processes of the future will show an increased degree of integration.
- *Realistic training for the users*. Being connected with modern working environments, they will have the opportunity to be trained according to the latest demands of the market.
- *Lifelong and autonomous learning*: The user has the capability to learn at home and has the opportunity to communicate with tutors, other users or experts.
- *Flexibility with regard to time, place and intensity of learning*: The user has the choice of place, intensity

and duration of study.

- *High training level* with the use of new technologies like the integration of multimedia technology systems (offering images, sound and video) and computer networks which allow the user to access information from digital libraries of other institutions (open and distance learning and computer based training).
- The exchange of experiences, knowledge and ideas between people separated by large distances.

3. Issues for Distance Education Applications that use the Internet

During the design period of the system we faced several topics that needed to be addressed before being able to offer a complete Virtual Education System over the Internet. These range from technical considerations to sociological aspects of learning without the existence of a physical classroom. Much study has already been done in distance education. While distance education can provide efficient utilisation of scarse resources, more fair distribution of knowledge, and timely dissemination of new knowledge, limitations in its effective use exist. Student motivation is critical. On-line instructors may need to take more time for the electronic courses. Limits to the number of students may be required to maintain quality interaction. While generalisations in the effectiveness of distance education are dangerous, a common set of advantages and disadvantages are emerging [Rossman 1992].

The web solves some problems of traditional distance education and brings new issues to the forefront. During our work we adressed the following issues:

- **Target Audience.** With traditional university courses, attendance is limited by the physical size of the training facility (about 50 students). Normally this means that the attendees are users and potential users of our facilities –researchers whose backgrounds, computing experiences, and expectations are somewhat similar. With a Virtual Education System, the size of each class will be limited by other non physical factors such as staffing requirements for account administration, limited consulting support and CPU resources required for the provision of on-line services. While we may now be able to directly impact a broader group of people, this group will be likely much more diverse in its background and computer experience. Having in mind the above problems the following issues are posed:
    - the policy on the individual computer accounts
    - the way that novice users will be supported by e-mail services and newsletters
    - the security policy that must be followed since the application should be protected from outside intruders.
- **Prerequisites.** The use of the system will require some basic knowledge of Windows, the main operating system used by the majority of Greek users. With traditional workshops held in training facilities the type of computer hardware, software and network connection is known. Although many of these parameters (such as network speed) are known in a University environment, the users coming from outside (e.g. logging in from their homes) have unknown properties. This situation could cause a number of problems. For example, some users may find that limited network bandwidth (a common problem in Greek public networks) does not provide a satisfactory learning environment. A simple solution would be to decrease the volume of the material (e.g. limit the use of multimedia) but this would mean reduced quality of the educational process. Since our main purpose was to have a fully interactive and media rich system, the use of multimedia objects was extensive even though some users would be eventually excluded from the learning process.
- **Learning Environment.** Extensive feedback from attendees at traditional workshops indicated that there were two benefits to learning in a classroom setting which were independent of the material covered in the course. First, students find the ability to get away form their other responsibilities and concentrate on learning the course material greatly increases the amount that they learn and retain. Second, the interaction with other students and instructors, whether this was side discussion or simply listening to questions asked by others, often resulted in rethinking of their own techniques and suggest new solutions to their problems. Our system should have the same attributes in order to ensure that students find the experience worthwhile and complete the course. This need can be satisfied only when the learning environment provides advanced interaction between instructors and students with the ability of whole classrooms to participate in questions and answers.

Technological Aspects of the System

The project aims to develop tools in order to combine the classical education methods into a complex, but efficient, system based on new technological achievements in the field of information & communication technologies. The technical basis of this educational system is formed by a virtual education centre that provides interactive educational courses over a data network. Precondition for the virtual education centre is an integrated software environment which makes possible that several users, tutors and experts use all different capabilities of the educational system at the same time [Repenning 1993].

New technologies are contributing to major transformations in the way people live, learn, work and interact around the globe. Important new technologies such as networking / internetworking, tele-communication, presentation / authoring, collaboration, visualisation/imagery analysis, conferencing and multimedia are getting more closely related to daily life. Consequently, a phenomenal alteration is changing the environments surrounding as such as virtual workplace, virtual classroom, virtual library, virtual school and virtual community.

The basis for the implementation of the system will be an integration of existing technologies (multimedia systems, computer networks). Images, text, sound and video will be sent via the network to the users. But the development of the system requires more that a simple integration of existing technologies. The training has to be «on-line». This demand sets new standards for the system, creates research activities and tasks to be done and produces challenging demands for the implementation [Brunner 1995]. The services to be developed will be presented to the user through a friendly user interface [EU 1996]. From a technical point of view, these services can be classified into the following categories:

Basic services

- Teaching materials (course modules) can be sent to the users by e-mail. The updates would be sent over the Internet
- *Electronic-Mail-Service*: Among other things the users will be able to receive, transmit and draw messages and pass them to other users or groups. In addition to modify the teaching materials, teachers may store messages in the server.
- *Notice Board*: An electronic notice board its also offered on which the user can write messages and each of the participants can read them. This function allows an exchange of information and questions between the participants.
- *Electronic Questionnaire*: A list of questions to be answered by the users electronically will give important response for the tutor.
- *Question-Answer-Service*: With the electronic questionnaires the users can ask questions in multiple choice, which can be evaluated automatically by a process which calculate the score, based on the given answers. This service will help the user to control the learning process.

Advanced services

- *On-line communication*: This system will make possible a visual and acoustic communication between the students or between the tutor and remotely sited experts, by using an integrated camera in the PC and a microphone. This will activate tele-coaching and a virtual discussion in the teaching groups.
- *Screen Sharing*: The screens of the students and tutors or experts will be coupled. There will also be an acoustic connection via a telephone line. The tutor may put his screen on the monitor of the student and vice versa. So it is possible to go through an error analysis or to demonstrate alternative solutions, online and in a participative manner.
- *Catalogue Service*: There will be a catalogue service in the server with a digital library and extensive search possibilities.
- *Information Service*: At any time the user can achieve world wide thematic topic information with menu controlled links to external services and information sources.
- *Application Service*: With this application several students will have access to shared application programs, at the same time. This system is a necessary precondition for virtual partners, teamwork and for tutorial support.

The main technological challenge that we face during the development period of the system is the use of multimedia over the Internet [Encarnacao 1993]. Different network based multimedia platforms provide different types of audio devices and services. Nevertheless, all of them offer a common set of functionalities, such as record, store and playback. Online audio exchange for communication purposes was realised based upon these basic functionalities. In order to provide cross-platform usability, a common, intermediate exchange format was defined and a number of online bi-directional converters supporting different platform-dependent audio formats were implemented. Video communication for learning environments requires a fast codec algorithm that can be performed in real-time on either low-end hardware or by software. Since the real-time issues for video as a communication channel were more important than high quality pixel and color resolution we decided to use the JPEG (Joint Photographic Expert Group) codec standard for our video sequences, referred to as M-JPEG (Motion-JPEG). Within the system, a multipoint audio/video communication environment allows real-time discussions between groups of up to six teachers and students. Its control elements are embedded in the GLS application. Within the WWW, online communication is supported by using the M-Bone technology which is driven by the same idea of having people communicate in a more natural way.

Conclusions

In this paper we described our on going work on a Virtual Education System which enables on-line training courses in a collaborative manner using state of the art technologies. It enables a high level of instructor-student interaction using network, database and multimedia technology. It is designed by applying strict pedagogical principles so as to achieve the greater acceptance as an educational tool. We believe that the aspiration of Virtual Educational Systems will be further approached with this effort.

Using a Template-Based Authoring System to Enhance Educator Control and Learner Performance

Vicki Jones
Jun H Jo
School of Information Technology
Griffith University, Qld 9726, Australia
{vicki.jones, j.jo}@maibox.gu.edu.au

Abstract: In this paper the development of structural learning environments for use over the Internet is discussed. Many educational programs are designed by specialist designers in consultation with educators. This can often be inconvenient, time-consuming and costly. The implications of this system will be discussed and a new template-based model proposed. With this new model the educator can be given more control over course structure, allowed easier modification of course material and have the option to embed teaching and learning strategies within the program. Ultimately, templates will be produced by multimedia designers and the educators, who use the templates to develop their educational programs, will then be able to work independently and at their own time, location and pace.

Introduction

Since automated teaching machines were first developed by Sidney Pressey in the 1920's (Sloffer, 1995), the development of educational programs has steadily advanced. The progress followed on from those early teaching machines, Eastman's educational films of the late 1920's (McReynolds, 1995), military training films (Shlechter, 1991), computer-based instruction (Reeves, 1991), interactive multimedia (Jones, 1998) to the current and wide-spread use of the Internet and the World Wide Web for educational purposes (McManus, 1996). Increasingly, the Internet is being used as a vehicle for delivery of educational material. This can be of particular relevance in the field of distance education (Carswell, 1997). Today it is possible for a student to complete an entire degree course through this medium.

Currently, design of Internet-based educational programs is often produced by a "project team", which consists of multimedia designers, a coordinator and the educator(s). The project team will use a set framework as the basis for design, producing a number of pages with common attributes. A good layout will incorporate consistent design features which include:

- buttons and entry/exit points which retain page position
- constant background pattern or colour
- uniform menu items

In this way the program can retain a user-friendly quality. The user has fewer navigational problems and is not required to learn new navigational skills for each page, section, lesson or subject.

In this paper, the focus is on the design of templates for Internet-based educational programs which allow for the incorporation of teaching and learning strategies, often overlooked by more conventional methods. A new template model, which applies the ideas put forward in this paper, is presented and discussed.

Templates in Internet-based Educational Programs

Templates have been used across a broad spectrum of applications and fields of study for many years. A template is basically a model of some type, which allows the user to add individual design features. Many people will be familiar with the plastic templates used to prepare programming flowcharts, chemical diagrams and geographical maps. More recently, word-processing templates have emerged. These templates provide a pre-delineated area to be filled out in order to complete a document. Apart from computer-based templates, there are many other types made of a variety of materials for use in a wide range of applications. The important thing to remember, and the unifying quality of a template, is that it is a "pattern" and it is "reusable" (Chia, 1996).

Templates can offer the same basic elements of design as provided by the project-team "set framework" approach. Pages can be produced with common attributes incorporating the consistent design features of buttons which retain page position, constant background pattern or colour and uniform menu items. In addition, when using the template method, the educator is able to both create and design the instructional program to be delivered via the Internet, leading to higher productivity and more efficient time management and cost expenditure (Jo & Jones, 1998). Current aspects of template use include uniform formatting, reuse of materials, easy modification and flexibility (Rebelsky, 1997). Much of the current template research and development results in interactive courseware products, such as CourseWeaver (Rebelsky, 1997), ASML: Web Authoring (Owen & Makedon, 1997) and DISCourse (Mispelkamp & Sarti, 1994). These template-based programs have many advantages, yet there is a tendency to concentrate on development from the designer's perspective rather than that of the novice user.

Incorporation of Teaching and Learning Strategies

The current approaches to template-based design may satisfy the needs for design simplification, clarity, cost effectiveness and time efficiency. However, the enhancement of learning performance, a crucial aspect of effective teaching, appears to take low priority. The issue of interactivity is also often overlooked. Interactivity helps the student remain focused and interested in the subject. A student-centred approach based on the learning theories of behaviourism and cognitivism, should play a significant role in the preparation of any educational multimedia product (Jones & Jo, 1998a). People tend to learn initially by behavioural methods. As they start to recognise strategies and patterns, cognitive skills are established (Lefrancois, 1988). It is interesting to note that Pressey's teaching machines, although primitive, incorporated the theory of behaviourism, using the stimulus-response method of teaching.

The fundamental principles of behaviourism can be implemented using the stimulus-response-reinforcement process. This does, of course, depend on the target audience, age group being an important factor. The subject and purpose of the lesson should also be considered. For a young target audience, the use of stimulus-response-reinforcement can be useful in obtaining and keeping the students' attention, whereas, for an older group it is perhaps more suitable to be used only in the feedback section of the course. Various stimuli, such as visual and audio prompts, can instigate a response from the user and suitable positive or negative reinforcement can be initiated. This may be in the form of a reward or remark, such as a pop-up comment, an offer to continue into the next phase of the lesson, or relevant links to other pages that may help with student understanding.

In an educational computer program, as in everyday life, users are at an advantage if they are able to apply previous knowledge. In this way they are using their cognitive skills (Lefrancois, 1988), as well as constructivism by forming new knowledge from the learning experience (McMahon, 1997). The processes used include recognition, perception and information processing. This is initiated by using "reminders" in the form of different coloured text, video clips or visual prompts to remind, represent or clarify certain points, and incorporating quizzes into the feedback structure. It is the belief of the authors that these approaches should be considered when designing templates.

Incorporation of teaching and learning strategies within the template can be achieved by embedding visual and audio prompts, time-out detectors, and a variety of user options, such as colour specifications. The techniques used are implemented by using HTML, DHTML, JavaScript and CGI scripts.

Template-based Educational Model

A number of templates may be necessary to suit the many and varied fields of study and age groups. The templates, designed by professional multimedia designers, need only be designed once thus reducing the cost of production. The educator, who uses the template for web page design, can enter course content material through a Web browser, then review and refine the program as it develops, making the whole process user-friendly and flexible. The educator is provided with more control as the program can also be modified or extra lessons added at a later date. The entire design process is represented in (Figure 1).

Figure 1 represents the step by step processes involved. The multimedia designer produces the design library. This large storage component comprises the designed templates held in the template library and an audio/video database. The multimedia designer has access to both the design library and the Web page generator for creation, maintenance and technical support purposes. When educators use the program, a template is retrieved along with any audio/video material they select for inclusion. They are guided through the design process in easy to follow steps, with various options including a default selection. Once the design process is complete the educators can store their design in their own personal design database for later use and modification. This only requires a limited storage capacity as specified by the designer on current context and preferences.

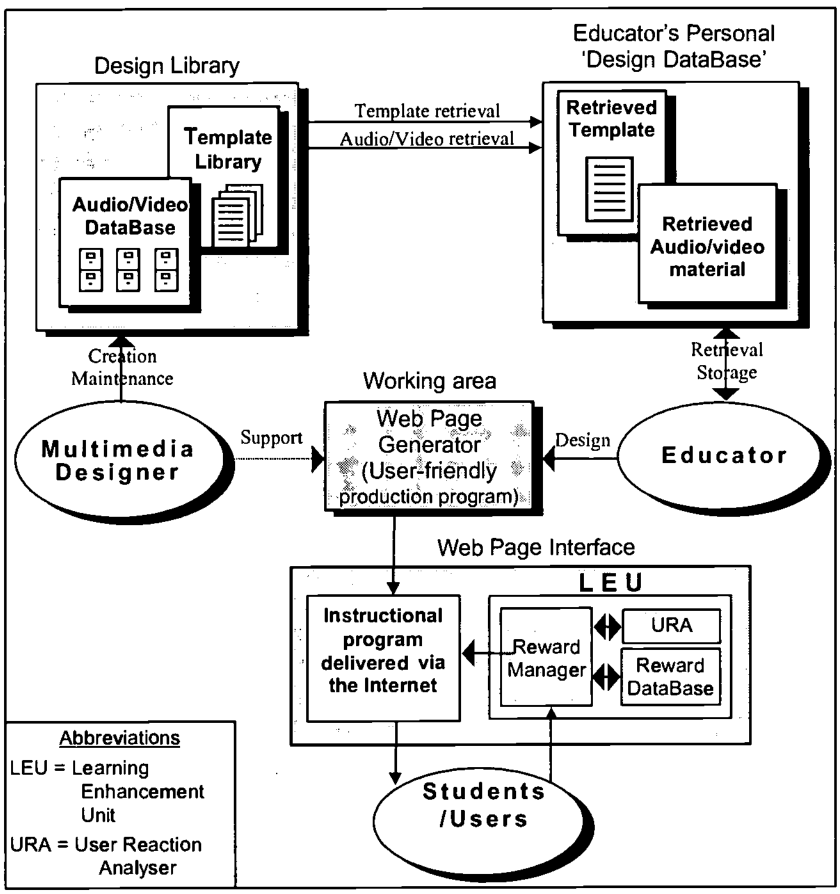

Figure 1. Template Model

The Learning Enhancement Unit (LEU) is an important factor in offering the student an interactive environment which applies teaching and learning strategies. The User Reaction Analyser (URA) is used to evaluate student performance. The Reward Manager receives input from the student/user and forwards this to the URA, a specially designed system which uses a series of "if ... then" statements to produce a range of suggested rewards or prompts. The Reward Manager draws a suitable reward, either positive or negative, from the Reward Database, and implements a reaction within the Web page (Jones & Jo, 1998b)

Issues that could be detected by this system include student comprehension, habits and preferences, as well as physical issues of hearing and vision. For example, the screen colour may cause difficulty for a colour-blind student. Other events include time-out detectors and question-answer analysers which detect the need for feedback to the student. The multimedia-based Reward Manager and Reward Database work hand-in-hand in determining and dispensing appropriate reinforcement. This includes positive and negative support, in the form of bonuses, penalties and encouragement or deterrents. The reward system functions by using pop-up remarks, visual displays, sound alerts, appraisals or the offer of a brief game or new links to other pages.

Conclusion

The template-based model for producing educational programs has been designed and developed using HTML, DHTML and JavaScript Web languages. The template itself consists of a series of easy to navigate web pages which guide the user through the design process offering many options. It is easy to use, especially for the novice user as no programming experience is necessary or assumed. As the program is written in Web languages, the pages appear similar to any web page and are just as easy to use.

With this model, educators work independently at their own time and pace. They are provided with the means to design, produce and modify their own instructional programs thus relevant teaching and learning strategies may easily be incorporated within a common design. This gives educators greater control over course presentation and learner performance. Using a template, the educator can effectively become the creator of an individualised learning tool.

Restructured, reengineered & realigned: Managing media in the digital age

Ian Hart
Centre for the Advancement of University Teaching, The University of Hong Kong. Hong Kong
ianhart@hkusua.hku.hk

Abstract
Information technology (IT) is critical to the future success of universities. Those universities that succeed in integrating IT will attract students and resources; those that get it wrong will suffer financial and structural difficulties. Any management scheme for IT in a university needs to balance five key factors: Strategy, Structure, Management processes, Roles and skills and Technology. Successful universities exhibit a high level of fit among these five factors. A poor fit means that a university is not functioning in a cost-efficient with respect to IT. Most universities have developed some form of educational technology support structure centred on a media unit, computing service or library. The paper concludes by describing three approaches to the management of IT support: a distributed approach (old universities) integrated approach (new universities) and parallel approach (divisional universities)

Engines for change

Technology is inexorably changing higher education as we move into the digital age of the third millennium (Negroponte, 1995). Of course technology is not the only factor at work here, but is one of many forces, and they are all inter-related.

Mass tertiary education.

In the 1950s and 1960s in most developed countries 8-10% of schools leavers went to university; in the 1990s the figure is closer to 40%. This has two consequences

- These students can't all go to the 'old' universities which have dominated the field for the past 100 or more years; new universities have been established to meet the needs of mass education
- Universities differ in quality: some new universities have developed niche positions and specialisations in non-traditional or cross-disciplinary fields; others are more like American 3-year colleges.
- Distance and flexible learning is attracting non-traditional students.

Learning theory

The past decade has seen a noticeable shift in learning theory from 'top-down' instruction-based teaching to a focus on the individual student's construction of knowledge. This is evidenced in changing curriculum structures such as Problem-Based Learning, Flexible Learning, educational multimedia and Web-based teaching.

Technological imperative

In a period of 10 years there has been a revolution in information and communication technologies that has affected almost every area of life, not the least education. Some of its manifestations have been:

- A convergence of technologies whereby different and distinct media such as print, video, graphics, photography and audio have converged into a single technology, multimedia.
- An information explosion, whereby an Internet user with affordable equipment can gain access to exponentially increasing volumes of information.
- The cost-performance ratio of IT has improved dramatically with technologies such as CD-ROM and the WWW, which enable flexible delivery.

Economic view of IT

Clark & Sugrue (1995) identify economics, particularly cost-benefit, as a driving force behind the adoption of IT in education. The arguments can be summarised as:

- New technologies promise the possibilities of new strategic advantages:
- Shift from the constraints of place to the freedom of space: learn anywhere, any time.
- Shift from focus on teaching by lecturer to learning by the student

New paradigms for higher education
New paradigms have arisen. The following table is an amalgam of many dichotomies found on the World Wide Web:

	Old	New
System	Take what you can get	Courses on demand
	Academic calendar	Year-round operations
	Terminal degree	Lifelong learning
Students	Students are 18-25	Cradle to grave
	Student as a burden	Student as a customer
	A 4 years revenue source	Lifelong revenue source
Learning	Books are primary medium	Information on demand
	Listen & learn	Solve problems
Teaching	Single product	Information reuse
	Delivery in a classroom	Delivery anywhere
	Single discipline	Multi-discipline
Faculty	Tenure	Market value
	Research is priority	Teaching is assessed
	Responsible for content	Part of a team
Funding	Government funded	Market funded
	Competition is other universities	Competition is everywhere
	Technology an expense	Technology as differentiation
Culture	University as a "city"	University as an idea
	Bricks and mortar	Bits and bytes
	Multi-cultural	Global
	Institution centric	Market centric
	University as ivory tower	University as partner in business

Table 1

Impediments to change

Not everyone agrees with this recent and sudden move towards IT and education. Universities, more than most organisations, value tradition and are institutionally resistant to sudden change. In most universities it is easy to observe an ongoing struggle between advocates of university tradition and of the new technologies.

Conservatism
Universities, even the new ones, act as if they are part of a long tradition going back to the early universities of Europe (gowns, ceremonies, arcane by-laws, titles, etc.) In this sense, universities are appropriately conservative and students value the traditions they conserve. In contrast, IT strategic planning often advocates major change in the delivery or form of education. The guardians of a university's reputation may, and probably should, resist such changes until they are convinced that this is not a flash in the pan.

Culture
Not everyone in a university shares the same culture. This is true in particular for technology specialists and academics. They have very different experiences and each often sees the other as uninformed.

- Academics typically have long formal training, 8-10 years for a PhD (12-15 years for a *habilitation* in Europe) and, frequently, little experience outside higher education.
- Technology specialists often have less formal training (but not necessarily less training) and typically have experience in a number of different industries but may not fully understand the university's culture.

IT Management

Rapid changes in IT and in the higher education sectors generally have stimulated changes in IT management processes. In some cases these changes have provoked knee-jerk reactions or have been grist to the mills of internal power plays: media centres have been closed, or moved into/out of the library or amalgamated under a central body.

In most university Senate debates and discussion papers about the role of IT there are a number of common key questions:

- Who owns IT?
- Where should it sit in a university structure?
- How do we get the cost benefits of centralisation as well as the value-added benefits of devolution and user control?
- Should IT report to Administration or to a PVC (Academic) along with other teaching and learning units?
- Is the head of Flexible Learning (an educator) at the same level as the head of IT (a technologist)?
- Should training about teaching and learning technologies be in the academic professional development unit or in Information Services?
- Should the professional development unit be in a faculty or in central administration?

Planning change - the MIT90 Model

Reflecting the new paradigms set out in Table 1, many universities are turning to business models in order to restructure their management, curriculum and communications. The four diagrams below illustrate variations of what is known as the MIT90 model, developed by Scott Morton (1991), and quoted by Yetton (1997) in an important paper on managing technology in higher education commissioned by the Australian Government.

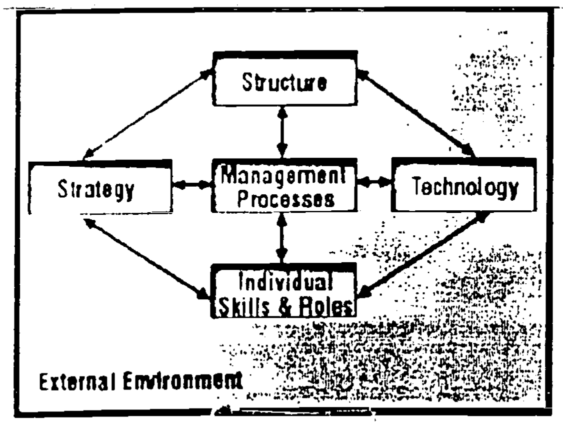

Figure 1

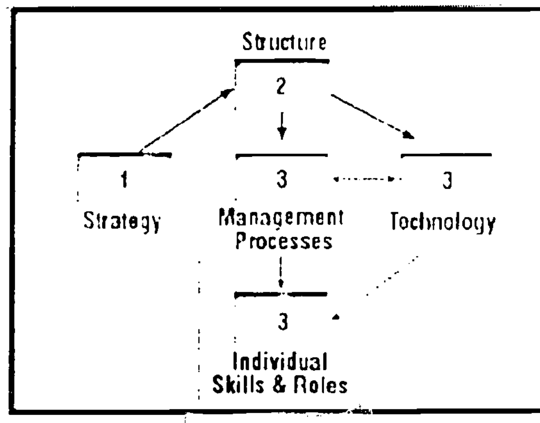

Figure 2

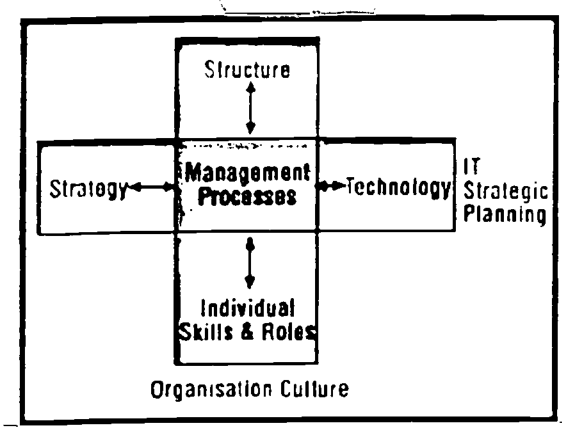

Figure 3

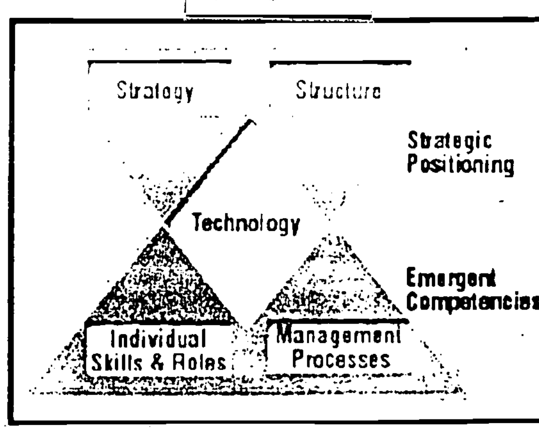

Figure 4

Strategic fit (Figure 1)

Yetton notes that successful organisations exhibit a high level of fit among five factors: strategy, structure, management processes, roles & skills, and technology. "It is a principal task of management to attain and sustain a high level of fit and, when strategic change occurs, to re-establish fit, and therefore high performance as soon as possible" (p.2).

Organisations in strategic fit have four characteristics.

1. The effective integration of strategy, structure, management processes, technology and roles/skills creates a focused organisational gestalt which simplifies formerly complex organisational and management demands.
2. This simplicity fosters clarity of understanding within the organisation, which reinforces and sustains fit. This means that the organisational structures, management processes (such as reward and control systems), and key technologies combine to support the strategic intent, as well as shaping the required task focus and behaviour of managers and employees.
3. Simplicity reduces the need for elaborate and complex coordinating mechanisms; thereby freeing up resources which can be focused on value-generating activities.
4. The high levels of performance created by this strategic fit serve to reinforce the process by which it is attained, and thus further simplify the fit among the elements of the organisational gestalt.

Such a tight fit, both internally among the elements of the organisation and externally with its environment, is associated with high performance.

Top down management (Figure 2)

In a time of change, when the balance between these factors has been altered (as described above, for example), how do we go about re-establishing fit? The most common method is to view strategic change as a three-step process, driven by a top down strategic positioning perspective.

1. A new strategy is identified and adopted.
2. The organisation is restructured to support that strategy.
3. The IT strategy and the management processes are redefined and aligned to the organisational strategy and human resources trained in these new skills as required.

This conventional, rational model of strategic change assumes that successful change is the result of a formal process of strategic planning, in which IT is aligned to the dominant strategic design. In line with business organisations in other fields, many universities have explicitly adopted this top down positioning model of IT-based strategic change. The most common outcome of this approach has been the drastic restructuring, or in some cases the dismantling, of existing educational technology services and the creation of an entirely new grouping, independent of teaching departments. Its mission is to speed up the employment of IT in teaching and management but it often meets resistance from areas of the university which have not been restructured.

Strategy vs. culture (Figure 3)

The MIT90 schema clarifies one of the common problems of strategic change with technology, when the impediments to change, mentioned above, come into conflict with the vision of university management. In Figure 3, strategic IT planning is the horizontal arm to the cross. When the organisation culture, the vertical post of the cross, is compatible with the implicit assumptions of IT strategic planning, there is close fit and few impediments to the realisation of the strategy.

Unfortunately, existing university culture is frequently not supportive of IT strategic planning. So as the university implements its change, it shifts out of fit and performance drops off. Unless it can bring its culture into fit quickly, then performance loss is likely to stall the change initiative.

Technology as the driver (Figure 4)

If we redraw the MIT90s framework to show IT at the centre of the five elements, we can visualise IT's role in both top down and bottom up management of change. The diagram shows two triangles illustrating the top down and bottom up dimensions.

Much IT-based strategic change involves altering the competencies of the organisation, and these are found in the bottom triangle. So as well as considering the organisation's strategic position (the top triangle), change requires careful attention to reconfiguring the bottom triangle. In fact an integrated top down and bottom up management of IT-based change is required (Craig & Yetton 1997).

Staff roles & skills

Of the five factors described in the models, the most contentious for academic staff is the requirement for change in "Individual Roles & Skills".

- Teachers need to have more theoretically grounded pedagogical knowledge, so that they can manage and direct projects using IT for creating resources and facilitating processes, otherwise they may come to regard technology as a panacea.
- In the new media of network based learning the teacher is not the primary source of content, but rather a resource person with content expertise. There is a shift in the 'power balance' between teacher and student. The use of contact time is more determined by student needs than teacher's agenda.
- Academic staff may take up technical roles related to media production (interface design, graphic design, instructional design, storyboarding, programming, media selection, file conversion etc.); there will be a greater emphasis on process design for teaching and increased emphasis on the roles associated with the development of distance materials.
- IT experienced staff need to be recruited as staff developers and trainers with respect to their colleagues in relation to communicating innovative practices and assisting colleagues to learn the skills required to use IT in their teaching
- More and different 'basic skills' are required for academic work. Teaching roles are becoming more information technology intensive, with demands for straight technical knowledge and skills increasing: word processing, presentation software, project planning, programming, graphics, sound and video are among the areas coming into contention for inclusion in the core skill sets of teachers.
- Academics are being required to take on increased administrative work with developments in networked administrative systems. Central data entry and report generation in areas like student administration are being devolved to Faculties and Schools, and some of this work, once done by administrative staff, is being taken up by academic staff.
- Heads of Schools who once understood the technologies of teaching (blackboards, classrooms and laboratories) are now required to make decisions about curriculum developments and equipment purchases with significant information technology components.
- The information technology component of work is increasing in all areas, and managers are also having to make decisions about the development, funding and maintenance of information technology intensive activities, often with a less than perfect grasp of the technical details involved.

Costs of production

A primary change brought about by Technology is the cost equation of producing and utilising new media materials:

- Universities are not accustomed to paying for the development of curriculum and teaching materials. Content and quality are typically seen as the private responsibility of teaching staff. Teaching materials are rarely considered to be university property.
- The use of IT-based teaching resources and processes demands much higher 'production values' than is the case for lecture notes and paper handouts - more staff and staff time in development, and the use of a range of production services.
- The process of recognising the true costs of teaching with technology based resources and processes, and of funding it appropriately, involves shifting the issue from the private concern of teachers to the concern of the institution.
- This shift has cultural, industrial relations and legal implications, all of which will have to be addressed.

Three models of IT management

We do not need to conclude that one of the approaches described above is right and the others wrong, in which case the task would be to discover the best approach. Rather, we can assume that each university will attempt to develop a different approach, based on some combination of the above models of change, to discover a new effective fit, and to satisfy its stakeholders' needs. The success of the approach adopted by a university will in part be contingent upon the fit with its current resource position, history and capabilities, as well as how effective it is in successfully differentiating itself and embedding the required strategic change in the organisation.

Old universities

Until comparatively recent times university education was an elite activity and the older universities offered degrees dominating the high status professions of medicine, law and engineering. These universities are located in or near the CBDs of capital cities and have long traditions of scholarship, endowments and research. Many of society's leaders are graduates of these universities.

IT Strategy

- A *distributed approach* with responsibility for IT-based teaching and learning developments devolved to local innovators across a range of faculties and units
- IT is used to enrich the old university's elite community.
- Concentration on maintaining the established base while funding independent new ventures.
- Successful ventures feed the established university community with their innovations in teaching, learning & research.
- Entrepreneurial ventures have the ability to select expertise with few constraints such as terms and conditions of employment.
- Attracts high status academic risk takers and innovators.

New universities
Many began life as polytechnics or specialised institutes and have recently been 'promoted' to university status; some have been created from scratch. There is little if any tradition of research and the emphasis is on establishing a reputation for teaching excellence, employment-oriented courses and quality facilities.

IT Strategy

- An *integrated approach* with a central unit managing the integration of teaching and learning with IT, emphasising support for professional development in educational and information technologies and linking it to university goals.
- IT is central to and critically underpins the strategic agenda.
- IT enabled teaching & learning is designed to deliver quality and reliability to a large number of students.
- Highly skilled experts in production and technology are recruited as required.

Divisional universities
Typically large and devolved, often an amalgamation of a number of institutions with multiple campuses and a high degree of specialisation in strong academic faculties. There is a strong emphasis on applied research and collaboration with industry, particularly in disciplines such as Engineering, Business, Health and Education.

IT strategy

- A hybrid, strategy that uses IT to obtain benefits of a low cost central IT infrastructure, while empowering innovation and student focus in strong academic faculties.
- Devolved faculties enabled by a powerful IT central infrastructure each has different competencies and strategic foci; each division has its own IT support and develops its own appropriate set of technologies, management processes, skills & roles.
- Focus on each division's core competencies in particular areas of applied research & teaching

Abstract: Internet delivered Continuing Medical Education (ICME) is a new learning mode for medical practitioners. This technique allows the delivery of CME material via the Internet, using the World Wide Web, regardless of geographic location. This paper reports a case study of GasBone, an early adopter and innovator in ICME. The Introduction describes the users and their characteristics, the educational goals addressed by the ICME project, GasBone, and the issues addressed by this paper. Study Methodology describes logfile and questionnaire methodologies together with a description of the different presentation methods included in the GasBone project. The third part discusses the findings from the logfile analyses and questionnaire results relating to ICME lecture presentations. Finally the results, conclusions and recommendations for organisations implementing remote delivery via the WWW are discussed.

Introduction

Medicine requires its practitioners to update their knowledge and skills on a continuing basis in order to maintain a license to practice. Continuing Medical Education (CME) is a term used to encompass the process of lifelong learning following initial graduation from medical school. Traditional delivery modes for CME include self-directed reading of journals and books together with attendance at conferences, courses and lectures. Access to group CME events are frequently limited by geographical isolation and/or the need to maintain medical services to the local community.

Medical practitioners have always undertaken CME activities but the pace of change now limits the effectiveness of traditional practices. The advent of the World Wide Web and ICME provides an important additional access to delivery that may solve some of the problems of geographical isolation and inequity of access.

The on-line environment is different from the traditional style of lecture. The learner can read the lecture anytime and anywhere as long as they have a computer modem and Internet connection. Even though in early 1998 Internet CME is still in its infancy, it may become the most common and convenient CME learning mode in the future. As an example, Malaysia, a developing country, has already planned to implement Internet CME under the Flagship of Telemedicine in its Multimedia Super Corridor (MSC) project. The relevance of this research into Internet CME and its potential for future development is high.

Suggs, Rose and Mittelmark (1993, 149) see CME not as a supplementary service to health professionals but as a necessity. The professional development of health care personnel is crucial as they have to adapt to the rapid (even daily) changes in knowledge generated by research and the technological advances made in medicine. Wallace (in Suggs, Rose and Mittelmark, 1993) lays the responsibility on the professions to improve and enhance the existing knowledge and pass it on to the coming generation. Miller, et al. (1997, 760) and Carney et al. (1995, 52) are in agreement that CME is designed to improve quality, knowledge and skills in order to maintain the competence and capabilities of physicians.

This case study examines the GasBone web project, an ICME site that specializes in the delivery of CME in the medical subspecialty of Anaesthesia. We wish to determine which formats and modalities of ICME are preferred by medical audiences. Both retrospective log file analysis and prospective questionnaire were performed during the study which was conducted over an 8-month period from late 1997 until mid 1998. Web server logfiles were analyzed covering the period June 1996 to November 1997.

In this research, GasBone, a project of the Division of Anaesthesiology & Intensive Care of the University of Queensland, Brisbane in Australia, was investigated as an example of ICME. This project was originally conceived as a way of linking geographically separate centers in a statewide medical department but grew into a major facility for the provision of CME for the international medical community. By late 1997 the GasBone project had been in use for CME and undergraduate medical teaching for 3.5 years (Palmer 1996a, 1996b).

GasBone provides a library of WWW/Internet lectures, presented in real time video, lecture slides with audio, lecture slides, graphic images and/or plain text page. This CME web site provides educational material specifically for specialist anaesthetists, anaesthetist trainees and GPs who practise anaesthesia. The GasBone project was a proof of concept project rather than a fully funded research project so new lectures were added as funding became available during the period under study.

The GasBone project includes 42 on line CME lectures in various formats including: text based web pages (19); text based slides (10); video only (6); text slides with sound track (3); slides with video (2); and text slides with audio and some video (2).

These lectures target various knowledge levels. Two thirds of the lectures are anaesthetic CME for practising anaesthetists and trainee anaesthetists. The other third of the lectures target undergraduate medicine and pre-medicine students.

The GasBone project was an early adopter of streaming video on the WWW with a VDO server installed in 1996. The web server and video server are separate software programs running on a common hardware platform (Pentium120, 128MB Memory, Freebsd2.2). User requests for video are processed by the web server but actual delivery of video is handled by the video server. The server has a permanent connection to the Internet via the University of Queensland network.

Study methodology

This case study uses both retrospective analysis of Web server log files and prospective mail questionnaire. Server log files will include data from all users, both local and international (Ng, 1998,4-4) and may also include a proportion of traffic from non-medical users. The mail questionnaire was however directed to all specialist and non-specialist anaesthesiologist trainees in Queensland, Australia The log file analysis gathered data on the monthly hit rate for five modes of CME presentation. Text only; plain text with graphical illustration; graphical slides with a sound track; slides with sound and video and video only. Data was collected for the monthly 'hits' data for the first page of a set of lectures from the time they became available until the end of the study period for all the presentation types available.

The mail questionnaire was sent to the 1041 specialist anaesthetists, anaesthetist trainees, and rural and remote practising GPs who also perform anaesthesia. These practitioners comprise the GasBone target group living in Queensland. Responses were received from 32% (332) of the target group. Only 19% (63) of them had participated in Internet CME at the time of our survey (February 1998).

We asked respondents to rank their preference for the following seven presentation types.

1. *Series of 20 slides from a lecture*: a linear online / Internet lecture, presented in the form of images similar to a PowerPoint presentation or a set of transparencies. The user can browse serially from one slide to another by using a mouse to click on either the previous or next button at the bottom of each slide.
2. *Sequence of 5 slides from a lecture*: same format as (1) except for much shorter series of slides.

3. *Slides with sound track*: an online lecture usually presented as just 1 slide with the speaker's voice recorded. Text is minimal.
4. *Slides with sound and video*: an online lecture presented in the form of slides with embedded sound and video. There are usually a number of slides for this type of lecture. Each slide has its own sound and video The user must install VDO plug-in software in order to view this type of lecture.
5. *Plain text only*: an online lecture presented as a web page with only text. The text is often in only one file but there is no indication of length aside from the scroll button included with the browser. The user browses through the whole lecture by using the mouse or arrow keys.
6. *Plain text with at least half pictures*: this online lecture is similar to plain text only lecture except almost half of the lecture is presented in the form of static graphics or pictures.
7. *Video only*: an online pure streamed video in which a lecture is presented in the form of a motion picture but with a quarter screen picture and very slow frame rate. This type of lecture also needs the VDO software plug-in installed in order to view it.

What Kind of Lecture Presentation Keeps Users' Interest?

Presenting web based learning materials is of little use if users do not or cannot access them. Disuse stems from a variety of problems such as slow modem lines, boring material, overly long sequences of material, the need for plug ins before the material can be used, sound either alone or with video that is indistinct or unintelligible, even content that is inappropriate to the user's learning needs.

The questionnaire provided data on respondent's subjective preferences for the seven types of lecture presentation on the Internet. Note however that less than 22% had direct experience of an ICME presentation. To gauge the difference between preferred information delivery method and the current practicalities of Internet CME this data was analysed separately for respondents with and without Internet CME experience, (Tab. 1).

Types of presentation	Rank (all respondents)	Rank (ICME experienced)
Slides with Sound and Video	1	2
Slides with Sound Track	2	1
Plain Text with Lots of Pictures	3	3
Video Only	4	7
A Series of 20 Slides from a Lecture	5	4
A Sequence of 5 Slides from a Lecture	6	5
Plain Text Only	7	6

Table 1: Comparison of rankings of Internet lecture presentations between all respondents and those with ICME experience.

Sound, video and pictures rank highly when the whole group of respondents is considered, but video drops in rank among those with ICME experience. We can see from the second column that Video Only, without the accompanying slides, was least preferred by this group. Video quality off the Web is still not good enough in comparison to television or even home video. The network bandwidth and currently available technology causes the download time to be lengthy, often exceeding user's patience.

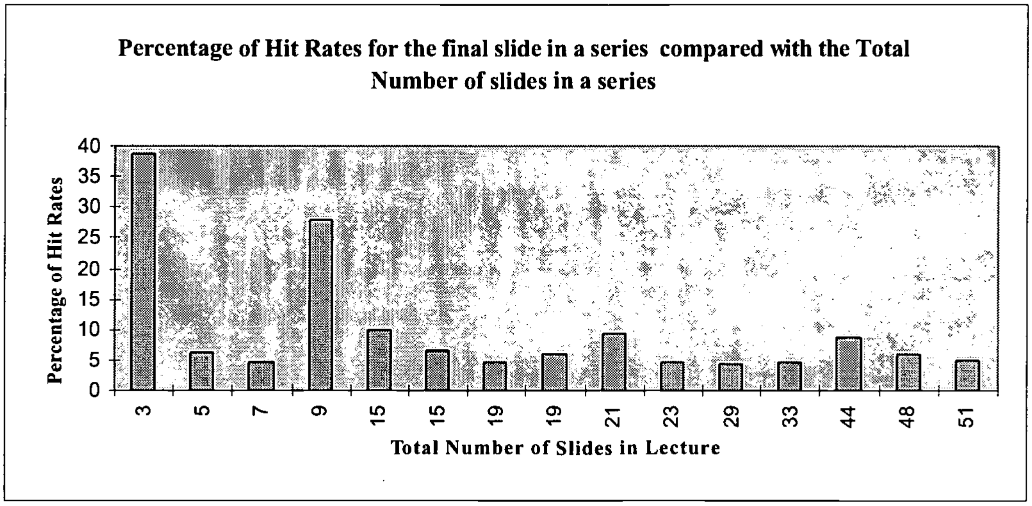

Figure 1: Retention of user interest by number of slides in the presentation.

Figure 1 plots the percentage of hits for the final slide in relation to hits for the first slide. The total number of slides in each presentation varies from 3 to 51. The graph clearly indicates the decline in retention of users as the total number of slides increases from 3 (39%) to 15 (10%) For lectures which consisted of more than 15 slides retention was generally well below 10% and fell as low as 5%.

The anomalies were those with content of particular interest (for example the total slides of 21, "Preoperative Assessment of Dental Patients", and 44, "Electronic Access to Medical Education") or those which contained elements which had slow load times (total slides of 5 and 7 are lectures presented as segmented video and requiring the user to have plug-in video software in order to start the lectures). Thus content and accessibility appear unsurprisingly to affect retention.

Comparing log file data for plain text and graphic intense pages, we found there was very little difference in the access rates for the two presentation methods. This seems to indicate that well chosen and sized graphics does not preclude user acceptance.

When the hit rates for plain text were compared with video pages we expected, but did not see a significant difference. However this may be spurious as Internet video was a technical novelty at the time of the study period and GasBone was an early adopter. The video requests may therefore have been high during the first few months of availability due to interest in the technology rather than the content. More recent feedback from the target audience indicates Internet video delivery is not as successful as a hybrid delivery that places the video on CD-ROM with dynamic links to the web site for updates.

Ten Months average hits for the six types of Internet lecture presentation

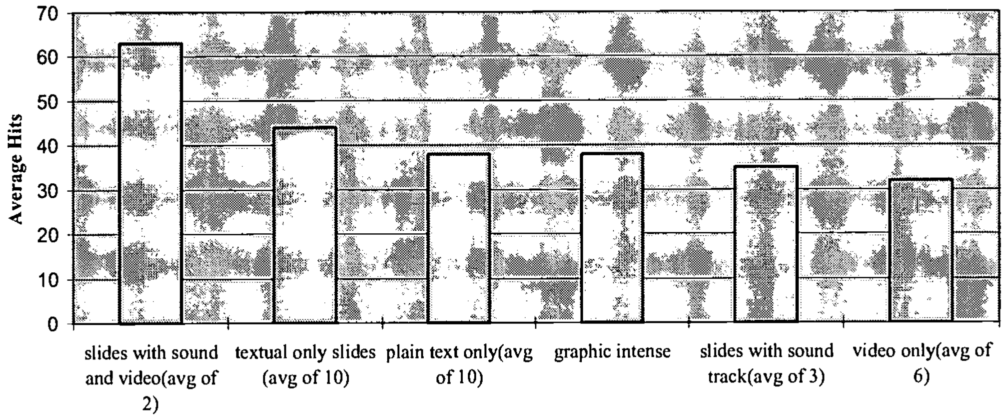

Figure 2: Average monthly hit rate by type of Internet lecture presentation

Figure 2 presents the average monthly hit rate for each type of presentation. It can be seen that slides with audio and video had a higher average monthly hit rate than any other presentation type. We believe that slides with media provide textual backup to the video or audio that augments the user's comprehension.

Slides with audio and video had the highest average hits in the log file data depicted in Figure 2 but ranked second among the ICME experienced respondents in Table 1. Appropriate use of video with audio is thus not just a curiosity, although the higher hit rates shown above can be partly attributed to the novelty factor.

Conclusions and Recommendations

The nature of the GasBone project presents challenges to data analysis. Materials were placed on the Web as they could be made available. As an early adopter of streaming video on the WWW, the developers experimented with video presenters, styles of presentation and modes of delivery. The apparent advantage of integrating video and audio into an otherwise textual slide that orients the user was indicated in this study and has proved successful in the longer term. Log file data is 'noisy' by nature and in the case of publicly available Internet delivered learning materials does not necessarily represent relative preference by the target audience.

In the interest of achieving a high volume feedback from the questionnaire, we felt that difference between perceived choice and what is viable and usable over current (particularly remote) WWW delivery was not fully reflected in the data gathered. Indications of reality emerged, however, from separate analysis of the responses of those who had participated in ICME.

In sparsely settled areas of Queensland, modem speeds were achieving no better than 14.4 kb/s at the time of this survey. The content of a streaming video would have to be outstanding before busy people like medical practitioners would be willing to wait for it to download. However, as indicated earlier, more recent efforts have shown hybrid delivery using a CD-ROM for video delivery to be viable. Slides with sound and video are another alternative and were more frequently requested than were the video only pages. There is a definite interest in video and one must monitor advances in these technologies that may allow wider delivery of useful video.

It is also important to honour the user's comfort zone. Medical practitioners are accustomed to learning from text. Providing long textual pages that can be downloaded in one hit for local printing are a useful delivery mechanism for this target group. Moving decorations are much less of interest, particularly with the bandwidth restrictions. However, well chosen and clearly laid out graphics can provide useful explanatory power.

While a broader group was not sampled in this study, similar results would be expected where the user population was well educated and in a profession where continuing education is required to maintain accreditation. Inferences about the problems inherent with remotely delivering complex materials can also be made. Further study would be beneficial to track whether the rapid uptake in Internet participation is extending into sparsely settled areas without the higher bandwidth found in urban centres.

Writing on the Web: Technology and Implications

Abstract: The Web is argued to be the next great technological tool to be used in the delivery of educational materials. The success of virtual classrooms will depend on a number of issues including pedagogy and the appropriate exploitation of technology. This paper describes the building of a Web site and experiences in using such a site, to support collaborative learning between students, experts and the course co-ordinator. Active Server Pages and database technology running on Microsoft Internet Information Server was used to create the system. Students wrote assignments on the Web that were reviewed by peers, experts and course co-ordinator. The course, based on modern educational principles, was found engaging by the students but was under-utilised by the peer and export groups. Also, the use of the Internet as a mechanism to stimulate open discussion appears to change the way in which papers are written and reviewed.

Introduction

The use of the World Wide Web as a mechanism to create virtual learning environments and to deliver other educational resources (such as lecture notes) is heralded as the next great educational tool that will solve many problems and make education cheaper and more accessible to a larger community. It is often argued that the World Wide Web can facilitate learning as the technology allows the easy integration of many disparate forms of media and communication technologies into a single delivery mechanism (Dwyer, Barbieri, & Doerr, 1995). During the past few years there has also been an explosion of the use of "Virtual Classrooms". However, Winn (1998) argues that "simply converting traditional university courses to web pages, or worse, just putting lecture notes on a Web page, is a serious mistake". A search using Infoseek (www.infoseek.com) with the key word "virtual classroom" returned 13 390 hits. Many of these relate to the use of the technology and not on the use of appropriate learning theories to support the development and deployment of virtual classrooms. Ryder (1996) argues that "the challenge for the postmodern educator is to discover the capabilities and natural constraints associated with distributed pedagogy for scaffolding learners in the age of information".

Alexander (1996) argued that the Web could be used as a platform for course delivery as hyperlinks closely map to the structure of the knowledge that it represents (see Kearsley, 1988), allows interactivity and collaborative authoring of content, and also integrate the learning experience. However, that authors also contends that new adopters of technology often concentrate on the technology and not on the learning. Presentation of content is insufficiency to promote learning (Winn, 1998).

In an extensive study, Saljo (1979) found that learning can be divided into five categories that include, quantitative increase in knowledge, memorisation, skill and methodological acquisition, making sense or abstraction of idea and interpretation and understanding of concepts. Schank & Cleary (1995) argue that teaching frameworks for learning should include simulation, incidental learning, reflection, exploration and include case-based scenarios. Constructivists argue that knowledge and understanding are actively constructed by the learner, not passively received from the environment, and socially constructed through experience with the physical world and social interactions leading to consensus (Piaget 1929, Ausubel 1968, 1977, Vygotsky 1978, Driver & Erickson 1983, von Glasersfeld 1989).

The use of Internet and database technologies allow for the easy development of resources where learners can easily create Web-based content, critically evaluate the submissions of other students and interact using discussion fora. However, the sociological effect of creating public content is not clearly understood.

In this paper I will describe a system that was created to teach a fourth year biology course where students investigated topics and reported their findings on the Internet, and thereafter discuss the use of the system. The basic question posed is: Can technology, and especially the use of the Internet, be utilised in such away that would allow individuals to work on theirs own yet have discussion, with and support from, their peers, other postgraduate-students, supervisors and experts?

Course conception

The six-week course consisted of three topics related to the use of computers in education. Apart from the students and course co-ordinators, four experts, external to the University and a number of postgraduate students participated in the course. A schedule outlining the topics and source material was provided. Each topic included a theoretical component (writing of an essay), discussion period, a mini project and a face-to-face final discussion. Some core source material was provided for each topic but it was expected that students would find additional information. Essay content was entered into database tables using Web-based forms. The content was added as blocks of information that the writer could reorder. During the discussion period the course co-ordinator, postgraduate students and experts attached comments to the student essays (using Web-based forms) and the discussion forum. Mini-projects were used to put what the students learned during the theory component into practice. In the face-to-face meeting students and course co-ordinators evaluated the learning that had taken place during the two weeks and attempted to integrate the different elements under discussion. The design of the course attempted to implement the five learning activities reported by Saljo (1979) and used constructivist methods where the teacher acted as co-learner with the students constructing their own knowledge both as individuals and as part of a larger group.

Students were evaluated using number of different criteria that include finding of relevant information, quality of their papers, interaction with peers and evaluators, quality of their Mini-projects, and a portfolio of work. The portfolio contained any three pieces of work undertaken in the course, any other information by independent research, additional notes or Web pages that they authored, a personal evaluation of the course and what they had learnt in the course.

Technology

Database technology allied to a Web server was used to create resources required for the course (http://www.nu.ac.za/biology/education). Microsoft ® Active Server Pages (ASP), a server-side scripting environment, can be used to create and run dynamic, interactive Web server applications. With ASP, Web documents are created from HTML pages, script commands, and ActiveX components. This technology is easy to develop, modify and deploy. The dynamic binding of database contents to the creation of ASP pages uses Microsoft ®Internet Information Server and Data Access Components (MDAC) that integrates information from a variety of sources including relational (SQL) and non-relational. MDAC consists of ActiveX ™Data Objects (ADO) and the Remote Data Service (RDS), Microsoft OLE DB Provider for ODBC, Open Database Connectivity (ODBC), and ODBC drivers. The server-side scripting environment uses VBScript or JScript that is executed on the Web server. The ASP technology therefore allows delivery of pure HTML code to the client that contains information stored in database tables on the server and provides an easy method to update server-based databases from content entered into forms on the client Web browser.

The Web site for the course was divided into a number of sections that included an Introduction, Schedule, Discussion Forum, Data Entry, Papers and Participant Information. All sections, except the Data Entry component, were open to all visitors. The Introduction and Schedule section were coded using Microsoft FrontPage while the other parts used ASP linked to a simple Access database (Fig. 1).

The database was used for two activities: entry of data (essays content and comments) and the discussion forum. A record, in the Users table, was created for each user that included the email address and password used to uniquely identify each user. The Group field served to identify the user as either a student, postgraduate, expert or course-co-ordinator. The other fields in this table were used to display information on the Participant Information section.

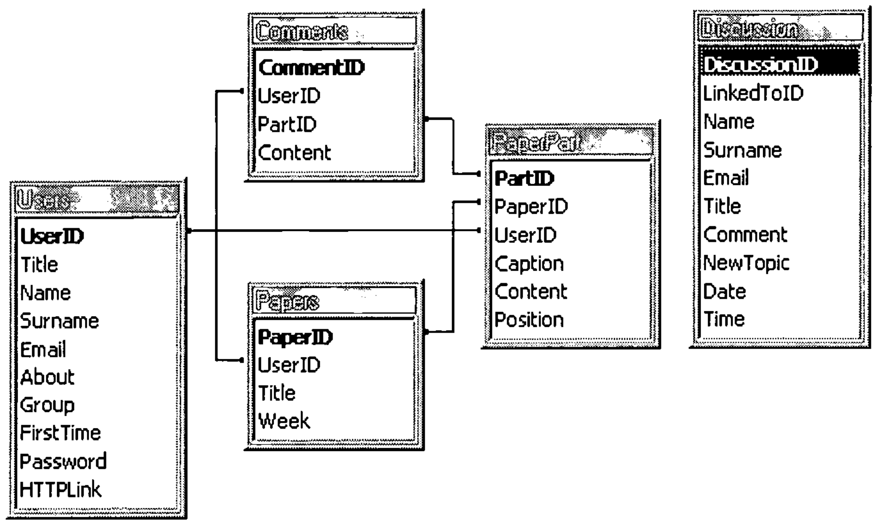

Figure 1. Database showing relationships between tables and unique keys (bold).

In the Data Entry section, users entered the system using their email address and password. User could then edit their personal information or access the papers. The Papers links worked differently depending on the group to which the user belonged. Student could add new papers or edit existing ones. Papers were entered as a number of sections that could be ordered. Other members could view contents of papers and add comments to each section. Records in the Pages table (Fig. 1) represent papers created by student users. Sections of papers were stored as records in the PaperPart table. Therefore, each paper consisted of a Page record and a number of PageParts records. Comments, related to each section of a paper, were stored in the Comments table.

The Discussion section of the Web site used the Discussion table (Fig. 1). Here the screen was divided into two main sections. On the left a list of topics was displayed in a tree format using Java applet (diputree, from dipu at http://www.dipu.com/root.html). Instruction on how to use the system, data entry and display of discussion topics were displayed on the right. A non-Java view of the discussion topics was also available. The Discussion table contained fields that allowed the records to be sorted and grouped according to the discussion thread and only one level was provided for each discussion topic.

In the Papers section both the essays and associated comments were displayed. Therefore the Papers, PaperParts and Comments tables were used to display the HTML pages associated with each paper.

ASP coding

To illustrate the ease of using ASP the code for the non-Java view of the Discussion topics is given in Fig. 2. The symbols '<%' and '%>' denote the start and stop of the script. Two subroutines, AddLinsLinks (Fig. 2, ❶) and AddLine (Fig. 2, ❷), were used. The AddLine routine displays the Discussion topic while the AddLinelinks adds all the records associated with that topic. To create the content for the page a RecordSet object is created on the server (Fig. 2, ❸), database opened using standard SQL and for each unique record the topic link and associated topic threads generated using the two sub-routines. Finally the database is closed (Fig. 2, ❹) and the end page HTML tags added.

```
<% ❶ Sub AddLineLinks( DiscussionID )
  set ra = Server.CreateObject("ADODB.Recordset")
  ra.Open "select * from Discussion;", "DSN=EDUCATION", adOpenKeyset, adLockOptimistic
  ra.Filter = "LinkedToID = " + CStr(DiscussionID)
  if (Err.Number > 0) then
    Err.Clear
  else
    if not (ra.RecordCount = 0) then
      while not ra.EOF
%>             
        <a href="showtopic.asp?id=<%= CStr(ra("DiscussionID"))%>"><%= ra("Title")%>
        (<%=ra("Name")%>)</a><br>
<%      ra.MoveNext
      wend
    end if
  ra.Close
  set ra = nothing
  end if
End Sub

❷ Sub AddLine (DiscussionID, LinkedToID, Name, Title, NewTopic)
if isNull(LinkedToID) then
  LinkedToID = 0
  NewTopic = 1
end if
%> <a href="showtopic.asp?id=<%= CStr(DiscussionID)%>"><%= Title%> (<%=Name%>)</a><br><%
  AddLineLinks( DiscussionID )
End Sub
%>
<html>
<head>
<base target="main">
</head>
<body  link="#FF0000"  vlink="#800000"  alink="#808080"  bgcolor="#FFFFFF"  text="#000000"
topmargin="0" leftmargin="2">
<table border="0" cellpadding="0" cellspacing="0" width="380">
  <tr>
    <td><font size="2" face="VERDANA,ARIAL,HELVETICA">
<%    On ERROR RESUME NEXT
    ❸ set rs = Server.CreateObject("ADODB.Recordset")
      rs.Open "select * from Discussion WHERE (Discussion.LinkedToId = 0);",
      "DSN=EDUCATION", adOpenKeyset, adLockOptimistic
      if (Err.Number > 0) then
        Err.Clear
      else
        if not (rs.RecordCount = 0) then
          while not rs.EOF
            AddLine rs("DiscussionID"), rs("LinkedToID"), rs("Name"), rs("Title"),
            rs("NewTopic")
            rs.MoveNext
          wend
        end if
     ❹ rs.Close
        set rs = nothing
       end if
%>   </Font>
     </td>
   </tr>
</table>
</body>
</html>
```

Results and Discussion

The objective of the study was to investigate the use of modern Internet technologies to build a virtual classroom where students could submit papers for evaluation and discussion by peers and experts. Use of Active Server Pages allied to a simple database was used to create the Web environments where students submitted papers for discussion, peers and experts reviewed the papers and all groups had access to a discussion forum. Each of these three aspects will be discussed separately.

Microsoft's ASP technology and Internet Information Server provided an extremely powerful environment for the development of HTML code that interacts directly with databases. Using VBScript and a simple Access database it was very easy to create the resources required for the course. While the coding of ASP can be tedious at times, it is not difficult to master or implement. All that is required is a fundamental understanding of database structures, basic SQL, VBScript and HTML tags.

Students found it very easy to gain access to the site, and while there were some initial problems with the system, were able to use the form-based interface quickly to submit their papers. The initial problems related to how parts of papers had to be entered into the system, students requiring a clearer explanation from the course co-ordinator and a postgraduate student of how to submit papers. Students suggested that papers could consist of more that one level, which would allow individual sections to be submitted in smaller blocks. While this was a fairly good idea it was rejected as it would require major changes to the database structure and further complicate the system of data entry. While using the core reference material to construct their papers, students also used both on-line and library references. Students appeared to enjoy the structure of the course and found the mini-projects valuable and allowed them to put some of the theory they had learnt into practice. The inclusion of a face-to-face tutorial for each section of the work was valuable. Here students and the course co-ordinator discussed and evaluated what the students had learnt. These discussions also helped the course co-ordinator in identifying problems with the system correcting student's misconceptions.

The use of the system by postgraduate students (peer review) was less than expected. While some postgraduate students made frequent contributions, others did not (the four students made 15, 7, 1 and 0 comments respectively). None of the postgraduate-students experienced any problems in using the system.

Four experts were invited to participate in the course. Of these, two were from South Africa (one at Durban), one from the USA and one from Australia. The input from the experts was disappointing. While two submitted comments, they did not use the system but emailed them to the course co-ordinator. Students appeared to appreciate these comments and reported that they further advanced their understanding. The lack of use by experts of the system is interesting. While there may be many reasons, such as time and commitment, in supporting a course for which there is no direct reward, the evaluation of student papers in a public forum (the Web) is very different from the traditional reviewing process that is normally only between teacher and student. Also, the course co-ordinator found the process of reviewing of papers on the Web very different from grading, or evaluating, a term paper. Such comments could no longer be briefly written in the margins of the paper, but full explanations had to be carefully constructed and formulated. Therefore, comments on paper on the Web required more care and additional time.

The Discussion Forum was not very successful. At first students posed questions via email to the course co-ordinator. During one of the face-to-face meeting a student suggested that the Discussion Forum be used for more philosophical discussion on the Web. While the group agreed that this would be a good idea, a thread started by the one student only contained one additional comments that was made by the co-orrdinator. Student did, however, appear to refer to the topics, for example dates for meetings submitted by the co-ordinator. However, they were not consistent in this activity and consequently all important course information was sent by email to the students. The failure to use the Discussion Forum by the students resulted in a steady stream of email message, from students, postgraduates and experts to the course co-ordinator. Those questions that appeared to be universal were answered using the Forum but many were answered individually resulting in more time being spent using email during the course.

Collectively, these observations highlight a number of important issues. During the past number of years many institutions have created virtual classrooms. Authors such as Winn (1998) and Ryder (1996) argue that such courses will succeed only when supported by appropriate pedagogy. However, the comment made by Ryder that we need to "discover the capabilities and natural constraints" associated with such courses delivered on the Web appears not yet answered. A fundamental question remains: "Does writing of course assignments and assessment on the Web, which is freely available to all visitors to the site, fundamentally change the way in which students approach their papers and the way in which peers and experts evaluate and report on such content?". Students appear to adapt rapidly to the use of new technology and are able to use it successfully to assemble their papers. However, the involvement of peer and expert review appears to be problematic. While both of these groups could make valuable contributions to student learning in a distributed system, neither gains any direct reward. Also, there is a crucial difference in evaluation of papers on the Web: no longer is the process private and confidential, but open. Academic review has for centuries been cloistered in anonymity and the use of the Internet could change this. Such a basic shift in evaluation may be required if we are to use all the power of the Web to teach, but as yet we do not have the experience or wisdom to do this wisely.

In conclusion, the development of a virtual classroom where students, peers, experts and course co-ordinator can interact is easy using Active Server Pages and database technology. Design of a Web-based course on sound educational principles appears to provide students with tools to submit papers and receive comments. However, the use of the Web for open assessment changes the way in which such activities are conducted. For the Web to succeed as a platform for the delivery of course content and the evaluation of student work we need to understand more clearly the move away from anonymity to open truthful and insightful discussion and criticism.

Abstract:
The forms of support needed by preservice teachers in the practicum setting relate mainly to access to relevant information, resources, guidance and support through communication with university instructors and competent peers. Too often these kinds of support are lacking for students on teaching practice in schools. This paper describes the development of a web-site where students can access a variety of support structures which enable them to reflect on their role and performance as teachers within a resource-rich and fully supported online environment. Through the website, student teachers can access resources such as: lesson plans, samples of teaching methods and activities, links to information sources, on-line and downloadable teaching materials, and discussion facilities to enable students to post problems and queries to peers and lecturers and to receive feedback.

A Reflective Approach to Practicum Support for Preservice Teachers

> I have come, over the years, in spite of all the reform agendas, to believe that the best we can do in teacher preparation programs, through a variety of courses and clinical experiences in intentionally selected schools, is to help academically able and socially committed students enter teaching with constructive dispositions and skills relating to young people, curriculum content, pedagogy, and the power of collective thought; well-developed habits of observation and reflection; reasonable confidence and an understanding that they are entering a process of learning something important every day, working toward the largest possibilities they can imagine. (Perrone, 1997, p. 649)

In today's overstretched curriculum, and with society's increasing demands for the teaching of a growing body of new knowledge, a competency-based approach for learning to teach is obsolete. Students cannot be competent in content and skills that are rapidly changing, or may not, as yet, even exist. As Perrone (1997) argues, it is better to provide students with generic and reflective skills that assist them in their continued learning of any new enterprise. Connecting these generic thinking skills to the context in which they occur is essential. If university programs do not do this they are likely to 'prepare teacher technicians rather than reflective professional educators' (Boyd, Boll, Brawner & Villaumer, 1998, p. 61).

Reflection is one aspect of a complex number of interrelated functions which contribute to task performance (Ridley, 1992), an aspect which is gaining increased attention in recent years after almost disappearing from consideration under the influence of learning models based on behaviorism (von Wright, 1992). Boud, Keogh and Walker (1985) define reflection as: 'those intellectual and affective activities in which individuals engage to explore their experiences in order to lead to new understandings and appreciations' (p. 19). These authors stress that such reflection must not occur solely at the unconscious level: 'It is only when we bring our ideas to our consciousness that we can evaluate them and begin to make choices about what we will or will not do' (p. 19). Kemmis (1985) points out that we do not reflect in a vacuum: 'We pause to reflect ... because the situation we are in requires consideration: how we act in it is a matter of some significance' (p. 141).

Many theorists see reflection as both a *process* and a *product* (Collen, 1996; Kemmis, 1985), and that it is action oriented (Kemmis, 1985). Knights (1985) contends that reflection is not the kind of activity which its name suggests—a solitary, internal activity—but a two-way process with the aware attention of another person: 'Without an appropriate reflector, it cannot occur at all' (p. 85). This view is strongly supported in the literature by others who point out that reflection is a social process (Kemmis, 1985), and that collaboration on tasks enables the reflective process to become apparent (von Wright, 1992).

Another important function of reflection is that it enables the learner to compare his or her performance or understanding to an expert in the field (Candy, Harri-Augstein, & Thomas, 1985; Collins, 1988; Collins, Brown, & Holum, 1991). Collins, Brown and Newman (1989) have also pointed out that it is important for students to be able to compare their performance with others at various levels of expertise. Access to expert performances and the modelling of processes has its origins in the apprenticeship system of learning, where students and craftspeople learned new skills under the guidance of an expert (Collins et al., 1989). Important elements of expert performances are found in modern applications of the apprenticeship model such as internship (Jonassen, Mayes, & McAleese, 1993), and case-based learning (Riesbeck, 1996). Such access enables narratives and stories to be accumulated, and invites the learner to absorb strategies which employ the social periphery (legitimate peripheral participation) (Lave & Wenger, 1991). Expert performances and the modelling of processes, allow students to observe and reflect upon a task before it is attempted. Such reflection, one might argue, is only possible in a learning environment which provides appropriate supports and communication channels to enable reflective learning to occur. And yet the typical experience of preservice teachers on professional practice is one of isolation, divorced from the support structures of their university environment, and without communication channels to their peers.

The purpose of this paper is to outline the development of a web-based resource that provides reflective support and communication to assist preservice teachers learn about teaching in the context of their school practice. Early childhood, primary and secondary education student teachers enrolled in Bachelor of Education and Graduate Diploma of Education courses at Edith Cowan University (ECU) are required to attend between 10 and 18 weeks of school practice during their training. These practices vary from continuous blocks of time in a school to distributed practice where, for example, students attend a half-day a week for one school term. In the context of reducing University and Faculty budgets, coupled with increased pressure on academic staff to increase their research output, there has been a dramatic reduction in university staff involvement in the supervision of students on school practice. This has necessitated developing alternative approaches to assisting students on school practice.

This project set about to provide an improved framework of support for student teachers during their involvement in school practice by providing them with a range of resources to increase content and skill knowledge, and to enable them to reflect on their teaching practice. Initially, the content focus centered on teaching mathematics, however, the generic nature of the skills being developed meant that these abilities could easily be transferred to other areas of the school curriculum. To support and develop generic teaching skills it was felt that students would benefit by having access to rich sources of lesson ideas, particularly those type of lessons that reflected constructivist pedagogy; and guidance and support through communication with content experts and their peers. In addition to their supervising teacher, students would be adequately supported in their practicum settings by having immediate access to:

- Quality curriculum materials to guide lesson planning;
- Examples of exemplary teaching to enable students to compare themselves to 'experts';

- Examples of lesson activities across a range of teaching strategies and content areas;
- Templates with which to build lesson plans and ideas, and teaching materials for use in lessons; and
- Open communications channels to discuss problems and difficulties with their peers and lecturing staff.

Providing support along these lines could be effected through an appropriately designed Internet-based database and information delivery system. The process of using the Internet to communicate between student teachers on school practice and university supervisors has been reported (Casey 1994; Hutchinson & Gardner 1997). Recommendations from these reports include extending the process of communication to students' peers and school supervisors. This project provides such a system with the construction of a WWW site with the following components and attributes:

- A database of prepared lesson materials accessible through a simple search engine;
- Short video clips of teaching approaches and activities to stimulate students' ideas when creating and preparing lesson formats and plans;
- Links to the various information sources useful to students;
- Answers and suggestions regarding known problems faced by students on school practice;
- Online and downloadable teaching materials; and
- Online discussion facilities enabling students to post problems and queries to peers and to staff, and to receive feedback.

All entering students at ECU are provided with an email address and access to the Internet through the university modem pool. The vast majority of students will have access to the WWW in the schools in which they will be doing their practicums. The benefits provided by this resource include:

- Immediate access to required information;
- Ability to collaborate in a virtual community during the practicum and be relieved of the sense of isolation so often experienced;
- Ability to contribute to the database by posting successful materials of their own;
- Ability to share the information passed in the discussion sessions without having to formally participate;
- Problems and queries which surface and are resolved during each practice will be added to the database of known problems and solutions for reference by subsequent students; and
- Problems and queries will provide a significant resource for lecturers and students in their pre-planning for school experience.

Using the Resource

To ensure the successful application of the WWW resource, students are made familiar with its information and organisation before going on school practice. They gain a sense of how best the resource could be used and the real advantages that could be gained through its use. Student use of the resource on school practice can be ensured through prior activities at the University where students are required to explore the resource and all its features and capabilities and to use the resource in simulated practicum conditions by preparing sample lessons. They are encouraged to add materials of their own to relevant sections of the database and to learn appropriate procedures for online discussion and communication through computer mediation. School supervisors are also informed of the resource and encouraged to contribute and use the email facility to communicate with University supervisors. This WWW site is an extensive resource with the features and attributes described above. The site incorporates the following features:

1. ***Interface Design:*** The WWW site interface (see Figure 1) reflects the forms of information contained, and provides an intuitive organisational storage and retrieval structure. Several navigation and data retrieval strategies exist which include hierarchical organisation based on year groups and mathematics topics and a keyword search engine to provide access to the materials.

2. ***Content Development:*** The project has involved the development of lesson activities (see Figure 2 for an example) across a broad range of topics and teaching strategies. There are at least 160 such elements in the database which provides an adequate starting resource for student teachers in schools. The project has involved lecturers in the department of mathematics education creating approximately 40 lesson activities in each of the categories: pre K-2; 3-5; 6-8; 9-12 (and these will grow as the students contribute their own lesson ideas).

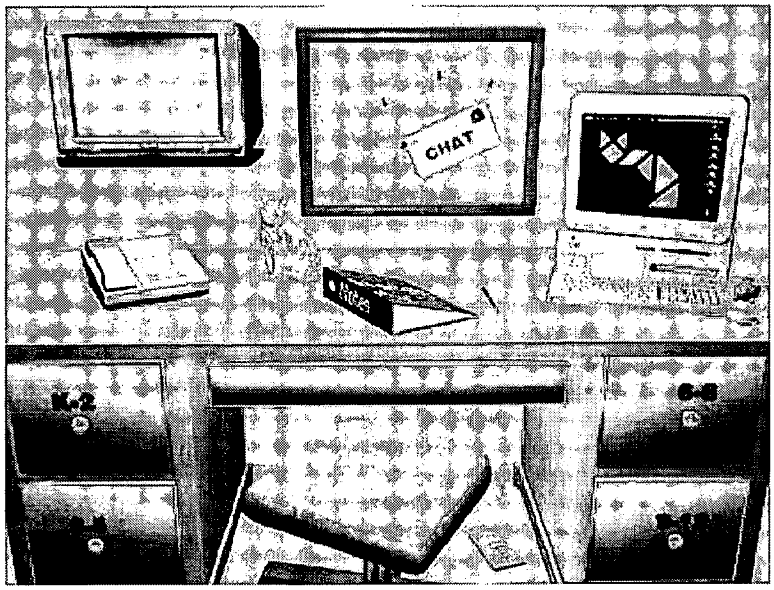

Figure 1: The interface of the web resource

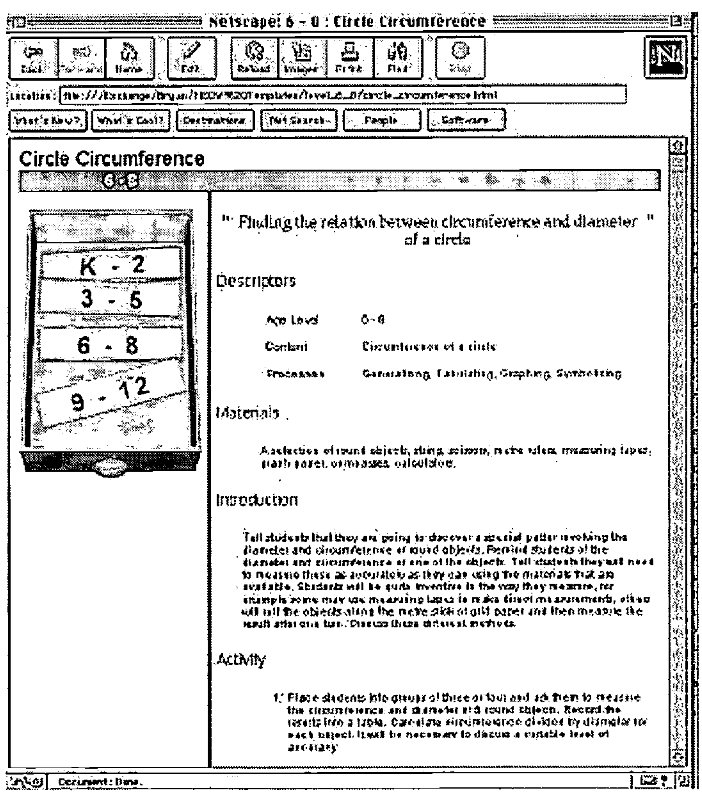

Figure 2: A sample lesson plan

The activities reflect the type of pedagogy encountered in the University methods classes and the directions advocated in such documents as the *National Statement on Mathematics for Australian Schools* (AEC, 1991) and the National Council of Teachers of Mathematics *Curriculum and Evaluation Standards* (NCTM, 1989). Many activities will have accompanying graphics and images, including images from real classrooms where the activities have been trialed.

3. ***Communications Components:*** The development of a customised discussion program for the site supports the forms of communication and discourse described above. The communication capability of the site enables students to cross-post messages and documents providing the full capacity for information and materials exchange. This is an essential component to enable the 'development of a rehetoric for interchanges' (Dede, 1996, p. 168) which is so important for the effectiveness of the students' learning support systems.

Outcomes for Students

Student teachers using this resource gain a diversity of expected learning outcomes developed within the context of mathematics education. These primarily relate to planning for teaching and applying appropriate teaching strategies and generic strategies developed using electronic forms of information, such as:

Generic planning skills:

- Plan mathematics lessons and program a series of lessons
- Select suitable learning experiences
- Select and prepare resources and contexts and plan for all pupils' needs.

Generic teaching strategies:

- Become aware of and apply a range of teaching strategies
- Adapt strategies for individual pupils' needs
- Motivate pupil interest.

Generic information processing strategies:

- Access, create and evaluate online information
- Communicate online.

Evaluation

The project is being evaluated formatively with students throughout the entire period of development in three ways: by student consultation, trial implementation and focus group discussion with student users. With a dynamic and responsive medium such as the WWW, formative evaluation is an ongoing feature, and necessary changes to meet the growing needs of the preservice teachers using the resource can be made at any stage. Summative evaluation of the resource will be conducted, in the first instance, with a qualitative study of a small group of preservice teachers. Students will be observed accessing the resource, then interviewed. The purpose of the investigation will be to assess the impact of the resource on students' selection and preparation of lesson material, the teaching strategies employed by students in their teaching practice, and their use of electronic media to seek information and use communication technologies to establish support networks. Further analytic studies will be conducted based on the findings of the interpretive research.

Conclusion

This paper describes the development of an online resource to be used by preservice teachers while on professional practice in schools. The resource has been designed to support reflective practice by these students as they prepare and teach their practice lessons. The value of reflective practice and its potential to be assisted through the web site comes from several sources. Firstly, the site enables reflective practice by providing a variety of resources from which to gain alternative perspectives on any teaching task. Secondly, communication technologies allow students to establish communication in the language of the culture, and to share stories and anecdotes of their experiences. Thirdly, the site provides exemplary performance and the modelling of processes, enabling students to reflectively compare their own performance to that of experts.

A resource such as this has the potential to transform the professional practice experience from an isolated and anxious one, where students work with minimal resources and supports, to one which is dynamic, collaborative, resource-rich, supportive and reflective.

Stimulating Reflection on Theory Using a Web-Repository of Student Reviews

Jan van der Veen[1 2], Maarten van Riemsdijk[3], Hans Slabbekoorn[3],
Iris van de Kamp[1]
University of Twente, Enschede, the Netherlands

Abstract: At the University of Twente many courses apply group based learning as a successful strategy for those educational settings in which the application and integration of theory is the main theme. Also the University of Twente encourages instructors to consider the use of information and communication technology solutions if appropriate (Collis, 1996). "People, Technology and Organisation-2" is a course focusing on organisation theory and its relevance for designing business organisations. Students work in project groups studying both theory and case-studies.
To stimulate the reading of theory articles a Web-site was set up. The whole set of 24 articles is too much for each individual student, so each group divides the articles among its members. Every group has to submit for each of the 24 articles sets of 'question & answer' that target the core of the article. The submissions on a particular article together form a resource for all groups, though only accessible for those groups who submitted a serious contribution themselves. In this paper we report on the problem analysis of the educational setting, the web-solution, and on the evaluation results of the experiment which took place in the period September – November 1998.

Educational setting

The University of Twente offers curricula in technical, social and business sciences. In the second year of the School of Management Studies curriculum, 180 students enrol for the course titled " People, Technology and Organisation-2". In this 200 hours course the students work in groups of 6 students each. Two instructors assisted by seven tutors (senior students) take care of lecturing and group support.

The learning goals of the course are (Smit & van Riemsdijk, 1998):

- Knowledge and insight in the field of organisation theory and design.
- Being able to apply this knowledge and insight in problem solving strategies.

The course uses the textbook of Daft (1998) and a set of articles from the research field. In parallel the students work on the evaluation of case-studies. In the course four phases can be discerned, together spanning a period of 10 weeks:

In the first phase, the main topic is an introduction into several schools of thought in the domain of human resource management. Starting with a re-examination of Taylorism, students are introduced to the work of Lewin, Mc Gregor, Trist & Bamforth. Parallel, students are asked to study the Uddevalla Volvo plant and the Nummi (Toyota/GM) plant with respect to human resource aspects of the production organisation. They are invited to reflect on these two plants using the literature. Finally, they are asked to suggest (first/preliminary) redesign options for Morgan Cars on this topic, after analysing Morgan Car Job design.

The second phase deals with contingency theory and organisation design. Technology and Organisational environment are the main topics. Using studies by Perrow, Thompson, Lawrence & Lorsch, Woodward etc. students are again stimulated to analyse the Nummi and Udevalla plant in this respect. The second half of this part is again devoted to analysing and "redesigning" Morgan Cars.

The third phase deals in a similar way with 'Power, Politics and Decision making', focussing mainly on a stakeholder approach and of course on decision theory. Again, Nummi and Uddevalla serve as a practical illustration and practice material, Morgan Cars as a serious effort for re-design. Finally in the fourth phase

[1] Educational Centre
[2] Centre for Telematics and Information Technology
[3] School of Management Studies
Information via: j.t.vanderveen@oc.utwente.nl

of the project, students are invited to attempt a full re-design of the Morgan factory on all topics touched so far and on all other aspects of the organisation that they think are relevant to the task.

Problem analysis

The first three phases of the course start with the study of about eight rather basic and theoretical articles. The concepts and ideas from these articles then have to be translated into practical ideas for changing a case-situation. In order to be able to do so, it is essential that all the articles have been studied rather thoroughly. Ideally, students will interchange insights and concepts encountered in the literature. Students are more likely to raise their problem solving capabilities when working together with fellow students with comparable but slightly better capabilities (Vygotsky, 1978). They are working in each other's "zone of proximal development". This means that in some way or other, a situation has to be created in which students that have read the same material can share their findings. Previously this was attempted by prescribing that at least two students in every group should read the same articles (Smit & van Riemsdijk, 1998). These students could then discuss the articles amongst themselves, and present their findings to the rest of their group. It turned out however, that students read not two but only one article each, blowing this strategy of communication about theories and concepts right out of the water. Instructors, as a consequence, found that in workgroup sessions, individual knowledge of separate articles was adequate, but that theoretical knowledge had not spread throughout groups but stayed firmly located with one 'expert-student' per article per group. This resulted in a lack of overview within the groups and in sub-standard knowledge and grasp of the different theories and concepts involved by all members of the groups. An additional problem would arise if individual students would not have understood the material sufficiently. Lacking any possibility of communication with other students within their group on a specific article (no one else would have read the same material) their problem could not be solved and would spread throughout their whole group. Given these results, obviously, something had to be done.

Solution design

It was concluded that the decisions on who was to read which article should be left to the responsibility of the groups themselves. To alleviate the problems mentioned before however a web-site was designed. The web-site was designed to solve several of the problems encountered. First, to stimulate the reading of the articles each group was obliged to submit a contribution through the Web-site (figure 1). This contribution should consist of two relevant questions and their correct answers about each article that was read. The submitted Q&A would be screened (figure 2) by tutors helping the instructors. They would accept or reject (with some comments) the contributions. This gives the students full flexibility with respect to the planning and execution of their tasks, while at the same time making sure that everybody does what is expected of them.

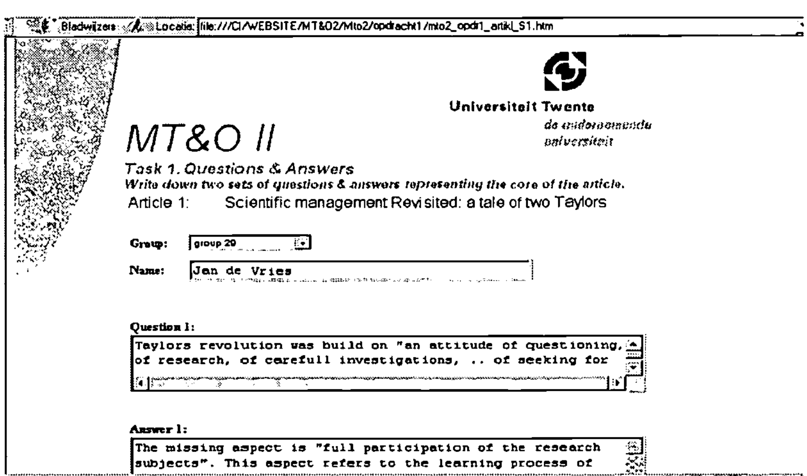

Figure 1. Web form for submitting 'questions & answers'.

Second, once acceptable questions and answers are submitted, the student gets access to another part of the site, allowing him/her to monitor all the other positively assessed contributions about his/her particular article, submitted by students from other groups. In this way also a treshold was built in to prevent 'free rider effects' when students copy from other contributions (Ronteltap & Eurelings, 1997). In the last step students rate the group submissions, indicating which five contributions they like best. The solution is described in figure 3.

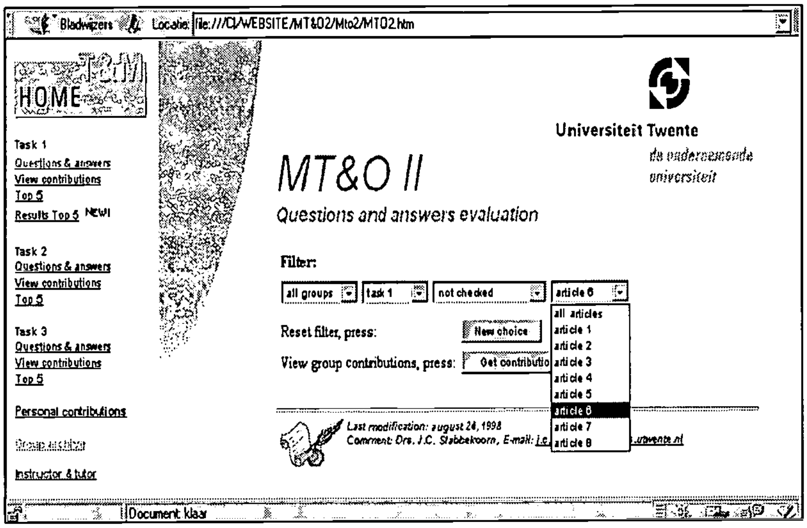

Figure 2: Tutor evaluation module, also showing the course menu on the leftside of the screen.

So, while accepting the fact that students would typically read only one article, we tried to provide for a workspace where some form of communication with other 'experts' would be facilitated. Students would be 'rewarded' for their effort a) by being allowed to enter the site and b) by being able to read other correct questions and answers about 'their' article. Using this broader knowledge, they would be more secure about the work they had done and be able to contribute more to discussions during their group meetings. At the same time, this had the advantage that we could be reasonably sure about the level of knowledge and understanding that students would have about the different articles. This, of course, was theory.

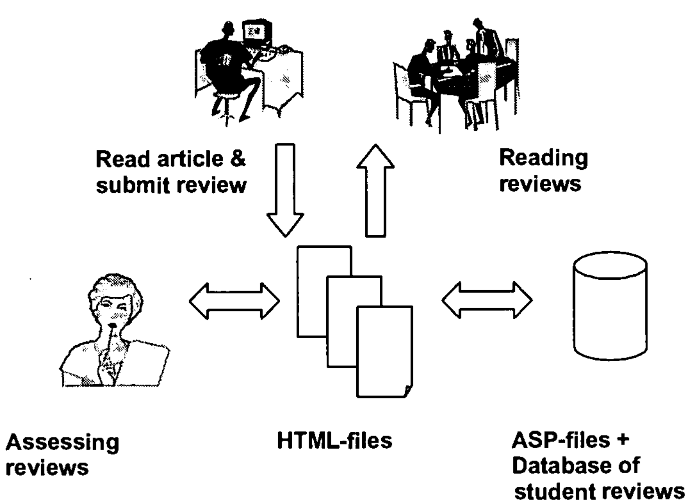

Figure 3. Main activities with respect to the Web-Repository of student reviews.

Technical set-up

Active Server Page (ASP) technology was used to implement writing to and querying from the Access database that contained all group contributions. To limit the access to the resources to only those groups that had made a proper contribution, the membership mechanism of BSCW (Basic Support for Collaborative Work) was used. After each assessment those groups entitled to access, were granted membership to those workspace folders containing the HTML-file making a call to the database (BSCW, 1998). The groups could also use BSCW workspaces as a group archive if they wished so.

Evaluation questions and methods

The main goal of the implementation and therefor the main question involves the value of the website in improving discipline of reading and improving insight of students in the theory described by the articles (Q1,Q3). We were interested to see how the web-site would support the work of the students (Q2, Q4), the tutors when assessing the quality of the questions and answers, and of the instructors when having a look of the progress of the students, and taking an overview with respect to the quality of the students contributions.

With respect to the technical side we wanted to built and implement the interactive website as described. And, as no special training was given we were interested in the ease of use, and were curious to know if the web-site would function well (Q5). To find answers, data are gathered in different ways with involvement of student, instructors and tutors. Our research questions and evaluation methods are summarised in table 1.

Evaluation methods **Questions**	Student questionnaire	Student interview	Tutor interview	Instructor Interview	Log analysis
Q1 How good is overall student insight in theory ?	*	*		*	
Q2 Did the intended use of the Web-site take place ?	*	*	*	*	*
Q3 Did student insights improve as a result of this ?				*	
Q4 Is the Web-repository perceived as helpful ?	*	*		*	
Q5 Did the Web-site technically function well ?	*	*	*	*	

Table 1. Research questions and evaluation methods.

Results and conclusions

With only limited efforts (80 hours) a Web-repository of student reviews and group archives was set up using a database driven Web-site (Q5). From the database and logged data we found information on the use of the web-repository, table 2. The submission of questions and answers was done by the groups as planned (Q2). Most groups (23 out of 28) submitted contributions for 20 or more articles (out of 24). The students reported that they used more than 30 minutes to read an article. They found it difficult to formulate a good question and answer, indicating that there was additional reflective effort needed after having read the article (Salomon, 1984). The instructors reported that students attending the lectures in general were better prepared compared with the previous situation (Q3, Q4).

	1st phase	**2nd phase**	**3rd phase**	**Overall**
Number of submissions	246	218	195	659
Positive assessed submissions	81%	58%	61%	68%
Reading other group submissions	79%	39%	26%	48%
Top 5 contributions	44%	16%	n.a.	n.a.

Table 2. Some statistics on the use of the Web-site of the course. Mistaken entries (66) in the database (empty forms, duplicates) are removed from statistics.

Overall 68% of the contributions was assessed positively. The drop in the percentage of positive assessed contributions in the second phase was caused by comments of one of the instructors urging the tutors to be a bit more strict in their assessment. During the same meeting, after the first phase, the tutors indicated that it is sometimes difficult to make a "ok" / "not ok" choice as sometimes a contribution contains both good and bad parts.

The percentages of students reading other group submissions one has to take into consideration that access was only granted to those that had submitted a good submission themselves. Therefor this 'reading peer contributions' percentage can never be higher than the 'positive assessed contributions' percentage. The top 5 competition was not used very much. Reading other groups submission does not have a high added value as perceived by the students. At the time of the submissions all learners are still in the orientation phase and most have not yet reached expert level (Q1). Also time pressure to move on to other deliverables is a reason for lack of interest in this feature. Because of this lack of interest the instructors decided to drop this feature in the third phase (Q2).

Via a questionnaire students (N=83, response=50%) were asked to indicate which workform had contributed to acquiring knowledge, improved insight and to learning better to apply knowledge. Compared with group discussions, tests and working lectures that were applied in the same course, the website repository received the lowest score, table 3 (Q4). It may be that the hoped for 'peer-to-peer' learning effects [Vygotsky, 1978] across groups, are too weak when the peer contribution is 'tunneled' through technology with no opportunity for discussion. Students report that they used the group discussions to share their individual findings on the articles within the group. It may be that working with the Web repository is a good preparation for this discussion, more than for exchange of opinions across groups.

	Tests on theory	Group discussion	Working lectures	Web repository
Acquiring knowledge	2.2	2.8	2.2	4.3
Improving insight	3.2	2.5	1.4	4.2
Applying knowledge	4.1	2.2	2.3	4.1

Table 3. Average student appreciation of work forms applied in the course (1=most important, 5=least important).

The web-site user interface was appreciated as easy to use (Q5), table 4, even though we feel that improvements are possible. Browsing through other group contributions for instance now takes four mouseclicks per item. This will be reduced to one mouseclick per item.

Question	Score
It was difficult to formulate a good question and answer set.	2.8
If I wanted to enter data in the Web-site, it was easy to do.	1.9
I had a good overview of what I still had to do.	2.5
It was fun to work with the Web-site.	3.7

Table 4. Student appreciation of the Web-site (1=agree very much, 5=disagree very much).

The flexibility to submit from any Internet connected pc was used not only by students, but also by the tutors when assessing the contributions. From the responding students 81% indicated that they had used their home pc for some of the submissions. Analysing submission time stamps shows that 47 % of all submissions arrived close before the deadlines on Mondays. For 90 % of the submissions the time stamp is between 10.00 and 17.00 hours. For this students mainly used their project room pc or other personal computers at the Department, possibly because from their home pc connectivity costs are a treshold.

The access mechanism for the overview of all contributions involves the tutors granting access. This human step turns out to be error prone. The failure rate of 6% dropped after the first phase towards occasional mistakes. Still the automation of this step will make the design as a whole more robust, at the same time preventing the good students from becoming frustrated when they find that access is not granted by mistake.

Discussion

It turns out that the discipline of reading theory articles has been enhanced. As a result of the need to formulate 'question and answer' combinations, student reflection was also stimulated. Of all submissions, 68% was of acceptable quality. But what is acceptable ? We wanted people to get to the core of things, but most students did not reach that level. It is now seriously considered that the students will have an optional course in their third year in which those interested in the course topic, can further improve their level.

The hoped for cross-group exchange of expertise on each article, was not adopted by most students. The reasons have to do with the effort needed to read reviews from more than 20 groups, which would take more time than reading the article itself. So most students no more than scanned the contributions of other groups, resulting in almost random top five scores. Also the mentioned quality aspect of the submissions, did not stimulate students to keep reading.

As our students report that they rely mostly on the exchange of expertise within their own peer-group, we plan to redesign the web-repository in such a way that it supports these group members first of all. We will ask the students to submit short summaries on the articles. Apart from basic quality assessment of the submissions, the tutors and instructors will make a shortlist of excellent submissions, adding some expert remarks per article as a conclusion. This way we hope the Web-repository will support each group by building a portfolio of article summaries per group, and by offering an efficient shortlist per article for the experts that have read the same article.

Acknowledgements

Many people contributed to the making and execution of this project, in particular we mention Eelco Laagland and Henri Holtkamp.

"Web-Constructivism Using Javascript"

Anthony 'Skip' Basiel, Dr. Matthew Jones and Dr. Kay Dudman

Abstract

This paper illustrates how the Constructivist Learning Theory can be demonstrated through the use of Javascript in a web-based learning environment. The power of stand-alone multimedia applications can now be replicated on the web through many types of plug-ins. However, they are tedious and time consuming to download. Client-side Javascript is the answer this research proposes as a fast, reliable alternative. By embedding Javascript throughout a web-based tutorial system the principles of Constructivism guide the Learning Environment Designer (LED) in the development of a web-based tutorial system.

Web-Constructivism

Constructivism is the current dominant learning theory [Bruner 1966, Hein 1995]. The Internet is a well suited distance learning media to support this methodology . This paper shows how using Javascript the following sub-set of Constructivist principles [Boyle 1997] can be adapted to a web-based learning environment:

1. Support the active construction of knowledge in the mind of the student.
2. Embed learning in a social experience.
3. Use multiple modes of representation (multimedia).
4. Support the sense of ownership and a voice in the learning process.
5. Give the opportunity for reflection. (Ideas must be revisited for learning to occur.)
6. Support interactivity with feedback, thus promoting motivation.

A more detailed explanation of Constructivism can be found at: http://skip.mdx.ac.uk/Report/Chapter2.htm

Two types of interactivity and feedback are offered to the student in this web-based tutorial system; 1) student and system 2) student and participants. The first is interaction between the student and the system. This can result in a navigational movement through the environment by clicking buttons / links .Feedback prompts (message boxes) can alert the student about their progress through the content of the tutorial. The second form of interactivity is between the participants in the learning system. One example of this is collaboration between peers, while the other is communication between the student and tutor / subject expert.

Javascript Tools to Illustrate Web-Constructivism

Although there are many multimedia options on the Web, most require specialist software which can be a slow, time consuming process of down-loading plug-in applications. The Minimalist approach suggests using the simplest method to attain the desired goal [Boyle, 1997]. Using a client-side scripting language, like Javascript, supports this approach in web-based learning environment design. The basic specification for viewing these examples is a Java capable browser that is set to view graphics / animated .gifs. An alternative method of distribution would be to place the files on a CD with a copy of a browser that would allow the information to be accessed locally.

This research supports a problem-solving seminar teaching strategy which encourages an active use of the students prior knowledge to argue with his peers to produce a resolution. There are several steps to this protocol [Jackson 1996, Bensusan 1995]:

1. A starting problem is introduced with its related real-world context.

2. Drawing upon prior knowledge and on-line research sources (i.e.- digital libraries, museums, universities, etc.) help form a preliminary conclusion.
3. Collaborate and confront peers to reaffirm or reassess that solution.
4. Compare this answer to a sample solution produced by the tutorial subject expert.
5. Reaffirm or reassess the answer based on that information

The main categories of functionality for using Javascript in a web-based learning system are discussed chronologically as they would appear throughout the lesson:

1. passwords
2. personal name entry
3. multimedia content
4. new browser windows
5. alert boxes
6. self assessment
7. e-mail tools
8. graphically representing feedback

1. passwords

Security is an issue for any on-line learning system. There are three levels of password protection [1] available with Javascript. An Alert Box prompts the student for passwords to enter the lesson. The collaborative nature of the web supports the second Constructivist principle (embed learning in a social experience) allowing participants on-line social exchange via e-mail, news groups, computer mediated conferencing (CMC), Internet Relay Chat (IRC) rooms and video conferencing [Laurillard 1996 & Brunner 1997].

2. personal name entry

To personalise the lesson introduction of the start problem Javascript can be used to prompt the student for their name [2] which is then placed at the top of the page for each use. This reinforces ownership in the learning process.(figure 1.1)

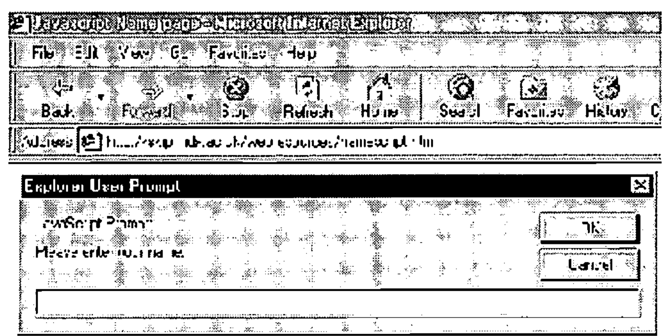

Figure 1.1 Javascript prompt for username

3. multimedia content

A number of Javascripts are available to present the start problem and related content which make use of multimedia to support multiple modes of representation. User interactivity with the material encourages motivation from the participant which supports the sixth Web-Constructivist principle listed above. Information can be in the form of text, still images, animated .gifs (slide show), .avi movie files converted to animated .gifs (using GIF Constructor Set software - http://www.mindworkshop.com/), a series of .gif images taken to simulate a circular pan effect [16] and/or sound as .wav and midi files.The graphics can be image maps which have clickable hyperlinks to increase interactivity. Other multimedia tools requiring special plug-ins are not recommended by this study (i.e. - Quicktime movies for a 360 degree virtual reality effect).

4. new browser windows

There is a Javascript [3] which allows a new browser window to appear over the original screen. This can vary in size, location and features. It can be used to reinforce the content by representing it in another modality. This 'top' window can contain animation to imitate a media player. Sound can be embedded in the HTML file to play upon the page opening or on a mouse click or mouse over event handler.[15] The new browser window can act as a 'windows-help-file' by placing hypertext to offer glossary terms or how-to instructions. (figure 1.2)

BEST COPY AVAILABLE

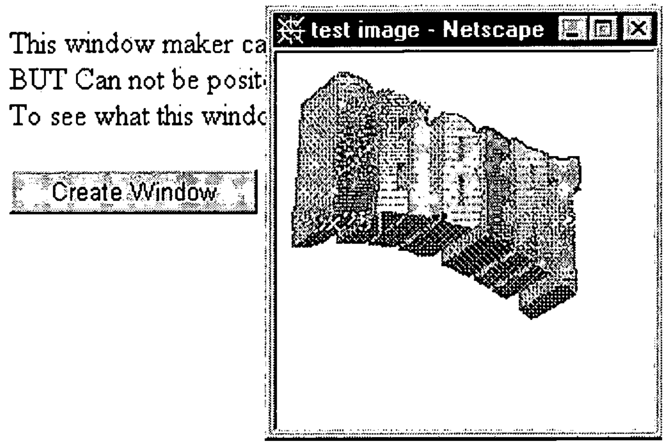

Figure 1.2 Javascript new browser window

The Annotation window is a variation on this theme allowing the student to bring up a on-line note pad of sorts. With the new browser window set to include the title bar menu the student has the option to open the window in the HTML editor of Netscape. This allows them to add text, images or links to an HTML document which can then be stored locally or FTP'ed to a public site [17]. This allows the student to keep an on-line logbook or journal. This can be used for assessed work or as an evaluation methodology [Mason 1996].

5. alert boxes

There are three main types of alert boxes; a) message b) feedback c) exit.

a) message

Alert Boxes (a.k.a.: message boxes, prompt boxes, etc.) are another Javascript tool to promote an active, immediate response from the student in the learning process. There are a variety of ways they may be placed throughout the delivery of the tutorial content. For example, upon entering the HTML page containing the sample solution an Alert message form [4] can prompt the student to confirm that they have developed their own solution *before* reading the tutor's example. This Javascript tools again illustrates the principle of increasing learning through interactivity.

b) feedback

At anytime during the delivery of the content an immediate feedback response is available by clicking a button which may produce an Alert Box response [5] or some text on the page [6]. The text can be a positive/negative prompt (i.e.- "Correct! Well Done. or Sorry! Try Again.") or directions to the location of supportive material (i.e. - "Correct: More details can be found at this URL: http://www.morestuff.com/ or Sorry! You may wish to review this material before going on: http://www.reviewstuff.com/")[7] . (figure 1.3)

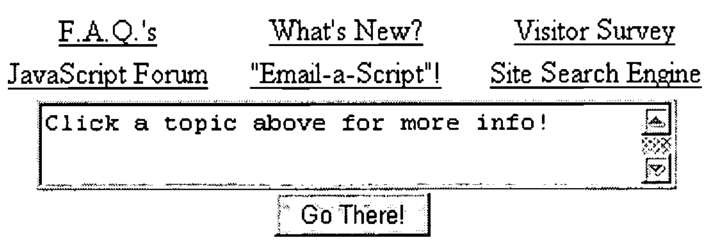

Figure 1.3
Javascript formative evaluation (feedback)

c) exit

Upon completing a section of the tutorial an exit prompt can be issued. Clicking a next or exit link will bring up a "Do you wish to leave this part of the lesson?" query [8]. These embedded Javascripts prompt the student to reflect upon their learning experience throughout the tutorial which supports the fifth principle (give the opportunity for reflection).

6. student self assessment

Student self assessment is a powerful method of encouraging reflection, a necessary part of the learning process [Laurillard 1994]. This research suggests using self assessment as a *formative* method of evaluation (feedback) in the learning system in addition to the traditional summative (end exam) assessment techniques.

There are three general categories of self assessment; a) closed response b) open response c) mixed.

a) closed response

Two closed methods are multiple choice questions [9] and matching [10] using Javascript. Both give immediate feedback, thus supporting interactivity between the student and the system illustrating the sixth principle.

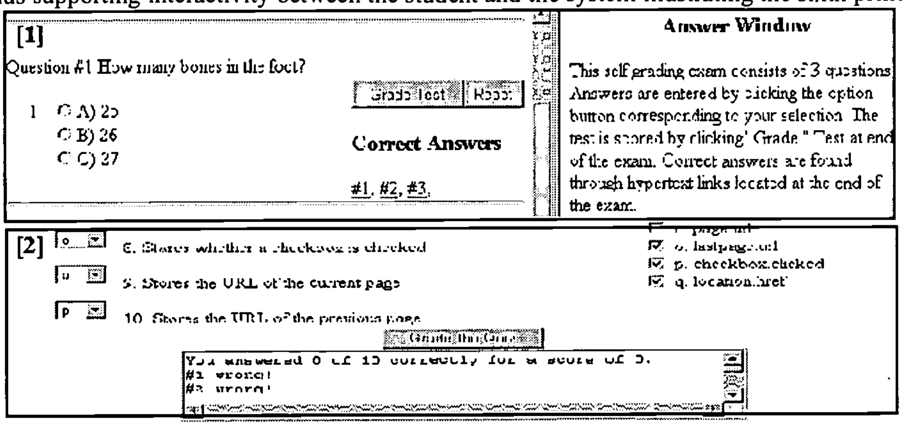

Figure 1.4 Javascript self assessment

b) open response

There are three methods for exploiting the e-mail Javascript tool; 1) preformatted distribution lists 2) use preformatted subject headings to filter responses 3) preformatted e-mail surveys

1) preformatted distribution lists

A Javascript e-mail distribution list illustrates an open response method. [11] By clicking a button a preformatted e-mail message box with an open-ended question can be automatically sent to the group for collaboration and discussion. The student's social experience (principle #2) is supported by this tool. The tutor may also receive a copy of the submission. The student will not be able to use the e-mail reply button since the message was posted to their own address. It is necessary to include the original URL for the distribution list link in the body of the message. The student has the flexibility to return there and reply to the comments .

2) use preformatted subject headings to filter responses

Many e-mail applications have filtering capability which would allow the e-mail generated with a preformatted subject heading to be placed into a specific folder [Brunner 1997]. This has the benefit of helping the on-line tutor organise the potentially large number of correspondence. Alternatively, the e-mail address used for the CC: prompt can be a separate account designated for that on-line class. Many free e-mail services are now available on the web which can be used to receive specific student responses (i.e. - http://hotmail.com/).

3) preformatted e-mail surveys

Reflection can be encouraged after the lesson is completed. On-line surveys can be submitted as HTML forms [12] or as preformatted e-mail questionnaires [13], both of which get mailed directly to the tutor for interpretation and action. This strengthens the learning process by supporting the fifth Web-Constructivist principle. (figure 1.5)

The text submitted from the HTML form will appear as one continuous line of characters in the body of the e-mail message. It is necessary to use software (such as *mailto:Formatter v. 4.01 - rpfries@interaccess.com)* to format the text into separate lines.

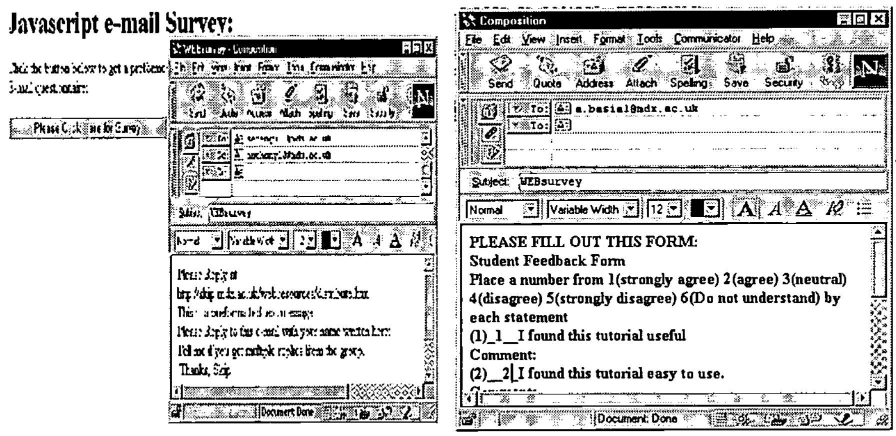

figure 1.5 e-mail surveys

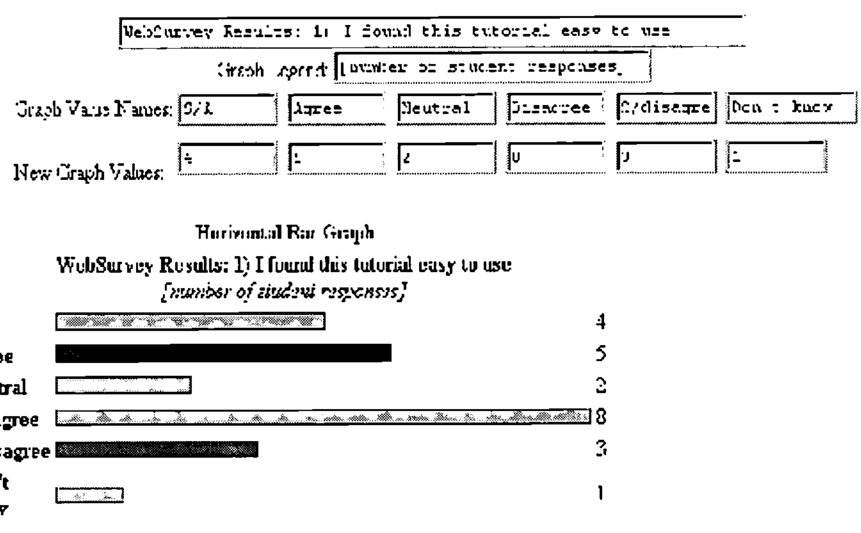
c) mixed

A mixed response combines a fixed reply and open-ended option. This form of feedback is the strongest methodology for gaining both statistical data and the 'unexpected' comment. An example of this is a Likert scale survey which includes an optional description (i.e. - I found the tutorial 1) good 2) fair 3) bad Why ___)(Mason 1992).

8) graphically representing feedback

The data collected by the web-survey can be inserted into a Javascript chart builder to provide a graphical representation of the student feedback for the tutor. [14] This can be printed with the current date on the page for record keeping purposes. This script supports the principle of using multiple forms of representation. (figure 1.6)



Summary

Javascript can support Web-Constructivist principles through every stage of the problem-solving seminar teaching strategy. The learner makes active use of the knowledge by interacting with the tutorial system, on-line resources and colleagues in the lesson. This social approach to learning can be achieved using Javascript e-mail tools. Information can be presented in a number of multimedia formats using images, animation, sounds and simulated virtual reality. An alert box which places the student's name on the HTML page empowers a sense of

ownership. Using formative feedback tools embedded throughout the tutorial the participant has the opportunity to voice their opinion, thus prompting change in the tutorial content or delivery methodology.
Reflection, an important principle in the learning process, is built into the teaching strategy protocol. At the start of the lesson the student is prompted to reflect in order to solve the starting problem. At the end of the lesson self assessment tools also allow review and support reflection. Web surveys prompt the student to reflect on the learning experience and provide the Learning Environment Designer (LED) with the formative feedback necessary to alter the tutorial system to meet the student's needs. Throughout the tutorial the student is prompted to interact with the system, participants and tutor / LED to promote motivation through feedback.
This research demonstrates that by using a problem-solving seminar teaching approach supported by Javascript tools and using the protocols developed in this study a true Web-Constructivist Learning Environment can be realised. An example of this can be seen in the research case study: DELBERT (Digital Environment Learning-Based Evaluation Response Theory) Tutorial System. The Development of Online Integrated Japanese Education System "Terakoya"

Shinichi FUJITA, ChunChen LIN, Kazuto YAMADA, Seinosuke NARITA
Department of Electrical, Electronics and Computer Engineering,
School of Science and Engineering Waseda University, Japan
Narita lab, Sci. & Eng., Waseda University 3-4-1 Shinjuku-ku Okubo, Tokyo, 169, Japan
fujita@narita.elec.waseda.ac.jp

Abstract: The times when computers were literally used only for computation have ended. Multimedia (the synthesis of text, pictures, sounds, etc.) has became a widely used term, as information technology progressed. This is not an exception in the field of education, where much research is being conducted, to make use of multimedia in Computer Assisted Learning (CAL) systems. This paper describes a Japanese education system using multimedia towards the non-Japanese.

1. Introduction

In recent years, the number of foreigners trying to learn Japanese has increased. However, it is difficult to master Japanese even after having lived several years in Japan. The singularities of Japanese, which we will show, remain the first reason.

- The Japanese language, besides hiragana and katakana syllables, uses Chinese characters (kanji). Hiragana and katakana are phonograms, while kanji are ideograms. Languages using combinations of phonograms and ideograms at the same time, in this way, are very uncommon in the world.
- On one hand, the alphabet used in America and Europe has about 50 letters, including capitals. On the other hand, there are over 3,000 kanji characters. In Japan, pupils are expected to learn over 1000 kanji during their 6 years of elementary school. Therefore, the speakers of native English as well as Indo-European languages are troubled by the complexity of kanji: their language does not require intense writing practice nor need to discriminate between numerous characters.
- Some kanji characters are very complex. Their shape is sometimes difficult to differentiate. (Fig.1)
- Many Kanji characters have several pronunciations, while others share the same pronunciation.
- Some words change their meaning depending on the position of the accent. For example "hashi" in Japanese means "chopsticks " when the first syllable is accentuated. It means "bridge" when the accent comes on the last syllable.
- Calligraphy (shodo), an important part of the Japanese culture, pays much attention to the stroke order and the shapes of the characters strokes: "hold", "sweep", "curve ", "stop" etc. (Fig.2) These concepts are essential to the foreigner who wants to master Japanese. They cannot be mastered without practice.

嫁暇禍靴寡歌箇稼課蚊我
戒改怪拐悔海界皆械絵開
街慨該概垣各角拡革格核
学岳楽額掛潟括活喝渇割
缶完肝官冠巻看陥乾勘患
勧寛幹感漢慣管関歓監緩
岸岩眼頑顔願企危机気岐
起飢鬼帰基寄規喜幾揮期
偽欺義疑儀戯擬犠議菊吉

Figure 1: Well-used Kanji characters in Japan.

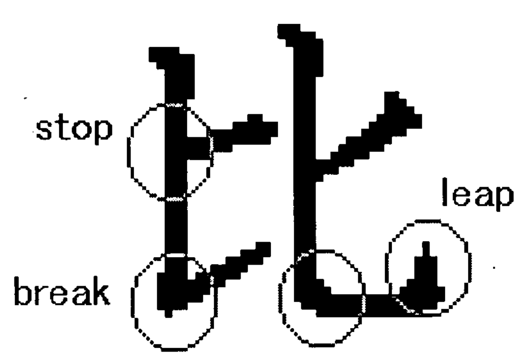

Figure 2: Stop,curve,break and leap

Thus, it is difficult for foreigners to master Japanese. However, the use of multimedia is effective in Japanese education. A sample animation movie can show the stroke order and speed, while the pronunciation and the accent of the word are heard. Of course we cannot ignore the effect of the interest. Using a computer is fun, especially for the children who like computer games. Besides, finding a kanji is faster when using a multimedia database.
Previously, we had developed "Terakoya on the Web" (Omae 97) and "Terakoya Kanta" (Fujita98). This time, we present "Terakoya", an Integrated Japanese Education System, which include them.

2.Past works

There are some software products for Japanese education. They can be classified into "dictionary" and "drill" types. They have the following features and problems.

2.1 Dictionary type

These are electronic dictionaries, giving information on characters. They allow quick reference to pronunciation, sample usage, number of the stroke, etc. But they cannot be used for self-teaching by themselves. They must be used with other materials, such as textbooks and/or drill books.

2.2 Drill type

These can be used for study with input devices, mouse or keyboard. There are three important skills to master a language.

1. Reading
2. Writing
3. Talking and listening

Many CAL software products for Japanese can teach only one of these skills, which is not enough complete to learn comprehensive language skills. Besides it, they tend to provide only little information on characters or words, and do not have much effect on their own.

When these two types of software are used in classroom situations, there is sometimes a big difference between what CAI provides and what the teacher wants to teach. The teacher may think "There is no Kanji characters in this software that I would like to teach" or "I don't like to teach this usage now" or "I want to use this sentence as example".
Our system has some functions to solve these problems as following.

- We developed four types of drill software. One to learn reading skills, another, writing skills and at last, talking skills. Each software is integrated closely. This system can achieve an integrated learning. Students can train reading skills, writing skills and talking skills for a chosen kanji.
- We have integrated database and drill software. This approach can compensate the lack of information in drill type software and the lack of teaching function in a database type software.
- Our system can be configured to fill up a gap between the teacher's needs and the producing of CAL. This is a good help to use CAL effectively in classrooms.

3. For effective CAL

Developing effective CAL requires careful consideration. Animation or sound effects, which would make some children happy, could be only disturbing for adults. For the learner, who wants to travel to Japan without difficulty, it may be unpleasant to be advised on some details, like the stroke order of characters. We must think over the situation in which the system will be used. Is it intended for self-teaching or will it be used in classroom? We have developed software with an eye on the following points.

Generation's gap
- Children: Joyful animations and sounds, easy comments.
- University Students: efficient use.
- Adults: Restful, easy handling.

Situation's gap
- For self-teaching
- In classroom with one computer.
- In classroom with many computers

The goal gap
- So as not to be in trouble during the trip to Japan.
- So as not to be in trouble living in Japan.
- For a native Japanese

We have prepared some learning modes and optional functions, like animation. Our software can compensate the difference of the learner's age or goal. Most software we know is developed for self-teaching or without a general idea of the target. Our software can be also used in classrooms.

4.Model case

In this section, we show an example of effective usage of our system.

Situation: In the Japanese class. There is a computer in the room and all students can see the monitor through the projector.

1. In the class, the teacher selects the character he wants to teach in the textbook or another paper document and searches it in the "Kanta" dictionary software.
2. All students study the information of the character on the projector: the pronunciation, the usage etc,
3. One or two of the students practice the character with the "Kanta" drill software. Other students can look at the appearance on the projector.
4. "Let's practice!" All students practice the character on the paper drill made by the making drill module of Kanta
5. At home, the students can review the lessons on the Internet with a PC.

Of course, besides this usage, our system can be used for self-teaching in classrooms with a computer for each person.
Until now, we could not find CAI software supporting the whole features, from the classroom to self-teaching. Our system does it.

5. Japanese integrated CAI system "Terakoya"

On this base, the integrated CAI system "Terakoya" is composed of three modules.

5.1 Database module

This module has all the information, which a paper dictionary has. Besides, it uses multimedia for the animation of the strokes and the pronunciation of the characters. Our multimedia database has the following good points compared with a paper dictionary.

- Our multimedia database uses animation sequences to teach the stroke order and rhythm. It is about "leap",
- In Japanese, the meaning of some words can changes depending on the intonation. For example, the word "hashi" means "chopsticks" if the accent is put on the first syllable. It means "bridge" in case when the musical accent is put on the last syllable. It is difficult to express these differences with a paper dictionary. We can do it easily with the sound of our multimedia database.

● The desired information can be found faster than with a paper dictionary.

This module is closely co-ordinated with drill module and the student can practice the character he encounters. Besides, the teacher can make paper drills by choosing the necessary data in our database module with the "making

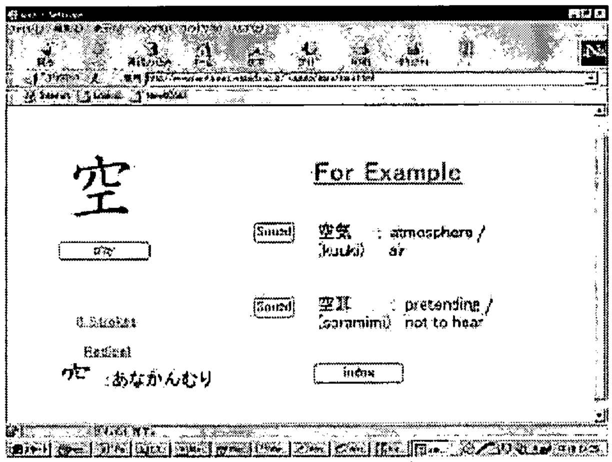

Figure 3: Database Module

5.2 Drill module

Our "drill module" includes two types of software. The first is dedicated to the learning recognition skills of the character. The second concerns the learning of writing skills. Software functions are co-ordinated and the student can practice a word through different stages. Furthermore, he can get information on the words through links to the "database module".

5.2.1 Drill for recognition skills, "Terakoya Web"

This software was presented as a stand-alone at the ED-media97. The student could get recognition skills by re-constructing a character randomly selected with a mouse to form a puzzle, (Fig.4), motivating his study.
In Japanese, some characters are similar in shape, while others are different in appearance from the fonts. (Fig.5) The student can be accustomed to recognize them by constructing their parts with his hand.

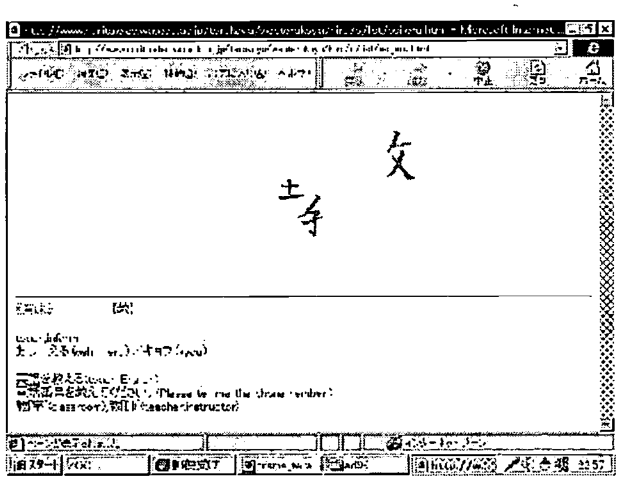

Fig4. Drill for recognition skill

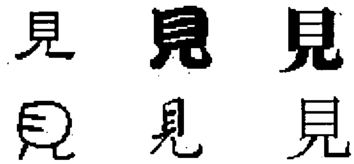

Figure 5: Difference depending on the font.

5.2.2 Drill for writing skills, "Terakoya Kanta"

This software has also been presented as a stand-alone at the ED-media 98. This software has been tested at the Richmond Primary School in Portland, Oregon and Waseda University Language Centre and has got a good evaluation.
The learner can practice the characters with a mouse or a tablet in this module, which advises and shows, like a real teacher, the score for the written character. Our software uses vector and stroke-rhythm information and can find wrong stroke order and other close points as "Hold", "Leap", "Sweep" and "Curve".
The learner can select the learning mode depending on his age or his level. Many animations and happy sounds are built-in for children as an option. This system can make the writing practice joyful.

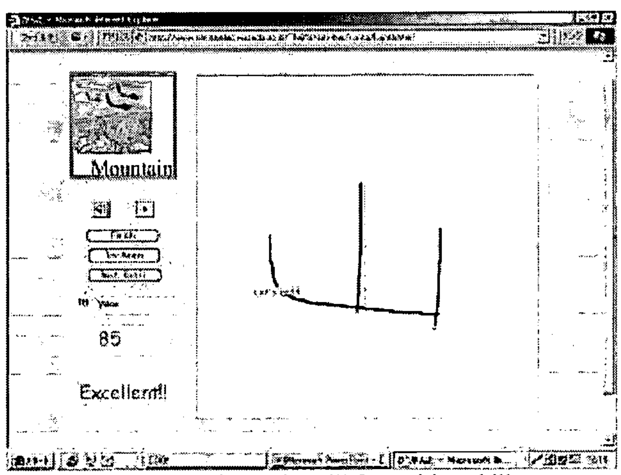

Figure 6: Drill for writing skill

5.3 Module for making drill.

As for the past works, the software of the database module can not be used for self-teaching and sometimes there are some differences between the contents of the database and the teacher's needs. Furthermore, only one person can use the software of the drill module at the same time and schools, which provide each student a computer, are the exception. Therefore we suggest that at first one or two students practice with the software in the presence of all students and then, that all students practice with a paper drill. A paper drill closely related to the drill software will be of great help to the students. To realize it, two functions are necessary.
The teacher can select the contents that he wants to teach from the database module, such as some pronunciations and usage of the word. Thereafter, selected contents should be shown in the drill module, which students do.
The teacher can print out the paper drill. That includes the contents, which the teacher selects.
Our system "Kanta" has these two functions.

6. Conclusion

Use of multimedia is one most effective way to learn a language. Because animation and sound, respectively samples of writing and pronunciation, will be a great help to master a language rather than paper or other media. Of course, we cannot ignore the motivation effect when using a computer. Besides, a much higher efficiency is expected when the learner utilizes the database module for reference.

However, such a system can hardly satisfy the needs of the Japanese education. One reason is the difficulty to teach Japanese on the base of its singularities. Most software we have found can train only certain skills, like recognition skills, writing skills or talking skills. Therewith, it is difficult to utilize them in classrooms because of the difference between what the teacher wants and what the software can produce.

To compensate these problems, we have integrated the database and the drill modules, allowing training recognition skills, writing skills and talking skills. This system is an integrated environment for mastering Japanese. The learner can find the information of a certain word in the database module, and then, can practice the recognition of certain words. At last he can try to write the word. For the use in class, the drill module can be customized according to the teacher's needs. The teacher can also prepare paper drills utilizing our database module.

Our system "Terakoya" is developed on a WWW base so that it can be used on any platform. We are preparing some options to achieve effective learning irrespective of the learner's age or aim to study Japanese. Our system can be used not only for self-teaching but also in classrooms.

7. Future works.

A network version of this system will be tested at Richmond primary school in Portland, Oregon and at Language Centre of Waseda University. (Stand-alone versions have already been tested and got a good evaluation there.) At present, we have a plan to develop a training module for idioms (Jukugo). We are also considering applying this system to other languages.

The Effect of Continuous vs. Discontinuous Feedback in a Simulation Based Learning Environment

Abstract: The aim of the this study was to apply cognitive theory about two learning modes to HCI and to investigate the effect of feedback on user performance in a simulation based learning environment. The effect of continuous and discontinuous feedback was tested in an experiment where the subjects first learned principles of illumination ergonomics with a simulation. After the learning phase the procedural and declarative knowledge were tested. The experiment shows that variations in feedback had no significant influence on the performance and behaviour in the learning phase, but feedback had an effect on declarative knowledge and the users confidence in procedural knowledge. The conclusion is that the discontinuous feedback condition increased the declarative knowledge and the confidence in the procedural knowledge. The differences between the experimental groups can be explained, in that the feedback conditions induced different learning modes in the subjects.

Introduction

Interface design should be theory *and* effect driven. Theory should guide experimental research, rather than phenomenological interest in technological features. On the practical side, knowledge about the effects of user-interface features should guide implementation, rather than technological advances. Today, computing power is not anymore a limitation for implementation, the problem moves from how to implement to what to implement. This paper shall give a better understanding of the impact of theory for interface design, and a context for how to make decision for the implementation of different interface features.

This study combines both cognitive theory and software ergonomics. The theoretical background is drawn from the increasing evidence that people can learn in two different modes (Reber, A.S., 1989; Hayes & Broadbent, 1988). An explicit mode is recognised by a conscious and selective attention towards the problem, while in the implicit mode, the learning is more unconscious and trial and error based. The success of employing each of these modes depends on characteristics of the problem. Previous experiments have shown that different user-interfaces can induce the two learning modes, and that different user-interfaces influence how people learn (Guttormsen Schär, 1998; Guttormsen Schär, 1997a). By way of example, a command-based interface can induce an explicit learning mode, and a direct manipulation interface can induce an implicit learning mode (Guttormsen Schär et.al. 1997b; Guttormsen Schär, 1996). These studies showed a benefit for the explicit learning mode for intelligible learning tasks. A study was designed to investigate the effect of the interface when the differences between the interface features become subtle. How subtle can variations in the user-interface be, and still induce two different learning modes?

The software ergonomics in this study address decisions for the implementation of user-interface features. The effect of continuous and discontinuous feedback of the actions with a simulation was examined. With increasing processing power, continuous feedback to the user is appealing. The effect of this kind of feedback should be investigated in order to gain knowledge of benefits and eventual disadvantages for the user. An effect of feedback in this case would not only be related to aspects of the feedback itself, but would also indicate the degree to which users are influenced by apparently unimportant interface aspects in general. Two actual examples from commercial software illustrate different forms of subtle feedback. The two examples represent continuous and discontinuous methods of feedback respectively:

1) A graphics editor such as Adobe Photo-shop offers filtering options, which are operated by dialogue boxes. In the dialogue box, different parameters can be changed interactively by moving small handlers on a bar. The effect of a change can often be seen instantly in a small preview box. This gives the user an immediate impression of the effect of such a change.

2) The use of 3D programs often involves the following situation: when rotating a three-dimensional object, the user is actually manipulating a simple copy of the object, i.e. a 'bounding box'. The real object is first shown when the rotation is finished.

The theoretical question was whether continuous and discontinuous feedback of users actions can induce different learning modes in the user. The software ergonomics question was whether continuous or discontinuous feedback can be recommended for simulation based learning. The following hypotheses were tested in the experiment:

1) An interface with continuous feedback induces an implicit learning mode.
2) An interface with discontinuous feedback induces an explicit learning mode.
3) Discontinuous feedback results in a better learning effect.

Method

Subjects

24 subjects, between 20 and 39 years participated. The subjects were sampled from different study directions, both men (10) and women (14) were represented. All subjects were paid 30 SFr. None of the subjects had experience with the learning content of the simulation.

The Simulation and the Interaction

The experiment used an interactive simulation of illumination ergonomics for the learning task. The main mask of the simulation is shown in Figure 1. The subjects could install and remove luminaries in a virtual room, and they could move and rotate a working place. The effect of the actual illumination, i.e. the ergonomics evaluation of the illumination configuration was shown on six different scales displayed as bars: *amount of light*, *shadows*, *glare*, *screen glare*, *work place visibility*, and *general satisfaction*. Hence, the scales gave feedback about how the actual illumination and configuration of the room influenced a virtual person. The ergonomics evaluation applied a scale from 0 to 10, and was indicated on the bars by a ruler. In addition, the bars were colour coded: a good configuration made the rulers appear within the green area of the bars. The red area of the bars indicated a bad illumination configuration. The simulation was operated by 'direct manipulation', the subjects could perform all operations by using the mouse to click on buttons, select and drag objects.

Feedback

The feedback in this experiment was directly related to the user actions with the simulation. The calculation of the ergonomics evaluations could proceed in one of two ways: it could be displayed continuously with tracking actions or alternatively the ergonomics evaluations scales could be computed discontinuously and the scales would be updated only when the mouse button was released. In the continuous condition the bars indicating the actual value on the ergonomic scales would instantly move with the tracking movements of an object. In the discontinuous condition the subjects would only see the bars change from the last position on the scale to the new position after the object had been moved to a new position.

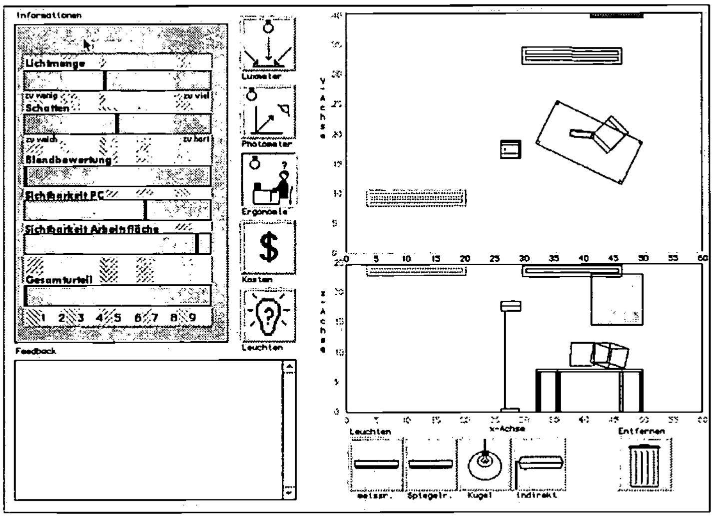

Figure 1: The main mask of the simulation

Experiment and Procedure

The experiment had a 2 X 5 mixed design, with feedback as the between variable and task as within. The independent variables were number of actions per task, total time per task, thinking time between each action, performance (i.e. total scores on the ergonomic scale), declarative knowledge about illumination ergonomics and subjectively estimated confidence in the knowledge from the post learning tasks.

Initially a test of the ability to use a mouse was administered. All subjects were required to complete a puzzle, which required precise positioning with a mouse. The time to complete the puzzle and thinking times were recorded in a log file.

In the learning phase, the experimental task was to create an ergonomic optimal configuration of the working place and the light sources (luminaries and window). All the subjects were required to solve 5 tasks. The tasks reflected variations in the external conditions in the room: the position of the window, and the conditions for the movements of the working place. The working place was initially positioned differently for each task. All the actions with the simulation, the effects on the ergonomics evaluation, and the time per action, were recorded in a log-file.

After the learning phase, 10 post-learning-tasks were administered to test the procedural knowledge of the subjects. The subjects were required to use the simulation to create an illumination configuration in the room. In these tasks the subjects could not see the ergonomic effects of their configurations. In five of the tasks the goal was to achieve optimal illumination evaluations, and in the other five tasks the goal was to achieve the poorest evaluations. After each task the subjects were asked to indicate on a scale from 1 to 100 how confident they felt that they had achieved the target, the objective ergonomics evaluation were not shown to them.

As a test of declarative knowledge, all the subjects were asked to write down their answer to a question, which was designed to measure the declarative knowledge about illumination ergonomics. The answers were evaluated by three independent experts on illumination ergonomics, who were uninformed about the difference in learning conditions during the knowledge acquisition phase. The mean scores of the experts were used as the measure of declarative knowledge for each subject. At the end all the subjects were asked to indicate on a five-point scale how difficult the learning tasks were, and how pleasant it was to use the simulation.

The experiment was run according to the following procedure: 1) Introduction to the experiment, 2) Direct manipulation test, 3) Introduction to the simulation, 4) Learning phase, 5) Post learning tasks + Confidence questions, 6) Questions about procedural knowledge, task difficulty, and user-preference towards the system.

Results

The learning phase did not result in any significant effects of feedback or interaction effects between feedback and task. There was also no difference between the groups on how difficult it was to solve the tasks or on user satisfaction.

In the post learning phase, a main effect of feedback was evident in the subjective confidence in achieving the goals of the procedural tasks, and in the declarative knowledge. These effects can be seen in Table 1. The procedural knowledge were not different between the groups ($p = 0.34$). The reliability between the three independent adjudicators evaluating the verbal knowledge was .86, which indicates an acceptable degree of agreement between the adjudicators.

Feedback	continuous	discontinuous	F	p
Confidence	75.33	83.56	20.28	0.0001
Knowledge	1.15	2.08	3.43	0.0783

Table 1: Effects of feedback in the post-learning phase

A main effect of the post learning task (target 'good' or 'bad') was found for satisfaction and confidence in the procedural knowledge. This effect can be seen in Table 2.

Task	good	bad	F	p
Satisfaction	7.35	2.68	179.25	0.0001
Confidence	75.89	83.00	15.82	0.0001

Table 2: Effects of post learning task

No sex dependent learning effects resulted in the learning phase. The mouse test revealed no significant differences between the groups. The results of the experiment can therefore, not be explained by biased distribution between the groups due to skills in operating the interface.

Discussion

The lack of effects in the learning phase (both on the interaction style and on the performance side) shows that feedback only had an effect on a deeper level. The effect of feedback is, evident by the post-learning tasks. The main effect of task (target 'good' or 'bad') in the post learning phase shows that the subjects succeeded in distinguishing the two targets. The differences in confidence of the procedural knowledge and the tendency of better verbal knowledge of the illumination principles, give reasons to conclude that continuous and discontinuous feedback can induce implicit and explicit learning modes, respectively. Hence, hypotheses 1 and 2 are supported. The cognitive theory predicts these effects. When learning in an explicit mode, people are expected to have explicit and rational reasons for their actions, while in the implicit mode the actions are more intuitive and difficult to verbalise. The negative effect of the implicit learning mode can be explained in two ways: either the illumination principles were not understood or the knowledge was cognitively organised in a way that made retrieval difficult. The latter explanation seems correct based on the fact that there were no difference between the group in the procedural knowledge for the post-learning tasks, i.e. both groups were able to employ the knowledge from the learning phase. Poor cognitive organisation of the learning material was reflected in the difference in confidence in the procedural knowledge between the groups. The subjects in the discontinuous feedback group solved the post learning tasks by relying more on explicit reasons, hence they also reported greater confidence in achieving the target. The effect of two modes of learning is also supported by the tendency of a difference in declarative knowledge between the groups. Learning in the implicit mode did result in procedural but not in declarative knowledge. The knowledge in the implicit group could not be verbally expressed as good as when learned in an explicit mode.

Hypothesis 3 was only partly supported because discontinuous feedback only showed to have a benefit for declarative knowledge and confidence. A stronger result would have been when the effect of feedback was evident for both procedural and declarative knowledge.

On the theory side, the results are in line with the conclusions of our previous experiments (Guttormsen et al. 1997b and Guttormsen, 1997a.) Guttormsen et al. 1997b applied an earlier version of the simulation used in this experiment. This experiment can therefore be seen as a replication of the effect of an explicit learning mode for tasks involving simulation based illumination ergonomics. When the subjects are encouraged to learn with more focused attention,

they are able to invent heuristic rules about the illumination principles, and to apply these rules. The more unfocused attention recognised in implicit learning, obscure the obviousness of such heuristics.

On the software ergonomics side, the results of the experiment may be surprising, because the difference between the feedback conditions was not large. There seems to be a tendency among software developers to not reflect much about the effects of such interface factors. A common opinion seems to be that it is good for the users to get fast feedback as long as computing power makes it possible. In this experiment it is, therefore, worth reflecting more about which practical effects the two feedback conditions actually implied for the subjects. In the continuous condition it is possible that the subjects focused their attention more on the ergonomic evaluation bars than on the actual configuration of the objects in the room. It was in principle possible to select an object and drag it without to look at the objects itself. Every mouse movement caused an instant updating of the feedback bars, hence the subjects could have been implicitly shaped to keep the attention on the ergonomics which navigated their movements of the objects in the room. In the discontinuous condition, the ergonomics values were only calculated and shown when a drag action was finished. Hence, the subjects could focus their attention more on the configuration of the objects in the room. The subjects in this category therefore have learned more about how to configure the objects in the room in order to achieve an optimal illumination and ergonomics evaluation.

Conclusion

Two aspects were addressed in this study: on the cognitive level, the applicability of cognitive theory to HCI was investigated, and on a software ergonomic level the question was whether subtle variations of the user-interface also have an effect on the learning performance. The experiment has shown that implicit and explicit learning modes can be induced in the users by means of continuous and discontinuous feedback respectively. The cognitive theory offers a background for explaining performance effects in the HCI context. This results in a more differentiated way of understanding HCI, as it incorporates the cognitive aspects. Traditionally in comparative HCI studies, the focus is on phenomenological aspects such as the user preferences or task completion times. Task completion time is a performance measure, which does not incorporate the quality of the achieved task solution. This study did not reveal significant differences in user preferences or task completion times. Hence, focusing on the cognitive aspects of HCI have resulted in a picture of the advantages and disadvantages of the user-interface that otherwise would have been ignored. The theoretical approach to an interpretation of user-interface effects is important in showing a more differentiated picture of the effects of various user-interfaces. The theoretical approach is particularly applicable to user-interface design in the computer aided learning context, where the aim is to acquire knowledge. The aim of a program is an important aspect, because the effect of continuous vs. discontinuous feedback could be quite different if applied to another context. Contexts, which are less focused on knowledge acquisition and transfer of knowledge to different task environments, may benefit more from continuous feedback. This may apply to tasks, which require creativity and possibilities to explore. The fact that the intervention by the user-interface was minor, but nevertheless induced different learning modes shows that users of software are extremely sensitive to any effect imposed by the user-interface. The advice for developers is therefore that even apparently minor user-interface features can have significant effects on performance and should be considered. All kinds of interface features should, therefore, be evaluated objectively in relation to perceivable advantages and disadvantages related to the task before they are implemented. Further research in HCI should continue to incorporate the cognitive aspects of using an interface, and effort should be put into investigation of differentiating aspects of user-interface technology.

Abstract: AIMS is a knowledge-based information system whose main goal is to help users to deal in the most efficient way with information within a specific domain in respect to their preliminary defined tasks. AIMS provides the user with an access to the whole information domain presenting to him/her information search, exploration and navigation facilities. AIMS is endowed with an explicit conceptual mapping of the domain knowledge structures and a user model. Within the general system architecture of AIMS we will focus on Information Retrieval and Information Visualisation tasks and will present a solution to some of the problems in this respect.

Introduction

Although the task of searching and finding relevant information is quite an old one, nowadays it becomes very prominent due to the presence of the World Wide Web and constantly increasing amount of dynamic information available there. There are a number of problems that are encountered in respect to this current and extremely large-scale information context. They are mainly related to the searching, filtering, navigation and browsing tasks. In this concern the issues of how to increase the effectiveness of information retrieval and information visualisation are becoming essential for the information management in such dynamic and complex environments.

In this paper we present an approach to Information Retrieval and Information Visualisation that employs the use of Concept Maps for representing classification knowledge. The latter allows for more efficient information retrieval and clear and attractive information visualisation. We discuss a prototype of an Agent-based Information Management System (AIMS) that implements the proposed approach applying the Intelligent Agents technology. The reported work is performed within the framework of some masters and PhD research projects related to the use of Intelligent Agents technologies in Virtual Study Environments. We believe that a combination of agent technologies and visualisation techniques in the context of concept mapping has a very positive impact on effectiveness, efficiency and user engaging in respect to information use, reuse and maintenance.

Information management systems are proposed as a way to improve the usability and maintenance of information. In our project we envisage the management of information as concerning two mutually complementing processes: these of retrieving the right information and visualising it in the right way. Thus the focus of the work is on information search, retrieval and effective presentation to the user. The aim is to support the user in accessing, selecting and understanding the requested information. The main idea was to integrate several technologies that supplement to each other in respect to more effective information management within the framework of distributed environments. The technologies we consider include: intelligent agents (IA), information retrieval (IR), information visualisation (IV), concept mapping (CM) and user modelling (UM).

When we speak about Intelligent Agents we have in mind software components that support a user in accomplishing some complex activities (composed of a number of tasks) within information environments, such as offering, finding, and editing information. Each of the atomic tasks is performed by one or more agents who are presented as autonomous, goal-driven and sensitive software entities with abilities to learn, co-operate and react within complex environments (Travers 96). Intelligent Agents are used in the context of Information Retrieval that involves search strategies over large collections of documents and classification of the available documents. Concept Mapping is one of the main techniques used to support domain ontology (structures). It is a way of graphical representation of concepts and their relations (nodes - link formalism) or visualisation of the human-like knowledge representation based on schema and semantic memory models (Collins, Quillian 70). It is not a new knowledge representation language but just a way to use existing languages for more flexible and dynamic knowledge representation. An important issue among the ones already mentioned is Information Visualisation. There are two main goals for embedding information visualisation techniques within information search and management. The first is to facilitate users' comprehension and provide means for easy manipulation of large amounts of information based on ontological structures and ordering (Welty 98). The second one is to provide an easy to manipulate overview of search results that can make the search process more efficient for the user and that will support successive refined or new searches.

The paper starts with a discussion of the information retrieval and information visualisation issues and their implementation in AIMS. In the following section we focus on a short description of the AIMS prototype. The last part presents some conclusions and future perspectives.

Information Retrieval in AIMS

Information retrieval involves two main issues:

- effective search strategies over large collections of documents;
- appropriate classification of the available documents.

Search strategies concern efficient document retrieval in respect to relevance and recall of the obtained results and effective document retrieval in respect to computation. The efficiency here depends heavily on the document description model. Classification, on the other hand, concerns the design and implementation of a framework for development of multiple classification subsystems used in a single document retrieval system.

The information retrieval approach we propose is based on using intelligent thesaurus represented by the Concept Map technique. This thesaurus plays the role of an active information/knowledge dictionary that supports the domain ontology. It assists users in identifying similar, broader or narrower terms and expressions within a specific information domain and obtaining the assigned information. The classification scheme we use is based on conceptual mapping of terms and relations in a specific problem domain. Our choice is based on CM analogy with human mental structures and means of handling information. Such classification facilitates the dynamic adaptation of the system to changes in the domain. In addition, CM-based classification correlates efficiently with an user model presented also in the form of a concept map of user knowledge, preferences, styles, and tasks. The use of conceptual representation of the domain knowledge and information structure makes the system dynamic and provides methods for automatic manipulation of its information and knowledge. Classification in IR concerns grouping and selecting document descriptors by using document text, statistics, user feedback, document interrelation, collaborative filtering or other criteria. The *DoCS* (Document Classification and Search) model used in AIMS is keyword-based, where each document is described by a correctly constructed set of keywords. The model is defined as a 6-tuple:

DoCS = (D, K, T, Q, E, P), where:
D is the set of all documents in the database: $D = \{D_i \mid D_i, i \in N[1,n]\}$;
K is the set of indexed keywords used in the document descriptors: $K = \{k_i \mid i \in N[1,n]\}$;
T (thesaurus) is a set of keyword-synonyms pairs, describing the relations among the keywords in *K*:
$T = \{(k_i, S_{ij}) \mid k_i \in K, S_i = \{s_{ij} \mid s_{ij} \in [0,1], i,j \in N[1,4]\}\}$, where s_{ij} is the probability that the user would relate the keyword k_j to k_i;

Q (user query) is a set of coefficients specifying the document with its keyword relevant to the query: $Q=\{q_i | q_i \in N[0,1], i \in N[1,n]\}$, where $q_i=1$ when keyword k_i is part of the user query, otherwise $q_i=0$;
E (extended user query) is the set of indexed coefficients for the calculation of the relativeness of a document to a query, $E = \{e_i | i \in [1,n], e_i = \Sigma_{j=[1,n]} q_j s_{ji}, q_j \in Q, s_{ji} \in S_i\}$;
P is the set of pairs (document, keyword set): $P = \{(D_i, K_i) | D_i \in D, K_i = \{d_j | d_j \in R[0,1], j \in N[1,n]\}$. It presents set of coefficients (probabilities) that relate the keyword k_j to the document D_i by the value d_j. This is interpreted as the probability with which the user giving the keyword k_j would be satisfied by the document D_i.

The matching value for the user query Q and a document D_l is obtained by the formula:
$m(Q,D_l)=\Sigma_{i=[1,n]} e_i d_i$, where $e_i \in E$, $d_i \in D_l$.

AIMS document database includes an extensive term thesaurus that defines a special synonym relation in order to support more precise and effective search approximation and selection. Every keyword has a synonym or a list of synonyms related to it with specified weights. Thus if keyword K_1 is related to (is a synonym of) keyword K_2 with a specified weight, this weight can be interpreted as the percentage of the meanings of K_1 that match or are near to some meaning of K_2. When a user gives a search expression the system searches not only for the words in the expression but also for their synonyms. Synonym relation is defined as a full relation, which means that any two keywords are considered linked but some with zero weight.

The search procedure for a query includes calculation of the matching value for each document and sorting the documents by these values in descending order. The documents with higher matching value are considered more relevant to the query than the ones with lower matching value. This algorithm has a simple and efficient implementation by the use of RDBMS and SQL. A SQL query implementing the search procedure would look like this:

```
select d.id, d.title, d.type, d.url, d.description
from doc_keyword dk, synonym s, document d
where (d.id = dk.did) and (dk.kid = s.kid2)
and (s.kid1 in [qkid1, qkid2, ... , qkidm*])
group by d.id, d.title, d.type, d.url, d.subtype, d.description
order by sum ( dk.weight * s.weight ) desc
(* qkid1..m are the keyword ids used in the query)
```

The presented model supposes independence of the documents, the keywords and the synonyms at the stage of document search. This does not affect the generality of the solution since relations between different objects can be accounted at the classification stage. Some of the advantageous properties of the presented model are that it is easy to understand and easy to implement; the matching function is intuitive and natural; the search procedure is computationally efficient in regard to speed and storage; the refine procedure is efficiently implemented by adding new query keywords to the old ones and restarting the search procedure, instead of keeping huge quantities of data between the refine queries. Such refined search is more likely to produce relevant results then the standard ones, which use only the documents retrieved after the first search was initiated.

Information Visualisation in AIMS

Information visualisation supports user's thinking and comprehension processes by activating his/her visual thinking and memory. Visualisation techniques come to reduce mainly user's overhead of finding the needed information and supports algorithmic achievements in finding potential relevant items.

Visual displays in our work are mainly concerned with consolidating the search results into a graph form that is easily processed by the user's cognitive abilities and provides him/her with an additional information about the context of the retrieved results. The graph is presented with the means of a concept map giving the ontology of the domain under consideration. It is the main skeleton for organising, structuring and presenting the documents to the user. It contributes to the effectiveness of search activities by supporting both relationship-guided search for relevant information and its visual presentation. Thus the user is able to navigate through the information hierarchy and focus on specific portions of it but still within the context of the domain as a whole (Fig.1).

Within the AIMS prototype we have defined a Concept Map (a domain term network of structured and related concepts) that explicitly describes the domain structure and knowledge in the area of Courseware Engineering. All documents are attached to the concepts (domain terms). Each concept is a node in this map and is related to other terms with means of labelled relations. A customised set of standard, canonical labels defined by (Lambiotte, Dansereau, Cross, Reynolds 89) is used, which is proved to be useful in mapping of most academic and technical domains. The map provides a spatial arrangement of nodes and links to communicate about concepts and to specify the multiple relationships among concepts in a given information or knowledge domain. This helps the user to process larger numbers of document resulting from searches in shorter time, and to develop a clear view (mind picture) on the information domain: all terms available and their conceptual relations (Jonassen, Marra 96). This type of creative visualisation activates user's imagination by providing him/her with an additional knowledge, context, meaning to the information used. Visualisation of the user search is also quite important part in making the information processing more effective and easy for immediate analysis.

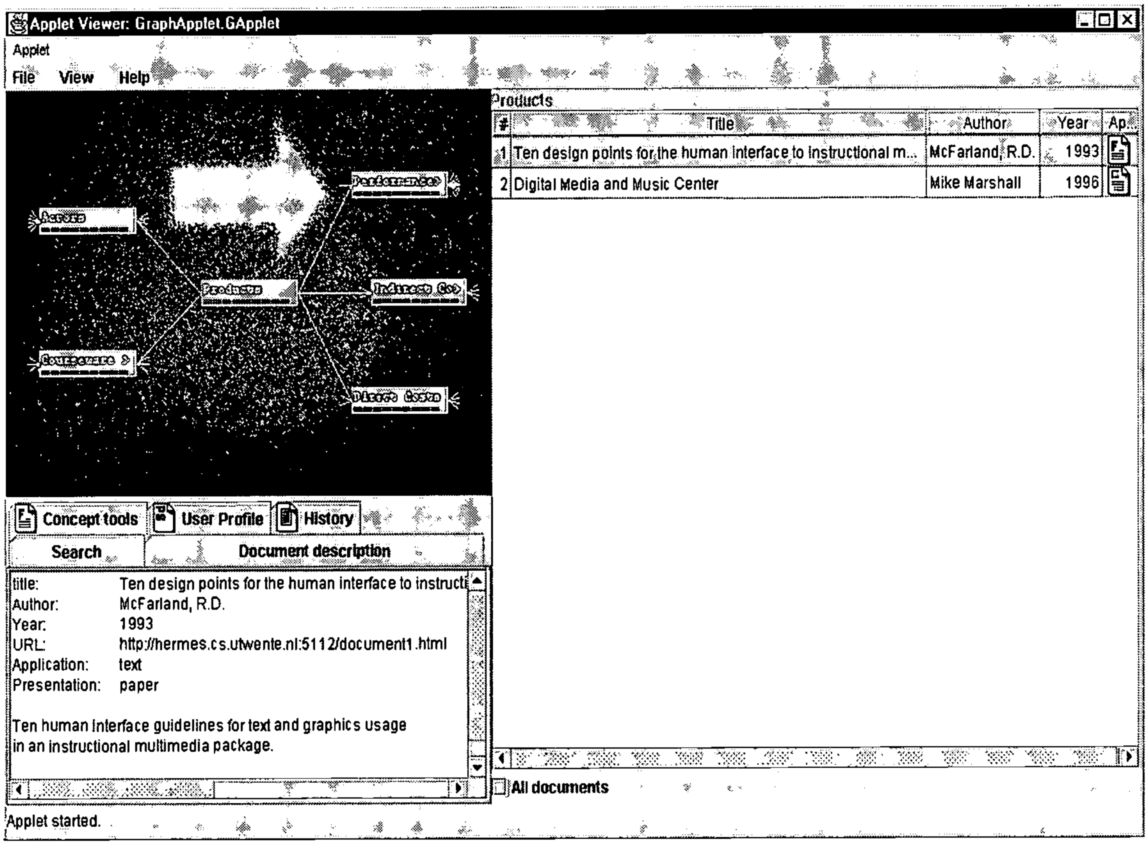

Figure 1: Interface of AIMS: display of search results.

AIMS: General System Architecture

In AIMS we take a social viewpoint to an information system, in which several agents interact by exchanging information, sending specific requests, offering services, accepting tasks, competing with each other for a task to be accomplished or even helping each other. Following this, the AIMS prototype was developed as an agent-based information environment for intelligent management, search and usage of distributed information resources. We look at information manipulation in complex information domains in a new way: we do not conceive it as a mere application of (simple) search engines to collections of information materials. We rather see it as a task that necessitates concise system architecture bringing together the main functional modules for manipulating collections of resources situated within a knowledge and information-sharing environment. A 3-dimentional architectural framework is applied employing multi-agent support for intelligent information manipulation over a visual representation of the information domain, and a conceptual organisation of information resources involving semantic mapping techniques (Aroyo, De Diana, Dicheva 98).

AIMS presents an attempt for integral solution for the organisational management of resources as they are available in a dynamic and constantly changing (electronic) information distributed environment. From architectural point of view the system is built as a multy-agent system. Agents perform different tasks, such as search, presenting the results to the user, user-modelling, etc. Each agent task consists of atomic sub-tasks. Agents have co-operation abilities (communicate with each other, change their behaviour depending on the user action), communication ability (exchange messages), activeness (could be active even when there is no clear user request). The primary task of the system is retrieving information and presenting the results to the user. The agents perform this working in parallel as separate but co-ordinated processes.

Three of the AIMS agents are related to Document Search, Classification and Visualisation task: the Search Agent, the Domain Expert (Classification) Agent, and the Interface Agent. The Search Agent employs the *DoCS* model to perform intelligent search activities over the given information domain. It receives messages that are well-specified queries and finds the documents relevant to those queries.

The Domain Expert Agent is responsible for a set of domain specific tasks, like maintaining the concept map of domain terms (add, delete, check, reorganise, etc.) and by doing this it is responsible for the changes going on in the domain database. Further automation of this agent module can lead to more sophisticated tasks in respect to learning and knowledge building.

The Interface Agent is responsible for the communication with the user. It visualises the information domain structures, search activities, and search results by presenting graphically different parts of the concept map. Its main task is to give the user attractive and effective information presentation in order to make the system more user-friendly and adaptable to single user profiles. In order to make it more natural for the user we have combined graphical representation of the concept map with textual presentation of list of documents related to each domain term in the concept map.

Conclusion

This paper presents an approach to effective and efficient information management by connecting together in one system intelligent agents, information visualisation and information classification techniques. We discuss an agent-based information system AIMS. The core of AIMS is a knowledge base containing the domain model, the user model and a set of rules for concept analysis, pattern matching and decision making. The different types of knowledge and information in the KB are presented and manipulated using the same Concept Map - based knowledge representation and reasoning techniques. This model allows organising the different topics around the key concepts (terms) of the domain. As a testbed we have developed a conceptual model of the domain of Courseware Engineering.

Using the ALICE Virtual Classroom for Higher Education

Shwu-ching Young
Center for General Education & Center for Teacher Education
National Tsing Hua University, Taiwan 30043
scy@cge.nthu.edu.tw

Abstract: This paper documents the rationale of the design of the ALICE virtual classroom to support an undergraduate course on web literacy offered in 1997-1998 at National Tsing Hua university in Taiwan. It describes the ALICE project, in which students used a variety of WWW-based learning materials to supplement collaborative group learning. Major findings of this study reveal that overwhelmingly most of the students were satisfied with the use of the ALICE virtual classroom. ALICE was perceived by the students to be a very innovative, useful and openly accessible virtual classroom that met their different needs and allowed learning at their own convenience and without limitations of time and space. This study also identifies the characteristics of those learners who can get most advantage from using this new medium. Implications for web supplement design and the role of teachers, and recommendations for further research are also discussed.

Introduction

The advent of Internet technologies provides educators with exciting and alternative methods of delivering instruction to and communicating with their students. Integrating the World Wide Web (WWW) and the Internet in higher education is a trend nowadays, and it has been the focus of much research on instruction and learning over the past few years (Wells, 1992; Lai, 1997; Collis, Andernach, & Diepen, 1997; Roussos, Johnson & Leigh, 1997; Freeman, 1997; Oliver & Omari, 1998). The use of the WWW and the Internet in educational settings can be presented in a number of forms, such as information access, interactive learning, networked communication and information presentation (Oliver & Omari, 1998) or overall in a virtual classroom which represents all possible class functions on the Internet (Porter, 1997). According to a study conducted by Wells (1992), with its technological capabilities, the Internet has become an increasingly effective way for teachers to offer computer-mediated distance courses without compromising the quality of instruction.

Using Telecommunication Technologies to Reform Education

Over the past few decades, constructivism has attracted the attention of educators in every discipline. Because the hyperlink techniques of the Internet support the basic ideas and claims of constructivism, the advance of telecommunication technologies and the rise of constructivism have brought fresh ideas to school settings. Following constructivist views, educators have made schooling more student-centered: learning happens when students assimilate information based on their individual experiences, values, attitudes and beliefs. Constructivists believe that learning occurs most effectively in contexts; educators, therefore, should establish real-world-like situations rather than decontextualizing learning in an isolated schooling environment (Jonassen, 1991).

According to Gibson's theory of affordances (Gibson, 1977; Gibson, 1979; Gibson, 1986), different types of instructional materials encourage or afford different types of activities. The affordances of the advanced telecommunication technologies on the Internet make a computer-supported real-classroom like learning environment available. Studies (Sun & Chou, 1996; Freeman, 1997) indicate that the use of Internet technologies with the affordances of multimedia presentation could provide learners with a more creative and innovative interactive learning environment in which flexible and alternative modes of content were delivered. Multimedia-based Internet courses could accommodate various kinds learners preferred mode of learning, such as hands-on learners, traditional learners, visual learnersc. If the courses on the Internet are well designed, they could offer learners a wide range of choices, so that learners could find the right mix of interaction and learning style to enhance their individual capacity to learn.

Description of the ALICE Project

ALICE, an acronym for Asynchronous Learning in Interactive Computer-network-supported Environments, is a research-instructional-oriented project funded by the National Science of Council (NSC) of Taiwan. It is basically a virtual classroom created on the Internet. The ALICE system intends to provide a rich, interactive and collaborative setting used to enhance learning and interaction for an undergraduate course on web literacy offered in the Center for General Education.

Based on the constructivist views of instructional system design in both concept and construction (Lebow, 1993; Jonassen, 1997), ALICE aims to be an inviting environment that integrates four major principles as follows:

A familiar distant interactive learning environment that is similar to a traditional classroom setting with the integration of computer networks, multimedia presentations, data bases, and the like;

1) A student-centered, openly accessible channel that encourages and supports students' active and self-regulated learning processes and that accommodates the needs of their personal learning style;
2) Both a well-structured and ill-structured environment that on the one hand provides the learner with a course pre-organizer, such as an on-line syllabus and rich and digestible domain knowledge in web applications; and on the other hand allows the learner to flexibly hyperlink and explore issues related to networking computer applications in learning and living;
3) An interactive and collaborative environment that provides settings for a community of practice (Lave & Wenger, 1991) through engaging and dynamic interactions in sharing information and knowledge between students and teachers and among students.

The ALICE virtual classroom is secured with the use of students IDs and passwords. Some pages, such as Bulletin Board, Conference Area, and Assignment, use forms and appropriate CGI scripts at the server end to manage the interactive messages. There are eight components in the virtual classroom, including:

1) Bulletin Board: providing learners with the most recent announcements;
2) Syllabus: including the rationales and goals of the course, tentative course schedule, weekly assignments, criteria for grading, required and suggested readings;
3) Instructors: presenting the instructor's personal background information, such as photos, degrees received, academic and research interests, correspondence;
4) Students: connecting to individual and group students' homepages that contain rich and various presentation styles;
5) Conference Area: allowing students and instructors as well as system masters to communicate with, post, share, reflect and discuss what they have browsed on the Internet. It expands the nature and scope of themes originally designed for the course;
6) Assignments: allowing each group to post their group discussion, reports and final projects;
7) On-line Readings: uploading weekly related reading materials in text-based, multimedia-based or powerpoint-based electronic forms;
8) Network Resources: linking to related web sites in order to fully utilize the rich resources on the Internet.

Methodology

1. Purpose of the Study

The purpose of this study was to investigate possible uses of the ALICE virtual classroom to support learning and instruction on an elective Web Literacy course in general education. The study sought to investigate answers to the following sets of questions:

1. What were the perceptions of students to the use of the ALICE virtual classroom as an information source and alternative environment to support learning?
2. Are learning styles, access to ALICE, and prior computer knowledge and experience important factors? What were the factors affecting the attitudes of the students towards computer-mediated discussion? What were the characteristics of learners who chose to take this course?
3. Did the use of the ALICE system support collaborative learning?
4. What challenges could a teacher be confronted with in using advanced technologies to support instruction?

2. Research Design and Data Collection

This study was conducted using both qualitative and quantitative research methods. The primary data collection methods included the use of observations, formal and informal interviews, and two sets of pre- and post- survey questionnaires which were administered to students to solicit information on demographic data, attitudes and prior experiences and knowledge toward computing network technologies. Observations were conducted weekly during class time in 16 weeks. The researcher kept field notes and reflexive notes immediately after each observation. Meanwhile, notes taken from informal interviews served as an adjunct data source. In addition, traffic on the web site was logged. The Webtrend program was used to analyze the traffic and provide summary access information on all of the files/pages presented at the site. Messages posted to the Conference Area were analyzed to examine the patterns of communication.

Triangulation was used to improve the probability that findings and interpretations found would be credible. Multiple sources of data verified that the data collected in the survey were consistent with what was being said in the interviews and observed in classrooms. Data were collected, transcribed, reduced, coded, categorized and analyzed in response to the research questions.

3. Participants

Participants involved in the study were 54 undergraduates, 49 male and 5 female students, enrolled in an elective general education course entitled "Computer Networks, Learning and Living". They were from 6 colleges (Science, Engineering, Electrical Engineering and Computer Science, Nuclear Science, Life Science, Humanities and Social Sciences) of a northern national university located in Taiwan. Their grade levels ranged from undergraduate freshman to senior.

4. Instructional Setting and Course Delivery

"Computer Networks, Learning and Living", a 3 credit-hour course, is basically an interdisciplinary course designed for learners from different disciplines. The purpose of this design is to get students from a variety of backgrounds to share and contribute their thoughts or techniques on web literacy from various perspectives. In addition to a weekly class-based two-hour seminar, the course places a great emphasis on the use of the ALICE virtual classroom, so that participation on the Internet counts for one credit hour. This pedagogical strategy was employed to increase students' involvement on the Internet.

All of the related information and reading materials were stored on the Internet. No handouts were distributed at the weekly class seminar. From the outset of the semester, students were requested to form 10 groups on a voluntary basis, and a mix of academic backgrounds and different computer experiences in each group was highly encouraged. Since this course was designed for collaborative learning, group scores were a big proportion of each individual's grade. The students were given a series of questions and activities to guide their readings and inquiry. Students were required to use the resources at the ALICE virtual classroom and other web sits to answer the questions and prepare for the group discussions, which formed the basis of the classwork each week. Each group leader was responsible for the postings of the group reports on the "Assignment" interface for critique.

Furthermore, students were directed to seek out new resources and were required as part of their course to recommend 10 relevant web sites with personal comments which represented a student's summary or impression of the information presented at the site. At the end of the semester, each group was required to complete a theme-based homepage project. Collaboration enabled them to learn about homepage production by HTML, Photoshop, GIF Construction, or CGI script. Each student was expected to have interactive hands-on learning experiences through a community of practice (Lave & Wenger, 1991).

Preliminary Data Analysis and Results

1. Students' Perceptions of ALICE

Major findings of this study reveal that overwhelmingly most of the enrolled students were satisfied with the use of the ALICE virtual classroom and were positive in their responses to questions regarding the value of information obtained from the links provided weekly. Feedback from the students indicated their love of the image of ALICE borrowed from "Alice in Wonderland" created by Lewis Carroll in the 1860s. They enjoyed the new interpretation as ALICE in Modern Wonderland--Cyberspace. Yes. It was expected that every student would become a happy ALICE and learn through the Internet. According to the students, ALICE was a very innovative, useful and openly accessible virtual classroom that met their different needs and allowed them to learn at their own convenience and without limitations of time and space. However, some students remarked on the frequent instability of university server systems and difficulties in accessing the virtual classroom when traffic might be heavy in the daytime. From the students' traffic patterns collected from the ALICE virtual classroom, it was found that students who possessed personal computers had more convenient access 24-hours per day than those who did not.

2. Who Can Benefit from ALICE ?

According to the data gathered from the questionnaires, among the 54 enrolled students, 49 (91%) were male students and 5 (9%) females. Referring to the undergraduate population of the same academic year of 1997-1998, the ratio between males (total 2601) and female (total 1073) was 2.6 to 1. Obviously, female students were underrepresented in this course. Their self-report data showed that 100% of the enrolled students had prior computer experiences, ranging from beginner to expert. Most of them claimed to be at intermediate level. When looking at students' academic backgrounds, we found that the distribution of their College origins was not even. 52% of the enrolled students were from the college of Electrical Engineering and Computer Sciences and the rest, 48%, were from College of Science (19%), College of Engineering (11%), College of Nuclear Science (9%), College of Life Science (7%) and College of Humanities and Social Sciences (2%). Consequently, students (52%) from the College of Electrical Engineering and Computer Sciences had strong interest in taking this course, while the lone student (2%) from the College of Humanities and Social Sciences expressed the least interest. In several interviews with students of College of Humanities and Social Sciences who dropped out of this course, they unanimously expressed their opinion that the course was difficult for them because they got stuck and frustrated on hearing a lot of terminology about the Internet at the first two weeks. Actually they did not use computers in their daily life. Lack of comfort and confidence with the computing technologies was the main reason given for dropping out.

3. Challenges to the Role of Instructors

The data collected from the instructor's field notes indicate that in addition to the weekly two-hour class seminar, the instructor had to spend an extra six to ten hours per week at the virtual classroom. In order to keep tracking students' weekly learning and their participation, the instructor spent large amounts of her time attempting to interact with students' email and WWW postings on the Conference forum and read through or visited related materials or web sites as recommended by the students. Ironically, the benefits of the Internet to the students could become an enormous burden to the instructor. Accustomed to the use of telecommunication technologies, such as e-mail and BBS, younger generations are gradually conditioned to get instant reply /feedback. If timely replies were not given, students expressed their impatience.

Offering web-supported courses is not an easy job for the instructor in terms of web course design, time involvement, system maintenance and so on. First of all, it takes extra time and efforts to create a web environment and design multimedia courses on the Internet. Along with the attributes of the new medium, such as high efficiency in communication and open access and interactivity, using the Internet for instruction is more labor intensive and time consuming. The role of educators is changing with the integration of modern technologies. Instructors in this computer-network-mediated instructional setting are becoming facilitators and learners as well. Because the technologies advance at amazing speed, instructors are actually learning from their students, particularly the technical aspects of advanced computing technologies. Instruction and learning are occurring at the same time.

Summary and Conclusion

The design and implementation of the ALICE virtual classroom to supplement a conventional course provided expected outcomes from the students' side but also several unexpected challenges to the instructors. This study indicated the appropriate integration of the Internet could produce real learning but not virtual learning only, as claimed by Ashworth (1996). Originally, the purpose of this course was to integrate the ALICE virtual classroom with teaching about web literacy for students from diverse backgrounds. This study supported our contentions concerning the potential of ALICE to provide more innovative, motivating, engaging, useful and convenient learning opportunities for the enrolled students even though at times ALICE as an information source proved frustrating and annoying to learners on several occasions when the server was down or the information could not be easily retrieved. However, the findings also revealed a numbers of factors which served to hinder learning opportunities for a certain group of students. For example, female students and those students from backgrounds in Humanities and Social sciences were underrepresented in this course. They, in general, lacked of prior computer experiences and were not confident and comfortable in taking computer-related courses. It is important to take these factors into consideration for future course design and offerings.

Incorporating advanced technologies into an existing learning environment can be an exciting but challenging task. How to help students learner better and more effectively, supplemented by advanced technologies, and how to make teachers enjoy giving the course without experiencing too much stress--these questions deserve further study from the aspects of instructional design, teaching load, intellectual property on the Internet, teacher training and logistical support.

Enabling Professional Learning in Distributed Communities of Practice:Descriptors for Multimedia Objects

Christine Steeples
Centre for Studies in Advanced Learning Technology (C SALT)
Lancaster University, Lancaster, UK
C.Steeples@lancaster.ac.uk

Peter Goodyear
Centre for Studies in Advanced Learning Technology (C SALT)
P.Goodyear@lancaster.ac.uk

Abstract: This paper explores how the use ofmultimedia communications technologies to enable elements of real-worldworking knowledge, that are tacit andembedded in working practices to be rendered into shareable forms forprofessional learning. Communications technology offers innovative ways forgeographically distributed professional communities to create, annotate,discuss and reflect upon multimediaobjects that capture working practices, such as problems of practice. Thepaper reports on work-in-progress on multimedia objects (primarilydigitised videoclips). Use of multimedia in professional learning isrelatively novel, and it is surfacing issues about the requirements for creating shareable, effective representations.Descriptors for multimedia objects have been developed and the paperfocuses on applying the descriptors to an example videoclip. The durationof the clip, it's use of artefacts and the social cues in the clip are considered key factors in creating ashareable representation for discussion and reflection in distributedprofessional communities.

Introduction

This paper concerns asynchronous collaborative multimediaenvironments used to support professional development; to enable key elements of real-worldworking knowledge, that are tacit and embedded in working practices, to berendered into shareable forms for improving working practices and forprofessional learning. We believe multimedia communications technology can offer innovative ways of: a)capturing rich examples of working practices (and the tacit knowledgetherein); b) rendering the examples into communicable objects; c) sharingand subjecting these objects to close scrutiny within a community of learners; and by so doing d) create authenticexperiential and reflective environments for learning.

Real-world practice as performed by professionals is highly complex.Skilled practitioner performance is underpinned by contextualised andvocationally-relevant knowledge (eg Schön, 1983; Lave & Wenger, 1991). This situated knowledge, tied to anddeveloped through practice, is considered highly valued for improvingactual working practices (Cervero, 1992; Koschmann, 1996). It is part of what shapes a community of practice and helps makes it an authentic'arena for learning' (Barab & Duffy, in press). However, since thisknowledge is tacit and embedded within practice, it can be very difficultfor practitioners to describe and share their knowledge (especially in a written text), without making an extendedaccount of the context, tasks, etc. Schön (1987) has argued by observing and reflecting on action, it is possibleto reveal the tacit 'knowing' implicit in 'doing'. This paper describes a new approach to sharing real-world knowledge for learning aboutprofessional practice: an approach that exploits asynchronous multimediacommunication technologies.

There are three key elements to this approach. Firstly, multimediatechnology enables us to capture (eg in video clips) rich and vivid examples ofpractitioners engaged in real-world practice. Secondly, the communicationstechnology enables the captured examples (or multimedia objects) to beshared and discussed among distributed professional communities. Not least, the asynchronous medium means the objectsand discussions can persist for revisiting, for reflection, and they can bemade available to other, especially newer members within a community.

Next, the context for this research is described and the kinds of representation that might be captured in amultimedia object are presented. The paper focuses on the creation of justone kind of representation, making use of descriptors to classify and tohelp understand key aspects in the multimedia object.

The SHARP and Voice Annotation of Multimedia ArtefactsProjects

This paper reports on two discrete but related projects: (i) aEuropean-funded project, SHARP (SHAreable Representations of Practice).SHARP concerns pedagogical and organisational aspects in the use of asynchronous multimedia conferencing(AMC) (see also SHARP Project Team, 1998); (ii) an ESRC (UK's Economic andSocial Research Council) project, Voice Annotation of Multimedia Artefacts.This project explores multimedia communications technologies used for reflective learning from group basedtasks.

In both projects, we have developed example video clips to help builda conceptual model, and as a way of simplifying and ordering the space ofpossibilities within which continuing professional development might occur when using distributedmultimedia communications technologies (Goodyear & Steeples, 1998)

Kinds of (video) Representations of Practice

Three broad categories and six potential 'kinds' of videorepresentation of practice have been identified. The distinction between*kinds* reflects their distance from the purity of a working practice, occurringin (non-observed) normal conditions. They therefore represent instancesalong a continuum from near-pure, through degrees of abstraction, to a wholly artificial rendering of practice. (see alsoGoodyear & Steeples, 1998). The broad categories include:

Near pure representations eg 'fly on the wall', and 'thinkaloud' or 'concurrent verbalisation'. To illustrate, we use theterm 'fly on the wall' for video clips which are, in some sense, 'raw'representations of practice: clips generated by techniques which TVdocumentary makers call 'fly on the wall', because the camera - and thefact that a representation is being created- are meant to have no significant disruptive effect on the practice.

Action with commentary representations eg 'commenting whiledoing', 'talking head', and 'prepared script'. Clips which we call 'actionwith commentary' are those in which the practitioner uses the voice track to a video representation of an unfolding practice,as a way of making that practice more comprehensible to others

While'near pure' representations may seem intuitively appealing as ones mostlikely to capture the *essence* of practice, trial work has revealed important difficulties in adopting such anapproach. For any kind of extended or complex practice, many hours of videowill likely be produced, requiring skilful editing. This suggests thesekinds of representation have a number of major limitations, not least in terms of their cost effectiveness. Incontrast, 'action with commentary' kinds appear to have a useful balance ofstrengths over weaknesses. They can still be firmly rooted in real worldpractice, but created without unduly excessive demands upon practitioners.

Descriptors for multimedia objects

To help make sense of representations, a set of descriptors can beapplied to multimedia objects. A four-way partitioning of the descriptorsis made under the headings of 'substantive', 'communicative', 'technical' and 'social' aspects. Figure 1below summarises the descriptors. The descriptors help to make sense of thevariety of factors that can be applied when describing a multimedia object.The descriptors help when looking in detail at exemplar (video) objects, to identify relationships betweenthe descriptors and to look for particular patterns emerging betweendescriptors. A brief outline is given below for the descriptors, using theterm 'subject' to denote the practitioner.

Substantive	Communicative	Social	Technical
• Nature of practice • Visibility Temporal extent • Involvement of artefacts • Role/status	• Intent • Audience awareness • Discoursemoves • Use of artefacts • Completeness	• Number • Gender • Role • Status •Cues given	• Method of capture • Duration •File size and format • Richness in form •Output provision

Figure 1:descriptors for multimedia objects

*Substantive*aspects include looking at the nature of the practice itself: eg what it isabout and whether there are sub-activities; who is involved; where ithappens; its frequency, etc. Substantive descriptors also include thevisibility of the practice especially if it is primarily a cognitive task,where little visible activity would normally occur. The temporal extent of the practice also needs to be considered.For example, the practice may last just a few minutes, or it may extendover weeks, even years. It may be important too, to examine the practice'suse of artefacts which might assist in the process of referential anchoring (Resnick, 1993) and thus may actas cognitive aids and help in communication about the practice (Säljo,1995). The subject's status/role in the practice may also beidentified.

Communicative aspects are those thatmake the object communicable and shareable. 'Intent' concerns thesubject's purpose in creating the representation, eg to show a practicebelieved to be of value to others, or to seek help, or to demonstrate aspart of an ongoing discussion. Communicativeaspects also include the extent to which the subject is aware of anaudience when making the video clip, and whether the subject draws uponartefacts to help give an explanation. 'Discourse moves' classify thelinguistic form of the representation eg as a question, a statement, a disagreement, etc. We are also interested inhow 'complete' an object might be, or whether it is reliantupon later elaborations, such as in an annotation, to render it intoashareable form.

Social aspects are primarily suggested for objects involving more than one person, where we might identifyaspects of group dynamics (such as gender and status) in multimedia objects. (Eg, of a video clip we might ask 'what is it about the way this groupwork together and the roles they adopt that helps create a thought-provoking representation of practice?').'Social cues' relates closely to communicative aspects, but concerns theextent to which the subject uses language, action or voice tone to suggesta sense of community, eg by inviting others into a discussion.

*Technical*aspects relate to the specifics of creating theobject including the method and management of capture.. Technical aspectsalso include the object's file size and its duration. Duration is likely tobe critical in determining the usability by others of a clip. Technically, the clip can also bedescribed in terms of its richness in form, ie whether it includes movingor still images and/or voice. Output provision will describe thefunctionality offered to users to control the play, eg whether the clip can be replayed, if play can be halted,moved back and/or forward, etc.

Applying the descriptors to an example multimedia object

In this section an example video clip, created with a practitioner inthe educational/training technology field, is examined using the descriptors for multimediaobjects. The reader may find it useful while reading this paper to look atthe clip on the SHARP website at:http://www.lancs.ac.uk/users/edres/research/sharpdemo/multimed.htm

Explaining a problem of practice

This video clip is used to explain and reflect on an authenticwork-related problem. In terms of *kinds* of representation, wesuggest this clip falls within the family of 'action withcommentary', and is closest to a talking head kind of clip. In this case the subject, Sonia, is using a computer program todesign and develop a paper-based A5 booklet. Sonia encounters this task anumber of times each year, but not sufficiently regularly to expendtargeted effort in learning how to cope with it in more time-efficient ways. The problem is usually met whenworking to a deadline, when it is essential to be working directly on task,rather than learning how better to use the tool.

Sonia explains to camera, using a booklet to demonstrate aspects of the problem. The clip provides a relatively easy way to show asshe talks. She can draw upon (and show) an actual artefact in ways that areinherently easier than if she were to create a text description. Thecapture method assists the communication process. The listener/viewer can see the artefact under discussion aswell as to hear/watch the explanation. The audience can see Sonia, hergestures or movements and hear her voice (including the changing tone ofher voice). The method of capture therefore has potential to assist the audience in making sense of Sonia'sproblem. The clip is prepared with an audience in mind.

Analysing the clip for relationships between key descriptors

The example video clip is a relatively generic problem of practice,sufficiently germane for widespread recognition by people accessing ourwebsite. It is distinguished by at least three key features, discussedbelow.

The duration of the clip and the richness of its form

It took just two minutes to prepare the clip, which lasts exactly 79 seconds. Beyond editing the start and finish of theclip, the recording was continuous and nothing has been changed. Ittherefore represents a concise yet coherent account of the problem, whichhas taken little effort or time in capture.

The duration over time is an interesting factor to probe further. Inthe 79 seconds, the subject speaks 180 words and makes 5 other utterances('ums'), which equates to 2.27 words per second. We made a rough andready, quick comparison by creating anaccount of the problem, in a textual message. This was similarly done "onthe fly" by one of our research team who was familiar with the content ofthe clip and who uses a word processor daily. In the test, it took 150seconds, to create the text and in that time 120 words were typed. No time was spent on correcting spelling orediting the message. On completion it was observed that the text messagehad taken almost twice as long to achieve, and though it does create acomparable description, it fails tocomment on three aspects that are spoken of in the video clip. Figure 2 and3 below illustrate respectively the transcript of the video clip and thetest (text) message. While a strict and rigorous comparative analysis isnot suggested between the two, the limitations of the text are apparent. It fails to capture the richnessof the clip: we do not see the subject or artefact, nor hear thesubject's voice and cannot see her gestures and references to the artefact. Andit does takes longer to create.

OK Ihave a problem in producing documents in A5 format like this. I do thisin Word.
I know there are other packages that would be better um such asPagemaker, would be better tools for doing this, such as Pagemaker but forvarious reasons I do this in Word.
I do it about four times a year and the problem is having a goodformat that enables me to number the pages in some automatic numbering way.
The way I do it currently is just to type in the page number and I workout by drawing diagrams um which page needs to be opposite which page so um page 2 is opposite page 11 and it carrieson like this in a way that is not immediately obvious. And each of thesepages is a page um within Word, divided into columns
It's a two column page, um, and it's a really clumsy way to do it andI know it's a clumsy way to do it, but I haven't thought of a better way todo it. So that's my problem

Figure 2: transcipt of the audio track on the video clip

Duration will also becrucial to the audiences for multimedia objects, such asvideo clips. Since video clips are inherently linear and sequential (inboth visual and aural terms), attention to their content is likely morelimited than attention to a text that can be visually scanned. Yet, theclip's *persistence* as a stored object and the control and playback provision provided couldprove influential for improving the *viewing* of multimedia objects ieto enable new forms of visual/aural scanning.

In time, voice technology will enable rapid, easier creation of textmessages. It is also widely suggested that the creation of text-based accounts promotesdiscursive and reflective representations, considered beneficial for'deeper' processing (eg Laurillard, 1993; Mason, 1994). We do not discountthe value of reflective text messages for learning, but the anticipated ease of use will not overcome the lack ofvivid, rich content *and* the support for social cues that areintrinsic features of multimedia, and requisite for 'showing anddoing' in professional learning

My problem concerns using a word processor, Word to creatbooklets such as A5 booklets.
I use word to do this but I know it would be better using a desktoppublishing package.
The problme concersn pagination of the pages.
In Word I have to splkiut an A4 pages into twocolumns and number the pages maually to get the right pages next to eachother in the final prionted document
because you need to have an oder that is notimmediately obvious such as page 19 being opposite page 2 so thats myprobmlem and I know I hanbndle it in a clumsy way
but there's never seemed an easier way to do it.
I hope you can help.
***Omissions from the text:** does not comment on number of times peryear doing this task; does not mention Pagemaker; does not mention drawingdiagrams*

Figure 3: test tocreate the same message using text

Use of artefacts as 'cognitive aids' and to 'ground' the representation inpractice

We believe the use of artefacts in video representations will beextremely valued for aiding the demonstration and unfolding of a practiceand for ensuring the clip is faithful to real-world practice and not anabstracted theoretical justification of it. A practitioner who is calledupon to describe their actions, without the referential anchor(s) of theartefacts used in, or produced from,the practice may well describe, in abstracted ways, the theory, rules orideals that are the starting points for their actions. The use of artefactshelps the practitioners' descriptions and explanations to be grounded inthe reality of their actions. In the clip Sonia makes verbal and (physical) visual reference to the booklet.She uses it to help *her* to explain the problem. The booklet is central to her representation; toextend her use of language. It mediates between thought processes and herspoken word. The booklet helps ground the explanation in the reality of thepractice. The artefact is also a mediational tool for the audience: to helpthem understand about and relate to the represented practice. It is avisible object that helps in creating a picture of a socially meaningful activity, among a community's members.

The artefact can also mediate between us and reality, in terms oftime. In this clip, the booklet (alongside Sonia's explanation) enablestime to be transcended. The clip shows the finished booklet and we hear about the pagination problem: we do not have towitness every stage/process in the booklet's development. Thisoffers timesaving opportunities by temporally delimiting the representation.

Social cues to the community of practice

Future working in *distributed* professional communities will probably mean many of its members will nothave physically met, yet we believe it will be important for learning insuch communities that there is a sense of identity and trust between themembers. Visual and aural aspects of the clip will help establish the community.Within Sonia's clip, through the images and sound track, we gain a sense about her. Wecan see what she looks like, hear her voice and gain a sense of her ways ofdoing. She suggests trust by confiding about her problem- eg in her reference to the "clumsy"way she currently performs this task. Sonia gives cues to her audience, toencourage responses from other members of the community. She is invitingothers to express their views or to offer advice

The duration of the clip and its richness in form, its use ofartefact and the social cues within the clip we suggest distinguish thisclip. Yet there is nothing inherently unusual in it that cannot bereproduced in other clips of practice. This suggests to us that video representations do offer innovative,vivid yet effective means for sharing in professional communities, whichwarrant further investigation.

Future work on annotating representations, especiallywith audio

'Near pure' video representations seem intuitively to suggest themselves for capturingpractice in near-authentic ways, yet if we want to stay closer eg to fly onthe wall kinds of clips, we see a rising importance to add annotation(s) tothe base representation, thuscreating complex multimedia objects. In our project work we will createvideo, voice and textual annotations to video clips. We are particularlyinterested in the use of stored voice annotations, to add to and toelaborate upon the video clip. We believe the use of persisting voice messages will offer new and effective ways toencourage professionals to articulate ideas about their working practices(Steeples, 1995). The video clip provides a direct and demonstrable exampleof practice in action, while making a voice annotation allows the subject to offer further (such asbackground or explanatory) information. Voice annotations will be used toencourage practitioners to explain their practices and also to reflect uponthem.

Summary

Thedevelopment of technologies that enable recording and digitising of multimedia artefacts(video clips that can be elaborated with video, aural or textualannotations) offers a radical departure for the design and use of onlinelearning environments. Multimedia technologiesoffer innovative ways to allow practitioners within distributedprofessional communities to create and share representations of problemsderived from real-world practices.

The next questions to consider in our work will include about thekinds of things that come to light when people are put in a position where they have tomake translations between tacit and discursive forms of knowledge. We arealso concerned to understand the kinds of translations people make whenthey have to talk about materials theyhave encountered in multimedia/video rather than in a textual form. Thework outlined in this paper will also be subjected to further scrutiny inforthcoming user trials, and will lead to a setof guidelines on bestpractice for using multimedia communications technologies in continuing professional development.

An Investigation of the Development of Dialogic Approaches to Teaching and Learning in Schools Through Interactive Television

Terry Evans, Elizabeth Stacey & Karen Tregenza
Faculty of Education, Deakin University, Australia
tevans@deakin.edu.au; estacey@deakin.edu.au; karent@deakin.edu.au

Abstract: This paper draws on the ideas underpinning a two year Australian Research Council Large Grant project which explores the extent, nature and problematics of creating and sustaining educational dialogue through interactive television (ITV) in schools. ITV has been introduced in many schools as a solution to the demands for increasingly complex curricula, high retention rates and equitable provision, all within tight budgets. The State of Victoria in Australia, is at the forefront of these initiatives. There is little research on ITV in schooling, especially as a means of developing and sustaining forms of interactive learning. This paper discusses some of the arguments concerning interaction and dialogue that are important to understanding the use of ITV in schooling.

Introduction

ITV has been introduced in schools of many countries as a solution to the demands for increasingly complex curricula, high retention rates and equitable provision, all within tight budgets. Australia, especially Victoria, is at the forefront of these initiatives however there has been little research on ITV, especially as a means of developing and sustaining forms of interaction which foster learning. Interaction is constituted as the capacity for the students to engage in contiguous or non-contiguous means of communication with other people in order to facilitate their learning.

The use of satellite, cable and, increasingly, digitised forms of ITV broadcasting and 'narrowcasting' to schools[1] has become an important feature of schooling in countries, such as Australia. In such countries, geography, demography and/or climate make it difficult to provide efficient 'traditional' schooling across the range of curricula required of schools from primary through to secondary levels. Canada and Scandinavia are two international examples where ITV is becoming increasingly significant in schooling (Haughey & Roberts, 1996; Meisalo, 1996). In Australia, Victoria has developed what is arguably the most widespread system-wide ITV provision of any similar school system in the world. The Victorian provision has spread to other states in Australia, and there are also other examples of smaller ITV networks (for example, in Western Australia and Queensland) in operation.

Whilst, until early this decade, broadcast television played a small, but important, part in schooling through the Australian Broadcasting Commission provision, the current emphasis is on school authorities using new means of television transmission to fulfil their mandate to provide schooling for all people of school age. However, unlike TV broadcasts, the emphasis in these new school-based providers has been on building *interactivity* into their provision; the sorts of interactivity which teachers and students expect of schooling, but not of television. Schooling, especially primary schooling, is one of the most interactive educational contexts and students are expected to engage in dialogue in order to learn; teachers find it difficult to imagine teaching otherwise. Given that much of the curriculum development in ITV has been in languages other than English, it is no wonder that the construction of ITV into a means of facilitating dialogue within the classroom, and within the broader ITV community (with other schools, the program makers and presenters, etc) has been seen as a priority. However, there has been a struggle to understand the practical construction of such forms of dialogue within the ITV community (Barty, 1996). This project provides research upon which policy, practice and theory can be built which addresses ITV in schooling

Educational Dialogue

The potential of ITV to be a more 'industrialised' and also highly centralised form of 'distance' schooling sits uneasily both with student-centred approaches to learning and also with teachers' (and teacher unions' and subject associations') concerns for professional autonomy. However, educational technologies, such

[1] We are focussing on schools and the use of ITV with children in this research. ITV has other, somewhat different, uses in other education and training sectors.

as ITV, can be used in ways which encourage dialogue and participatory forms of learning, if the programs are designed to foster such and if the local teachers and learners work accordingly.

The 'dialogic approach' is not yet a dominant paradigm in research, theory and practice in distance education, educational technology and open learning but it is becoming very influential (Buckley, 1992: 81-84; Lockwood, 1992: 41-49; Morgan, 1990; Paul, 1990: 88-90). As part of this approach, educational technology has joined dialogue as a central concept within a framework which views teaching practices as mediated processes relevant to their social and historical circumstances. 'Educational technologies are not simply the tools of educators—although this is a popular misconception, rather they are the knowledge, values and practices which constitute the development and use of those tools' (Evans & Nation, 1993b: 198-199). The interactivity of ITV suggests some useful lines of inquiry and analysis in terms of the local adoption and adaptation of the programs to local conditions, and even the reflection of local issues and concerns, through interactivity, into the global broadcast.

The School Contexts of ITV

The Victorian ITV network includes interstate provision, which is leading to a broader national significance, not only for ITV itself, but also for the proposed research project. The international significance of the ITV initiative is that the Victorian network is held to be the most comprehensive state education, system-wide, ITV network in the world. There are many examples of interactive television in educational contexts (Bruning, et al 1993; Zhang & Fulford, 1994), however, the use of ITV in schools is relatively unusual (there are instances, in Canada and Scandinavia, for example Catchpole, 1993). Typically, school and other educational sector uses of interactive television are based on dual or multi-site 'video-conferencing'. Broadcast uses are generally not interactive, (such as the Open Learning Australia broadcasts in Australia, or those of the Open University in the UK, or the Open Learning Institute in Hong Kong). It is in this context that a study of the use of ITV in Victoria is internationally significant, especially in terms of the potential benefits of the findings for future government policy and for educators and scholars, both in Australia and overseas.

The potential impact of ITV is significant for schools. Although current evidence suggests that usage in schools is generally patchy, the pressures on schools to provide a wide and varied curriculum, and the predicted decline in the numbers of teachers—particularly in specialist areas such as languages other than English—points to ITV, and other communications and computer technologies, adopting a higher profile. In Victoria, these trends are already in evidence, and ITV usage is increasing steadily. Interstate usage is less clear, but it is understood that ITV is developing similarly, but is less widespread (Mark, 1995). Evans and Nation (1993b) found that the ways educational organisations initiate and foster change is a complex social process which is replete with conflicts and contests. Such conflicts and contests spring from the different values and interests of the parties concerned. Other work by the researchers (eg. Evans & Newell, 1993; Evans & Tregenza, 1993; Stacey, 1995) points to the importance of systematic support and appropriate resourcing in order to facilitate change. In this case, it is hypothesised that Victorian schools are likely to reflect more widespread and effective use of ITV, than interstate schools, due to the weaker support and resourcing provided.

Exploring these processes of change surrounding ITV within the context of different schools, as well as including a consideration of the central players in the government departments, is achieved using qualitative research approaches in a case-study form. Such approaches are particularly important where the focus is on the interactive elements of the teaching and learning process as it is mediated and shaped by ITV. We are more and more in a position where ITV and other communications and computer technologies (which share many common features with respect to the issue of shaping and mediating interaction and dialogue) could become substantial media for reshaping the ways schooling is managed and practised. However, this will only occur to the extent that ITV actively engages the lives of teachers and children, and through such change the practices, management and culture of schools. To achieve this end in ways which are worthwhile for teachers, students and schools, it is necessary to understand the practices and processes of such facilitated and mediated interaction which ITV provides.

ITV and Children as Learners

A significant aspect of this research focuses on the children as learners through ITV. Current literature, inspired by Vygotskian theory, which researches the significance to learning of social interaction and discussion, has provided a framework for observing the role and impact of technology as a mediator in this interactive dialogue (Stacey, 1997). Through observations and interviews, the research provides findings concerning the ways in which children interact with ITV and interact within the classroom with their teachers and peers as a result of the strategies deployed through ITV. This will be particularly focussed on analysing the learning outcomes achieved though ITV as identified and described by both the teachers and students. An important element of the research will be to assess these outcomes against the students' relative ability-levels in their ITV program subject area as compared with their teachers' expectations and other similar students' performances who do not use ITV. This will make a very significant contribution to our understanding of the effectiveness of ITV, in terms of both particular subject areas, and also for particular age and ability levels.

Given the range of evidence and experience on the gendered nature of schooling in general, it is important that gender is considered in relation to the use of ITV, especially in terms of boys' and girls' interactions and experiences. In these respects the research extends Evans's previous work in terms of the gendered nature of schooling (1982, 1987a, 1987b, 1988) and relates to the work which identifies the gendered nature of technology in society more generally (for example, Wajcman, 1991). Therefore, the research design ensures appropriate representation of gender issues, in addition to particular observations of the gendered life of the ITV case-studies.

The Case-studies

The research uses qualitative research methods founded within educational ethnography including case-studies, interviews, observation and document collection to develop case studies of the implementation and use of ITV in the selected schools. Qualitative methods best allow us to explore the processes of change surrounding ITV within the context of different schools. Interviews are conducted with relevant teaching staff, students and Department of Education personnel.

This project explores the extent, nature and problematics of educational dialogue through interactive television (ITV) in primary and secondary schools. In particular it is designed to:

- investigate, record and analyse, the use of ITV in primary and secondary schools, especially in terms of the development of interactive and dialogic approaches to teaching and learning.
- study the processes through which teachers and students adopt, and adapt to, the interactive and dialogic elements of ITV.
- analyse the findings in terms of the changing nature and demands on schools, and to relate these to issues of the social and cultural conditions of schooling, including gender, rurality and ethnicity.
- analyse the findings in terms of educational theories and practices of dialogue, and especially to those concerning mediated forms of educational dialogue, such as in open and distance education theory and practice.

Research Plan

The first phase of the research in 1998 involved the selection of five primary schools each being from either a country, regional or metropolitan region. Two of the selected schools are non-government schools. In each primary school ITV case-studies have been conducted simultaneously each being split between the main curriculum areas of ITV (Science and Technology, and Languages other than English). Throughout the year teachers have been invited to discuss the children's learning with ITV, as well as their own experiences of teaching with and alongside ITV. Typically, the ITV broadcasts are only part of the timetable for the particular curriculum area and the teachers work with the children 'off-air' in other timetabled sessions. These lessons are also observed in addition to the actual ITV broadcast sessions which may be either watched live by the class, or taped and played back at another time.

The second phase of the research to be conducted in 1999 will involve the nomination of three secondary schools where six case-studies will be developed. The curriculum areas selected for study at these schools will be chosen from those used via ITV. In addition to the specific focus on the case-studies, a sample has been made of other uses of ITV in the schools and by the Department of Education.

A phase of the research includes the development of six mini case-studies across New South Wales and South Australia for the purposes of comparison and contextualisation. This involved one day visits to one primary school in each state during 1998; and two secondary schools in each state during 1999. These mini case-studies involve visits by a project team member for the purpose of observing ITV sessions in progress and subsequent follow-up lessons, and to interview staff and students about their experiences with, and use of, ITV.

ITV Programs

The Victorian Department of Education regularly transmits a number of programs to schools through the satellite learning network, the main curriculum areas being Science and Technology Education in Primary Schools (STEPS) and Primary Access to Languages via Satellite (PALS). Other 'special' programs are also broadcast throughout the year. In 1997, 600 hours of programs were broadcast, 2,500 schools participated and an estimated 100,000 students learned another language via satellite.

STEPS consists of a series of programs that assist teachers in the delivery of science and technology education within the framework of the Victorian Curriculum Standards Framework. Students are able to participate in each program as it is broadcast live to air. This provides opportunities for the students to interact with the teacher (presenter) in the studio. Each school participating in STEPS is provided with comprehensive classroom support materials comprising a list of resources required for each program, the expected student outcomes, a brief summary of the program format and detailed descriptions of the activities to be undertaken. The programs, either thirty minutes or one hour duration depending on the year level, are broadcast fortnightly catering for the Prep; 1/2; 3/4 and 5/6 year levels. Schools are required to complete work and activities to prepare for the broadcast and also post broadcast. STEPS also integrates the use of multiple media through their World Wide Web site which provides general information, a teacher discussion page and a student discussion page. This Web site complements and enhances the programs rather than just duplicating the printed materials and the transmissions.

To facilitate the teaching of another language, PALS programs are broadcast to primary schools twice a week covering languages including Italian, Indonesian, Mandarin, Japanese, French and German. A similar concept has been developed for the teaching of another language at the secondary school level called SALS (Secondary Access to Languages via Satellite). As with the STEPS programs, teachers are provided with comprehensive classroom materials that support and complement the language programs. These programs run for thirty minutes and encourage students to interact live with the studio presenters. Students are required to complete pre and post broadcast activities to facilitate their learning.

One example of a 'special' ITV broadcast is *Communicating over the catchment*. This is a student conference concerned with conservation of the environment. Each year it is developed and broadcast live from Melbourne Zoo with support from the Murray Darling Basin Commission. The annual satellite broadcast consists of two, one hour long programs about conservation issues, and provides students with the opportunity to interact live with zoo experts via telephone, fax, email or a special Web Chat facility. The broadcast is only one aspect of the interactive program. There are also preliminary activities through interactive communication through a Web site, and also through use of a student resource kit and professional development support materials for teachers.

Preliminary Findings

The observational data from the first year of the study has begun to provide a range of emerging themes. Teachers' strategies and planning are integral to the best use of the ITV programs and several important factors are beginning to appear in the results of the study.

Interactivity

As predicted in establishing the study, the interactive element of the ITV programs is an important component of the use of this technology and it is established in a number of ways. These ways of interacting with the program are varied and the programs are designed to include the children in activities before and during the broadcast so that they are not always passively receiving the broadcast but are regularly given the opportunity during the program, to participate in teacher managed interactive discussion within the classroom.

These interactive points can also be part of the broadcast if the classroom teacher sets up the process and representative groups of children in the classrooms observed have had opportunities to interact with the program presenters through telephone links during the live transmission of the program or more rarely, as participants in the studio production and broadcast. These are heard and seen over the broadcast and are a very motivating aspect of the children's learning by this medium. All the participating students have been excited to hear their school acknowledged and this motivational factor, as much as the opportunity to answer a question, or report on an activity has kept the classes focused on and interested in the programs. The students also respond to these interactive points with interest when children from other schools appear, so the peer interaction appears to be an important factor in the success of the programs.

Schools also send work into the program producers which is also acknowledged and read out during the broadcast and this again provides students with an motivational involvement in the program.

Some schools tape the programs and then can stop the program and interact through teacher managed activities and discussion allowing more time and repetition. This has been observed to be a useful repetitive interaction particularly with the language programs (PALS) where sometimes the speed of the new vocabulary use and the difficulty in comprehending the language used in the broadcast requires help and translation to be effective.

Management

The different ways schools use the programs, alluded to above, seems to make a difference to the effectiveness of the programs for learning. If preparatory classes are held and the content of the program is integrated across the curriculum of the class, there is more interest and involvement from the children during the broadcast. In one classroom observation, the familiarity of the children with the Indonesian song and their physical placement with their notes with the song's words easily accessible, meant they could all participate in singing together during the program. However at another site, the children did not attempt to participate as they were less practised with singing the songs and had no easy access to the words, making the broadcast less interactive for them.

The flexibility of the whole school's approach to the technology use impacts on this aspect of the program's effectiveness as well. If an ITV program cannot be scheduled easily into a busy school program or there is inflexibility in the manner and timing of the school's broadcast of the program, classroom teachers cannot always vary the live and taped broadcasts to suit the children's learning, and cannot customise the progams to their students' learning as effectively.

The teachers' use of the program notes in their curriculum planning depends on them receiving this information in sufficient time. This management issue was one that has been frequently mentioned by teachers as an important factor if the broadcast team's planning cycle does not concur with the planning timeline of the classroom teachers.

Media Integration

Greater integration of the ITV media with electronic communication is a emerging factor of importance as the Victorian schools become networked and provided with an easier access to electronic communication. The schools who watch the STEPS programs and access the Internet most confidently are able to use a wider range of multimedia activities provided through the STEPS World Wide Web site (http://www.sofweb.vic.edu.au/steps/) and through emailed activities devised by the STEPS production team.

As Victorian schools are all included on a new VIC One network by the end of 1998, this aspect will begin to be available to all participating schools and will provide a new communicative aspect to ITV use.

Abstract: Formative evaluation and iterative prototyping seem an interesting approach for building collaborative learning systems. Our approach to create our software system consisted on iterating successive stages of analysis, specification, implementation and evaluation. At the end, the process turned out to be a five-pass cycle, carried out in two years, with a major reimplementation between the third and the fourth prototype version. We describe the main features for each version, as well as the evaluation techniques followed. The first cycle is presented in more detail and relevant aspects are summarized for the rest. Each evaluation includes the design of a learning activity, the configuration of the prototype to carry out the experience, the set-up and observation of the activity performed with real students and tutors, and finally the drawing of conclusions including the improvements to consider for a next design phase.

Introduction

For a number of years we have been involved on research and experimentation with collaborative learning at a distance in an effort to identify and deploy appropriate uses of the new media to support a distance learning community. In this paper we focus on the process of designing a software environment to support collaborative learning activities in an integrated way. The design of collaborative software has proved to be hard. Theories and metaphors in the CSCW field have emerged but are still a matter of big debate and further elaboration is needed to produce models supporting the practical design of CSCW applications. The difficulty comes from the complexity of the situations to be considered, where the technical perspective is one part of the picture. In a specific work situation, technology should support human activity taking into account the social setting: an organization with rules, structure and working practices.

Formative evaluation and iterative prototyping seem to be an interesting approach for building collaborative learning systems. Conducting experiments to find out how the prototype is used and what is learned from its use provide insights, not only into how to improve the system but also into how to motivate further extensions. A conceptual framework is still needed to analyze and capture how the technical solutions in each version of your prototype will support the group of learners to attain their goals. The socio-cultural framework provides the concept of Activity (Nardi, 1996) as a unit of analysis, with a rich internal structure to make the context of a situation explicit, specially the interlinks between the individual and social levels stressing the role of the tools as mediating artifacts.

One of our systems serves here as a case study to illustrate the potential of combining user-centered approach (Gould & Lewis, 1985) with Activity Theory to design collaborative learning software. The next section describes our context, and elaborates on the kind of learning tasks and collaborative framework we have considered. In section three the main features of the iterative design are presented and learners' experiences discussed. For a detailed description of the system itself the reader can consult (Barros & Verdejo, 1998).

Context, goal, and premises for defining the learning approach

Collaborative learning research has paid close attention to studying pupils interactions during peer-based work in order to analyze and identify the cognitive advantages of joint activity. As Crook (1994) points out the benefit of the collaborative approach for learning lies on the processes of articulation, conflict and co-construction of ideas occurring when working closely with a peer. Participants in a problem-solving situation have to make their ideas explicit (assertions, hypothesis, denials..) to other collaborators. Disagreements prompt justifications and negotiations, helping students to converge to a common object of shared understanding.

The computer provides opportunities to support and enhance this approach in a number of ways (e.g. offering computer-based problem spaces for jointly create and exploit structures of common knowledge and shared reference). Furthermore networks made possible the opening of collaborative frameworks to distributed communities, providing remote access to these spaces as well as computer-mediated communication to support interpersonal exchange and debate. An increasing number of collaborative learning environments for open and closed virtual groups have been built for a range of learning tasks (Scardamalia & Bereiter, 1991) (Edelson & O'Neill, 1994) (Wang & Johnson, 1994) (Suthers & Jones,1997), and experiences of use are reported from school to university level (Bell, Davis & Linn, 1995) (Collis, 1997).

The potential of collaborative learning, within the framework of a distance learning institution, has to be explored taking into account the traditional practice of individual and stand-alone study in distance education. Not only faculty but also students are reluctant to carry out collaborative practice. Network facilities are widely appreciated as a way to improve the efficiency of how course material is delivered rather than an opportunity to change patterns of teaching and learning. So the challenge for developing collaborative activities in a traditional distance learning university is not only to build appropriate tools but also to transform established practices in the community. For these reasons, it is quite critical to look for opportunities of implementing collaborative learning experiences where collaboration could be perceived by students as a clear added-value to existing learning practices.

So we want to propose that our distance learners, geographically distributed, work together in small groups to prepare an overview of a topic related to their professional profile. There are a number of ways in which this collaborative activity can be organized, one of the procedures that we have implemented consists of a phase of joint involvement in the preparation of the work within each group, followed by a period of individual reading. Then participants engage in a dialogue to elaborate collaboratively a synthesis according to a schema. Variants can include a phase of planning and the negotiation of the schema before to the collaborative writing. A further step could be mutual presentation of the final products between groups.

From the learning point of view the task fulfills the requirements of been relevant (it corresponds to a real practice in a research context) and co- constructive in the sense that they have to build their own shared understanding of the topic. Furthermore the discursive nature of the procedure and the deferred mode for the debate afford opportunities for the students to reflect on the way they perform the collaboration process.

The iterative design process

Our approach to create the software system consisted of iterating successive stages of analysis, specification, implementation and evaluation. At the end, the process turned out to be a five-pass cycle, carried out over two years, with a major reimplementation between the third and the fourth prototype version. Next we will describe the main features for each version, as well as the evaluation techniques followed. The first cycle is presented in more detail and relevant aspects are summarized for the rest. Each evaluation includes the design of a learning activity, the configuration of the prototype to carry out the experience, the set-up and observation of the activity performed with real students and tutors, and finally the drawing of conclusions including the improvements to consider for a next design phase.

The first cycle. *The prototype*

The first prototype, installed on a web server, offered the same services to all clients. The access was remote and the mode asynchronous. Each user had a login and a password and belonged to a group. The system supported a number of small groups operating at the same period of time.

The main metaphor in the prototype for sustaining a learning activity is the concept of *space*, a virtual structured place with resources and tools to perform a task. Three types of spaces were available: an individual workspace, private for each user, and two shared spaces for each group (one workspace for debate and joint construction, the other for coordination purposes). The information handled is mainly textual, so a variety of editing tools and file management facilities was available, as well as links to other relevant electronic sources of further information for the task at hand. The shared workspace provided support for conversation in the form of semi- structured typed messages. When learners express their contributions they have to select a type from a predefined set. These types include: proposal, contraproposal, comment, question, and clarification. The system dynamically builds a representation of the discussion process going on in each workspace, in the form of an index of related contributions for each subtask. This index was fully deployed and represented on the left part of the workspace screen.

The evaluation phase

The first evaluation addressed the central point of the adequacy of the shared workspace to support a group of learners to perform a discursive task. The design of the learning activities was carried out by our team, as well as researchers we are also teachers. Two kind of learning situations were considered. We describe one of them, characterized in terms of Activity Theory (Kuuti, 1996) (Cole & Engestörm, 1993) as follows:

The object of the learning activity was to synthesize the state of the art in a focused research topic. Two topics were selected: one in Artificial Intelligence (AI), the other on Educational Technology. *The outcome* of the activity was an essay, pointing out the key ideas. The schema for the essay was previously defined by the tutor, and included in the shared workspace. *The community* involved in the activity were pairs of graduate students in a Ph.D. distance teaching programme, in UNED, our university. Students were part time, geographically distributed, usually interacting in disjoint time slots. *The subject*, each individual student, had either a technical or non technical profile, but groups were formed by people with the same background. The topic for the groups with technical profile was in AI

Mediational tools included: (i) humans, a tutor and a technical assistant both from our team (ii) artifacts: the phone, a set of documents and (iii) the prototype: a networked computer environment including the script of the activity, private and shared structured task spaces for peer argumentative discussion, coedition and coordination, as well as access to other electronically available sources of information. *Rules* for the activity were stated explicitly and have to be accepted before starting. They include the commitment to finish the work, the script for the activity and the protocol for the collaborative debate. Some of these rules were embedded in the system, for example, the conversational graph defined the way one can contribute after another peer contribution. Others were the full responsibility of the learners, such as the way to organize the discussion, the way to agree, as well as aspects of time management and deadlines. The only direction given was to use the coordination space to deal with all these matters, using the coedition workspace only for the topic discussion. Students in each group had the same responsibility. The task is divided in subtasks but there were no predefined roles for *division of labour*.

Performing the activity

Once the learning activity was designed and the prototype ready, the experience went to a set-up phase to organize the formation of groups, fix the training strategy for the use of the tool, prepare the support strategy and establish the evaluation framework. In this case students were recruited on a call for volunteers. The groups were made up by the tutor. A handout for the use of the system was distributed to all participants, and a session of practice on their own was recommended before starting the activity to became familiar with the tool. Moreover an interactive training session, using the phone and the system, was offered and carried out with one of the students. Technical support for the whole period of the experience was provided, a person could be reached either electronically or by phone to deal with questions or problems related to technological aspects.

For content or pedagogical related matters, a teacher was also available. Along the running stage of the experience her role was to act only on request, however for evaluation purposes she was observing actively the use of the system. Events and data were all recorded. This information together with teacher and assistant notes, as well as individual interviews for dropping-out cases, were the main sources for the assessment of the prototype.

Results

Three groups started the activity and only one arrived at a completion state. All the groups performed the preparatory phase, but one of the groups dropped-out early, before engaging in the collaborative step, another student dropped-out in the middle and we had to redefine the learning task for the remaining student to allow him to continue alone. Finally the third group worked well and accomplished the whole activity, having a balanced participation.

This 50% ratio of drop-out is comparable to a standard course. In the first group both students changed their job and were not interested anymore in the course. Some students needed help and technical assistance for the communication infrastructure, being the first time they had connected and used Internet. The system was considered easy to use, and students in the third group stated the experience as successful, appreciating the benefits of collaboration, despite the additional constraints this form of work demanded on them. Added-value was perceived in three dimensions: more depth in content related matters, becoming familiar with new technologies, and improving collaboration abilities.

The concept of structured shared workspace proved suitable for the learning task, however, as expected, significant problems were pointed out: some regarding either the interface, the functionality of the prototype, or the accessibility and reliability of the server; others to group related aspects of engagement, participation or tutor intervention. Related to the interface, the representation of the discussion as an index fully deployed on the left part was uncomfortable to handle when it became long. Some problems of consistency with buttons for editing operations were also detected. Related to the collaborative task, students missed the explicit agreement option. This was considered to be a natural way to conclude a discussion. An important issue was the lack of a separate representation for the process and the outcome. The possibility to look for what was being achieved -drafts of the essay- at different stages of the process, separated from the discussion was perceived as useful.

The coordination space, a public list of messages, suffered from lack of privacy. Students wanted to send messages not only to groups but also to individuals, particularly the tutor or the assistant. Facilities for browsing and reading related messages with different criteria, for instance topic, date, etc., were not provided. The period of the experiences lasted for the '97 spring term.

A second experience using the same prototype was carried out, involving three groups of students in a master program of another, non distance, university. In this case students combined face to face teaching sessions with collaborative discussions through the system. Groups consisted of three students who knew each other previously. The patterns and style of the interactions were clearly different and specific problems of mutual awareness and concurrence arose due to a more synchronous use of the system. Comments from students, feedback from tutors, and improvements suggested by designers were discussed in the analysis phase of the second version carried out during the summer, in order to have a prototype ready for the 97/98 autumn term.

The second and third cycle

The main redesign for the second version concerned the structure and function of the shared workspace. Instead of a unique workspace, three related subspaces were defined, one for the joint elaboration, a second one, the result space, to keep separately the outcome, and the third, the version space, to save the process and the outcome at different stages. The conversational graph included agreement as an option. Once all participants had performed this action for a particular proposal, the system automatically loaded the text on the corresponding subtask section of the result space. Thus, each subtask has to be finished by explicit consensus. The conversational graph, wired in the first version, was configurable from an external data file so that it could be different for different tasks. Moreover, the number of workspaces was an option to be defined at the configuration of the prototype, depending on the needs of the learning activity.

Related to the interface, these were the main new features:

- As the number of spaces increased, on the upper part of the screen, a button bar enabled the user to go directly either to the information space, the individual space, the shared workspaces or the coordination space.
- All the shared working spaces (version, result and elaboration) were directly accessible from each other, by buttons, and they have a similar interface.
- The representation of the discussion process on the left part of the elaboration workspace was redesigned in order to allow the folding and unfolding of the content index of the contributions for each subtask. This helped to reduce the amount of visible information, focusing on the task at hand.
- The interface was rewritten in English to allow a wider use.
- Messages in the coordination space could be one-to-one or one-to-many.

As in the first cycle, the evaluation phase consisted of steps for fixing the objectives of the evaluation, designing, setting-up and performing the learning experience. In this cycle we aimed at two different scenarios to test the versatility of the system regarding other communities and activities. The first one was to support the discussion of a group of international experts, distributed all over the world, previous to the celebration of a working conference. The second one involved a teacher and their graduate students, all external to the designer's team, using the system as a complementary activity. The learning activity was fully designed by the teacher. In both cases the prototype was configured by a member of the research team to generate an environment adapted to the activity, i.e., number of workspaces, its structures, associated conversational graphs, and links to other sources, as well as roles and participation rules. All these features were different in each experience.

Results

From users the main feedback in this cycle was the need of: (1) having notification when new things happened related to the group activity; (2) seeing at a glance where new things were placed.

From the monitoring of these and previous experiences, we also concluded:

In relation to collaborative aspects

- In the case of students, procrastination is a problem, support for explicit time management as well as negotiated intermediate deadlines should be considered.
- For full distance learners, a preliminary phase to set up the group, establishing common objectives and protocols is a must to ensure their engagement as well as to enforce their feeling of belonging to a group.
- In the case of larger, open groups, a well-specified purpose, shared responsibility and the role of a moderator are key factors to promote interaction and participation. The only existence of the mediational tool does not, of itself, generate patterns of collaboration.
- Teacher intervention along the collaborative process remains an open question: whether this should be supporting the group spontaneously or on request, being involved as a member of the discussions groups with

an specific facilitator role, or entering as commentator at specific time of the process. Students feelings were quite controversial on that point.

In relation to the system

- On-line help, guidelines for each activity, and rules of participation should be included in the system, in addition to handouts (i.e. the more integrated and self contained the system, the better its usability). For Spanish students, English for the interface was accepted, if all the rest was available in Spanish.
- Facilities, beyond notification, to handle, monitor and analyze the collaboration processes are required. Both during and after the experience.
- A configuration mode should be available to generate tailored web sites, as automatically as possible from the data provided by the designer of the learning activity.

The fourth and fifth cycle

At that point we decided to rethink the whole system architecture, characterizing levels and generic components and implementing the workspaces on a database framework. For further details on this point see (Barros & Verdejo, 1998). Besides the full reprogramming, the improvements for the next version concerned two aspects:

- The definition of roles for shared workspaces allowing to distribute responsibilities for a learning activity. For each role a profile of features was defined, where accesses and privileges for different uses of the system could be configured. A simple mechanism of notification was also introduced and could be enabled or disabled in the role profile.
- The redesign of the coordination space to provide not only an enhanced e-mail facility including a variety of filters to browse the messages with different criteria, but a new tool, a group agenda to facilitate time management matters.

Evaluation Phase

The evaluation followed the same steps as in the previous cycles. This time the new issue addressed was to test how easy the system could be adapted by the users themselves, for instance, allowing learners to configure workspaces completely tailored to their needs. This possibility opened the range of learning activities that the system could support. For instance, students performing design tasks or negotiating among themselves their collaboration schemas. So we planned and executed an experience where the learners, using the system, could also participate and decide aspects of the learning activity they have to perform in collaboration, such as the conversational graph structure for the elaboration process, roles and their distribution, or the schema for the outcome. We launched an experience comprising three learning activities. The first one, a collaborative synthesis on an Educational Technology topic. The second one, the selection and definition of a case study; and the third the elaboration of a detailed proposal for the case study. A teacher, a technical assistant and two groups of three part-time students following a Ph.D. course worked together for 6 months.

- The objectives for the first activity included acquiring knowledge of a selected topic, and developing collaborative abilities as well as becoming familiar with the use of the system.
- The second activity was a preparation for the third one, students had to attain three goals: (1) to select, discuss and agree on a case study, i.e. a learning activity, (2) to write a detailed plan to develop their proposal including the structure of the outcome, and (3) to fix the responsibilities of each one on completing this proposal.
- The third learning activity included the configuration of the shared workspaces where they could develop the design of their case study.

They started to work with the third prototype. This time as the experience lasted for a longer period as soon as some problems were detected we decided to work simultaneously on the system, so that they started with version 3 but finished with version 4. New features were included. For instance the initial bar included all the activities and there was the possibility to state temporal restrictions between activities so that spaces were accessible only when the time conditions were fulfilled. Agreement methods were extended and could be selected between consensus or majority. Further tools were also provided for global and individual evaluation: the representation of accesses per hour, work evolution in the experience period and number of contribution type. For global analysis there were an option for visualizing the evolution of the discussion by access and by user and the evolution of work by section and user. These results could be visualized in graphics or textual form. Also a tool to create, fill, submit and, automatically process WWW-forms was provided in order to systematically collect student feedback.

Version four

A major extension in version 4 was the concept of an organizational learning memory. This was a structured repository of collaborative learning activities containing selected events and outcomes (Barros & Verdejo, 1998). This memory was defined and implemented with a range of editing and searching facilities. Initially we filled it with relevant data collected in previous evaluation cycles. This resource can be exploited for a variety of educational purposes, two of them, scaffolding and peer evaluation, were tested on the latest cycle developed during the last three months of the 97/98 academic year.

Two experiments were carried out. The first comprised two learning activities. One was fully defined by the teacher, the other only partially predefined. The learners once the first activity was completed had to select outcomes of cases stored in the organizational memory to perform a peer review. The second experiment followed a similar approach but this time students could use previous cases as guidelines for their own work and not only for the peer evaluation step.

Results

- The experiences in this cycle, as well as the system, were more complex. Close monitoring from the teacher became critical, but also a clear state of affairs was very helpful for students. Notifications provided automatically from the system to learners and the teacher about selected events improved the "what is going on" with respect to the other versions, but the solution to present the "what is new" required some further analysis. In short this information has to be presented not only in quantitative terms but also in a more qualitative flavor.
- There were also problems with the generation of tailored versions of workspaces. The configuration procedure demanded additional understanding of the system, and the students were not prepared to invest time on that point. They preferred to specify what they wanted and have the technical assistant doing it for them. This suggested that more training on the tool and better configuration facilities are needed.

These two points were addressed on the next, current version, of the prototype. The current architecture of the prototype is organized in levels: configuration level, performance level, reuse level and reflection level. We consider the tool robust and versatile enough to finish the development phase and to proceed to a wider dissemination in order to prepare a summative evaluation phase.

Concluding remarks and further work

Formative evaluation has been essential to guide the team in tuning the tool and for suggesting directions for further extensions. Prototype testing with real users helps not only to reach technical validity but more importantly, to face the complexity of implementing collaborative learning. Social and institutional factors are essential when designing collaborative learning activities, specially in a conventional educational framework. In this sense Activity Theory seems a promising framework for modeling learning situations with a global approach. Issues for the next evaluation are, on the one hand, to look more closely at pedagogical and collaborative effectiveness, and on the other to collect more experiences. We perceive that practical guidelines for designing and performing these activities, not only looking at learning objectives but also dealing with social and organizational issues, are indeed needed.

Abstract: This paper proposes a method of learning assistance for a physics learning environment. The learning objective of the environment is to acquire ability of recognizing forces acting on physical objects. Because the knowledge of applying fundamental concept and rules, such as the concept of gravity and Newton' law, is empirical knowledge, learners need training to acquire the ability. We propose a method of triggering off reflection by comparing two physical systems. Our method generates a physical system depending on the cause of a learner's error. By comparing the generated system and the originally given system, the learner gets some clues to recognize forces acting in the original system, or some clues to recognize inconsistency of the learner's solution.

1. Introduction

One of important features of intelligent tutoring systems is to provide assistance that is tailored for each individual learner. There are different teaching strategies, among which is to make learners reflect on their processes of working out solutions in order to acquire correct knowledge when they make some mistakes. Because assistance should provide information that leads the learner to aware inconsistency about the solution, it must be prepared depending on the causes of the learner's errors.

This paper proposes a method of providing feedback for a physics learning environment (Takeuchi & Otsuki 1997). The learning objective of the environment is to acquire ability of recognizing forces acting on physical objects. Learners have to apply fundamental concept and rules, such as the concept of gravity and Newton' law, on a given physical system in order to recognize forces. Because the knowledge of applying fundamental concept and rules is empirical knowledge (Anzai 1986), they need training to acquire the ability. The assistance of promoting reflection is, therefore, effective to activate thinking. We propose a method of triggering off reflection by comparing two physical systems. Our method generates a physical system depending on the cause of a learner's error. By comparing the generated system and the originally given system, the learner gets some clues to recognize forces acting in the original system, or some clues to recognize inconsistency of the learner's solution. Section 2 describes the overview of the learning environment, and the method of triggering off reflection by comparison is given in section 3. Examples of assistance are given in section 4. Section 5 describes evaluation.

2. Learning Environment for Physical System

Fig. 1 shows the structure of the learning environment for physical system modeling. Learners try to apply physical rules on a given physical system to recognize forces, and illustrate forces in order to express their understanding on the graphical user interface. Fig. 2 shows a snapshot of the user interface. When they want to study specific physical systems, they are allowed to construct arbitrary physical systems. Tab. 1 shows available physical elements. The causal relation model deriver in Fig. 1 creates the causal relation model from a given physical system. The causal relation model represents relationship among forces and elements. The student's kinetic model deriver creates the student's kinetic model from learner's illustration of forces. The student's kinetic model represents learner's understanding of the given system. The student's kinetic model has the same structure as the causal relation model. These two models are used as the source of diagnosis.

FIGURE NOT AVAILABLE

Figure 1: Overview of the Learning Environment

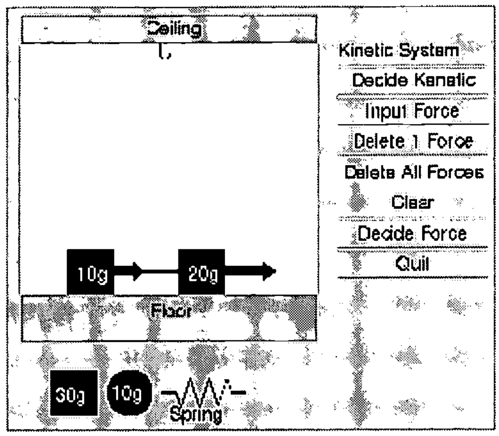

Figure 2: Snapshot of the User Interface

Table 1: Available Physical Elements

Class	Kind of Element
Finite mass	Block, Ball
Zero mass	Spring, String
Infinite mass	Ceiling, Wall, Horizontal plane, Slope

The learning support part detects learner's errors by comparing the student's kinetic model with the causal relation model. There are three kinds of erroneous phenomena about forces; missing (learners cannot recognize existing forces), extra (learners recognize non-existing forces), and error (learners make some mistakes on attributes of forces). The learning support part decides a method of assistance according to causes of learner's errors. This paper focuses on one of the assistance method; "presentation of a system for comparison".

3. Presentation of a Physical System for Comparison

We propose "presentation of a system for comparison" as one of assistance methods for learner's errors. Physical systems for comparison are generated by transforming the original system based on some rules. Purposes of the assistance are both helping learners to recognize forces acting in the original system easier and giving learners some clues to recognize errors and contradiction by thinking about similarity and difference between the original system and the generated system. Because the method of presenting systems for comparison is an indirect instruction and it doesn't communicate knowledge of physics directly, it is based on the assumption that learners have knowledge of fundamental physical rules but failed to apply these rules. This kind of errors often occurs about internal forces, i.e. tension and normal forces. The assistance method is, therefore, effective in cases of missing tension, errors of tension, missing normal forces and errors of normal forces.

3.1. Generation Process of Systems for Comparison

The generation process of systems for comparison consists of the following four steps.
1) To generate candidate systems by applying transformation rules to the original system. The transformation rules are described in section 3.2.
2) To derive the causal relation model for each generated system.
3) To check whether each generated system satisfies conditions of effectiveness as systems for comparison. The

Conditions are given in section 3.3.
4) To decide the order of priority, if more than one systems for comparison satisfy the conditions at 3rd step. Ordering rules are given in section 3.4.
Fig. 3 shows a generation process.

3.2. Rules for Automatic Generation

Candidate physical systems for comparison are generated by applying transformation rules to the original system. There are eight rules; deletion of a finite mass element, deletion of a external force, replacement of a finite mass element with an infinite mass element, replacement of a slope with a horizontal plane, deletion of a string, deletion of a spring, and replacement of an external force with an infinite mass element. In general, these rules are applicable repeatedly on an original system. However, we restrict the application time only once, because the resemblance between the original system and a generated system becomes low and it becomes difficult for learners to compare. These rules reduce complexity of the original system from the viewpoint of the number of physical parameters or the order of motion.

FIGURE NOT AVAILABLE

Figure 3: Generation Process of Systems for Comparison

3.3. Conditions of Systems for Comparison

Generated systems are effective as systems for comparison if they satisfy one of the following two conditions.
Cond.1) Learner's wrong interpretation of the original system holds in the generated system.
Cond.2) The same physical causalities about which the learner made an error exist in the generated system, and complexity of the generated system is lower than the original system. The complexity is measured by the number of physical objects and the order of motion.
Examples that satisfy the conditions are as follows.
Ex.1-1) The force that the learner has missed in the original system doesn't really act in the generated system. Or the extra force that the learner illustrated for the original system acts in the same way as the learner's illustration in the generated system.
Ex.1-2) The force that is equal with the learner's erroneous force acts in generated system. Correct forces that the learner illustrated for the original system also act in the generated system.
Effect of Ex.1-1 and Ex.1-2: The learner's interpretation of the original system holds in the generated system. Since forces actually acting in two systems are different and hence the motion of them are different, the learner will find inconsistency in his/her interpretation. Because the generated system is less complex than the original system, it is easier for the learner to understand generated system correctly .
Ex.2) The Learner missed a force in the original system and a force of the same kind as the missed force acts on the same element in the generated system and the element stands still.
Effect of Ex.2: Forces which act on the element balances in the generated system, because the element stands still. Because the generated system is less complex from the viewpoint of the order of motion, it is easier for the learner to recognize the missed force. Since the generated system preserves causalities between physical parameters, the learner will recognize the causalities of the original system.

3.4. Order of Priority of Systems for Comparison

In most cases, more than one candidate systems for comparison satisfy the conditions described in section 3.3. In order to select the most suitable system for comparison, the order of priority is decided according to the following criteria:
* It is easy for learners to find forces, if elements in a physical system stand still.
* It is easy for learners to compare two physical systems, if they are alike in appearance.
The order of priority is defined by both motion of elements in the system for comparison and the degree of

resemblance between the system for comparison and the original system. Tab. 2 gives items to be considered to decide the order of priority of the systems for comparison. As for a string, a spring, a finite mass element and an external force, the degree of resemblance is high when the score in Tab. 2 is high. As for motion, the score is high if a physical system stands still. The score of each physical system is calculated by summing up each item's score. The order of priority is decided by total score of each system.

Table 2: Check Item For Order of Priority

Check Item	***Score***
Motion	
All of finite mass elements stand still	2
At least one finite mass element stands still	1
All of finite mass elements don't stand still	0
External Force	
The force act in the same element of the original system	1
The force act in the different element of the original system	0
The force do not act	0
The force are replaced with an infinite mass element	0
Finite mass Element (for each finite mass element)	
The element exists in the system comparison	2
The element is replaced with an infinite mass element	1
The element is deleted	0
String, Spring	
String or Spring exists	1
String and Spring don't exist	0

4. Example

Fig. 4 shows an example of candidate systems for comparison generated from a given system. Eight candidate systems are generated by applying transformation rules. Here we assume that a learner made one of the following four mistakes.

1) missing tension of both ends of string.
2) missing tension of one end of string, and the value of tension of the other end is wrong.
3) missing tension of one end of string.
4) the value of tension of the string is wrong.

Tab. 3 shows the result of selecting appropriate systems for comparison. Numbers indicate appropriateness of eight candidates for the above errors. These numbers are the order of priority for each system, and the smallest

FIGURE NOT AVAILABLE

Figure 4: Generated Systems as Candidate for Comparative Systems

one is the most suitable system for comparison. Each number in the parenthesis is a total score of each system. Asterisks mean that candidate systems don't satisfy the conditions of the systems for comparison.

Table 3: Score (Our System)

Error	System1	System2	System3	System4	System5	System6	System7	System8
Missing tension-1	1(7)	6(3)	5(4)	*	3(6)	1(7)	3(6)	*
Missing tension-2	*	4(3)	*	3(4)	2(6)	1(7)	*	5(2)
Missing tension-3	*	3(4)	*	*	2(6)	1(7)	*	*
Tension error	*	*	*	2(4)	*	1(7)	*	*

5. Evaluation

We evaluated the result of generating systems for comparison. In order to investigate which physical systems are appropriate for comparison, we asked five university students to select effective systems for each error in Tab. 3 from eight candidate systems. Tab. 4 shows the result of the selection. Numbers indicate the percentage of university students who answered that learners would notice the error or contradiction by presenting the physical system when learners made the corresponding error.

Table 4: Score (University Students)(%)

Error	System1	System2	System3	System4	System5	System6	System7	System8
Missing tension-1	100	60	80	40	80	80	80	40
Missing tension-2	0	40	0	60	80	100	0	60
Missing tension-3	0	60	0	20	60	100	0	20
Tension error	0	0	0	40	40	80	0	0

By comparing Tab. 3 with Tab. 4, we confirmed that most of the physical systems selected by the learning system were judged to be effective for learner's errors by university students. And when the order of priority that our method decides is high, the percentage which they judged the physical system to be effective is high, too. From the above facts, we conclude that our method selects effective physical systems and the order of priority is proper.

6. Conclusion

We described a method of learning assistance that presents physical systems for comparison. From the result of evaluation, we confirmed that effective systems for comparison were chosen and the order of priority is proper.

Simulation based interactive learning environments are widely accepted in the domain of physics (Tiberghien & Mandl 1991). Simulation is useful to understand fundamental concept of physics by experiment and to grasp system behavior by observation. Stevens's innovative work (Stevens, Roberts & Stead 1983) combined a quantitative simulator with qualitative representation to emphasize causality. Qualitative simulation (Kuipers, 1986, Forbus & Falkenhainer, 1990) is also useful to explain causality explicitly and to help learners to understand causal relations of physical parameters. Both qualitative and quantitative simulations are based on equations of motion. Learning objectives of these methods are, therefore, to understand nature of constraints among system parameters. In contrast to these learning methods, we focused on acquiring ability of modeling physical systems or ability of deriving equations of motion, which provides justification of causality. The assistance method presented in this paper aims to activate learners' thinking.

Because similar cases or examples are effective for learning, some of intelligent tutoring systems have mechanism to manage similar cases. (Schult, 1993) proposed a similarity measure and (Reimann, 1993) proposed a method of solving problems by using a case-base in the domain of physics. Learners expand their knowledge by considering similarities. In contrast to these systems, our method uses similar physical systems to give learners clues to revise their errors. (Asami, Takeuchi & Otsuki, 1995) also proposed a method to generate physical systems that give learners to correct mistakes. Their viewpoint for remedy is the same as ours, but generation method and learning situation are different .

Though each module has been implemented, they have not been integrated into the learning environment at present. Validation of the method in real learning situation is future work.

ABSTRACT: In this paper we describe the design of a WWW-based course-support environment for a course in instructional-design theories, give an overview of how the environment was used as part of the course experience, and summarize the student evaluation of the course. Our conclusion is that such a course-support environment can extend the teaching and learning process, if well designed, by bringing added opportunities for communication, coaching, and the increase of student self-responsibility. We do not see such a tool as replacing the instructor, but extending him or her. The design of the environment should reflect this. Although the article describes the particular case of a course about instructional design, we argue that the conclusions can be valid for courses of a variety of disciplines and instructional approaches.

Introduction

Despite the sophistication of many computer-related learning materials, we believe that sooner or later a teacher is required to motivate the students, to coach the students in the use of problem-solving methods, to explain the descriptions and interpretations of the subject matter, and to model the learning and practicing of skills. However, the typical classroom or course setting is not particularly conducive to stimluating communication with individual students in order to recognize their intellectual and motivational problems, to explain to them a difficult part of the subject matter, to provide clear tasks, and to coach the students' problem-solving activity. The often-repeated criticism of the whole-class approach has done little yet to change the system and increase personal contacts and coaching between the teacher and individual students.

We believe that the integration of computer technology with data communication, what is called in Europe telematics, creates new possibilities to support and amplify the communication between a teacher and the students and among the students themselves even in a large class; increases the opportunities for the instructor to coach on an individual basis; and provides the students a possibility to become more self-reliant in their approach to studying, while still retaining the benefits of the familiar face-to-face class setting and textbook. WWW-based environments in particular can combine the strengths of computer-based learning with those of instructor-guided learning and can help to overcome the mass-production aspects of the large course in higher education. But how does one design a WWW-based course-support environment to reflect this instructional philosophy? Are there instructional-design principles to follow? We address these questions via an example, a course about instructional design at the Faculty of Educational Science and Technology of the University of Twente in The Netherlands. The case we describe is just one of over 30 courses in our faculty that are taking advantage of WWW-based course-support environments to enrich teaching and learning, for students in the regular institutional setting as well as students sometimes or even primarily at a distance from that setting (see Tielemans & Collis, 1998).

A Description of the Course Instructional Design Theories

Instructional Design Theories is a 120-hour senior course in the Faculty of Educational Science and Technology at the University of Twente. Students in the course represent a mixed cohort, in terms of background relating to the theoretical principles relating to instructional design and of mother tongue. The language used in the course is English. The textbook used for the course is a scholarly analysis of the theoretical foundations of instructional design and of key research approaches (Tennyson, Schott, Seel, & Dijkstra, 1997). Moreover the meaning of the theories for solving instructional-design problems is shown (Dijkstra, Seel, Schott, & Tennyson, 1997). Because the students have different levels of prior knowledge coming into the course, their learning needs are different.

Design of the WWW-Based Course-Support Environment

Based on this, and also the key principles for all students of (a) supporting and amplifying the communication between the teacher and the students and among the students themselves, (b) increasing the opportunities for the instructor to coach students on an individual basis, and (c) providing the students the possibility to become more self-reliant in their approach to studying, the following requirements were established for a WWW environment to support the course:

- The site should provide access to prerequisite knowledge for those who need it.
- Examples of how instructional-design theories and models are applied in practice should be available
- The information presented in the textbook should be extended by showing different perspectives in the topics discussed
- The meaning of critical terms should be clarified
- The students should be supported in searching for additional resources and examples illustrating the course concepts via the WWW
- The students should be motivated and supported in discussing and sharing information.

Using the possibilities made available through the *TeleTOP* database-generated course-support system at the faculty (see http://teletop.edte.utwente.nl, and also Tielemans & Collis, 1998; De Boer & Collis, 1998a,b) a course-support environment was created with the following basic components: (a) a news/update area, for general communication from the instructor to the students; (b) a matrix-like roster, in which the weekly organization of the course is given, and linked to this extra study materials, links to discussions, opportunities for students to enter assignments and new materials into the course site, and for the instructor and other students to give feedback; (c) a communication area, supporting direct e-mail among all participants in the course; (d) a section with general information and background about the course; (e) a shared-workspace area where groups of students can work and discuss together on topics in the course; (f) a glossary, with communication options added so that students can suggest new entries or ask for clarification about terms; and (h) a resources area containing a large number of links to external resources relevant to the course, some to serve as prerequisite material, some for illustration of concepts and theories, and others to serve as enrichment and examples of professional interactions relating to instructional design. Figure 1 shows the roster of the course.

Figure 1. Roster of the *Instructional Design Theories* course-support site

A closer look at the roster

The roster works as a course organizer. For each session, it shows the date and place of the session, gives links to self-study activities that should take place before the session, links to notes to accompany the face-to-face session, links to materials created by the students for presentation during the face-to-face sessions, and follow-up activities after the session. The session notes are prepared by the instructor to help the students deal with each of the chapters and topics in the course. The notes also allow the instructor to update the material, add links to views of other specialists, provide links for further exploration, and to illustrate concepts with examples and real-life applications.

There were three types of follow-up assignments: discussion questions, assignments relating to the creation of reports, and self-tests. For the discussion assignments, students took part in discussions relating to instruction-design issues available via the Internet. This serves to increase their sense of the application of the concepts in the study materials, and also helps them to articulate and defend their own ideas. They also discussed among themselves, using the shared workspace, each entering some reflections and then commenting on the reflections of the other students in their group. The instructor occasionally intervened, to support and motivate, but the main focus was on communication with others in the field as well as one's classmates. For the report-type assignments, students needed to search the Internet to find additional resources to support their ideas. Also, they posted their reports on the course site for peer-review. Again, the instructor coached and commented on an individual basis when useful. The TeleTOP course environment allowed the easy entry of comments and files, as well as feedback and follow-up to materials that have been entered; all the instructor and students need to do to type in their responses or upload previously created files. The entries are immediately entered into the course database and integrated into the course WWW environment. The self-testing was done with Java-enabled test items that provide immediate feedback after the student submits an answer. The students were free to make as much use of these resources as they wished. An important part of the course site was the glossary section. In the glossary, all terms in the course are defined, and external links provided to lead to more-detailed information about each term and concept. In addition, a communication form was provided so that students could immediately enter a suggestion for an addition to the glossary, or ask for clarification. The instructor would then respond, sometimes with an email, sometimes with a new entry in the glossary, sometimes by a further comment during the next face-to-face session.

Student Evaluation of the Course

At the conclusion of the course, the students responded to a questionnaire embedded directly in the course environment. The questionnaire contained 22 multiple-choice questions and 12 open questions. Among the main results of the evaluation are the following points:

- In general, the students enjoyed the site and especially appreciated the well-organized extra resources.
- The students immediately contributed to the site by adding their own PowerPoint presentation materials to support their class presentations. The students indicated they planned to continue using the resources for other courses.
- Although they appreciated the follow-up assignments, they often did not have time to carry them out if they were not given points but only offered on a voluntary basis.
- Students need an initial demonstration of the site, and how to use its features such as the shared workspace and the facilities for uploading and downloading files and giving comments. Students do not read the user manuals provided.
- Students appreciated being able to read the contributions of other students in the shared workspace.
- Students made particular use of the site when studying for the examination.
- Students appreciated a convenient way to communicate among themselves and with the instructor.

The students did make constructive critical comments about the design of the site, and the manner of integrating it into the course (i.e., its fit with the instructional design of the course). In particular, while they appreciate rich resources, they feel they lack the time to exploit them unless this time is included in the marking scheme of the course. This is especially true with discussions; in order to get a critical mass of discussion activity, students appreciate the stimulus of getting points for their contributions. Students also commented that learning from each other also has limitations: *Learning form the presentations of others is not always good, because they can tell wrong things or they cannot explain well. When the instructor explains, it is interesting, but there is often not* *enough time because of student presentations.* An evaluation of the 1998-1999 cycle of the course will be presented at the ED-MEDIA '99 conference.

Discussion

The site was used as a support for the course, to lead the students to decide for themselves what extra materials they wish to select and study. The goal is to support their increased self-responsibility for learning. But students also need a push, or a reward; in the following cycle of the course, points will be given to acknowledge participation in the discussions. The most important function of the course site was to stimulate a more-active learning process among the students, by providing valuable exercises and letting them participate in building the course site by finding or creating resources and sharing them with others. The purpose of the course site is more than putting instructional content in a form ready for study. If our aim as instructors is to coach students to think critically and to reason about concepts and issues, as well as having the ability and motivation for learning independently, then the instructional design of the course-support site should reflect these aims. For example, using the site to search for additional, and relevant, information and examples, and presenting them within the site so that the other students could reflect on each others' choices is a valuable activity for our aims. In the case of students all working in a language which is not their mother tongue (English), the asynchronous nature of the course site allowed them the time to construct their responses without the difficulties of speaking spontaneously.

Extending our experiences to other types of courses

Although this case study has focused on a particular course, it is our experience from working with the instructors of 30 courses within our faculty during the past year that our main conclusions are relevant to a large variety of courses. With all of these courses, the following guidelines have been appropriate, although the way of realizing them varies considerably from course to course:

- A WWW-based course-support environment should extend the boundaries of the traditional teaching that occurs in the classroom.
- It should support while challenging students' thinking.
- It should include a resource center for the investigation of a variety of information, with an emphasis on the students evaluating this additional information in terms of its meaningfulness to the course.
- It should support discussion, exchange of ideas, and peer evaluation, and these activities should be part of the graded activities in the course.
- It should allow the students to organize and restructure information as well as create and contribute their own resources.
- It should present a convenient way for students to participate in collaborate work and in the communication of ideas and questions, in ways that cannot take place in the classroom due to restricted time and the difficulty of making reflective comments in a classroom setting.

Critical to all of this is a user interface that makes contribution to the course site simple for both the instructor and students. Thus other major requirements in terms of the instrumentation of the course site are:

- The course site should allow students and the instructor to enter comments, and upload and download files, without having to know any technical aspects of the process.
- The access to the course site should be through the usual WWW browser, requiring no separate software for either instructor or students.
- All course-support resources should be integrated within a single WWW environment.
- Students should be co-builders of the course resources, and thus need to be able to see and give comments on the entries of their peers into the course site. Thus the course environment must grow during the process of the course, based on student entries, and thus must be flexible technically to handle this and still maintain the underlying database relationship.

Conclusion: Toward an Instructional Design for Course-Support Environments

The value of a WWW-based course-support environment depends entirely on how the environment is designed and how it is integrated into the rest of the teaching-learning process. But because of the newness of the WWW, instructional-design models for the whole instructional communication in which WWW sites are included have to be developed. Such models could retain the skills and insights of the personal instructor and at the same time make use of the time involvement, specialisation skills, sophisticated tools, and task division possible in the professional development team (Collis & De Boer, 1998b). This is the situation now at the University of Twente. We hope that the guidelines suggested in this article can contribute to an instructional-design model for courses making use of WWW-based support environments.

Note: This paper is a shorter version and revision of Dijkstra, Collis, & Eseryel (1998).

Abstract: Educational hypermedia is often seen as an improvement of textbooks. In this paper we show how educational hypermedia can be improved by understanding it as a completely new paradigm that has quite few in common with books. The benefits of features such as continuous media, user-driven interaction, layered structures, and adaptation can only be fully exploited if they are not just seen as additional possibilities for textbook writing.

A Change of Paradigms

Educational Hypermedia/Multimedia is a completely new paradigm and should be treated that way. This especially means that it can't be compared to books, it does not compete with books, and it has almost nothing to do with books. It does not make sense to read a novel from a computer screen as it does not make sense to learn statistics from a book -- even though millions of people did so for hundreds of years.

Especially for educational and informational purposes Hypermedia/Multimedia is the paradigm of choice, as it

- allows the integration of differently encoded media, such as text, graphic, audio and video,
- allows interactivity
- provides possibilities for non-sequential and even non-hierarchical structures,
- enables multi-dimensional navigation (hyperlinks, guided tour, glossary) and
- allows adaptation to the current users prerequisite knowledge and preferred learning model.

In this paper we describe some of the experience we made during the last four years developing educational hypermedia within the DIALECT project (*Digital Interactive Lectures*). This experience is based on an empirical evaluation (Weiber, 1997), user surveys, user interviews, and user observations. We will concentrate on the first four aspects, for more detailed information about adaptation see (Caumanns, 1998).

Multimedia

Computers are not books and information can be provided by other means than text (ask your kids!). We suggest that the media of choice for educational hypermedia should be animation and video. Animation in most cases is the best way to make abstract knowledge visible and therefor more understandable. Video stories help providing an authentic context for embedding the theoretical part of the application.

Since our first application in 1996 (Apostolopoulos et al., 1996) until now we have made a radical shift from text to video and animation as the main means of delivering information. Our first application about marketing had a rate of about one animation per seven screen pages and an average of less than 40 seconds of video and/or animation per screen page. The latest application we completed was about taxes (Buchmann & Geukes, 1998). It contained more animations than screen pages with an average of more than 4 minutes of video and/or animation per screen page. The average animation length nearly increased by a factor of two (from 98 to 167 seconds). The amount of text decreased as radical as the amount of continuous media increased.

The Use of Text

Currently most educational hypermedia applications that were not particularly designed for kids are still heavily based on text. Especially web-based educational systems still use text as the main media for transporting content. Many of these applications look as if someone transformed a book chapter-by-chapter into a set of hyperlinked HTML pages, without taking care of the differences between paper and computer screens:

- Reading speed from a computer monitor is about 25% slower than from paper (Nielsen, 1997a).
- Only 16% of web users read texts word by word (Nielsen, 1997b). This figure might be higher for systems not based on the WWW, but possibly even for these applications it won't exceed 50%.
- Images always catch more attention than text. Whenever there is an image, a diagram, or a video on a page, text is read last.

These figures don't imply that text is completely useless or waste of space, but they suggest to restrict the use of text to where it is best suited:

- giving short summaries,
- structuring screen pages, e.g. by headlines and subheadings, and
- listing items, keywords, links, etc.

Providing information just by text easily leads to inert knowledge - knowledge that might help a student to solve a test but never to solve a real-life problem. E.g. most textbooks and hypermedia applications about statistics contain a sentence like *"The median is more robust than the mean as it is not influenced by outliners."* Pupils will remember that (at least until the test) but only a minority of them will think about it and understand it. Providing this knowledge by an animation - e.g. by showing a distribution with its mean and median and slowly moving an single data point to the left or right - does not guarantee the students will be able to write such a well phrased sentence about robustness, but they will understand its meaning.

Especially rather abstract or more sophisticated concepts can best be mediated by animation or video, e.g. how a superscalar and superpipelined RISC processor works, or how certain distributions can be mapped to real-life problems.

Context and Authenticity

The advantages of video in general and video stories in particular are well known and have been discussed in detail by various authors (e.g. Bielenberg & Carpenter-Smith, 1996). Video is

- more motivating,
- more engaging,
- easier to remember,
- and has a higher content bandwidth

than any other known media. Further on, video is best suited for creating an authentic learning context (CTG, 1992). Especially for constructivistic approaches such as *Situated Learning* (CTG, 1992), *Digital Interactive Lectures* (Apostolopoulos et al., 1996), and *Cognitive Apprenticeship* (Collins, et al., 1989) a video story in most cases is an integral part of the application.

For all of our applications we try to create a story that not only provides a learning context but also shows the relevance of the topic. It is very important for the students to see that the knowledge obtained by the application can be useful for their private or professional life. The main actor of our stories always is either a student or a young employee, who is faced with a problem he or she cannot solve on his/her own. Help to solve the problem comes from various sources: professionals, friends, teachers, etc. These characters work as a bridge between the story and the theoretical part of the application, as they are the only ones who explicitly talk about theoretical aspects of the knowledge domain.

One of the drawbacks with continuous media we had to solve was the hyperlink-problem. Using text with educational hypermedia is attractive as currently text and images are the only media that can contain embedded hyperlinks - either as hot words or as hot zones. We solved this problem by introducing *hot frames*. A hot frame is a very simple yet powerful tool to bind a certain frame of a video or animation to an event. We used these hot frames to provide a list of hyperlinked keywords - whenever a certain concept is mentioned in the video an appropriate keyword is displayed. Clicking this keyword, the user either gets additional information about that concept by a popup window or a jump to the screen page containing information about the concept.

Interaction

Computers are not books and users should be able to do more with a hypermedia applications than just switching pages. Interactivity is certainly one of the most over-used buzz-words in our business: A video is called interactive if it can be stopped; a graphic is interactive if it contains hot zones; a text is interactive if it contains hyperlinks; a screen page is interactive if it contains a *next page* button; a diagram is interactive if it can be scaled; ...

Interaction is the most powerful tool we have at hand to help users learning new and abstract concepts. The obvious reason for the strength of interaction is that it inherently supports the idea of "learning by doing". The not so obvious reason is that it permits users to check their newly obtained knowledge.

Unsupervised Interaction

Interaction in educational hypermedia in many cases is unsupervised; there is no right and no wrong. Typical tasks with unsupervised interaction are "Change the data and look what happens" or "Connect these objects and check the result". An example in the domain of statistics would be a raw data set and a boxplot: The user changes the raw data, the boxplot changes. The system does never say, that any of the changes done was right or wrong.

Especially when abstract concepts can be visualized easily - e.g. by diagrams - unsupervised interaction follows the idea of "learning by doing". Users can prove their own theories or even develop new ones by "playing" with the system.

In our current application about statistics unsupervised interaction is realized by the *Statistics Laboratory (StatLab).* The Statistics Laboratory is a toolbox of visual and statistical objects including worksheets, data generators, various diagram types, text fields, and an S+ interpreter. Connecting these objects, students can create complex filter graphs, where data "flows" from a source (e.g. a worksheet) through various filters (e.g. S+ Interpreters) to a sink (e.g. a diagram).

The basic ideas that led us to the Statistics Laboratory were

- **Immediate Response:** Whenever the user changes data at the source of the filter graph, these changes are immediately visible in all objects that are somehow connected to the source.
- **Unlimited Possibilities:** *StatLab* puts nearly no restrictions on either the kind of data used or on the calculations performed. This allows users to experience their own topics. They choose the data and the method. The drawback of this flexibility is that any kind of supervision of the users actions is impossible (see next section).

Other examples for unsupervised interaction in an application about statistics can be found in (Schulmeister, 1996).

Supervised Interaction

The latest application we finished contains two kinds of interaction: multiple choice questions and spreadsheets for solving some real-life problems that were derived from the video story. Before the initial test phase we thought that users would favor the (unsupervised) spreadsheet problems as they were "more interactive" (users could enter arbitrary numbers and formulas, visualize the data in various ways, etc.) while multiple choice questions are rather "boring" in a way that interaction is reduced to clicking a radiobutton. After the first test phase we knew that it was just the other way round, as one of the mostly stated suggestions for improvements was "There should be more multiple choice questions".

Multiple choice questions are an example for supervised interaction: the user clicks a button or enters a number and immediately gets a response whether he was right or wrong. The problem with supervised interaction is that its coding complexity increases exponentially with the possibilities left to the user. Multiple choice questions are simple: The user can only select between a fixed number of choices, some of them are right and some are wrong. If checkboxes or radiobuttons of a multiple choice test are exchanged by edit fields where users can enter their answer as natural language, things start getting difficult. They even get harder if a problem is made up of several smaller subproblems which might be solved in arbitrary ways and in arbitrary order.

In order to provide supervised interaction not the user but the application must be in control. Each action of the user must be tracked and matched with a list of correct and wrong solutions. Restrictions must be set up to prevent the user from doing something completely silly that is not contained in the right-and-wrong list. All problem-solving interaction that contains some kind of mathematics is faced with the "magical number"-problem: e.g. The user introduces a new variable named "x" with a value of 42. What does 42 stand for? Is there a reasonable meaning on "x"? We don't know and a piece of software surely cannot know either. To prevent this problem, generation of numbers may only be allowed by using a well-defined set of functions. But would you like to force your users to type in a more or less cryptic command just to sum up 1 and 1?

Within the last years some progress has been made in the area of supervised interaction without restricting the user too much (e.g. *Cognitive Task Analysis* (Lovett, 1998)). But most of this progress has been made in the domain of mathematics, statistics, and programming languages, where the alternatives of the user are inherently restricted to either numbers or a well-defined set of symbols. Future will show if some of these ideas can be mapped to less structured and/or less formal domains such as economics or language learning.

Structure and Navigation

Computers are not books and access can not only be provided by a table of contents. To access the contents of a book the table of content or the index is used. To access the contents of most hypermedia application the table of contents or the index is used as well. Still most educational hypermedia are build on hierarchical structures: two levels of headings lead to sequences of screen pages.

There is nothing wrong with hierarchical structures as in most cases they reflect the structure of the knowledge domain of interest very well. They just get inappropriate for hypermedia applications if there is more than one reasonable structure on the knowledge domain or if they provide the only possibility to access.

Tracks in Hyperspace

One of the experiences we made is that users - especially if they are unfamiliar with either the contents or the presentational form of educational hypermedia - like to follow a sequential track. This track may as well be a video story as a guided tour or some kind of "where to go next" hints.

As a consequence of this experience our current application about statistics contains two sequential tracks: a video story as a central thread, and a collection of problems for explorative learning. The theoretical part of the application is structured as a layered hierarchy of concepts (e.g. descriptive statistics, univariate data, measurements, mean and median, calculating the mean from classified data). An user may enter the application either by watching the story, by solving problems, or by working through the theoretical part.

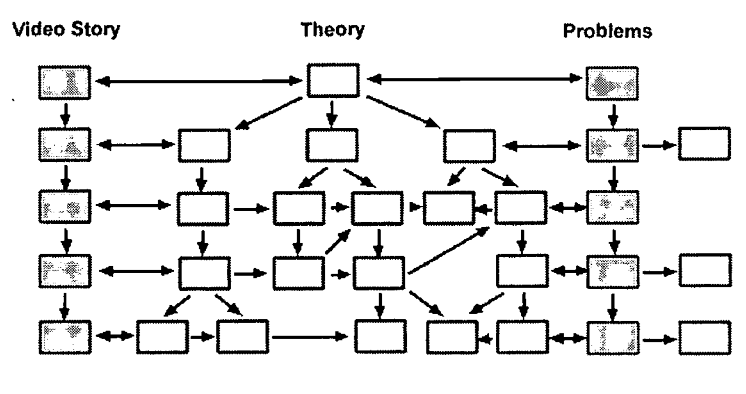

Figure 1: The logical structure of *Statistics Interactive*: Two sequential tracks - story and problems - and a "classical" tree-structured main-part.

Switching between the three parts of the application is made as easy as possible:

- The video story can be split into a number of small clips. After each clip users can either continue watching the story or switch to the theory to glean information about the concepts introduced by the last clip.
- If the user needs some further hints while working in the *StatLab*, he/she can always jump to the theoretical part to learn about the concepts or formulas required.
- After working through a concept in the theoretical part of the application, a user may either jump to the *StatLab* to practice and proof his/her new knowledge or go to the story track to see how this knowledge is used to solve a real-life problem.

Providing multiple ways to access the content of an application will be attractive for both inexperienced and experienced users. Learning to understand, learning to pass an examination, learning about a whole domain, and looking up a single keyword or formula is all supported by providing multiple tracks.

Layering

Some knowledge is more important, fundamental, or useful than other knowledge. Knowing about purpose and application of a concept is more fundamental than knowing its definition or formula. Knowing a formula is more useful than knowing its proof.

Currently many hypermedia applications still make this layering of importance only explicit by using textual explanations. We prefer to make it explicit by means of structure. Therefor we suggest a cascaded, four-layered content structure with the most fundamental and most important knowledge at the top layer:

- **contextual knowledge**, e.g. what is the purpose of measures of central tendency
- **conceptual knowledge**, e.g. what is the arithmetic mean
- **abstract knowledge**, e.g. how to calculate the arithmetic mean
- **additional knowledge**, e.g. proofs and less important measures

From each screen page a user can either go on to a page about the next concept on the current layer or jump to the first concept of a deeper layer. E.g. the page about measures of central tendency on the contextual layer has two successors: contextual knowledge about measures of dispersion and conceptual knowledge about the arithmetic mean. The page about the mean on the conceptual layer has also two successors: the median and calculating the mean from raw data.

By allowing both horizontal navigation (staying on the same layer) and vertical navigation (jumping to a deeper layer), users will easily see how important and how fundamental a certain concept or topic is for understanding the whole knowledge domain of interest. By layering information we further on allow users first to get an overview of the whole domain before getting into details.

Conclusion

In this paper we tried to point out how educational hypermedia currently is still captured by many old textbook paradigms. Especially the overuse of text, missing interaction, and pure hierarchical structures very often hide away the advantages of this new teaching paradigm. To overcome these deficits we propose to put very strong emphasis on the subterms "multi", "hyper", and "media" in "educational multimedia/hypermedia":

- Text is only suitable if it is printed out, it is not suitable if it must be read online. **Continuous media** should be used instead whenever possible. Low-bandwidth yet high-quality encoding techniques like streaming video (e.g. *RealMedia*) or vector animation (e.g. *Macromedia Flash*) make video and animation the media of choice even for web-based applications.
- **Interaction** is hypermedia's sharpest sword. It not only supports the idea of "learning by doing" but even allows users to proof their newly obtained knowledge. An optimal interaction design should be unrestricted, users should be able to click, switch, or enter whatever they want. This demand is difficult to uphold if interaction is supervised as keeping track with and interpreting the users actions usually is a task of exponential complexity.
- Hypermedia applications should be **structured** in a way that allows for multiple access. By providing a sequential story or case study together with a hyperlinked theoretical part the demands of both novice and experienced users can be satisfied. Differences in importance and relevance of topics and concepts should be made explicit by structural means.

- **Navigation** should be horizontal and vertical, that the user might either navigate on the same layer of abstraction or go into detail about a certain topic by switching to a more concrete layer. Guided tours and overview maps should always be provided as alternative ways of navigating through the application.
- A **video story** cannot only be used for motivating and for creating a learning context. It is also well suited as a navigational item as it provides users with a central thread through the application.

We are going this way of strong definition from conventional textbooks for four years now. When we started, we were less radical than we are now. We thought that users always wanted something familiar, but that was wrong: users don't want something familiar - they want something good!

Information Location in Instructional Hypertext: Effects of Content Domain Expertise

Diana Dee-Lucas
Department of Psychology

Pittsburgh, PA 15213 USA
E-Mail: dd7t@andrew.cmu.edu

Abstract: This experiment examined the effects of content domain expertise on the ability to identify goal-related units on a hypertext content map. Novice learners based their unit selections on similarities between the wording of the unit titles and learning goals (i.e., short-answer questions). Wording similarities had significantly less effect on the selections of experts. Experts' and novices' confidence ratings indicated that both groups were able to predict accurately the probable correctness of their selections. These results show that novices studying hypertext may select information on the basis of superficial text features, while experts can use prior knowledge to identify goal-related units. The fact that novices had less confidence in their incorrect selections suggests that they may readily correct these selections with further use of the content map.

Introduction

Instructional hypertexts can potentially facilitate study efficiency by permitting students to determine the order and content of their learning material according to their individual needs. However, efficient learning from hypertext depends on how easily readers can locate the information required for the study goal. To aid information location, many large instructional hypertexts provide an overview of the text through the use of content maps (Dee-Lucas & Larkin, 1995). Content maps display titles indicating the subject matter of the hypertext units (i.e., brief segments of information in the hypertext). Students select units to read by clicking on the titles on the map. This experiment investigated how learners' expertise in the hypertext content domain influences their unit selections from a content map. It compared novices' and experts' ability to identify hypertext units relevant for answering short-answer questions when the wording of the questions varied in its similarity to the unit titles on the map.

Subject matter expertise influences the cues readers use to guide text processing when studying traditional texts. For example, novices studying science texts consider the same information to be more important when it is expressed in the form of an equation as opposed to a written sentence, while experts are not influenced by information form in their importance judgements (Dee-Lucas & Larkin, 1991). Novice readers rely to a greater degree than experts on superficial characteristics of the text structure and content to guide text study (Kieras, 1980, 1985; Dee-Lucas & Larkin, 1986,1988a). Experts use their knowledge of the content domain to develop effective study strategies (Alexander, Kulikowich, & Jetton, 1994; Dee-Lucas & Larkin, 1988b; Spilich, Vesonder, Chiesi, & Voss, 1979).

Traditional text research suggests that readers' subject matter expertise will influence how they identify goal-relevant units on a hypertext content map. The initial unit selections made by novices may be based on superficial text features, such as wording similarities between the learning goals and unit titles. If so, the accuracy of their selections would depend on how well the unit titles matched the learning goals. Because experts can use their knowledge of the subject matter to guide unit selections, the accuracy of their selections may be less dependent on the degree of similarity between the goals and units.

This experiment examined the effects of wording overlap between unit titles and short-answer questions on the units selected by experts and novices from a hypertext content map. Students were given two sets of questions and were asked to identify on a content map the units that they thought contained the answers. One question set included all or part of the title of the goal-relevant unit within the questions; the other set posed the same questions without the wording overlap. It was expected that novices would look for wording cues to select units, and therefore would be better able to identify the correct units when the titles were incorporated into the questions. Experts were expected to use their knowledge of the content domain in selecting units, and thus perform similarly on both question sets.

Method

Materials

The content map was taken from a hypertext about the scientific measurement of length and time (see Figure 1). Because the goal of the experiment was to determine the effects of expertise on unit selection, only the hypertext content map was used. Prior research using the complete hypertext indicated that students were able to use this content map effectively when studying for a variety of learning goals (Dee-Lucas, 1996b).

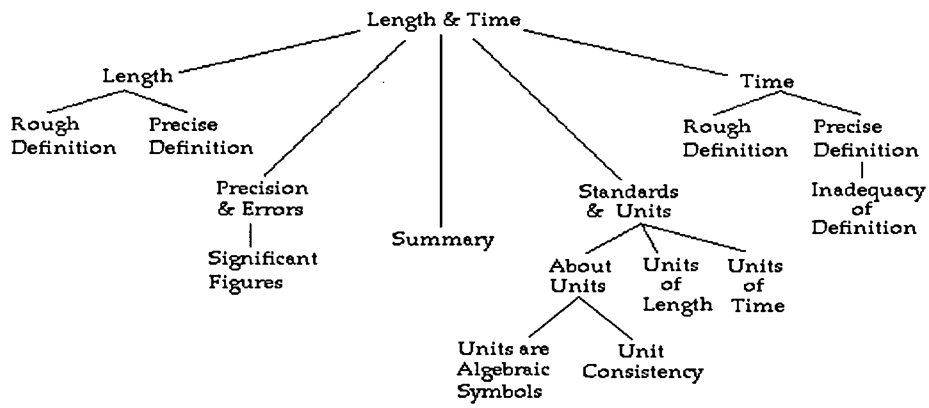

Figure 1. Hypertext content map.

A set of six short-answer "target" questions was developed, with two versions of each question. In one version, the questions contained all or part of the titles of the units providing the answers (i.e., "Overlap"). The other version contained the same questions without the wording overlap (i.e., "No Overlap"). Some of the questions are shown below.

Unit Title	Target Question without Overlap	Target Question with Overlap
Significant Figures	How much variation would be expected in a measurement written as 1.524 m?	How much variation would be expected in a measurement written with 4 significant figures (for example, 1.524 m)?
Unit Consistency	What makes this equation obviously false: **x** m = **y** ft/s (where **x** and **y** are numbers)?	What inconsistency makes this equation obviously false: **x** m = **y** ft/s (where **x** and **y** are numbers)?
Standards & Units	What does "SI" stand for?	In specifying standards and units, what does "SI" stand for?

In addition to the six target questions, three "distracter" questions were included that did not have the same pattern of wording differences as the target questions. Both versions of the distracter questions contained wording suggesting specific units as potentially relevant. The No Overlap distracters signaled an incorrect unit as relevant; the corresponding Overlap questions signaled the both the incorrect unit and the correct unit as possibly providing the answer to the question. Two versions of a distracter question are provided below.

Unit Titles	Distracter Question without Overlap	Distracter Question with Overlap
Precise Definition of Length (incorrect)	What is defined as the distance traveled by light in a vacuum during a specific period	What unit of length is defined as the distance traveled by light in a vacuum during a

Units of Length (correct)	of time?	specific period of time?

In the No Overlap distracter, the phrasing "defined as the distance traveled" suggests that the unit "Precise Definition of Length" might provide the answer. The parallel Overlap version directly signals "Units of Length" as important by including this title in the question, but also includes the wording indirectly suggesting that "Precise Definition of Length" might be relevant. Thus the Overlap versions of the distracter questions suggested more than one unit as the potential source for the answer to the question. The distracter questions were included to help ensure that readers did not detect a pattern between the two question sets.

Procedure & Participants

The participants in the experiment were 16 physics graduate students (experts) and 16 history graduate students (novices). The study was conducted as a paper-and-pencil task in order to allow greater flexibility in data collection. Participants were given the content map and one of the question sets. They were instructed to write down the title of the unit that they thought contained the answer to each question, and to indicate their confidence in their response using a 1 (very sure) to 5 (just guessing) rating. They were told that they could use the same title for multiple questions.

There were two sessions. Participants received the No Overlap questions in the first session, and the Overlap questions in the second session. The questions were given in this sequence to examine the extent to which readers' ability to identify question-related units improved when portions of the unit titles were incorporated in the questions. The second session was conducted at least 5 days after the first to minimize the effects of completing the first question set on responses for the second. Readers' did not have their responses to the No Overlap questions available during the second session.

Results

All data were analyzed with an analysis of variance including expertise (expert vs. novice) as a between-subjects variable and wording overlap (overlap vs. no overlap) as a within-subjects variable.

Ability to Identify Question-Related Units

To assess readers' ability to identify question-related units, the proportion of correct unit selections for the target questions was analyzed. The results indicated significant main effects due to expertise and wording overlap, and a significant interaction between these two variables (see Figure 2).

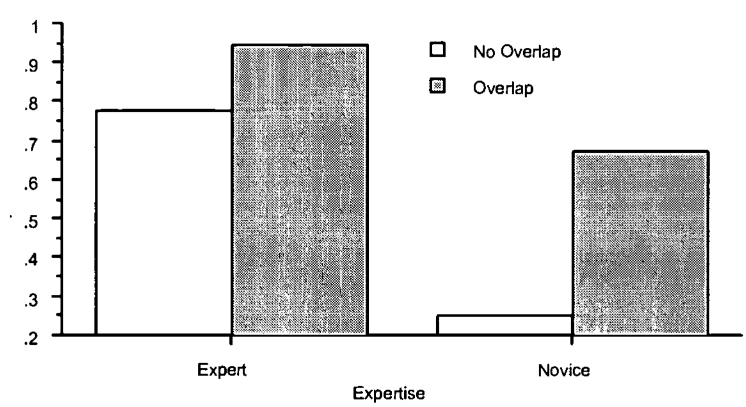

Figure 2. Mean proportion of correct unit selections by each group for each question set.

Experts made more correct selections than novices, and both experts and novices performed better on the Overlap than the No Overlap questions. However, the improvement in performance on the Overlap questions was greater for novices than experts. These results indicate that both groups used wording overlap as a cue for information location, but experts did not require this cue to the same extent as novices. Additionally, experts performed significantly better than novices on the Overlap questions, indicating that subject matter expertise provided an additional advantage beyond the wording cues for identifying goal-related units.

The unit selections for the three distracter questions were also analyzed. The results indicated only a significant effect of wording overlap, with both groups making more correct selections for the Overlap distracters (a mean of .48 correct) than the No Overlap distracters (a mean of .18 correct). This indicates that readers with the Overlap questions selected on the basis of title overlap as opposed to the indirect wording cues (signaling the incorrect unit). Although there were few questions in this set, the lack of effects due to expertise suggest that both groups experienced a similar degree of difficulty when the questions contained misleading or multiple selection cues. These results suggest that experts may be influenced by wording cues when plausible alternative units are suggested by different information sources (i.e., prior knowledge, indirect wording cues, wording overlap).

Changes in Unit Selection

To further examine differences in the use of wording cues, the proportion of unit selections that differed for the No Overlap and Overlap versions of the target questions was analyzed. The results indicated a significant effect of expertise, with novices changing a mean of .63 of their initial selections and experts changing a mean of .20. This result reflects differences between groups in their ability to identify question-related units, and further indicates that novices used wording cues in making their unit selections.

A parallel analysis of the three distracter questions indicated a trend towards more changes by novices which did not reach significance ($p<.077$). Novices changed a mean of .60 of their initial selections, while experts changed a mean of .44. The lack of a significant effect of expertise again suggests that experts had more difficulty with the distracter than target questions.

Confidence in Unit Selection

To determine if experts and novices differed in their ability to predict the accuracy of their selections, the mean confidence ratings assigned to correct and incorrect responses by each reader were analyzed. Because readers made more errors on the distracter questions, both target and distracter questions were included in the analysis to provide more data for assessing the relationship between confidence and response accuracy. The results indicated significant main effects of expertise, wording overlap, and accuracy, and an interaction between expertise and wording overlap (see Figure 3).

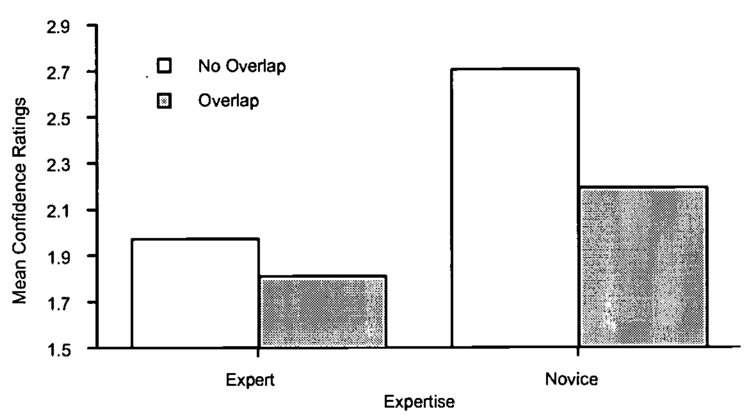

Figure 3. Mean confidence ratings given to each question set by each group.

Both groups of readers had greater confidence in correct selections, and experts were more confident in their responses overall than novices. However, the interaction showed that while experts were equally confident in their responses to both versions of the questions, novices were more confident of their selections for the Overlap questions. This interaction is consistent with differences between experts and novices in their ability to identify the correct units. This again suggests that experts relied on their prior knowledge in selecting units, in that their confidence ratings were independent of question wording. Novices, on the other hand, were more confident when the questions included wording overlap, indicating that they used wording cues in selecting units.

Discussion

Goal-directed learning from hypertext depends on the ability to select and organize the relevant text content. The results of the current research indicate that familiarity with the text subject matter influences how students identify goal-related units on a content map. Novices used wording similarities between questions and unit titles to guide unit selections, and had difficulty identifying goal-related units without such cues. Experts were also influenced by question wording, but to a much lesser degree than novices. This suggests that experts were able to use their prior knowledge to determine which units contained the information needed for the learning goals.

The results of the current research indicate that expertise is more likely to influence hypertext study when the hypertext lacks structural and/or content-level support for selecting goal-appropriate content (Dee-Lucas & Larkin, 1995). Such support would probably not be important for experts, but would be helpful to novices in locating the information they needed. McDonald and Stevenson (1998) reported similar findings in their comparisons of more- and less-knowledgeable readers studying differently structured hypertext. They found that prior knowledge facilitated information location when the hypertext lacked cues as to the content structure of the subject matter, indicating that the knowledgeable readers were able to use prior knowledge to structure the content. Research by Dillon (1991) also suggests that subject-matter experts have an advantage in being able to rely on familiar domain-specific organizations to guide electronic text study.

These findings are also consistent with research showing that novice learners use hypertext more effectively when the access facility provides detailed information about the text content. Dee-Lucas (1995, 1996a) compared novice learners' ability to complete a variety of learning goals when the hypertext content was divided into many small units (with relatively specific unit titles) and fewer larger units (with more general unit titles). The content map displaying many small units facilitated information location for a greater variety of goals. This finding may have been due to differences in the specificity of the unit titles. The more specific titles of the smaller units may have provided a closer match to the wording of the learning goals than the more general unit titles. The general titles may have not provided enough wording overlap to prompt selection of the relevant units for some goals. The current research indicates that the Dee-Lucas findings would not necessarily generalize to experts because they do not rely as extensively on the match between unit titles and learning goals in selecting units.

Although novices in the current research had more difficulty selecting goal-related units, their confidence ratings indicate that they were able to assess the potential accuracy of their selections. There was no difference due to question wording in the confidence ratings of experts, but novices were more confident in their selections for the Overlap questions. Both novices and experts had more confidence in correct than incorrect selections.

The fact that novices recognized when their selections were not well-founded suggests that they may be able to readily correct their selection strategy with repeated use of a hypertext. Learning from hypertext requires the student to make decisions and predictions about the relationship between the information in the text and the requirements of the learning goal (Mohageg, 1992; Wenger & Payne, 1996). If novices recognize when their selections are tentative, they may be more likely to attend to content cues within the units which would enable them to subsequently make correct choices, increasing their study efficiency over time.

The findings from this research indicate that the effects of expertise on hypertext study are mediated by the relationship between the study goals and the information access facility. Subject matter expertise can increase study efficiency when the access facility does not provide a clear indication of the location of goal-related content. These findings emphasize the central role of the access facility in determining the effectiveness of hypertext for novice learners who lack prior knowledge to guide text study. From a methodological viewpoint, the findings indicate that research investigating variables influencing information location (e.g., hypertext structure, learners' background, content domain, etc.) needs to take into account the relationship between the study goals and the access facility provided in the experiment in interpreting the effects of other variables.

Abstract: This paper reports on the findings of an evaluation conducted on Web-based course authoring tools. A comprehensive framework encompassing pedagogical, institutional, and ethical aspects among others, was used to examine the instructional effectiveness of the online learning environment by applying the framework to completed courses rather than assessing the specific features of the tool under investigation. A review of these courses and the attributes of the tools used to deliver them revealed several conclusions. In order for Web-based instruction to be effective it must be pedagogically driven, dynamically designed, interaction oriented, and content specific. Focus should be placed on designing a pedagogical approach appropriate for the content, inclusion of organization and interaction strategies that enhance the student's processing of the information, and integration of the medium's attributes to support the designated goals and objectives of the course.

Introduction

The move to online technologies is an evolving and dynamic process of investigation particularly in the area of examining the ability of such technologies to improve the teaching and learning process. In the case of Web-based course authoring tools (also known as Internet-based training tools), several evaluation frameworks or guidelines have been used to determine the degree of success of those tools in designing, delivering, and managing instruction. For example, Hansen and Frick (1997) suggest four areas that should be addressed by a Web-based course authoring tool for it to become a standard for the development of Web-Based Instruction (WBI): presenting information, providing human interaction, assessment of learning, and course management. Another example is the framework used by PC Week Labs (August, 97) in conjunction with its corporate partner, Wisconsin Technical College System, to evaluate courseware authoring systems for Web-based training. The products used to create the training programs and the resulting programs themselves were judged on conformity to the corporate and education landscape, exploitation of the Internet/intranet, manageability, flexibility, and ease of use. In another effort aimed at helping educators and administrators select new online delivery methods, Landon (1998) conducted an analysis of online delivery software in which he describes and compares these applications by focusing on their technical specifications, instructional design values, media capabilities, features/tools, ease of use, accessibility to persons with disabilities, and potential for collaboration and connectivity. Although useful, these frameworks (and others) have focused on the technological aspects of the features that enable the development of online instruction (Dabbagh & Schmitt, 98) and have adopted a piecemeal approach to the evaluation process which makes it difficult to form an authentic representation of the learning environment generated. As asserted by the Australian National Training

Authority (ANTA), Web-based authoring tools seem to be adhering to a common pattern of development and analysis:

> An emerging pattern for the development of online courses is that of a staged and incremental process. In the first round of investigations, the focus for developers is more on understanding the potential of the technology and exploring its features (March, 98).

The purpose of this paper is to use a more comprehensive framework to evaluate Web-based course authoring tools encompassing pedagogical, institutional, and ethical aspects among others, and to examine the instructional effectiveness of the online learning environment by applying the framework to completed courses rather than assessing the specific features of the tool under investigation. The term used to describe such courses in this discussion will be Web-Based Training (WBT).

The Framework

The proposed framework known as The Framework for Web-Based Learning (thereafter referred to as WBL Framework), was developed by Khan (1998) and consists of eight dimensions: pedagogical, technological, institutional, ethical, interface design, resource support, online support, and course management. Each dimension has various items addressing its constituents in relation to Web-based learning environments. For example, the pedagogical dimension addresses issues such as instructional goals and objectives, the overall design approach of the course, content sequencing and organization, instructional methods and strategies, the instructional medium (the Web in this case) and the extent to which the course uses its attributes, accuracy of subject matter, and learner assessment. For more details about this framework and its dimensions see: http://www.gwu.edu/~etlkhan/keynote/dimensions/framework1.html.

There are three issues to consider when attempting to answer this question. First is the issue of the transformation that traditional courses experience when redesigned for Web delivery. Typically such courses undergo a "pedagogical reengineering" (Collis, 1997) because of some of the inherent features of the Web that are integral to the design of WBI (Dabbagh & Schmitt, 98). Second is the purpose of the Web-based course in the learning environment. Is the course a supplement to on-campus/on-site instruction or is it intended as a distance learning alternative in which the instruction, interactions, and feedback are delivered via the Web? Third is the type of authoring tool used to develop the course for Web-delivery and the features it affords the developer. For example, integrated application suites (authoring tools) refer to applications that provide specific tools designed for each of three user groups: learners, instructors, and technical administrators whereas component applications refer to more specialized applications that generally provide few instructor tools (Center for Curriculum Transfer & Technology, http://www.ctt.bc.ca/landonline). We will address these issues by applying the WBL Framework to six WBT sites that have been developed using six different Web-based course authoring tools (see table 1). We will then use the results of this evaluation to determine the extent to which the technology of delivery, in this case the Web-based authoring tools, can shape the pedagogy of courses and assist course developers in focusing on instructional considerations when capitalizing on the attributes of the medium.

The Courses

Selecting the courses was not an easy task. We searched for complete courses that demonstrated a full and authentic use of the application. All of the product Web sites contained at least one demonstration course that could be accessed by registering and receiving a password or a log-on ID. These product site courses, however, varied in their ability to demonstrate all of the components of the authoring tool. A few of the courses were designed and taught by instructors for accredited programs, but no longer included the student exchanges, student projects, tests, and complete content. Other courses were designed specifically to demonstrate the product and therefore were not actually used by instructors or students in a learning context. In the quest to obtain courses that reflected a more realistic use of the Web-based course authoring tool, we were able to obtain access to a few uncorrupted accredited courses which we felt were sufficiently representative of the authoring tool and therefore befitting the purpose of this chapter.

The Evaluation

Due to the comprehensiveness of Khan's framework, which includes eight dimensions and more than sixty sub-components, a simplified strategy was selected for our informal evaluation of these courses. Mapping the framework to the various courses revealed specific strengths and weaknesses of each course that could be aligned with many of the framework's components. To avoid unnecessary complexity, we chose to focus on the major course attributes in relation to the framework. The major attributes of each course which emerged, both positive and negative dictated our interpretive evaluative approach using the WBL Framework.

Marketing Certificate in Small Business Management

This comprehensive demonstration course highlights many features of WebCT. Most notable is the student guidance for on-line learning and navigating the course as well as excellent content organization. Developed in an on-line mode format (Brenda, is this redundant?), this course provides the student with extensive explanation of the purpose, objectives and activities involved in addition to directing students to recommended approaches for learning the material in this delivery format. The instructional content is thoroughly presented in a program-centered manner (WBL framework) providing the student with clear and concise partitioned segments of content. There is evidence that the instruction was originally interspersed with interactive elements such as forms, and assessment elements such as on-line quizzes.

On first glance, the course seems to represent a more objectivist pedagogy (WBL Framework) primarily in delivering content but inside collaboration is also included with discussion email and on-line chat mechanisms as well as conferencing bulletin board sessions that automatically create a conference topic relevant to the current content section chosen. Administration and tracking mechanisms are also included providing some metacognitive suppport for the student in resuming their place in the course and tracking progress through presenting the number and history of pages viewed and section printing capabilities (WBL Framework). Assessment of student learning through on-line quizzes and case study responses are evident; however, it is not clear how the students receive feedback on their responses. Efforts for formative evaluation on the course are elicited through various methods of response including email and forms.

SUNY TopClass Virtual Lounge & HelpDesk

WBT Systems, the distributor of TopClass, recommended a course designed and conducted by William Graziadei of the State University of New York, Plattsburgh, as a demonstration of their Web-based course delivery system. In spite of its title, "SUNY TopClass Virtual Lounge & HelpDesk (STCVL)," this is a complete course. STCVL is meant to provide a self-paced guided training for SUNY students and instructors who will participate in online teaching and learning using the TopClass application. The course overview states that Professor Graziadei hopes the discussion portion of the course will become a forum for faculty and students of different disciplines to share their experiences with online education.

The course overview encourages contributions through email (which is always available on the tool bar at the bottom of each screen), and discussions can be accessed through the course homepage, however, group interaction and collaboration (WBL Framework) are not an integral part of the course design. Only one folder, the "live interactive tutorial," appears to provide interaction between student and instructor. Unfortunately, access to this tutorial is restricted to the SUNY community. Another weakness of the course is the absence of a search engine, index, or glossary to help students who return with specific questions, sift through the profusion of information presented under each topic/unit. Also, considering the amount of information in some folders, the topic of Online Education could have provided many more outside links to resources on distance learning and instructional design strategies relevant to this delivery medium.

Effective Business Writing English 1007

The purpose of this course is to be delivered half the time in a face to face format and the other half fully online. This is known as the mixed mode compared to an adjunct or an online mode. In an adjunct mode, the online portion of the course is intended as a supplement to enhance traditional classroom instruction. The online mode is when the network serves as the primary environment for course discussions, assignments and interactions. These modes are referred to as 'modes of teaching' by Virtual-U; the tool used to develop this course, and are offered as guidelines for instructors in the Instructor Tools and Support component of the tool.

The course begins with four options to choose from; course syllabus, course overview, course calendar, and glossary. These options are not standard. They can be customized to reflect different choices based on the content of the course thus providing structural flexibility (WBL Framework). The course syllabus is an advance organizer and contains hypertext links to the course topics, units, assignments, tests, activities, resources, and online conferences and discussions. The links encompass a wide variety of electronic media utilizing virtually every attribute of the Internet and the World Wide Web. They include text files, tutorials, audio files, video clips, animations, graphics, online resources (with built-in search engines), and PowerPoint files to present course content and learning activities, as well as, synchronous and asynchronous communication forums ranging from email to a virtual cafe for socializing. Although intricately rich in multimodal representations and interaction levels, the variety is overwhelming and could present a level of complexity for first time users. However, it is evident that online support, resource support, and inside and outside collaboration is demonstrated through the use of these features (WBL Framework).

With each of these views there are Use features that can be accessed by the student and the instructor to perform certain activities. This Use feature promotes a student-centered approach to learning, which is one of the underlying instructional principles that Virtual-U supports. The workspace interface is a good anchor point for the user and perhaps should serve as the primary navigational structure for the course. It will improve the user friendliness of the interface.

Health Care Management

Health Care Management first conducted in the fall of 1997 provides an example of a course delivered via Web Course in a Box (WCB) authoring software. The course is structured using face to face class sessions interspersed with at least five electronic seminar discussions. This demonstration course highlights the main features and aspects of the WCB software but is currently deliberately restricted in content and resources as well as corrupted by multiple users experimenting with the authoring tool. However, in reviewing the structure and content that is available, many attributes of the course and the software are revealed.

The primary strengths of this course are the instructor's apparent attempts at management (WBL Framework) and organization of the content within the software constraints in addition to adequately addressing the on-line support issues (WBL Framework) necessary for student participation. These factors have pedagogical as well as interface usability implications. The electronic seminars focus on discussions about the off-line readings. These discussions are well directed with specific objectives and clearly outlined expectations established prior to providing a link directly to the conference on that topic. This organization facilitates the discussion of a specific topic focusing student contributions and easily directs students to the related conference session. Additional management issues are addressed in the course such as providing a help section and learning links dealing with Web development skills, however, the relationship of these skills to the required assignments could not be clearly determined. Inside collaboration (WBL Framework) between students in the course is fostered by WCB's providing space for personal biographies as well as individual and public class email capabilities.

Hospitality Industry Law and Liability

LearningSpace featured Hospitality Industry Law and Liability, a course from the University of Wisconsin-Stout, Department of Hospitality and Tourism. The course was entirely Web-based having no classroom component. The class databases were modified to remove copyright material, student discussions, and student profiles. Only a few units of the course are shown in their complete form, however, those sections demonstrate both the efficient ordering of content to help the learner achieve the objectives (Kemp, Morrison, & Ross, 1994) and clear expectations of what the student is required to do (WBL Framework). The units featured in the "Schedule" section provide reading assignments, content and process objectives, the purpose of the unit, as well as student and instructor evaluation criteria. The WBL Framework suggests that the course promote inside collaboration for working on joint projects. The instructor of this course requires collaboration with team members on many assignments, such as critiquing case studies. Collaboration is facilitated by the LearningSpace structure. It provides a shared workspace for team assignments. Teams may choose to restrict access to this space to members only. A message appears on the assignment link to indicate whether the work is "In Progress," "Ready for Grading," or ready for "Instructor Review." Collaboration is further promoted through discussion, which may be directed to the entire class or to team members.

Programming Your Avilar VCR

This course is intended as standalone instruction. It is self-contained and designed using tried and true instructional design principles. The pedagogical philosophy used in the overall design of the course actually shapes the learning environment (WBL Framework). The course starts out with clear instructional objectives and user directions on "how to take the course". Using a frame-based interface, the course is conveniently divided into six modules: lesson, exercises, questions, review, resources, and assessment. Buttons for each of these modules remain accessible throughout the entire lesson, however they are disabled and enabled based on where the learner is in the lesson. One must complete a lesson module first; then complete related exercises, answer questions, get feedback, review the lesson, and take the assessment. The progress through the lesson is therefore dictated by the organization of the content (to a large extent) and proceeds from basic to more complex learning outcomes. Although there is not much structural flexibility (WBL Framework), it is possible to jump between course modules using embedded hypertext or the Course Contents menu. It is recommended, however, that first time learners complete the course in the intended sequence. The modules can later be used as a reference or a job aid if one forgets how to perform a certain function.

The assessment and questions modules demonstrate a variety of multiple-choice question formats that can be used to evaluate learners' mastery of learning outcomes. Equally evident is the feedback feature after each response and the instant grade reporting that follows an assessment. Web Mentor supports the use of email, conferencing, chat rooms, application sharing, and other synchronous and asynchronous interactions that foster collaboration and interactivity. The course content however was not appropriately matched to the capabilities of the delivery medium (WBL Framework) and the use of a familiar methodology in designing instruction for a new technology may have once again contributed to the under-utilization of the tool.

Discussion and Implications

As is often evident in face to face courses, the Web-based courses demonstrated a mix of methods, strategies, and pedagogical approaches. Various strengths and weaknesses were noted in each case when mapped against the WBL Framework. Some courses adopted an objectivist, straightforward approach of content segmentation and delivery for mastery (see Programming VCR - Web Mentor), while others capitalized more fully on the inherent collaborative attributes of the Web in providing students with shared workspace (Hospitality Industry Law and Liability - Learning Space) and a constructivist student-centered approach (Effective Business Writing - Virtual U). Most presented a clear, logical and organized format (SUNY Top Class Virtual Lounge and Help - TopClass) and well-directed objectives and expectations (Health Care Management - WCB) while some provided exceptional guidance for learners with recommended approaches to the material (Marketing Certificate in Small Business Management - WebCT).

In examining the courses and hence the Web-based authoring tools, we found that the WBL Framework is an effective tool for informal evaluation and a good guiding mechanism or checklist for the development of Web-based courses. Our position is clear in attempting to promote a more comprehensive evaluation of courses developed with these authoring tools rather than examining the tool itself. Educators do not evaluate a classroom course merely by the technology of delivery, (e.g. attributes of overheads, LCD display, teacher-directed discussion) therefore we should not discern the effectiveness of on-line learning environments merely by dissecting the delivery tool.

Our review of these courses and the attributes of the tools used to deliver them revealed several conclusions. In order for WBI to be effective it must be pedagogically driven, dynamically designed, interaction oriented, and content specific. Focus should be placed on designing a pedagogical approach appropriate for the content, inclusion of organization and interaction strategies that enhance the student's processing of the information, and integration of the medium's attributes to support the designated goals and objectives of the course. Developers of Web-based training and educational materials need to place emphasis on these tasks and view the technology in relation to its capacity to deliver the planned design. This focus is perhaps best promoted by ANTA:

> While we are constantly reminded that learning must be developed around learning needs, meeting educational objectives and producing viable graduates, the lure of 'exploring the technology' is often at the expense of equal investment in the underpinning educational design.

The intersection between pedagogical considerations and the attributes of the Web-based authoring tools may, in fact, yield the most educational impact. Our reviews of these courses showed that attributes of the technological tools may also influence the pedagogical aspects of the course. This has been previously demonstrated in a case study by Dabbagh and Schmitt (1998) whereby a course that was redesigned for Web-delivery underwent a pedagogical reengineering from a primarily instructivist pedagogy to a more constructivist one due to the focusing of the developer on the inherent attributes of the Web through the use of the authoring tool. Web authoring tools which include components that facilitate the team process, such as LearningSpace, promote the inclusion of collaboration as an instructional strategy. Therefore, if the content and planned strategy dictates a strong focus on students working together then taking advantage of the attributes of this particular authoring tool may in fact enhance the educational effectiveness of the course.

Unfortunately no one tool can deliver every possible instructional approach. The software tools seem to have some common attributes as well as individual strengths and weaknesses. Most current web-based course authoring tools can also be viewed as restrictive in nature due to the visual metaphors employed by each tool that place constraints on the organization of content and the potential learning strategies employed. This factor certainly can restrict the learning environment produced and may prompt the need for web-based tools that are more open-ended, comprehensive and customizable. Hedberg & Harper make the valuable suggestion that new metaphors for authoring should be developed to match current theory. This notion seems a good start, however, a comprehensive advisement mechanism included within Web-based authoring tools providing guidance in the areas of pedagogical approach, instructional strategy, and on-line support and resources, may go further to support the developer who is lacking instructional design skills.

The Effect of Hypermedia Presentation and Relevance on Peak Experience

Tom S. Chan, Dept. of Comp. Sci. & Info. Sys., Marist College, USA, tom.chan@marist.edu

Abstract - This study investigates the effect of hypermedia presentation, its activity relevance and the interactions between the two on peak experience. The results suggested that the activity content has major influences on motivation but presentation is a double-edge sword. Hypermedia presentation adds appeals to instructions that motivate students if they are used appropriately. When the content relevance is complicated, complex presentations can be distracting. Consequently, hypermedia elements should be used sparingly at the beginning of a lesson when challenges are high and students are unfamiliar with the material. As the lesson progresses it could be used gradually as the content challenges are reduced.

Introduction

Hanaffin and Dalton (1993) proposed new technologies facilitate instruction in six areas: adaptability, realism, hypermedia, open-endedness, manipulatibility, and flexibility. Technology brings realism to instructions with greater breadth and depth. Norman (1994) illustrated the situation with this example. A large screen with high-quality sound improves the ability to be captured by the events. The relatively small screen and sound system of the typical home television distance the viewer from the event. In any environment, an event best captures the attention and improve concentration when the sensory experience is maximized and distraction minimized. However, Moore, Burton and Meyer (1996) cited that while much of the evidence from research supports multiple-channel design to provide additional reinforcement, the overall evidence on its effectiveness is inconclusive. They proposed that human information processing has its limited and is subjected to overload. This proposal is supported by the cognitive load theory: our working memory limits our learning capacity. The prescription of instruction requires careful analysis to consider the memory load implication of the different combination of content and instruction, sequencing and pacing (Sweller & Chandler, 1994). Unfortunately, the prescription is mainly related to instructional contents. The impact of hypermedia presentation on learning and its interaction with contents are largely unexplored.

The Internet signifies different things to different people. While some often find it a frustration, others view its as an end in itself. They report a great sense of involvement and excitement. Working with new technology such as the Internet appears to induce flow experience (Miller, 1996; Norman, 1994). Flow is an optimal state described by Csikszentmihalyi (1975, 1982, 1985, 1988, 1990, 1994,1997). During flow, people become so intense that nothing seems to matter. The experience is so enjoyable that they will do it for its own sake. When people reflect on how it felt when they are in flow, they mention these aspects: (a) sensing that one's skills are balanced challenge; (b) engaging in a goal-directed activity; (c) receiving clear feedback; (d) feeling in control; (e) intensifying concentration, with a sense of (f) merging action and awareness; (h) disappearing of self-consciousness; and (h) distorting sense of time; and (i) experiencing great gratification that the activity is intrinsically rewarding. Flow represents a descriptive dimension that signifies some purer instances of intrinsic motivation. When highly intrinsically motivated, we become extremely aroused and experienced such emotion as flows (Deci & Ryan, 1985). As indicated by flow theorists, flow experience is affected by contextual factors, including the task structure and quality of presented information. This study was designed to investigate how task relevance and quality of presented information influent flow experience in instructional activities.

Perelman (1992) predicted demise of the traditional educational system. A new wave of knowledge technology, the hyperlearning technology, is coming. It enables anyone to learn anything, anywhere, anytime, with same effectiveness as classroom instructions. While business is relying less on traditional instruction, students from kindergarten through university are using technology as supplemental, not substitutes for formal classroom. Although the Internet has a limited reach today, it is growing exponentially. Statistics show that by the year 2000, 95% of public school will be connected to the "Information Superhighway". Despite the great hype and promise, and its ability to connect us to a vast amount of information in text, picture, animation and sound, this "great technology hope" also gives us a sense of déjà vu. Cuban's (1986) examination into the optimism, enthusiasm, hesitancy and frustrations of integrating technology and education revealed the great complexity of the issue. Unfortunately, the educational system is propelled into the "Brave New World" at great momentum, even if we are not quite ready, and its impacts are far from certain. In this age of expectation and uncertainty, the effect of new technology on learning is a critical research issue.

Methodology

Four groups of 20 students were randomly selected, then randomly assigned to a treatment. Searching for information is motivating because of the perceived need for the information (Krikelas, 1983). By seeking research information or browsing on irrelevant material, we change the motivation level. Embellishments increase novelty and complexity that positively affect motivation (Lepper & Cordova, 1992). Using hypermedia or traditional computer platforms, we also change the motivation level. With a 2x2 design, the two levels of content relevance and two levels of presentation quality are as the following:

1. Reading MS Word - students browsed over a text file about dinosaurs. The tasks were imposed not negotiated, and they were not told about the purpose of the activity.
2. Reading CD-ROM - students browsed on a CD-ROM on dinosaurs that contained image, audio, video coupled with a hypertext organization for non-linear navigation.
3. Searching on ERIC - students searched the ERIC via remoter connection with a monochrome text-based system, where they searched for material on a class project.
4. Searching the Web - students searched for material on the Web using a Netscape browser with a list of sites pertinent to their course project.

The Flow State Scale (FSS) was developed to assess flow during sport participation (Jackson & Marsh, 1996). It has 36-item, 5-point Likert-type scale, with 4-item for each of the 9 flow dimensions. The instrument was adapted for assessing flow in computer-based activity (Appendix). A score from definitely-5, agree-4, may be-3, disagree-2 and definitely disagree-1 point was assigned. Strong agreements suggested a high degree of flow, and flow subscales. The proposed FSS dimensions, and its construct validity have been theoretically supported by research (Csikzentmihalyi, 1988; 1990; 1992). Psychometric assessments of the original instrument (Jackson & Marsh, 1996), and the adapted instrument (Chan, 1998) reported alpha from .71 to .93.

Data was collected during class activities in spring 1998. At the last 40 minutes of a regular class session, students were ushered into a PC lab with the necessary computer application loaded for the randomly selected treatment. After 30 minutes, students were instructed to stop. They were asked to reflect upon their experiences during the session while completing the questionnaire. The procedure was repeated for the next class section with the next randomly selected treatment until all treatments were administrated. Univariate Normal Plot, Hartley Fmax, reliability and correlation analyses were conducted to examine the data characteristics. Data were examined with two-way ANOVA on the total and subscale scores of the Adapted FSS. If the interaction effect was significant, simple main effect for the content and presentation will also examined.

Results

Out of the total enrollment of 97 students, 80 participated in, and all completed the study. The sample comprised majority female (72%), between age 18 to 25 (74%), Anglo (73%), with 39% Junior and 24% Sophomore. Cronbach's alpha yielded .93 for the flow total, and .69 to .88 for the subscales. Descriptive statistics reported the highest score for the flow total scale: CD-ROM (low content, high presentation, M=119.70, SD=15.50), ERIC (high content, low presentation, M=114.15, SD=19.53), Internet (high content, high presentation, M=111.55, SD=18.36), and MS Word (low content, low presentation, M=105.50, SD=14.31). Normal distribution and homogeneity of variance held for all treatments. Pearson r was reported from .58 to .89 between the flow subscales and total scale.

The autoletic subscale detected significant main effect of presentation ($F_{(1,,76)}$=27.61, p<.03). Significant interaction effects were reported for the flow total ($F_{(1,,38)}$=9.07, p<.005), and subscales: challenge ($F_{(1,,38)}$=14.79, p<.0004), goal ($F_{(1,76)}$=9.36, p<.0031), feedback ($F_{(1,76)}$=7.75, p<.0068), awareness ($F_{(1,76)}$=11.41, p<.001), control ($F_{(1,76)}$=4.15, p<.04), and consciousness ($F_{(1,76)}$=5.23, p<.025). Simple main effect analyses reported participants using high presentation quality platform scored higher on the total ($F_{(1,38)}$=9.07, p<.005), challenge ($F_{(1,38)}$=14.79, p<.0004), goal ($F_{(1,38)}$=11.37, p<.002), feedback ($F_{(1,38)}$=5.39, p<.02), awareness ($F_{(1,38)}$=21.11, p<.0001) and consciousness ($F_{(1,38)}$=10.94, p<.002) subscales at the low content relevance activity, and but no significant presentation quality effect on flow and flow subscales at the high content relevance activity. It also reported participants in high content relevance activity scored higher on the challenge ($F_{(1,38)}$=6.56, p<.01), goal ($F_{(1,38)}$=5.78, p<.02) and feedback ($F_{(1,38)}$=5.72, p<.02) subscales while using the low presentation quality platform. However, participants in low content activity scored higher on the challenge ($F_{(1,38)}$=7.00, p<.01), awareness ($F_{(1,38)}$=21.73, p<.0001) and consciousness ($F_{(1,38)}$=11.90, p<.001) using high presentation quality platform.

Discussion

The study revealed strong interaction between content and presentation on flow experience. Presentation quality enhanced flow (d = .46), as measured by challenge, goal, feedback, awareness and consciousness in low content relevance activities. However, it did not have significant effect on flow in high content activities. Content relevance, on the other hand, enhanced flow experience (d = .36) while using low presentation quality platforms. However, it impeded flow experience (d = -.43) while using high presentation quality platforms.

Hypermedia is a double-edge sword for instruction. While not necessary increase learning, multimedia adds appeals to the instruction, motivate students and facilitate flow, as long as they are used appropriately. Multimedia should integrate gradually into a lesson. When the content relevance is high and adequate challenge is already provided, high presentation quality is distracting. As instructional designers, we must integrate multimedia into the lesson carefully, or it has negative consequences. Multimedia elements should be used sparsely in the beginning when challenges are high and students are unfamiliar with the material. The elements should be incorporated gradually as lesson progresses when challenges are reduced, at which multiple-channel stimuli will no longer impede performances.

However, multimedia can be an effective mean in alleviating boredom for expert students. An intrinsic problem in instructional design is its necessity to aim at an average or normative level. As Csikszentmihalyi (1982) noted, easy material makes schooling a bore for many students. For others, the difficulty of the material causes great anxiety. When the content relevance is low and inadequate challenge is provided to students, high presentation quality has a positive effect on motivation. Findings in this study suggested that instruction could be designed to present materials to expert students with more hypermedia elements. High quality presentation with advance technology can be employed to maintain students' motivation.

Autotelic or intrinsically rewarding experience is the most important dimension of flow and directly related to intrinsic motivation. Significant main effect of presentation in the autoletic subscale indicated that students preferred high presentation quality regardless of the content relevance of the activity. The richness of hypermedia increases motivation, despite its negative impact when the students' capacity is already stretched during high content relevance activities. Interestingly, the result indicates that students are not very effective in self-monitoring. The excessive stimuli during a high content relevance task impede flow. Nevertheless, students still prefer the multi-channel presentation, and are unable to realize its negative impacts.

This study is only a beginning step to the formulation of a prescriptive model for the motivational aspects of instructional design based upon the flow theory. There is absolutely no reason why the classroom cannot release as much excitement, energy and achievement as are seen in sport stadium and playing fields around the world every weekend. More researches and explorations in the motivational aspects of instructional design will help transform the classroom from a place where students "have to be", into a place where students actually "want to be".

Abstract: User Centred Courseware Development (UCCD) offers an alternative approach to courseware design. Instead of the traditional approach involving only the designers, UCCD provides a learner-centred design approach. It offers a comprehensive alternative design process, involving different activities, practices and methodologies appropriate for the different phases of system development. This paper describes UCCD in the context of a case study involving the development of courseware for a high school in Stafford, UK (students aged 11-18). It shows how UCCD can be used to design effective and usable courseware which meets users requirements and expectations.

Introduction

In this paper we will give a brief review of User Centred Courseware Development (UCCD) a novel courseware development process building on principles of user centred design from human-computer interaction and information systems. We will start by giving a short overview of the background and structure of UCCD. The main part of the paper will look at UCCD in more detail as applied to a specific case study, the development of courseware about World War 1 for 13/14 year olds in a Stafford high school. This will be followed by a short analysis of the lessons learnt from this exercise and for user centred courseware design in general.

User Centred Design

Traditional courseware development is normally carried out by designers, who take complete control. It is rare that the end users (who include the teacher and learners) are involved. Although the courseware produced may be effective, it often lacks usability. User-centred design is an approach to integrate user requirements, user interface, validation and testing into a design process to make the software usable. Rather than being technology-driven, user-centred design focuses on the people, or users.

The benefits of adopting UCD to courseware design are that it accelerates software development and improves quality of life of users by reducing stress and improving satisfaction. This in turn improves user interface and system functionality, which improves the level of productivity of users with fewer errors. Overall the system is easier to understand and use, thus reducing training costs, and finally software maintenance in terms of support calls and documentation errors is dramatically decreased.

Methods for User Centred Design

There are several methods which are applicable to the development of user-centred courseware. Two of the well-known methods that have been used successfully in software development are Participatory Design (PD) and Joint Application Development (JAD) (Carmel 1993). There are several similarities between PD and JAD. Both methodologies stress a high degree of user involvement as imperative to good design of software systems. Both represent new thinking on the traditional forms of user involvement. Both involve the users in workshops and to various degrees, encourage creativity and new thinking. Practitioners in PD and JAD often employ simple, low-level documentation and visualisation methods in their workshops.

User Centred Courseware Development

We have developed a method known as User Control Centred Development (UCCD) which incorporates some of the principles of PD and JAD using prototyping. At a high level, major steps in developing a courseware application in UCCD include those shown in Figure 1.

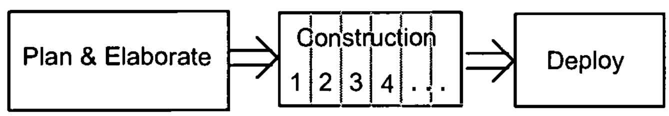

Figure 1. Macro-level steps in UCCD development process

The process is an iterative and incremental development process, in that the software is not released in one "big bang" at the end of the project. An iterative life-cycle is based on successive enlargement and refinement of an application through multiple development cycles of analysis, design, development, implementation and evaluating. The application grows by adding new functions within each development cycle.

The first phase of UCCD is the plan and elaborate phase. This phase includes the initial conception, investigation of alternatives, establishing the rationale of the project, planning, specification of requirements and so on. During this phase we also collect more detailed requirements, do high-level analysis and design to establish the baseline architecture and create a plan for construction. The construction phase consists of many iterations, in which each iteration builds production-quality courseware, tested and integrated, that satisfies a subset of the requirements of the project. Each iteration contains all the usual life cycle of analysis, design, development and evaluation. Each iteration or development tackles a relatively small set of requirements. The system grows incrementally as each cycle is completed. This is in contrast to the traditional courseware cycle in which each activity (analysis, design, and so on) is done for the entire set of system requirements. The advantages of using an iterative development process include the complexity is easier to manage because early feedback is generated, because implementation occurs rapidly for a small subset of the system. The last phase is the deployment of the application into actual use.

Case study: UCCD

The UCCD method is described in a case study concerned with the development of a courseware for students aged 13-14, learning history on World War I (1914 - 1918). The users involved are the history teacher and the students in her class. The subsequent sections of this paper document the UCCD process.

Plan and elaborate

The first session was scheduled with the teacher and students at the high school. As designers we believe strongly that correct and thorough requirements specifications are essential to a successful project. The primary goal of the requirements phase is to identify and document what is really needed in a form that clearly communicates to all participants. During our first meeting we conducted a conceptualisation process. Conceptualisation is the process of coming up with an idea for a system, along with a general idea of its requirements and form. It finishes the statement, "The system we want is ......". The primary output from this process is a set of core requirements for the system.

We started the conceptualisation process by conducting a use case analysis to identify the actors involved in the system. Use Case analysis was first popularised by Ivor Jacobson who defines a use case as a typical interaction that a user has with the system in order to achieve some goals (Jacobson 1994).

An *actor* is a role that a user plays with respect to the system. There are five actors identified for the school: headmaster, teacher, students, secretary and, of course, the computer systems itself. Actors carry out use cases. A single actor can perform many use cases. Conversely, a use case may have several actors performing it. Actors do not need to be human. An actor can also be an external system that needs some information from the current system. Figure 2 shows a Use Case Diagram for the high school in question.

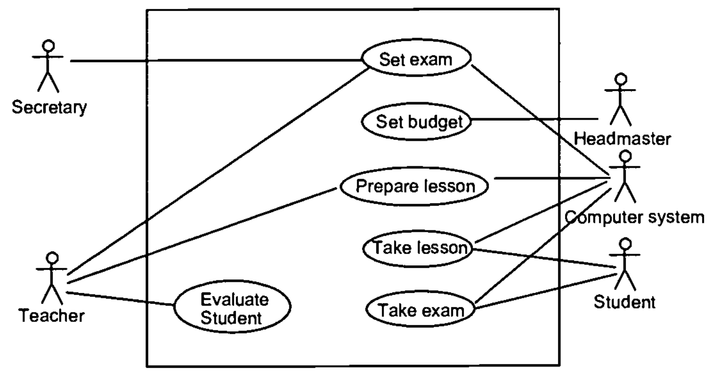

Figure 2. Use Case Diagram for the School.

Following the identification of the actors involved in the system, we, with the teacher, then tried to determine the requirements of the system. The goal identified following our conceptualisation process was "To develop a courseware for the students to learn the history of World War 1 using the computer." In order to improve our understanding of the requirements we created high-level use cases to quickly obtain some understanding of the overall major processes involved. Examples of the use cases identified include: (I) to describe the events leading to World War I; (ii) to show the timeline of World War I; (iii) to discuss the horror of wars; and (iv) to understand the implications of the use of machine guns in World War I.

A prototype was created, using storyboards, to verify the requirements based upon the use cases identified. The main purpose of the prototype at this stage was to aid understanding of the problem and establish requirements. The students and the teacher evaluated the prototype. The identification of use cases was probably the most critical part of the plan and elaborate phase. The main purpose was to determine the tasks the learners must perform to achieve the goals. An important result of the elaboration is that we have a baseline **architecture** for our system. The architecture consists of a list of use cases that tell us what the requirements are and the domain model that captures our understanding of the subject and serves as the starting point for our key topics.

The architecture is the foundation of our development. It acts as the blueprint for later stages. Included in this phase was the plan for the project. The essence of the plan is to set up a series of iterations for construction and to assign use cases to iterations. The plan is fulfilled when each use case is put into iteration and each iteration's start date has been identified. The use cases obtained are then categorised and the level of priority assigned to each use case. For each prioritised use case it is also necessary for us to estimate the length of time each use case will require. Another important analysis that is necessary is that of the learners. The purposes of analysing the learners are to determine the entry-level of the course and the relevant characteristics of the learners. It is also important to identify their intellectual abilities, language level, and learning styles.

Construction

The construction phase of a project involves a repeated development cycle or series of iterations within which the system is extended. The final objective is a working courseware application that correctly meets the requirements. Each iteration is a mini-project. We do analysis, design, development, evaluation and integration for the use cases assigned to each iteration. We finish the iteration with a demonstration to the users and perform evaluation to confirm that the use cases have been built correctly. The iterations with constructions are both incremental and iterative. The iterations are **incremental** in function. Each iteration builds on the use case developed in the previous iterations.

The development cycle

Development cycles are organised around use case requirements. The development cycle is assigned to implement one use case. The methodology chosen for the development cycle or iteration is the Uden Courseware Engineering Methodology (Uden 1997). UCEM is a courseware development methodology based on the construction of models from analysis to implementation. It provides a seamless transition from analysis to implementation, allowing a clean traceability between models. Both the teacher and the students were involved throughout each development cycle. Besides the teacher, about six students were chosen to be co-designers. For each iteration development at least three meetings were conducted. The first meeting normally only involved the teacher and ourselves. During this session we carried out the analysis and design phase of UCEM.

Analysis

Domain analysis is the most critical step in the courseware design process. The main purpose of the domain analysis is to determine the tasks or topics to be learned, i.e. what is worth teaching. The domain is gathered by interview and brainstorming sessions with the teacher on the history of World War I.

During domain analysis each of the high-level use cases identified during conceptualisation would be expanded to show more detail. From each of the use cases we produced a domain model based on the domain analysis carried out for each use case. The domain model illustrates meaningful concepts in a subject to be taught. The domain model is a representation of concepts in a subject matter. It can be illustrated with an object diagram showing the topics, and subtopics, their associations as well as their structures. An example of the domain model produced using an object diagram is shown in Figure 3.

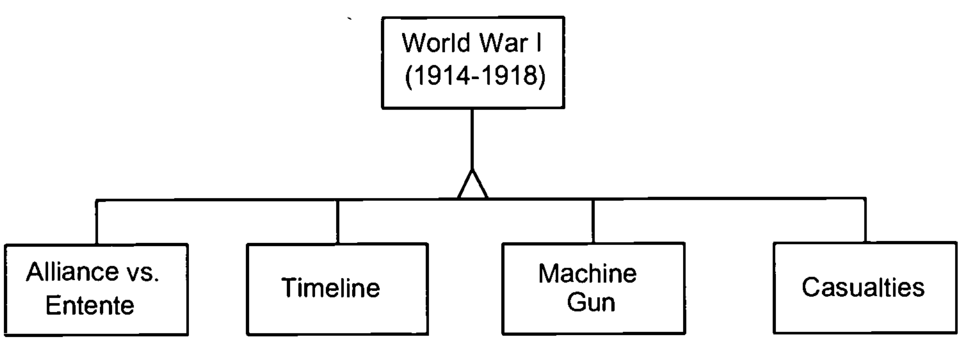

Figure 3. Domain model of world war 1.

Design

The design phase is concerned with the construction of the pedagogical model. It involves the identification of learning objectives and the design of assessment items and instructional strategies. The pedagogical design deals with the modelling of the instructional aspects of the courseware. The main objectives identified for the history lesson are to describe the events that led up to World War l; and to show the effects of these events.

To determine if the students have learned we must assess them. This involves designing tests. The tests designed must match the objectives stated earlier. According to Gagne (1965) there are different types of learning and each requires different learning strategies. Depending on the learning outcomes, we need to design the instructional strategies for the instruction. This completes the pedagogical model ready to be input for development.

Development

The development phase of UCEM was carried out by us, the designers. The pedagogical model produced must be transformed into software, which can be input to the computer. This is carried out in the development phase of UCEM. Development consists of three sub-processes: conceptual modelling, navigation modelling and interface modelling. During conceptual modelling the pedagogical model is translated into software. If hypermedia is used, the conceptual model is then transformed into the navigation model taking into account the design of the navigation structures. This is followed by the interface development for the courseware. The courseware with the complete development is then ready for implementation.

Evaluation

Evaluation is essential to make sure that the iterative development satisfied the requirements. Evaluation usually uncovers problems that may not have been noticed during development. The evaluation was carried out by students and the teacher. This happened during the second meeting of the development cycle. The developed courseware was given to the students to evaluate. The users, including the teacher, were encouraged to come up with suggestions for improvements. We stayed 'at a distance' in order to let the users themselves explore the prototype. There was no intervention or suggestions for improvements by us in the process, except in breakdown situations in which the users had problems. The groups which consisted of a dozen students worked enthusiastically with the prototype and came up with constructive suggestions for each session. All of the recommendations and suggestions by each user were recorded by us. Any unclear issues were taken up with the users to make sure they understood what was needed. No suggestion was considered too trivial. We wanted to make sure the users were happy and that felt they were part of the team. Users were happy to co-operate and valued the opportunity to be co-designers. The suggestions or recommendations were incorporated as we received feedback from the users. The revised courseware was then given to the students to be further evaluated. The development cycles continued until all the use cases were completely developed and integrated into the courseware.

Discussion and suggestions

Although the outcome of the project was a positive one, there were also many problems. This was particularly so when we came to the design of the pedagogical model. Being a subject expert herself, the teacher was only concerned about the content of the subject. It was very difficult for her to see the importance of objective definitions in the design. We are firm believers in having sound principles from instructional design theories incorporated in the courseware. Unfortunately this was rather alien to the teacher. Much time was spent in having to explain the concepts to her. Although she might not have had much knowledge of the processes involved, she did make considerable contributions in each of the activities and was very supportive. As World War I was not a subject with which we were particularly familiar, we had to learn fast in order to become competent. The teacher was very patient with us and taught us a lot. With hindsight, we could have better prepared ourselves.

Another problem, which often surfaced during the development, was that we often did not see things from the same perspective. There were ideas that we considered as essential and pedagogically sound which were not necessarily acceptable to the teacher. For example, for learning the timeline we suggested the drawing of bar charts should be used. This was rejected because students are not expected to do this in a history lesson. We found the teacher's insistence that this activity was the province of a Mathematics lesson quite disturbing, although this was not really the teacher's fault. Traditionally learning in school is concerned with particular content in discrete subject disciplines. A holistic approach is seldom encouraged, resulting in students passing examinations but not being able to apply knowledge in a wider context.

Finally, users who are not very conversant with technology often have higher expectations of what can be achieved. We found that, due mainly to media hype, they demanded more than we were able to provide. For example, they wanted video footage of World War I, which we were unable to obtain. On the positive side, the teacher found the co-designer process helpful and learned much about the importance of instructional design principles and appreciated their use. Because the teacher was part of the design team and thus had ownership of the problem, she was more willing to adapt to an unfamiliar teaching situation. The resulting synthesis of ideas led to a very usable product. For the students, they also experienced the ownership of the problem and took upon themselves the fact that it was their project too. This lead them to become more motivated in their learning of history. They found learning fun because they were creating their own learning materials and deciding what was good for them. The interactive nature of the computer with its powerful graphics facilities also fascinated them.

Lessons Learned

We learned many things from UCCD. Firstly, users rarely know what they want at the start of the project. As designers we must provide the scaffolding to guide them in identifying their learning objectives. Secondly, working with the prototype allows the users to get a better 'feel' for the proposed courseware lessons so that they could be more confident with the system to be built and be able to contribute constructively. Thirdly, when users saw what the prototype could do, their expectations changed and they wanted more features. It is important to set a realistic threshold on their requests. Fourthly, as users were part of the team, they were very keen to be involved and felt they 'owned' the problem. Fifthly, UCCD shows us the importance of designing for the users and their requirements. Sixthly, the process enables us to produce a system that is more tailored to the users' needs. Finally, for user-centred courseware design to work, it is important to have a graphical user interface tool such as Visual Basic, which allows us to produce a quick product.

Conclusion

To develop usable courseware is a difficult task. Typically, courseware development based on the expert approach does not always produce systems that meet users' requirements. For courseware to be usable it must be accepted by the users and meet their needs. This means that users must play an active role in the design and development process as co-designers. Designers and users must join forces together in the design. Because the users know best the context of their environments, they are able to overcome many of the problems that designers are not able to envisage. The user-centred design paradigm enables designers to produce courseware that will meet the users' needs. We have learned from our case study that Experts alone cannot design systems that will satisfy users. Only the users - in the context of their work or learning - can provide the necessary expertise for successful design.

Abstract: Making intelligent learning supports available on World Wide Web (WWW) is a potential way to enhance a student's learning capability by integrating the flexibility and adaptability of intelligent supports with world-wide availability of WWW-based applications. In this paper we present the design and implementation of a collaborative intelligent learning support environment called CILSE-GCE for global climate exploration on WWW. The task domain is inherently a scientific classification problem, in which students are expected to induce climate classification rules and develop their own interpretations by making observations of a couple of climatic features. Based on a collaborative study-based learning model, we develop a set of tutoring strategies and implement the corresponding intelligent learning supports. As the classification task involves fuzzy climatic features, we develop an intelligent fuzzy tutor to evaluate and keep the student's exploration going toward target knowledge.

Introduction

This is a prosperous age in terms of rich learning theories, instructional designs and computer technologies. Their integrated efforts have made pervasive influences on the ways we teach and learn, and definitely have created great possibilities and chances to build an ideal learning environment, where students enjoy, share and appreciate the learning itself. In recent years, research and development of intelligent learning environments (Major & Reichgelt, 1992; Chan, 1994; Bell, Davis, & Linn, 1995; Edelson, Pea & Gomez, 1996) have been growing rapidly and widely. This paper demonstrates a project working toward this trend. In this project, advanced computer technologies, such as artificial intelligence, World Wide Web (WWW), Geographic Information System (GIS) and multimedia are integrated successfully with the collaborative constructivist learning theory (Black & McClintock, 1996; Honebein, 1996), resulting in a collaborative intelligent learning support environment on WWW.

This two-year project, beginning from mid 1998, aims to build a collaborative learning environment (named CILSE-GCE, Collaborative Intelligent Learning-Support Environment for Global Climate Exploration) that provides constructivist-inspired learning tools for open-ended inquiry as well as communication tools that support multi-learner collaboration. In this environment, students learn by exploring the global climate patterns, sharing their discoveries and producing the target knowledge collaboratively. Special attentions would be paid to the kinds of learning supports the system could provide for the student's exploration and collaboration processes. The ultimate goals of this project include investigating the collaborative constructivist learning model and instruction design principles, the development model of learning environments and system functionality, and the feasibility of applying artificial intelligence to support constructivist learning.

Based on the collaborative study-based learning model by Black & McClintock (1996), we develop a two-level group learning model suitable to be practiced in so-called *virtual classrooms*, and implement the corresponding teaching supports and communication utilities. Besides, as the classification task involves fuzzy climatic features, an intelligent fuzzy tutor is designed and implemented to evaluate and keep the student's exploration going toward target knowledge. It could also help students in the construction of climatic interpretation models as concept maps.

This learning environment is designed with the intention not only to teach students the target knowledge, but also the scientific ways of study and communication skills. We believe the students will achieve higher learning goals through the collaborative process of creating knowledge by themselves. These might include the ownership of knowledge, high-order thinking skills, and the potential of becoming a long-life learner. Preliminary formative evaluations have been performed during the late 1998 and early 1999, while a more complete evaluation is scheduled to be performed and investigated in the second year of this project. Hence in the following we will focus mainly on the design and implementation issues of the learning environment, and present some preliminary findings of the first year research.

The Collaborative Study Model

We adopt the perspective that the basis for cognition is interpretation based on background knowledge and beliefs (Winograd & Flores, 1986). Thus, the key consideration in our design is fostering the construction of interpretations based on observations and background contextual information. This learning process is often referred to study (Black & McClintock, 1996), in which students make observations, construct interpretations and arguments via access to background and contextual materials. All stages of the study can be performed collaboratively. Based on the aforementioned theory, we propose a two-level group study model suited for virtual classroom practicality, as shown in Fig. 1

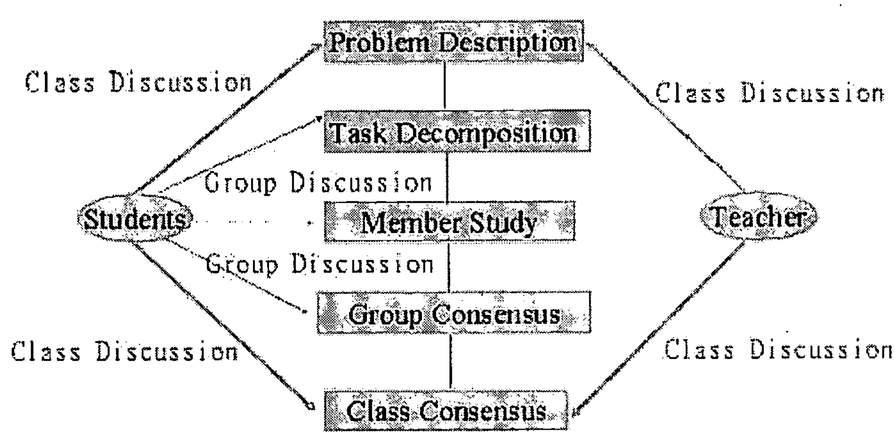

Figure 1: The two-level group study model.

In the two-level group study model, there are two forms of discussion. One is the *class discussion* and the other is the *group discussion*. Students are first pre-assigned to specific groups as they wish, except with the only constraint of group size of 5 to 6 (a variable that needs further investigation). The human teacher then announces the target problems to the student groups and coaches some basic problem-solving skills through the class discussion. Then the student groups commence the collaborative study process by first negotiating a proper decomposition of tasks. Each group member is assigned a specific learning task and starts to explore the problem in the learning environment, trying to work out the answers and put down the results in notebooks and concept maps. Each group then negotiates, defenses and integrates the member products to achieve group consensus and generate their final group product. Finally, the teacher and all students start to discuss, defense and evaluate all group products one by one to achieve class consensus. As a result, students could develop their social communication skills and learn to investigate problems from different perspectives as illustrated by the works of their colleagues.

The Global Climate Domain

The target domain draws sources from the instructional material in the geographic climate course of senior high schools in Taiwan. The contents consist of: (1) constituting attributes of climates, (2) influential attributes of climates and (3) twelve climate patterns on the earth. The constituting attributes include the atmosphere temperature, atmosphere pressure, wind system, and so on. The influential attributes encompass the degree of latitude, topography, distance from the sea, etc. Finally, the climate patterns include the tropical wet climate, temperate wet climate, and so forth. The domain knowledge could be interpreted in a two-level abstraction as shown in Fig. 2. The first knowledge level is about each climate pattern, which is recognized as a specific set of the climatic attributes. The second knowledge level is a deeper, causal knowledge that involves the influential attributes and their interactions, which comprise a scientific interpretation model that explains a terrain's climate.

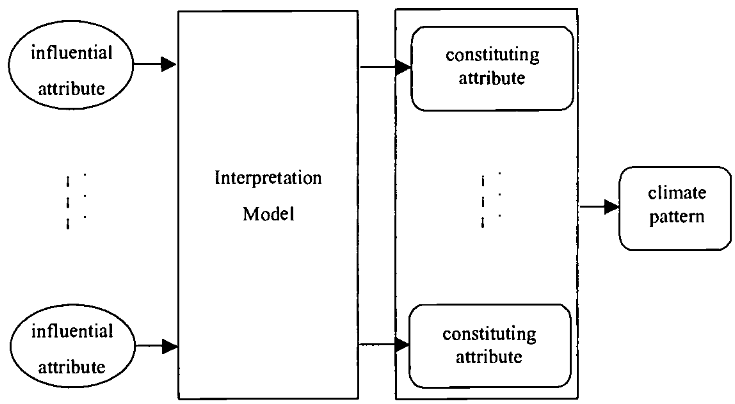

Figure 2: The knowledge structure of the climate patterns.

The task domain, global climate exploration, is inherently a scientific classification problem. In the member study phase of the group study model, each student is expected to induce classification rules by making observations of a couple of climatic features. A visualized information system based on the GIS technique is developed to help students make observations, data collections, comparisons and recordings about climatic features within and between any regions of the globe. The student could send his/her findings to a fuzzy tutor that evaluates the results and gives proper suggestions about the student's exploration process. Students are also required to construct an interpretation model of the climate patterns, explaining why and how the features interact to each other. The *concept map* (Jonassen, etal., 1997) is used as a mind tool for recording such kind of learning states. The concept maps along with the electronic notes serve as the basic contents for knowledge collaboration process.

The Learning Environment

Three components of the CILSE-GCE learning environment are presented in this section. They are the Virtual Classroom, Visualized Data Viewer, and Intelligent Fuzzy Tutor, respectively. The system architecture is shown in Fig. 3. To facilitate our further research, all learning activities of the students in this environment are logged and could be queried back later for more analysis. The Virtual Classroom serves as the origin where teachers and students coordinate and collaborate. Through the Virtual Classroom, students could access the multimedia course base, the climatic GIS database (via the Visualized Data Viewer) and the historical literature database. These rich data sources allow students to observe, search and collect related information in different aspects regarding to the problems at hand. Editing tools like the electronic note and the concept map editor are also provided to help students write down their discoveries and final works. All these personally created stuff are stored and managed by the system automatically, and if authorized, can be accessed by other students, thus enriching the system data resources in a multi-perspective manner.

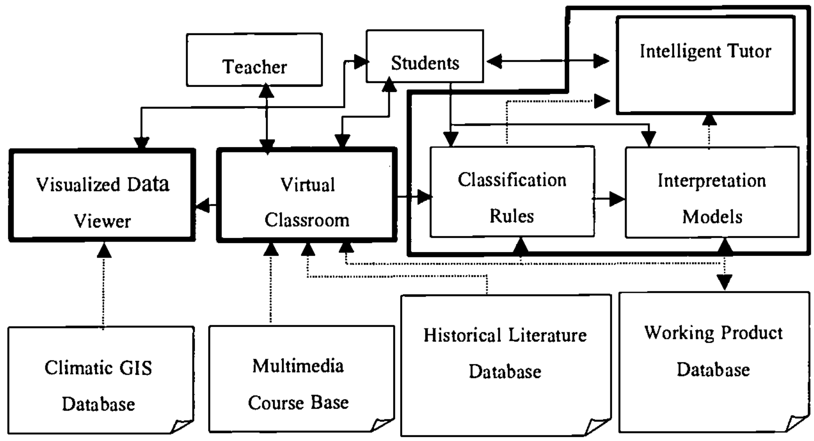

Figure 3: The system architecture of CILSE-GCE.

In the Visualized Data Viewer, the climate information could be displayed in different layers of maps covering the globe. Students could select, resize and combine different information layers for display to investigate the climate attributes in different perspectives. Hotlinks to climatic data and statistical graphs associated with the typical cities are also provided to allow students to do some measurements and inferences.

We design an intelligent fuzzy tutor to help students induce the classification rules, which are represented as a setting of the constituting attributes of the climate patterns. During the rule induction process, a student has to identify what the settings of the relevant attributes are by exploring resources of all kinds. When he/she determines a specific set of attribute values, the intelligent tutor would evaluate the student's answer, and give suggestions to guide the student's further exploration. As the classification task involves fuzzy climatic attributes, we develop an intelligent fuzzy evaluator to assess and keep the student's exploration going toward target knowledge.

When the student arrives at correct settings of the attributes, he/she is encouraged to construct an interpretation model that explains the causal relationship between the influential attributes and the constituting attributes. Students might query the material database to investigate the explanations of the various phenomena, and then deduce the causal model for the climate patterns. The intelligent tutor would check the models that students build, and give remedial hints if anything goes wrong.

Detailed Design Decisions

Learning Thoughtfully versus Learning by Memorization

In this section, we briefly summarize some design issues that were tackled for the CILSE-GCE learning environment. The first issue is to cope with the traditional problem of learning by memorization, a strategy adopted ubiquitously by Taiwanese students in geographic climate classes. Learning by memorizing facts empowers students for solving routine problems efficiently. However, it leads to inflexible use of the memorized knowledge in novel situations. On the other hand, learning to study things thoughtfully helps students to solve complex problems. Thus we provide a manipulable visual environment, in which students could engage themselves in the whole study process thoughtfully. In this visual environment students could observe real world data in different perspectives, derive their own classification rules and test the rules.

Whole Learning Tasks versus Component Skills

The second issue is about the argument of focusing on whole learning tasks or component skills. Having students perform whole tasks has the advantages of practicing the integrative skills that are necessary, and developing strategies suitable to the tasks as a whole. But it is difficult for students to focus on a particular weakness in the tasks. On the contrary, making students focus on sub-skills is sometimes very productive, but ideally this should occur when a weakness has been diagnosed. Our solution is to start by involving students in the whole induction tasks, and then to proceed to component tasks when appropriate. In this environment, students first visit the visual environment, considering the problem in all its aspects, and then develop and test their own classification rules. These rules could be assessed by an intelligent fuzzy tutor, which would identify the weakness in the student's exploration and provide some suggestions such as the important aspects that should be focused or the appropriate ways to investigate the climatic features.

Levels of Learning Supports

The third issue is related to the determination of levels of learning supports. Learning supports should be effective but not deprive the students of their learning opportunities. For example, the hints or suggestions given by the fuzzy tutor should not be so direct such that the answers can be derived straightforwardly. The scaffolding should also prevent students from answer-guessing activities. For example, an entry list for the student's answer should not be defined in advance, instead, it should be a freely-input entry. Besides, the evaluation feedback of student's induction results should not be just wrong or correct. It would be better, for example, to give some questions that require the students to think about another possibilities. Accordingly the environment allows students much more flexibility to explore.

For example, we design an intelligent agent to support the induction of climate classification rules. The student inputs the climate attribute values (i.e., a set of numerical ranges) and sends the answers to the tutor agent via the internet, and then the tutor receives and makes a fuzzy evaluation of the student's inputs. Finally, the tutor sends back the evaluation results, including suggestion messages, and the fuzzy degree of correctness of each climate attribute. The system also makes a log tracing the whole induction process of the student so that the studcnt could see and backtrack his/her induction process to a better position towards the target goal.

The Collaborative Study Process

The last issue is about the determination of the collaborative study processes. We develop a virtual classroom on WWW in which students study and work in groups. The human teacher first assigns problems to the students and coaches some basic problem solving skills. Then the student groups start the collaborative study process, working out the answers, and making defense within and between groups. We believe this collaborative process will foster all the constructive design principles mentioned in (Black & McClintock, 1996; Honebein, 1996), including observation, interpretation construction, contextualization, cognitive apprenticeship, collaboration, multiple interpretations and multiple manifestations, ownership of knowledge, self-awareness of construction process. Besides, our emphasis on classification induction problems is distinctive.

Conclusion

We adopt a form of iterative design to develop the CILSE-GCE environment. There is a strong connection between many of the design decisions taken and the results of formative evaluation. During the whole development process, we found that the most challenging task is to identify the information needs of the students. What material should be, and in what way, stored in the material database? Did we provide enough information and investigation tools for the students so that they could learn the greatest from this environment? These questions worth further investigation in our second year project. The answers to these questions are not only essential to this environment but also important to the research area of developing educational systems.

It is also indicated that during free exploration of a problem space, greater learning occurred if students adopted more systematic strategies for rule induction (Vollmeyer, Burns & Holyyoak, 1996). In our environment, students would experience the process of looking for patterns. However, students are different in the degree of systematicity with which they formulate and test their hypotheses. It is therefore important to provide instruction in the use of such strategies in order to allow maximum benefit from free exploration of the problem space. Further evaluation tests will be conducted to provide evidences of such kinds of learning. Another direction for future work would involve analyzing students' study strategies and examining their transfer performance in the consequence of problem solving.

Designing an Open Architecture of

Agent-based Virtual Experiment Environment on WWW

Chi-Wei Huang, Chang-Kai Hsu, Maiga Chang and Jia-Sheng Heh
Department of Information and Computer Engineering, Chung Yuan Christian University
Chung Li, 32023, Taiwan, Tel: 886-3-4563171 ext. 4725
E-mail: jsheh@ice.cycu.edu.tw

Abstract: This paper proposes an open architecture of *virtual experiment environment* on WWW by using intelligent agent techniques. Several experiment components and a science experiment agent are analyzed and implemented to support teachers to quickly assemble a social learning system. Such design is based on distributed network architecture to attain high reliability and efficiency.
This architecture of agent-based experiment environment is composed of two major layers, *Coordinate Layer* and *Communication Layer*. And KQML (Knowledge Query and Manipulation Language) is used to realize communication protocols and information sharing language for the interactions among experimental equipment and science experiment agents. A workable experiment system based on our architecture, called *SoftLab*, is implemented on WWW to demonstrate its feasibility and flexibility.
Keywords: *virtual experiment, experimental equipment, WWW (World Wide Web), KQML (Knowledge Query and Manipulation Language), intelligent agent*

Introduction

In the last ten years, personal computers have sparked a revolution in education. Everyone from preschool children to senior citizens can now develop science projects and prepare reports by using computer technology at home. Besides being passive learning tools as textbooks, paper and pens, computer-aided education (CAE) systems can prompt learners some feedback and responses in appropriate ways during learning process. (Diessel 1992; Futtersack 1992; T.-W. Chan 1995) Take interactive tutorials for example, this kind of CAE systems can not only teach learners specific knowledge, but also evaluate what learners has been learned and re-teach based on the evaluation. Any paragraph in a course of study can certainly be reviewed to meet the needs of learners. (J.C. Gonzalez 1992; H. Lianjing 1992)

Considering the practicum of conventional education, "learning by doing" design brings the idea of situated learning into computer environment, as the interactions of human cognition are studied and improved in different computer-based learning environment. (Brown, Collins & Duguid, 1989) Hence, a simulated platform which provides learners experiment with visual equipment on computers, called *virtual experiment environment* (VEE) had been constructed on the computer network. (Y.-W. Jeng *et al.* 1996 J.C. Gonzalez *et al.* 1998) This paper proposes an open architecture of agent-based *virtual experiment environment* on WWW.

Section 2 identifies these problems when establish a *virtual experiment environment* on WWW. Besides several important issues are analyzed, an open architecture then can be constructed. After the open architecture is proposed, more detailed designing for a specific agent-based architecture are designed by Section 3. An experiment system constructed on WWW, is so-called *SoftLab*, providing a workable agent-based platform of physics in Section 4. Section 5 makes a summary and discusses those possible future works.

Architecture of Agent-Based Virtual Experiment Environment

The great advantages of WWW are information transmission and knowledge sharing. Unfortunately, those capabilities to support high quality interactive learning, retaining information of learners and even tracking the learning progress are still under disputed. Since an open architecture of agent-based *virtual experiment environment* on WWW is proposed, the idea of Software ICs (Integrated Circuits) should be taken into consideration.

Based on the precompiled binary code, *components* become independent of the language in which they were created. Furthermore, there are two more characteristics of components: reusability and flexibility. *Reusability* means that components can be used in many applications, continually enhancing and improving without having to recompile. On the other hand, the *flexibility* of components provides that suitable components can be simply chosen to extend the standard functionality for the specific needs.

Although the Software ICs are very useful for establishing such open architecture on WWW, there must have a container comprised several ICs and channels for exchanging data. It implies that if some experimental equipment used for experiments, an experiment environment must exist firstly. And than the experiment can be observed through those interactions in experiment environment. According to such viewpoints, a uniform interface among components is also necessarily provided by the open architecture.

Cooperative learning can improve both professional and social skills of learners, including face to different opinions and interdependence of group members. (Jamie C *et al.* 1998; Chanchai Singhanayok 1998; Doug L 1998) Therefore, the communication mechanism between participants of experiments has to design is also an important issue in order to achieve the goal of constructing synchronized and cooperative experiment environment.
As mentioned above, all issues are taken into consideration. The architecture of agent-based virtual experiment is then constructed as (Fig. 1) shown.

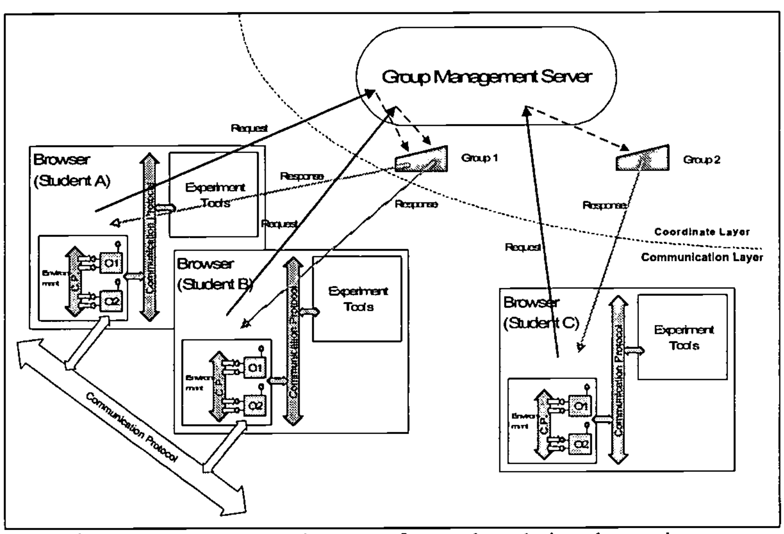

Figure 1. An open architecture of agent-based virtual experiment

(Fig. 1) indicates the architecture is composed of two major layers, Coordinate Layer and Communication Layer. Because distance learners may use browsers to participate in the collaborative online activities, the responsibility of *Coordinate Layer* is to deal with the cooperative learning when experiment in the virtual environment through the computer networks. And learners can work together for accomplishing a common task or experiment through the agency of *Coordinate Layer*.

Besides these interactions among participants, interactions among components in the *virtual experiment environment* have to handle. To describe and maintain this sort of relations between the equipment, such like ball and slope in the experiment, a management manner as *Communication Layer* provides is necessary.

Generally speaking, there are some standard physics laws illustrating the relationships between equipment (or simulated objects) in the environment to regulate the interactions. Two-ball collision is a good example for explaining. The key point is that balls never know they have a collision with the other one. They only know that if they are forced, then they must response an action corresponding to the excitation. So the environment must provide a mechanism to coordinate the behaviors of the objects and transfer the responses appropriately.

Although an open architecture with agent-based virtual experiment on WWW is constructed in this section, more detailed designs still need be done before this architecture can really open for educational purposes. After the *Communication Layer* is well designed, either learner to cooperatively /competitively learn with learners or teacher to teach/evaluate/answer learners will be replaced by intelligent agents (IAs).

Designing the Virtual Experiment Environment

Besides the utilization of component technology, more important issue which makes the architecture constructed in the previous section becomes open is a graph model for representing the relationships between experimental equipment. The detailed explanation for the graph representation is in the following.

Actually, experimental equipment in VEE must be embedded in such an experiment board in the environment so that these interactive relations between experimental equipment can be generated based on the interaction principles. There is three-stage mechanism in the experiment board to make the interactions between experimental equipment come true. At first, the relations between experimental equipment are described, and a directed graph is adopted to describe the experiment and store it in the form of adjacency-list. Secondly, the standard physics laws are pre-stored in the experiment board. It means each node in the adjacency-list will be searched, and a mapping from experimental equipment into the desired physics laws. The last stage implements the experiment based on the standard physics laws and those data structure produced in the second stage.

The relations between experimental equipment are described as a *directed graph* $G(V, E)$, where V is a finite set and E is a binary relation on V. The *vertex set* V of G contains all the *experiment equipment vertices* in this experiment; whereas, the *edge set* E of G stores all the *relation between the equipment.* (Fig. 2a) represents an example directed graph G of vertex set $\{1, 2, 3, 4\}$. If (u, v) is an edge in graph G, then the equipment u will interact with equipment v. An adjacency-list of (Fig. 2b) stores the relations between the equipment vertices in (Fig. 2a).

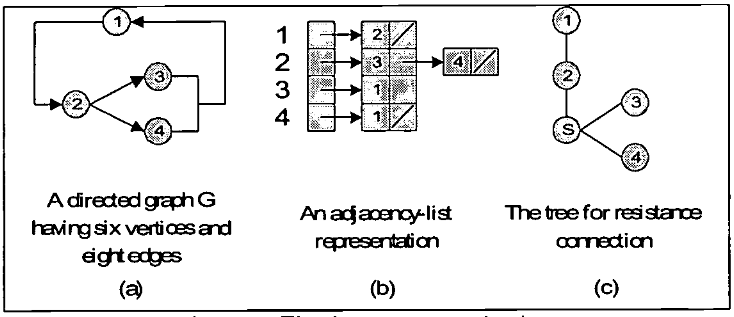

Figure 2. The three-stage mechanism

Take electric resistance connections for example to illustrate the above three-stage mechanism. The electric experimental equipment in (Fig. 3) is added as battery, resistance 1, 2 and 3. From (Fig. 2a) the representation of experiment after transformed into graph is shown in (Fig. 3), which means graph G has four vertices: V_1-Battery, V_2-Resistance 1, V_3-Resistance 2, V_4-Resistance 3, and five edges: (V_1, V_2), (V_2, V_3), (V_2, V_4), (V_3, V_1), (V_4, V_1).

After the first stage, the experimental graph then will be stored in the form of adjacency-list as (Fig. 2b) shown. Finally, a specific tree is generated from the adjacency-list based on the standard physics laws just like (Fig. 2c) shown. Accordingly, all the physics quantities in the electric circuit of this experiment can then be obtained.

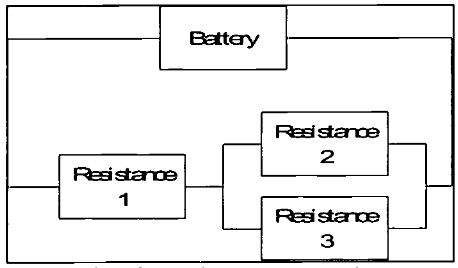

Figure 3. Electrics resistance connections example

Regarding the agent-based issue, intelligent agent's behaviors for the educational proposes should be analyzed first. Three behaviors can be simply told out as follows:
1) Online recording,
2) Online replaying,
3) Online navigating.
In most cooperative learning systems, it is necessary to design a communication protocol for information and knowledge exchange. In the open architecture of *agent-based virtual experiment environment*, the most useful agent communication language, *Knowledge Query and Manipulation Language* (KQML), is chosen as our communication protocol in *Communication Layer*.

KQML focuses on an extensible set of performatives, which define the permissible operations that agents may attempt on each other's knowledge and goal stores. The performatives comprise a substrate on which to develop higher-level models of inter-agent interaction such as Contract Nets and Negotiation. (Tim Finin 1992)

Conceptually, a KQML message consists of a performative, its associated arguments which include the real content of the message, and a set of optional arguments which describe the content in a manner which is independent of the syntax of the content language. For example, a login to a group learning system might be encoded as:

(*tell* :*content* (Login (Ken (jk1234y, user)))
:*language* list
:*ontology* Group-Learning)

In this message, the KQML performative is *tell*, the *content* is (Login (Ken (jk1234y, user))) and the assumed *ontology* is identified by the token :Group-Learning.

Implementing the Virtual Experiment Environment on WWW

(Fig. 4) in the following depicts the architecture for electricity, only with minor differences from the original one. An experiment system of physics course then is implemented under the open architecture proposed, called *SoftLab*. Besides these synchronous and asynchronous tools for Web-based learning, an intelligent science experiment agent, called *Lancelot*, is also added in *SoftLab*. The specific science experiment agent owns its architecture just like (Fig. 5) indicates. Distance learners are allowed to participate in those collaborative on-line activities through browsers. And with the characteristics of Web technology, it even can increase students' awareness of related concepts through the inclusion of hypertext links to other Web-based information. Chat-room is the only component that can be used by learners to communicate with others in VEE. Teacher, moreover, can also use it to give hints and comments.

Considering the benefits of component-oriented analysis, Microsoft ActiveX is chosen to implement the experiment system described above. It is easy to divide the whole system into components with abstract models of abilities and behaviors. Each learning work is implemented as an independent component. Owing to ActiveX technology, Microsoft Internet Explorer is chosen as the platform of VEE. And Visual Basic Script is then the bridge between components.

When designing the experiment system, performance issue of the system is the most important. The traditional BBS (Bulletin Board System) server is analyzed and modified in order to solve this problem. The major modification objectives include discussion board, flow control of learning, privilege management and group management. There are three parts in the whole *SoftLab*, including VEE, experiment tools and the science experiment agent Lancelot, as (Fig. 6) shown.

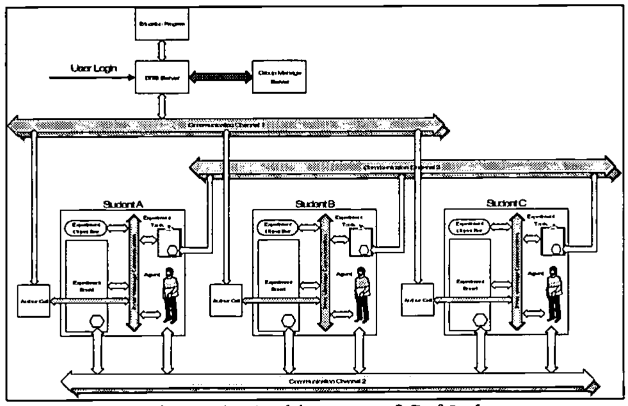

Figure 4. Architecture of *SoftLab*

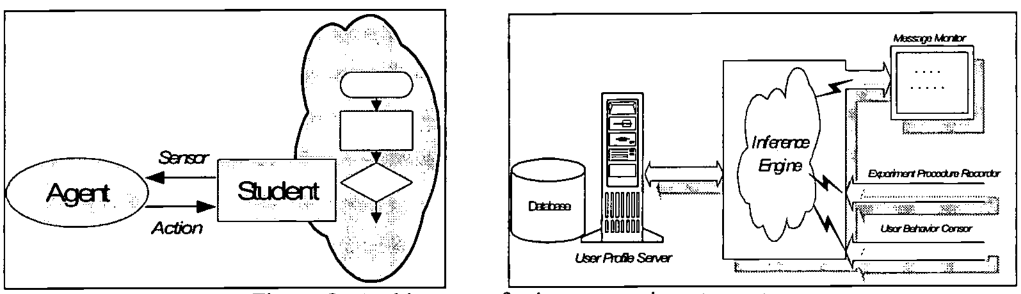

Figure 5. Architecture of science experiment agent

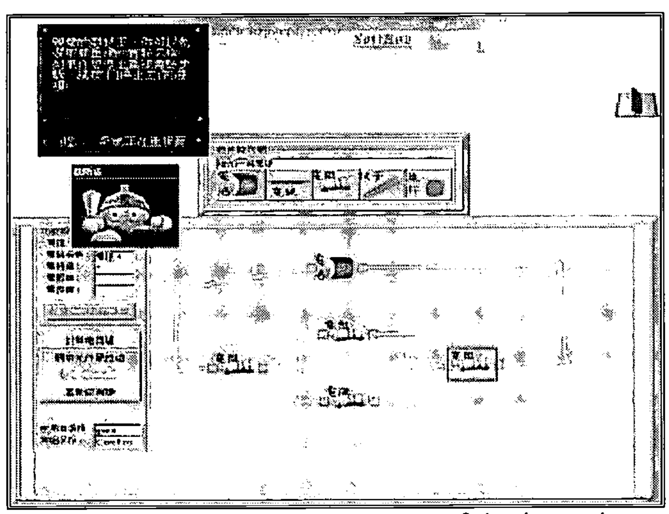

Figure 6. *Virtual experiment environment* of circuit experiment

Conclusion

In this paper, the possibility of constructing an open architecture of agent-based VEE on WWW is fully discussed and analyzed. Two major layers compose the architecture of agent-based experiment environment that are *Coordinate Layer* and *Communication Layer*. And the interactions between *experimental equipment* are realized by KQML. *SoftLab* is a workable experiment system implemented on WWW based on the architecture proposed in this paper to demonstrate the feasibility and flexibility.

Another interested research direction is the courseware and visual components design when an interactive user interface is used. As mentioned in the introduction, we believe that only those learning workspace systems designed with open architecture, such as VEE, can be extended easily. Furthermore, an intelligent agent system approach, such as the mechanism of knowledge formation during learning, might be analyzed deeply. In the agent-based VEE, learners can process a *virtual experiment* with agent cooperatively/competitively. Hence, how to evaluate the learning progress of learners is also a good research topic.

Tele-Training on the Job
Experiments and Experiences in Media Integration

Sabine Payr
Forschungsgesellschaft Informatik (Research Center Information Technology), Austria
s.payr@fgi.at

Abstract:
The as.fit course has been developed for training office employees of SMEs in the use of advanced ICTs for telecooperation and e-commerce. It is delivered via tele-training to the workplaces of the participants, using a combination of online and offline media. The research work accompanying this course focuses on the question of how to define the adequate mixture of media in tele-learning and how to integrate them into a learning environment for effective training on the job.

1 The *as.fit* Course

Small and medium sized enterprises (SMEs) today face the challenge of adapting to the new conditions of doing business in the Information Society (see Alpar 1998, Reichwald 1997). The changes that cut deep into the organisation of the company can be characterized by acceleration, globalization and virtualization. The basic question for SMEs is: how can they manage change actively so as to be among the „Information Society winners"?

One of the preconditions for profiting from new opportunities is to master the new information and communication technologies (ICT) and the implications of their use. By „mastering" we do not mean their simple operation, but the skills and qualifications that are necessary to integrate them into the enterprise and to create management structures that allow for rapid change and flexibility.

With the project *as.fit diploma* we offer building blocks of these qualifications. *as.fit* (Advanced Skills for Information Technology and Telecooperation) is a tele-training course for administrative workers in SMEs. The principles of this training are

- embedding training into the company: involvement of management, contents that fit participants' needs
- tele-learning on the job: use of different technologies for interacting intensely with the student
- embedding learning into practice: problem-oriented tasks and activities; unity of tools for learning and working.
- The learners whom we address with our training are administrative workers (primarily secretaries or office managers) of SMEs. We consider the administration of an SME to be the future nerve centre of information management in a company. We involve the company with preliminary investigation and interviews and with accompanying consultancy and support.

With its contents, the course centers on today's practical needs of companies on their first steps into telecooperation, e.g.

- How to communicate efficiently via e-mail
- The legal aspects of doing business via the Internet
- The use of the Internet for efficient information retrieval and processing
- Which Internet services are appropriate and effective for the marketing of the company's products
- The role and purpose of the company's website, and consequently its design and contents.

- The choice of adequate communication technologies for the company's internal, business-to-business and external communication needs (e-mail, video-conferencing, mailing lists, newsgroups, chat, interactive web pages etc.)

These issues are treated in ten modules, varying in length from one to three weeks. The duration of the complete course is 20 weeks. It contains only three face-to-face stages – at the beginning, in the middle, and at the end, respectively. This shows that the course relies heavily on tele-learning.

2 Pedagogical Setting

2.1 Motivation for tele-learning

The pedagogical setting we chose for this course is tele-learning in a combination of communication media and self-paced study. By tele-learning we here mean distance learning supported by electronic media, or - the other way round - „the application of telematics for learning-related purposes" (Collis & Fisser 1998).

The main motivation for delivering this course via tele-learning is to take training to where it is immediately useful. This has always been the aim of „training on the job", e.g. in models of apprenticeship. In the ideal case, learning and practising merge imperceptibly. This ideal case, however, demands constant presence of a trainer and training for individuals or very small groups. Tele-learning can recreate some elements of training-on-the-job for larger and dispersed learning groups. This requires intensive communication with various tools and individualized coaching of the learner in the transfer from training to practice (Baumgartner & Payr 1998).

2.2 Technologies used

The range of technologies and media that we use in the course is broad:

- *Video-conferencing:* students' and trainers' PCs are equipped with desktop video systems connected via ISDN lines that are also used for telephony and Internet access. The result is not high-quality image and sound, but experiences (Wiendieck et al. 1996) have shown that the quality is sufficient to create a „presence". On the other hand, the technology we use is the same that can and will be used in the very near future in any office for communicating via video. The conference is switched via the multipoint control unit of a telecom operator (Post & Telekom Austria PTA). Video-conferencing is used for short lectures to the whole group of students (up to 20 persons), but also for individual communication between students and the trainer, or among students. The working groups that students form to work on given tasks or projects will also use video-conferencing at times, with and without the trainer.
- *Web server and web-based groupware:* The material for self-paced study itself is delivered in printed form (textbook) and on CD-ROM (interactive courseware). However, materials created during the course - by the trainer (resumes, feedback, additional explications, task sheets etc.) and by the students (feedback, results, solutions, questions, criticism, etc.) - are made available on the web. For this purpose, we use a simple groupware system (GMD's BSCW = Basic Support for Collaborative Work) with the typical basic functions of groupware: shared and versioned documents, closed user group, and a discussion forum.
- *E-mail and mailing lists* come in as those media that allow „pushing" information instead of the „pull" principle of the web. With these tools, we can make sure to reach the students immediately, and vice versa.
- *Chats* complement video-conferencing as another synchronous communication tool. Chats are used mainly in groupwork.

The following table (table 1) lists the technologies used in *as.fit* by the characteristics of communication:

Communication	synchronous	asynchronous
1:1	phone, video-telephony, chat	e-mail
1:n	video-conferencing	mailing list
n:n	video-conferencing, chat	discussion forum

Table 1: Communication channels and media used in as.fit

2.3 The Training Scenario

The basic „unit" of the course is the weekly lesson centered around a specific issue. The lesson is introduced in a short video-conference with all participants, where the contents and tasks of the week are presented. During the following two working days, students work on the subject using their textbook and, where available, the interactive courseware developed specifically for the course and distributed on CD-ROM. Task sheets and questionnaires for individual work can be downloaded from the groupware server. Questions and requests for help and clarification can be sent in via e-mail (to the trainers only) or circulated via the mailing list (for the attention of all participants).

The second general video-conference, halfway through the week (and the lesson) gives answers and additional information on the questions and issues raised by the students. By that time, the first part of the week's tasks have already been done and sent in, so that a preliminary overview of the students' progress is available. The second video-conference also sets out the second part of the week's workload. The final video-conference coincides with the first one of the following lesson: the results of the lesson are resumed and commented, before the course goes on to new contents.

Work in small groups (three to five students) plays an important role. It takes place with and without the trainers' participation. Most of the tasks contain elements of cooperation or at least the request to exchange and discuss results. Students use the same technologies for their work in group as for communication in the big group, in particular e-mail, chat, and video-conferencing. Each student has to take her turn in leading and animating groupwork, e.g. by setting up a video-conference, requesting contributions, editing final texts that have been written collaboratively.

3 The Challenge of Media Integration

3.1 Self-paced vs. scheduled training

The use of both self-study materials with asynchronous communication (distance learning model) and scheduled video-conferences and synchronous chats (course model) is at once a challenge and a necessity.

Most participants are not familiar with distance learning and don't possess the required „learning skills". Together with a setting where learning takes place at the workplace, during working hours, the risk of students who drop out because they can't manage their schedule is particularly high. So we combine this method of learning with scheduled sessions and, especially at the beginning of the course, with a relatively rigid weekly plan for responding, sending in work results, etc.

On the other hand, the rather short periods of time dedicated to self-paced activities require an almost constant presence of the trainer team, because the tight schedule does not allow for long delays between requests from students and replies from the trainer. In this respect, the course has indeed aspects of „training-on-the-job".

3.2 Tools for training vs. tools for work

The intensive use of different communication technologies that we require from the students serves two purposes: one is, obviously, to allow for intensive trainer-trainee-interaction. The other is to put the contents of the course to immediate use. The tools that are used for learning are the same that the participants learn to use for doing their job efficiently. They are thus encouraged to practise immediately what they have learned. At the end of the course, they are experienced users of a wide range of Internet services and of video-conferencing and can support the implementation of new communication and e-commerce practices in their company.

The seamless transition from learning tools to working tools is taken into consideration in the choice of software tools for the delivery of the course. For example, we refrained from using dedicated tele-training systems that combine e.g. video-conferencing classroom tools with groupware and discussion functions. We use instead nothing but the software that is installed together with the desktop video system, separate mailing lists, Internet chat, and a separate web-based groupware system.

3.3 Classroom vs. group vs. individual training

The first generation of tele-training via video-conferencing appears today like the revival of the „good old classroom teaching" with the addition of a new technology. The reason for this was partly the special equipment that was needed – or considered to be needed – for video-conferencing, i.e. TV-studios or studio equipment with several cameras, professional sound engineering, and the like. The other part of the reason have been and still are educational traditions, where the first thing that came to mind as the use for video-conferencing was the classical „lecture" that could be followed simultaneously on-site and at one or two remote sites.

Only gradually it became clear that the new technology both requires and enables new methods of teaching. Video and sound quality in themselves are not what tele-training aims at, but a new quality of remote social learning. Video-conferencing is an educational tool that has to be available to both trainers and trainees to establish virtual learning communities. Students in the *as.fit* course are therefore encouraged to use video-conferencing not only to participate in the „classroom" sessions, but also and even more to establish individual contacts among the student group and to collaborate on their coursework.

3.4 Online communication vs. offline courseware

It is clear that even in a tele-training course that relies heavily on synchronous and asynchronous communication technologies like this one, individual study still takes up most of the participants' study time. The „bulk" of the subject matter to be dealt with is therefore delivered quite traditionally on paper. In our case, there is no added value in using e.g. the Web for delivering text material. In this reasoning, we follow a simple principle: use each medium for what it is best for. And paper is still the best medium to read from, in a situation where none of the advantages of web-based texts supersedes – e.g. making texts available to anonymous readers at unspecified locations and times.

We also use courseware that we have developed specifically for this training measure. While a non-negligeable part of the development effort went into this courseware, its place in the range of educational media is again restricted to a specific role that cannot be fulfilled by other media: each courseware module presents a problem that students are confronted with in their daily work, e.g. how to deal with an order that comes in via e-mail, or how to search the Internet efficiently, how to organise the findings and make them available. The courseware thus offers the „missing link" between the factual knowledge in the textbook and the practice that students acquire by using the „real" software tools for their coursework and their daily work.

The method of learning that the courseware focuses on is problem-solving and decision-making (cf. Baumgartner & Payr 1994). In each situation, the student is offered several choices for solving it. Different alternatives can be followed and can lead to a solution – as in real life, there need not be exactly one „right“ answer or procedure. The cognitive map of each module is therefore represented dynamically by a complex graph.

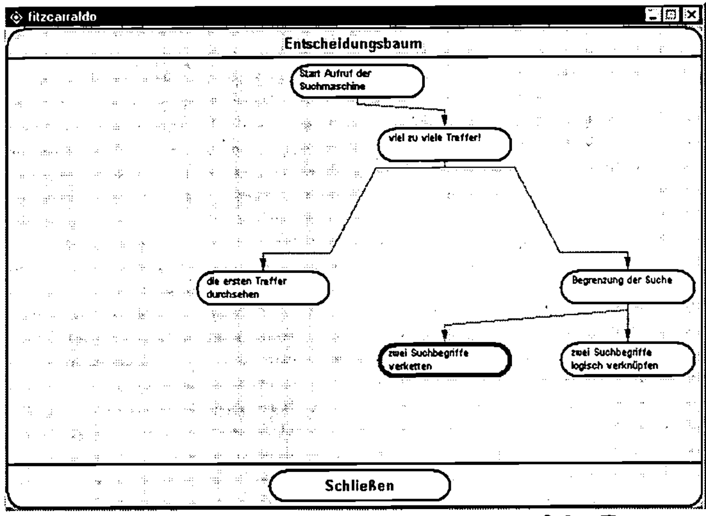

Figure 1: Dynamic decision tree as clickable cognitive map of the Fitzcarraldo courseware

Each node of this graph consists of a graphical representation of the contents (currently a screen, document, or drawing – but also images and video clips are possible) on which the two actors, a „trainer“ and a „trainee“ discuss, offer comments, questions and answers.

4 Questions for Research

From the point of view of research, we set up a „real-life experiment“ with this tele-learning setting. Most projects of this kind have to deliver „real“ and possibly efficient tele-training without a pre-existing basis of acquired knowledge and rules on how to develop and use the different media that are available today. So we cannot speak of a classical experiment where the various parameters can be changed at will and where failure is allowed as a valuable source of knowledge. We are rather in the domain of design, where modification and adaptation are possible underway, but where the basic hypotheses have been set in advance.

4.1 Finding the right „media mix“

The main research question is: what is the most appropriate combination of media in this setting for tele-learning? How much communication, scheduling, individual coaching and tele-cooperation is necessary, sufficient and desirable for creating a remote social learning environment that supports learning efficiently? What are the preconditions for successful tele-learning? What is the adequate „mix“ of online and offline, of synchronous and asynchronous, textual and visual media? The aim is to offer a model for tele-training that can be applied to other contents, target groups and social settings.

4.2 Methods

Progress of the students is continuously monitored through the coursework they have to send in, the requests for support they submit, their communication activities with the trainer team and with other students. Texts (e-mails, contributions to lists and chats, etc.) as well as video-tapings of the conferencing sessions are analysed using qualitative methods, drawn mainly from discourse and conversational analysis (Schmitt 1997, Weinig 1996). With these methods, we expect to gain insights into

- the specific nature of remote didactic interaction
- the conditions for successful training via video-conferencing
- the conditions for successful learning on the job
- the conditions for the viability of virtual learning communities
- the appropriate combination of educational media in different tele-learning settings

At the time of this Conference, a pilot course will have been completed and analysed. Two regular courses are under way at different stages, modified and adapted according to results from the pilot phase. The presentation therefore focusses on the latest experiences and empirical results.

Turning Learning Environments into Learning Communities: Expanding the Notion of Interaction in Multimedia

Richard A. Schwier, Ed.D.
Educational Communications and Technology
University of Saskatchewan
Canada
Email: richard.schwier@usask.ca

Abstract: Emerging approaches to developing rich learning environments combine multimedia, computer mediated communication, and a host of interactive strategies to connect people in varied and robust ways. But traditional understandings of learning environments and interaction usually stop short of the kind of engagement that will allow learning communities to form. This paper examines theoretical and practical issues around promoting the growth of virtual learning communities. It considers issues surrounding virtual learning communities that can emerge using communication technologies in formal and informal learning environments.

The metaphor of community has been used to describe a wide range of contexts, from communities of practice in the corporate world (Brown & Isaacs, 1995; Wenger, 1998) to virtual community networks (Brook & Boal, 1995; Horn, 1997; Rheingold, 1993; Schuler, 1996). Given the right circumstances, any of the range of communities can act as learning communities, typically when they engage purposefully in the acquisition, transformation or creation of knowledge. But these entities do not focus exclusively on learning. For example, a community of practice may give much of its energy to identifying tacit knowledge in a corporate setting and making the tacit knowledge explicit for the good of the company (Wenger, 1998). Similarly, virtual or online communities may devote their resources to connecting people in new ways, and the substance of the connections may include anything from sharing information to building interpersonal relationships (Cohill, 1997), but they may exclude learning entirely.

Regardless of their focus, little is known about how people in virtual environments are influenced by those environments. We glibly suppose that people who are connected electronically are enriching their interpersonal network of relationships, whereas some emerging research suggests that electronic saturation may actually contribute to a sense of isolation among participants (Kraut, Paterson, Lundmark, Kiesler, Mukophadhyay, & Scherlia, in press). Social critics of technology voice concerns that the values and strengths of communities are undermined by the very technology that promotes new ways of interacting with others (Ehrenfeld, 1996; Selznik, 1996). With equal force, critics of distance learning suggest that technology-based courses emphasize transmission of information and isolate learners by placing technological barriers between learners and real people (Farrow, 1999).

In this paper I will argue that what may be most restricting about electronic types of learning environments is that they fail to promote a sense of community, that they remain interactive, yet fall short of becoming communities of learners. When technology is introduced to learning communities, there is a risk of promoting interaction without the concomitant elements required to turn a virtual learning environment into a virtual learning community, and this paper will explore what those elements are.

A Definition of Virtual Learning Community

Drawing on the definition by Kowch and Schwier (1997), communities are collections of individuals who are bound together for some reason, so a learning community emerges when people are drawn together to learn. A learning community is a group of individuals engaged intentionally and collectively in the transaction, or transformation of knowledge. Although learning communities emphasize outcomes in education, their power resides in their ability to take advantage of, and in some cases invent a process for exchanging ideas and learning collectively. Virtual learning communities happen when the process of learning takes place outside the boundaries of face to face contact, typically electronically. For the purpose of this paper, I want to use the broadest possible notion of learning. Learning as discussed here may include anything from formal education to very informal forums of exchange—any context that people can use to learn something of benefit to them.

A virtual learning community usually depends on the participation of relatively autonomous, independent individuals who are mutually engaged in the learning process. Outside mandatory attendance in some school settings, participants can not only leave the community, they can sometimes participate in the community without revealing who they are to the other participants. Autonomy and independence present difficult challenges for educators who want to build and maintain a learning community.

Growing Virtual Learning Communities

How does one begin a virtual learning community? First, we need to realize that building a community is not an organizational engineering problem — the problem is one of motivating participants to create a community and giving them an opportunity to do it. Clark (1998) uses the apt term "growing" in place of "building" or "constructing" to emphasize the organic nature of doing this kind of work. Ultimately, communities are built or dismantled by those in the communities, not by the people organizing or managing them. It is therefore a matter of providing an appropriate structure and sufficient support — the conditions for a community to develop. Some of these conditions include:

- A leader or leaders. The leader sets the agenda and the tone for the virtual learning community, and is the person known to all of the members of the community as the touchstone for protocol and administrative issues
- Transparent support technologies (Norman, 1998). Transparent technologies allow participants to concentrate on the tasks, relationships and ideas at hand. Extensive usability testing (see Nielsen, 1994) should be implemented at each stage of development to with the explicit goal of increasing the transparency of the interface.
- A safe and open mixture of interpersonal contact. People need to feel comfortable to participate, and unless the invitation to participate is explicit, and the boundaries of acceptable behavior are shared and understood, people will not be as likely to take risks in their communication with other members of the community. It is reasonable to publish written codes of conduct to keep communities on track (Bruckman, 1996).
- Liberal use of narrative. Clark (1998) makes a persuasive case for the use of narrative in virtual learning communities. He argues that because virtual communities are worlds of words, then the stories we tell are a powerful and appropriate vehicle of expression.

Elements of Community

Selznick (1996) identified seven elements of community--features that must be present to give an entity the label of community. Selznick's elements underscore the idea that communities are complex. Any adequate description of virtual learning communities needs to address these elements, and recognize that they are variables that interact multidimensionally. A successful community, actual or virtual, will exhibit a balance of these elements.

- **Historicity**. Communities are stronger when they share history and culture. Conversely, they are weak when they are based on general interests and abstract ideas.
- **Identity**. Communities foster a sense of shared identity. Successful virtual learning communities need to have boundaries—an identity or recognized focus.
- **Mutuality**. Communities spring from, and are maintained by interdependence and reciprocity. Participants construct purposes, intentions and the protocol for interaction.
- **Plurality**. Communities draw much of their vitality from "intermediate associations" such as families, churches, and other peripheral groups.
- **Autonomy**. Within the emphasis on group identity, it is important that communities respect and protect individual identity.
- **Participation**. Social participation in the community, especially participation that promotes self-determination supports autonomy and sustains the community.

- **Integration**. All of the above elements depend on supportive norms, beliefs and practices.

It is probably apparent from this list that these elements are not realized by chance. Communities do not just happen. But neither are they created. What we are attempting to do as educators is promote the development of virtual learning communities by nurturing the conditions under which they can arise. A sampling of ideas for promoting virtual learning communities is presented in Table 1.

Element	Implications for Virtual Learning Communities
Historicity	Incorporate what members have done in the past, and make their stories part of the community culture. Explicit mention of the culture, value and context of the virtual community. Make public the history of the community.
Identity	Use team-building exercises, develop community logos, and publicly acknowledge accomplishments by the group and individual members within the community. Articulate the focus or purpose of the community, and outline the requirements and rituals accompanying membership in the community.
Mutuality	Include group exercises, assignments, activities that require each member to contribute to the final product. Ask leading questions that encourage members of the community to invest in concerns held by other members, and to share ideas and possible solutions.
Plurality	Encourage membership and participation from and association with groups related to the learning focus. These might include businesses, professional associations, or groups in other countries exploring similar issues.
Autonomy	Foster individual expression and comment explicitly on its value. Set up protocol for respectful communication and reach consensus in the group. Create strategies for settling disputes or inappropriate behavior.
Participation	Allow members of the group to shape learning agendas. Give guidance to new community members, and promote opportunities for established members to go outside the boundaries of the learning event or focus. Encourage lurkers and voyeurs.
Integration	Articulate a set of belief statements, and identify group norms as they emerge and evolve. Adopt and firmly adhere to a learner-centered philosophy, and employ pedagogy that celebrates individuals while building a group identity.

Table 1. Representative implications of Selznik's elements for virtual learning communities.

Lifecycles of Virtual Learning Communities

It is reasonable to think of learning communities as having a life, one that goes through fairly predictable stages. There are at least three distinct stages: the formative stage, the mature stage, and the metamorphosis/declining stage.

The formative stage in the life of a virtual learning community is characterized by the attraction of new members. The identity of the community is malleable, and participants are typically somewhat tentative as they try out communicating and making connections with other community members. This stage of development requires a great deal of leadership. The leader at this stage is trying to set the tone of the community, attract and welcome new members to the community, and lay out the purpose and guidelines for participation with the group as it forms. At this point, the virtual learning community will be evolving from what its creators first imagined into what it will ultimately become. The purpose may change, expand or constrict, and it is the first place in which the members will either successfully or unsuccessfully impose their will on the makeup of the community. Users will test the boundaries of the community and determine whether they will remain as members. If required to be members, they will be deciding how significant the community will be to them, or how they can shape it into something they can use. In all, it is a time of testing, negotiating, and shaping, and the match between the purpose of the community and the importance of that purpose to members will determine the length of its survival and the strength of its influence.

The mature stage of life in the virtual community is ultimately achieved once the purpose, shape and operation of the community are settled. At this point the leader doesn't have to play as central a role in negotiating the purpose and monitoring the activities of members. The purpose and codes of conduct are known, and the members of the community exercise their control over the community by doing much of the monitoring. In later stages of maturity, the community is more institutionalized and entrenched. Codes of conduct are more rigid, as are the boundaries around acceptable topics and modes of expression. A mature community may start to take on the trappings of terrestrial communities, and become much more formal in its operation. This may be characterized by the introduction of some form of governing body or fund raising activities, for example.

Ultimately, most virtual communities will be challenged to change, to go through a metamorphosis and become a new entity with a focus that is different from the original conception of what the virtual learning community would be. It is possible that one indication of this change will be resistance to change—with the focus of those who manage the virtual community on the preservation of it; the focus on maintaining the organization itself rather than on extending its purpose or mission. One of the possibilities at this stage of life is that the virtual learning community has made its contribution and is now in a state of natural decline. There may be the rare virtual community that becomes so entrenched that it will survive without significant change, but most virtual communities will face greater volatility.

Research Issues Raised by Virtual Learning Communities

If educators choose to support the development of virtual learning communities, a number of issues emerge. Some issues are financial and logistic—how does one assemble the technological and personal systems necessary to construct and maintain a communication system. But the more important questions centre around the design, implementation, pedagogy and effects of virtual learning communities—the socio-educational aspects of learning through this means of communication. A few of these issues which invite investigation are listed below, although many more seem to arise every day.

- How do people select virtual learning communities and how do they make use of them for learning?
- How do voluntary members of virtual learning communities differ from those who are assigned to learning communities in formal educational contexts?
- Are there rules of engagement or particular protocols for insinuating an individual into the fabric of a virtual learning community, and is the process contextually or culturally bound? Does the process mirror interpersonal group learning contexts?
- Are there power relationships in virtual learning communities, and how do they interact with learning variables?
- Do Selznik's elements of community exhibit themselves in virtual learning communities, and do they inform our understanding of how these communities contribute to learning environments?
- What is the nature of learning in virtual contexts, and how do architects, active members and spectators describe their experiences?
- What value do administrators, educators and learners place on virtual learning communities? How do political, social, educational and personal agendas interact in the development maintenance and alteration of virtual learning communities.
- Do virtual learning communities exhibit lifecycles, and what significance does this have for their design?

- What are the pedagogical issues involved in virtual learning communities? How can they be used for teaching?

Algorithm Animations supporting the Education in Distributed Systems

Arnulf Mester, Heiko Krumm
Dept. of Comp. Science, University of Dortmund, Germany
mester@acm.org, krumm@cs.uni.dortmund.de

Abstract: In order to support the education in distributed system fundamentals and to elucidate the function of distributed algorithms and protocols we apply animations of formal models which concentrate on the mediation of aspects of the dynamic system behaviour. For this purpose we adapted and extended approaches and tools supporting the animation of sequential algorithms. Besides of sets of special animations, the results comprise a set of view types providing for the convenient presentation of dynamic properties. Furthermore we report on experiences we gained from a series of corresponding educational experiments.

Introduction

With respect to the general introduction into distributed systems the experience shows, that many students have problems to grasp abstract conceptions such as concurrency, partially ordered causality structures, and nondeterminism. Moreover, even less abstract characteristics of distributed systems – like allocation of activities and resources to several sites, message exchange based cooperation mechanisms between autonomous parties, distributed state components, loose synchronisation, variable transit delays and faults in unreliable communication systems – cause problems since their demonstration mostly has to be based on non-trivial example systems which tend to be difficult to survey. In particular, subjects concerning the dynamic behaviour of distributed systems tend to overtax the imagination of students. Therefore, we developed animations of distributed algorithms and communication protocols in order to complement the traditional means of education by facilities which enable students to experience dynamic behaviours of models. The animations concentrate on the elucidation of distributed system characteristics, on the design of suitable views supporting the understanding of distributed systems, and on the exemplification of protocols and algorithms.

The animation of distributed systems is based on results imported from the research field of sequential algorithm animation (Brown 1987, Stasko 1998). In particular, we use the Zeus algorithm animation system (Brown 1992) which supports the animation of Modula-3 based algorithm implementations (Harbison 1992). Furthermore, there are animations accessible via World Wide Web which are implemented as Java-applets in HTML-pages (Arnold et al. 1998, Ragett 1998).

The objective of supporting the education in distributed systems by animations was pursued by a series of experiments. We started with the ZADA project (Mester w/o date). It was performed in the course of a so-called group project where about 10 students cooperate during one year in order to achieve a development project goal and to experience team work and cooperation means. The student group extended and applied the Zeus system and developed a set of protocol and algorithm animations. In particular, they designed suitable types of views supporting the visual presentation of the animations. The team presented its results to the audience of a fundamental distributed system lecture and learned from the feedback. The ZADA project supplied relatively universal animation platforms to students and suggested to them to design animations and to perform experiments for their own. In comparison to this, the provision of well-prepared and well-designed animations can structure and accelerate the learning process. Especially, it can help students to gain a first access to new subjects. Presently we therefore offer World Wide Web accessible lecture note complements which introduce into the field of distributed systems and provide for applets animating the execution of distributed algorithms and protocols (Krumm 1997). In the distributed system lecture references to the complements are made. The feedback from oral examinations is very positive.

Algorithm Animation

Algorithm animation is a section of software visualization, which Price et al. define as "Algorithm visualization or animation is understood to be the visualization of a high-level description of a piece of software, which is in contrast to code or data visualization (which are collectively a kind of program visualization) where actual implemented code is visualized." (Price et al. 1993). Algorithm animation is typically used as learning aid, as high-level debugging aid, and as design aid.

Most algorithm animation systems (e.g. Zeus (Brown 1992), Tango/Xtango (Stasko 1992) with several successors) provide for execution of sequential algorithms, interactive control, e.g. at least different speeds, single stepping, breakpoints, and algorithm input determination, as well as the mapping between the state and/or the actions of the algorithm onto the state and/or actions of some or all of its visualizations. Furthermore it synchronizes between the algorithm and its visualizations. Animation designers are supported with an animation library leveraging the effort of building sophisticated views (including animated graphics, 3D, sound). Animations built ad-hoc without an animation system would have to reimplement major features of this environment.

The architecture of Zeus separates between the algorithm and the views of the animation. One has to annotate the source code of the algorithm (Zeus: Modula-3) to be animated at 'interesting' (i.e., animation relevant) locations with directives to emit a stream of 'interesting events' to the animation system on execution. The animation system then filters the events according to the users interests, distributes the events to connected views (separate windows) and synchronizes among them, i.e., assures the concurrent handling of the same event in all views. Events normally cause display changes in views. The algorithm system may also provide for a channel back into the algorithm, i.e., manipulations of program data displayed in views effect changes of program data variables.

Still missing are systematic guidelines for successful visualization, though some empirical studies about specific aspects exists (e.g., Stasko 1997). The current trend in algorithm animation is its seamless integration into Web-based electronic textbooks / courseware, which also allow for other types of media. Another trend is to provide for collaborations between learners (e.g., Brown et al. 1997, Guzdial et al. 1997).

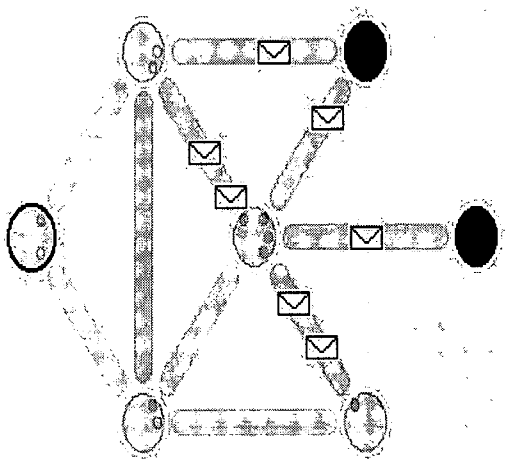
Distributed System Animation

In comparison with the animation of sequential algorithms, the animation of distributed systems imposes additional requirements. Animations have to handle the concurrency of activities. They must model the distribution of activities and resources to sites as well as the distances and transit delays between sites. Furthermore, the inherent non-determinism resulting from varying transit delays and processing speeds has to be managed. On the one hand, these requirements demand special features of the animation system. On the other hand, they ask for special design and layout principles in order to offer convenient presentation interfaces. Special features of a suitable animation system are:

- Distributed system definition language; it has to support the definition of processes with private resources and the definition of communication networks supporting the exchange of messages. Additionally, the definitions of the animation events have to be supplied.
- Scheduler; the execution of activities during animations has to be controlled by a scheduler component which achieves the selection, synchronisation, and management of concurrent and nondeterministic actions. Preferably, the scheduler provides for different scheduling strategies (e.g., arbitrary action selection, systematically exhaustive depth-first or breadth-first exploration, user-defined action priorities, user-interaction controlled selection) which can be combined with several processing speed controls (e.g., continuous processing with user-chosen processing speed, single-step execution, stop at break-points) and suitable experiment control strategies (e.g., forward processing, backward processing, reset, choice of alternative execution sequences, repetition of sequences).
- Node and communication system models; while distributed system nodes commonly are represented by event-discrete models which perform actions from time to time, the communication system preferably reflects the continuous propagation of signals over links. Therefore the execution machine has to support more fine-grained communication system steps as well as more course-grained node actions.

While concurrency and nondeterminism mostly result in complex and intertwined activity threads, the presentation interface of the animations has to provide for clear impressions which support gradual learning processes. In particular, special view types for distributed system animations are of interest. The views shall refer to common paradigms and emphasize the properties of interest.

The views influence the convenient perception of animations. Following main view types were identified and defined: a) Topology; the view depicts a graph representing the nodes and links of a network. b) Message sequence charts; time-distance diagrams clarify the propagation of messages. c) State machines; state machine diagrams elucidate the control flow of nodes. d) Petri nets; nets and 'token games' can support representations of the system and its concurrent threads of activity as a whole. e) Code; often, details of a system are preferably demonstrated with reference to its definition text where the constructs of momentary interest are emphasized.



(Fig. 1) presents the screen shot of an animation of a parallel network exploration algorithm. The figure exemplifies the topology view type which comprises icons of nodes, links, and messages. Message types are coded by color. Additionally, the major state component values of nodes are represented by the color of the node icons. The values of essential minor state components influence the color of links (i.e., the exploration state of a node and the state of the spanning tree under construction). Moreover, the bright points in the nodes act as indicators for minor state components of nodes (i.e., the management of exploration messages and acknowledgements).

Figure 1: Topology view
(live applet: http://ls4-www.cs.uni-dortmund.de/RVS/MA/hk/OrdnerVertAlgo/EchoAlgoText.html)

Thus, (Fig. 1) also exemplifies the graphical representation of state component values. We recommend to our students, firstly to observe system executions in this topology view, since it provides for an intuitive understanding of distribution, message propagation and concurrency.

(Fig. 2) gives an example of the message sequence chart view. It also presents an animation of the parallel exploration algorithm. On top of the picture we see the topology view again which is known from (Fig. 1). Mostly, we use the topology view as recurring main view. A mapping was applied which linearizes the topology area in order to support the direct correspondence of x-coordinates in topology and message sequence chart view. On bottom of (Fig. 2) the code view of the animation shows the definition of the last action of the selected node. The selected node is highlighted in the topology view. Since the selection feature is combined with a break point. The animation stops whenever the selected node performs an action and the user can investigate the definition text of the action.

Finally, (Fig. 3) depicts the state machine view. The figure is a screen shot of an animation of the Alternating Bit Protocol. On top, the topology view is used again as main view. Here, the minor state component values of the sender and receiver buffer contents complement the icons of the nodes. Below, the animated transition diagram of the selected node represents a state machine. Old and new states, as well as the fired actions are highlighted by colored borders. Note, that the state diagram concentrates on few major state components. Additionally, it is important, that the action names of the diagram directly correspond to the action names of the code view.

ZADA Project

Within the project 11 students and two advisors from the distributed systems group tackled the problem of making the comprehension of the functionality (i.e. dynamic behaviour) of distributed algorithms easier. The aim of the project was the development of methods and tools for an utmost simple generation of effective visualizations of protocols and distributed algorithms. As only few original work to this problem existed, which mainly focused on parallel algorithms or on examplary animations of isolated examples, this project was targeted more exploratory. The group explored existing animations and animation systems and quickly turned to both didactical and technical matters: (1) elaboration of guidelines for the effective visualization, (2) development of
an approach to and a tool for the modelling, the execution and the instrumentation of distributed algorithms, (3) selection and implementation of typical representatives for a broad range of distributed algorithms and protocols, and – based on the didactical guidelines – (4) exploration of visualization facilities (and implementing them as views) for this class of algorithms, as well as (5) evaluating meaningful views for the algorithms selected. To validate the ideas, (2), (3), and (5) have been bundled with the Zeus animation system to form a collection of 'Zeus-based Animations of Distributed Algorithms and communication protocols (ZADA)' (6).

(1) Not all that is technically possible also is didactically feasible. Therefore, a framework for the systematic design of animations was developed. It profited from contributions in cognitive psychology and science of education and covers topics like how to represent specific distributed algorithm event classes (e.g. message send/receive, loss, node state change), how to place views, how much information can be presented in one view, in how far views have to be explained or augmented, how much parallel activities are feasible, how to help the viewer to relate correlating activities in different views, which colors and color combinations fit best, what can be supported with sounds, etc.

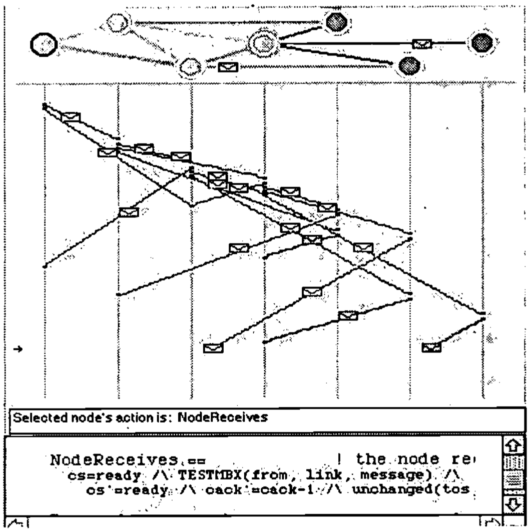


Figure 2: Message sequence chart and code view (live applet: http://ls4-www.cs.uni-dortmund.de/ RVS/MA/hk/OrdnerVertAlgo/EchoAlgoText1.html)

(2) For modelling, the Actor-model has been adopted and utilized in Modula-3. The adaption allows for a nearly direct take-over of pseudocode descriptions from common textbooks into a Modula-3 program for later integration into the animation system. For execution, Zeus has been selected as underlying animation system. It has been extended by an animation scheduler component which models the propagation of messages in the communication system and triggers the actions of the distributed system nodes. For instrumentation, standardized events for distributed algorithms have been defined (e.g. message send/receive, node status change), which are raised automatically by the animation scheduler without the necessity of further annotation of program texts.

(3) The selection of algorithms described abstractly in Modula-3 can be regarded as broad, since all relevant algorithm subclasses are represented: a) *application oriented*: consistency of distributed data, distributed transaction, and distributed computation. b) *control*: consensus, network exploration, adoption, backward error correction, election, net structure exploration, shortest path, and termination. c) *communication protocols*: alternating bit and sliding window protocol.

(4) The examination of possibilities for the visualization of distributed algorithms resulted in a collection of canonical and specific animation views. The views stem from the three animation view classes: direct visualization on different abstraction levels, functional visualization, and views serving as overviews. The following animation views were build: topology, instance, time/distance, petri-net, finite automata, message queues, area codings (polygon view), waves, state trees over time, checkpoints, and timer. Reusable views are parametrizable in their visualization characteristics at object instance-level (e.g. legend, colors, icons, action triggering by events). (Fig. 4) depicts an area/polygon view, where the major state of the local node is represented by a colored area around it. (Fig. 5) shows a wave view on the same topology, where growing circles represent spreading knowledge about e.g. a value.

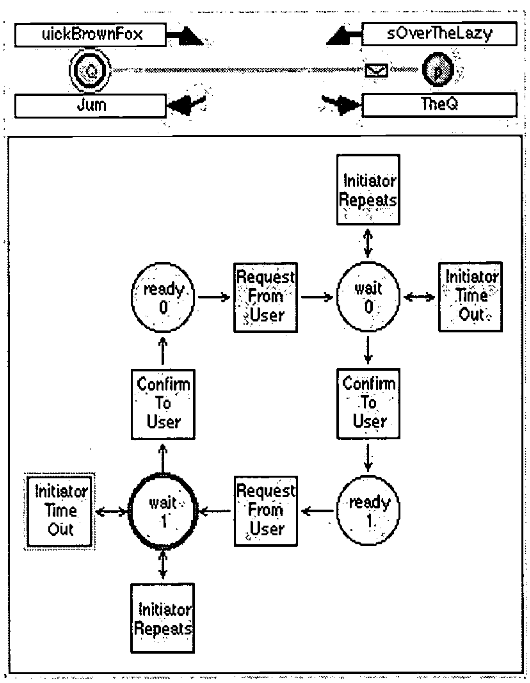

Figure 3: State machine view (live applet: http://ls4-www.cs.uni-dortmund.de/ RVS/MA/hk/OrdnerVertAlgo/AltBitText2.html)

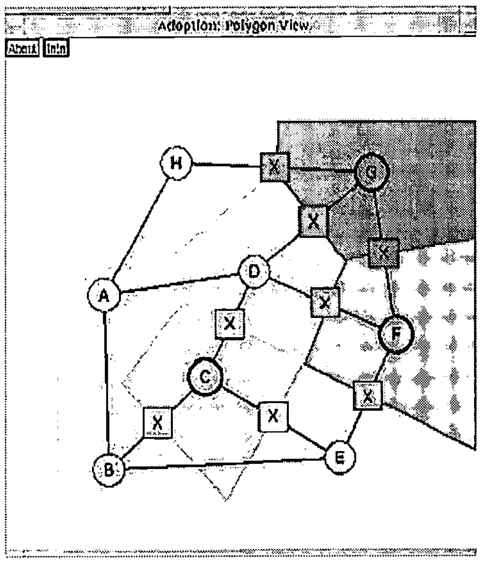

(5/6) The collection of animations, suitable views, guidelines, modules, and experiment parameter files forms ZADA. In connection with animations it recommends experiment parameters to support common learning experiences: Specific settings (topologies, algorithm input data, initiator status, etc.) have been prepared and documented in order to facilitate a common base for discussions and individual explorations.
The ZADA package primarily adresses students in higher classes for computer networks and distributed systems. It serves as interactive tool for exploratory learning of selected algorithms. Mainly, the students will use the preplanned experiments. Moreover, advanced students can design experiments for their own. They can concentrate on the modelling of the algorithm, since re-usable canonical views and the standardized instrumentation provide for an automated creation of animations.

Figure 4: Adoption Area/Polygon View

Animations in Complementary Lecture Notes

We offer two courses which refer to animated models in complementary lecture notes. One course introduces into computer networks and distributed systems in general. The other course concentrates on distributed algorithms, their specification, and verification. The complementary lecture notes are accessible via World Wide Web (Krumm 1997) and can be experienced by Java-enabled HTML-browsers. Presently, the notes contain the following animations (introductions into these algorithms may be found in (Raynal 1987): a) Parallel network exploration, b) Serial network exploration, c) Message extinction principle, d) Distributed snapshot scenario, consistency, and snapshot algorithms, e) Alternating Bit Protocol.

Each topic is delt with a small series of animations in few different views. At the one hand, there is a lot of work necessary to develop convenient animations. On the other hand, we do not want to overload the perceiption of the students. Therefore, we presently provide for a relatively small set of animations only. We propose that the students start with the observation of a system in topology view in order to get impressions of the global behaviour. All other animations refer to the topology view as main view. Stepwise executions combining the topology view with the code view are of interest to introduce the formal system definition. It supplies the definitions of the process types containing the declarations of the state variables and the definitions of the process actions. A combination of topology and message sequence chart view can clarify concurrency and message propagation issues. Finally, state machine views can help to structure and understand the local behaviour of nodes. (Fig. 1), (Fig. 2), and (Fig. 3) are screen shots from such animations and exemplify this sequence of views.

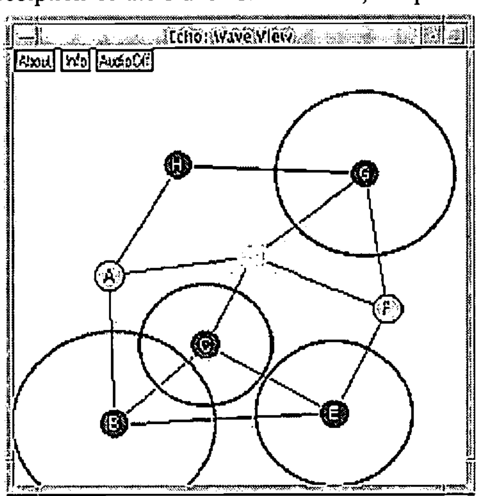

Figure 5: Wave View

All animations provide for restricted interaction facilities. Students may control the animation speed. They can start, stop, and continue an animation. Moreover they can select nodes in order to choose the focus of state machine and code views. The code view selection is combined with an automated break after each action of the selected node. Additionally, a general single step mode is available. There is a deterministic scheduling which is defined implicitly with the system definition. Some models provide for nondeterministic execution variants resulting from varying message delays. In general, we do not want to provide for an universal animation experiment platform. We only want to offer a small and preplanned set of marked animations which mediate the essentials in an efficient way. Animated topology and message sequence chart views shall support a first access to the properties of distribution, concurrency, and nondeterminism. Animations of the Alternating Bit Protocol shall exemplify the cooperation of protocol entities and their use of basic channels. Finally, animations of snapshot scenarios shall clarify the snapshot problem, the role of the causal dependency relation, and ist influence to the concistency of snapshots.

Results and Experiences

We used educational animations of distributed system models in two different ways. We reported on the work of the students of a project group which deepened their knowledge of distributed systems by developing an animation system, designing animations, and evaluating the feedback of other students to the animations. Furthermore, we outlined the World Wide Web accessible complementary lecture notes which support the introduction of distributed system essentials and aim to the time-efficient mediation of subjects.

As the experience showed so far, there are the following main aspects of animation application and animation design which should be coordinated with each other: a) Team objectives and size, b) Available period of time, c) Guidance, d) Scope of experiment design, e) Interaction facilities, and f) Animation development automation. For instance, the animations of the complementary lecture notes (cf. Sect. 5) are mainly used by single students, who belong to a larger course group but perform the experiments alone in order to support their individual learning. While there is no tuition which directly addresses animation experiments, the lectures preferably rely on common experiences of the students which result from the fact, that all students experienced similar experiments. To support the similarity of experiments, the scope of experiment design is relatively small and the interaction facilities are restricted. This is of interest also because our students tend to be very sparing with their learning time and consider well-prepared animations only. Therefore, the animations had to be designed creatively. Of course we used a common framework supplying basic features and guidelines. In particular, however, the design of suitable scenarios, the selection of meaningful state components, and the design of striking icons could not be automatized. They resulted from individual efforts and dominated the animation development.

Concluding Remarks

In summary, our experiences plead for the provision of animations for the education in distributed systems. In order to support more fundamental courses, however, the animations have to be designed very carefully and therefore bind many development resources. Hence, the exchange of animations between universities and cooperative developments are of great interest. They can be supported by World Wide Web and Java technologies, which also support access for students learning at home.

Culture On-line: Development of a Culturally Supportive Web Environment for Indigenous Australian Students

Catherine McLoughlin,
Faculty of Community Services, Education and Social Sciences
Edith Cowan University
Western Australia
c.mcloughlin@cowan.edu.au

Abstract

The degree to which technology can serve the needs of culturally diverse students is dependent upon the adoption of culturally appropriate and inclusive instructional design models. We can adopt Papert's (1993) idealistic belief that "the computer changes who can do what, and at what age" and regard the computer as a tool for liberation, achievement and multicultural learning. But we must do more to realise the objective of culturally appropriate instructional design. Technologists and multicultural educators need to plan for cultural pluralism when planning and designing instruction and delivery options, if Web sites are to cater for diverse learning needs, cultural perspectives and learning styles. The design of a World Wide Web learning environment for Indigenous Australian students is outlined, and multiple cultural model of instructional design model that informed the development is discussed. The cultural aspects of the design process are outlined, and implications for design of Web sites for culturally contextualised learning are drawn.

Context of the study

The use of information technology by Indigenous Australians is very limited. As part of The Commonwealth Government's *Access and Equity Policy* in Australia, there has been increased funding to support greater Indigenous use of communications technologies and for information literacy skills. In 1998 Edith Cowan University in Western Australia successfully obtained funding to launch its pre-university bridging courses on the World Wide Web to cater for the state's Indigenous population. The online learning environment and content were designed to enhance the participation of Indigenous students learning in Web-based learning, and to increase their academic success through increased proficiency and awareness of computer technology. In addition, the initiation and implementation of the project was intended to produce other outcomes, such as insights into learning styles and how students responded to the on-line environment.

This paper describes the design and epistemology of a culturally appropriate Web site for the Indigenous Australian students who are novice users of the technology, and who are making the transition to tertiary studies. The project is planned to extend over three years, and in this time six units of a tertiary bridging course will be redesigned and made available to learners in an open learning mode. Until this point in time learners have accessed the materials in the print mode only. The project, entitled *Indigenous Online Network (ION)* aims to provide appropriate learning materials and contexts for Indigenous students to access study skills courses online, and provide a communications network for Indigenous Australian academics within Australia.

Theoretical aspects of WWW design: Cross cultural dimensions

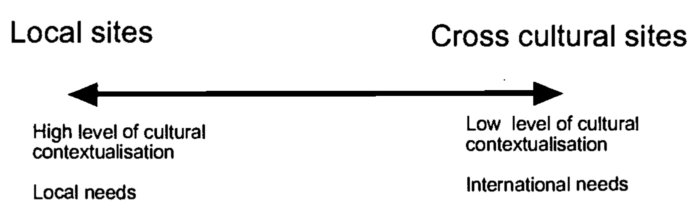
The question of cultural contextuality in the creation of a Web site for a specific cultural group can be regarded as a central issue in the design of both interface and learning activities. Often, minority cultures wishing to incorporate technology in their learning are not well served by instructional approaches designed for mainstream values (Roblyer et al 1996). As learning is a cultural activity, the design of a Web site is also infused with cultural meaning and with cultural nuances and identity issues, and instructional designers and developers bring their own viewpoints and perspectives to the design process. The World Wide Web can attract global audiences to the many sites that can be accessed. But to what extent is the

Web increasing cross-cultural understanding and bridging the gap between cultures? Can we assume that the content, interaction and learning experiences afforded by the WWW will have the same relevance and meaning to diverse audiences?

Collis & Remmers (1997) have defined two categories of sites that have cross-cultural implications:

(i) Sites that are made in context and culture, but visited by other cultures
(ii) Sites designed specifically for cross-cultural participation. (See Figure 1.)
The provision of Web sites for Indigenous Australian students would fit into category one, as they are intended to cater to the needs of a particular cultural group. In designing a Web environment for this target group, it was envisaged that other Indigenous groups and individuals from around the world would visit the site. However, the primary objective was to cater for the needs of Indigenous students seeking a bridge into university. In applying an instructional design model for the sites, our objective was to create a culturally appropriate learning environment for the design of this and future sites for Indigenous students. Primary considerations were influenced by the educational values, needs and learning styles of Indigenous Australian students, and the integration of these cultural variables into the design process. In addition, it was hoped that the initial experience of the students would be monitored so that feedback on learning processes and on line interactions would enable us to further refine Web sites tailored to the specific needs of these learners.

Figure 1: Categories of Websites



Indigenous epistemology and values

Our first step in designing the Web site for the Indigenous students was to ensure cultural inclusivity in all aspects of pedagogy, form of interaction and learning processes. This involved review and analysis of a broad range of literature and extensive consultation with Indigenous students, community members and academic staff. In order to define and plan instruction for the particular educational setting, the adoption of an appropriate instructional design model was essential. Henderson (1996) reminds us that instructional design is an intangible aspect of culture, but once it is transformed into a material object, it becomes an artefact of the culture is which it is embedded. In support of this view, Flechsig (1997: 27) affirms that " instructional 'designs' are specific ways of cultural transmission and of organising learning processes". From the outset, therefore, the design process was infused with the awareness that the development of the Website should be contextualised within the epistemology, pedagogic philosophy and models of knowledge construction that underpin Indigenous values and approaches to learning.

The literature on Indigenous epistemology provides several insights that can inform the design of learning activities and pedagogy. Christie (1988) suggests that in genuine Indigenous Aboriginal education the basic goal is to teach the harmony and unity of Aboriginal life. An important goal is to preserve continuity with the past, the land and the people. From an Indigenous perspective, cultural integrity and survival are fundamental concerns. Triandis (1990) describes the distinction between individualism and collectivism as the most important dimension of cultural difference in social behaviour. If it is accepted that Indigenous students differ significantly from peer groups of non-Aboriginal students concerning values that serve collective/community as opposed to individual interests, this is likely to have planning and design implications. In practical terms, for the design of the learning environment, this involved:

- community-based communication processes and task orientation;
- consultation and decision making by Indigenous students; and

• participatory planning in the design process.

For adult Indigenous learners, cognitive orientations to instruction have been found to be unsupportive of traditional values and ways of learning (Ryan, 1992). Instead, educational models based on concepts of community and social participation have been found most productive (Whatman, 1995). The successful design of the Web site therefore depended on the adoption of an instructional design approach that was congruent with Aboriginal values, participatory structures and way of communicating.

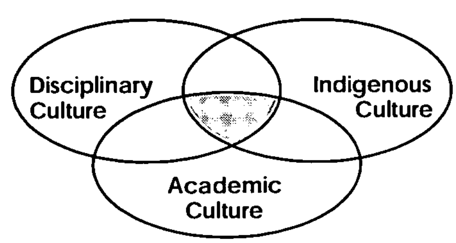
Throughout the planning stage, there was constant discussion within the Indigenous community about content, graphic design and instructional approaches. To further support the cultural relevance of the site for Indigenous learners, it was essential to conceive of the development within an appropriate theoretical framework.

Theoretical framework

Through the process of consultation, two interrelated theoretical models of learning were found to be supportive of Indigenous values and pedagogies. To support the notion of community, the creation of a 'community of practitioners' (Lave, 1991) affirmed the processes of dialogue, shared interest, participation and collaboration. This concept permeated the design at various levels, from the creation of the on-line environment through to the design of learning activities, support structures, and collaborative links with the community. For students, the concept of belonging to an online community resonated with their own community-based expectations, and allowed them to see technology not only as a means of widening their own circle, but also as a means of taking newly found skills into their own communities. Thus, the social, communicative and collaborative aspects of the 'community of practitioners' approach were culturally appropriate. For Lave & Wenger (1991), social action and communicative praxis are primary, and learning is both social and a language based practice. Another tenet of this theory is "the increased access of learners to participating roles in expert performance" (Lave & Wenger, 1991: 17). This means that learners are always participants in the learning process and acquire greater expertise though observation, and "legitimate peripheral participation" (Lave & Wenger, 1991:29). Even as novices, learners have access to different levels of activity, and learn initially by taking on simpler tasks but gradually moving towards full participation.

Supports for learning and collaboration were incorporated into the design and were conceptualised and augmented by the theoretical framework of Vygotskyan theory (1978) in which learning is viewed as being a participant in a particular social world. For Vygotsky, learning is development, and through the processes of social interaction and dialogue with more experienced others, learners are assisted in achieving higher levels of competence. Another fundament tenet of Vygtoskyan theory is that learners continually re-enter new zones of development recursively throughout their lives. As technology is increasingly used to deliver instruction and to facilitate communication, information literacy skills for Indigenous students can be interpreted as entering new zones of development. For Indigenous learners, it is nevertheless important to retain their own sense of cultural identity, and to integrate new skills with other learning needs, ie tertiary literacy skills and Indigenous cultural knowledge. (See Figure 2).

Figure 2: Multiple cultural model of online learning



The "zones of development" for Indigenous learners on-line would therefore have to combine the skills associated with the academic culture, of university with Indigenous cultural perspectives and relevant disciplinary skills for tertiary success. By integrating the participatory pedagogy of Lave & Wenger (1991) based on a community of practice, an emancipatory learning experience was conceptualised as collaborative groups of learners working at appropriate levels while acquiring new skills. In this way, a theoretically valid and culturally appropriate pedagogical framework was developed for the Web site.

Instructional design: Limitations of existing models

Linked to the theoretical framework of the community of practitioners, an instructional design model was sought to support the learning activities of sharing knowledge and learning through participation, while recognising the unique cultural tenor of the Web site. There are many current instructional design models and paradigms, each of which can be interpreted as culturally and socially determined (Branch, 1997). Instructional designers however, may not always incorporate cultural understandings of technology into the design of learning materials. Instructional design models include cognitive, social and pedagogical issues, but may not acknowledge the need for cultural contextuality. Reeves & Reeves (1997) for instance, outline ten pedagogical dimensions that can be used to design interactive multimedia tools and learning environments. Cultural sensitivity is described as building in diversity and adapting instructional design to cultural norms. Henderson (1996) argues that cultural issues are fundamental, as instructional design is about the creation of cultural identity: "Instructional design cannot and does not, exist outside of a consideration of culture" (Henderson, 1996, p. 86). In creating a learning space for Indigenous learners, the development team had to ask: *How can the dimension of cultural contextuality inform the instructional design process?*

An important part of Henderson's (1996) work is the identification of several design paradigms, each of which reflects particular world views, values, pedagogies, inclusions, and exclusions that result from the designer's own societal context. As instructional designers are instrumental in creating and developing interactive multimedia, courseware and learning environments, they can also influence cultures of learning. Among the paradigms identified by Henderson (1996) there are three, all of which are limited with respect to cultural dimensions of learning and pedagogy. For example, the inclusive paradigm which is motivated by equity issues, acknowledges diversity and multiculturalism in the design of learning materials. However, this type of design tends towards soft multiculturalism which ignores the complex issues involved and includes only superficial aspects of the minority culture that do not challenge the majority view. The inverted curriculum approach takes the minorities' perspective, and criticises the status quo, or dominant group pedagogy. However, it does not empower students who must try to survive within the mainstream academic culture.

This consideration of ID models alerted the development team to issues of tokenism, soft multiculturalism and cosmetic multiculturalism. To arrive at an appropriate design model, several questions were posed to all interested parties, including prospective students, community members and teachers, so that the design would be informed by Indigenous perspectives.

- What kind of learning environment is most familiar to the students?
- How does the cultural background of the students influence their use and view of time?
- How do Indigenous students conceive the role of the teacher?
- What kind of relationship do students want with a teacher?
- What kinds of assessment tasks will be fair and unbiased?
- What rewards and forms of feedback will be most motivating for these students?
- Is the locus of control congruent with these students' own sense of personal control?
  What cognitive styles characterise the target group?

Responses to these questions contributed to the development of the Web site and to the creation of learning activities, pedagogical support and collaborative task design. The adoption of an 'eclectic paradigm' or multiple cultural model allowed variability and flexibility and that enabled students to learning through interaction with materials that:

- reflect the multicultural realities of society;
- include multiple ways of learning and teaching; and
- promote equity of learning outcomes.

The adoption of the multiple cultural model is reflected in different 'zones' of learning that matched the cultural experience of Aboriginal students entering university. (See Figure 2.)

Pedagogical features of the on-line community

A constructivist approach aligned to student centred approaches to knowledge interpretation was built into the design process. As knowledge extended beyond the classroom into the community, the concepts of knowledge and teaching were redefined for the Indigenous learners. The creation of a community of learners online was achieved through task design, communication forums, shared spaces for working and collaboration and dialogue and support from peers and tutors. Each distributed group of students had an online mentor or virtual tutor who provided feedback and fostered further dialogue.

A broader view than just designing instruction for mastery of content was adopted. The Web site fostered conceptual transformative learning by creating a holistic learning environment where social processes, community consultation and learning strategies for tertiary study were built in. These features are summarised in Table 1.

Table 1: Features of the online community of inquiry

Feature of community of inquiry learning	Cultural/cognitive application
• Epistemology and pedagogy congruent with community needs	Socially situated learning based on Lave's (1991) community of inquiry
• Communication forums and interaction	Negotiation of shared meaning; peer teaching and conversation
• Shared experience and knowledge	Participatory tasks, collaborative learning and group projects (Scheel & Branch, 1993)
• Supportive teacher roles and responsibilities	On-line tutors scaffold learning through mentorships, dialogue and modelling
• Creation and manipulation of shared spaces	Use of bulletin boards for shared experiences and talk; Use of the larger space of the WWW to find & share resources
• Student roles and responsibilities	Clear statements of outcomes; negotiable tasks; posting of shared problems to a FAQ space
• Situated discourse and collaboration	Use of Lipman's (1991) model of inquiry: mutual, questioning, feedback & deliberation through problem-based tasks
• Support mechanisms within the community and outside the community	Access to peer scaffolding; outside experts. mentoring by online tutors through online help, group forums
• Social interaction to support group cohesion	Use of multiple forms of communication and dialogue & tasks designed for collaboration.

Task design incorporated instructional tools to enable students to formulate and develop responses to problems, and develop culturally pluralistic ways of perceiving information and skills. This approach was based on Vosniadu's (1994) notion of conceptual change as embedded in existing conceptual structures and revisions of these through authentic learning experiences.

By providing a community focus for learning and task design , the Indigenous learners were able to make connections with the instructional environment itself, through the use of culturally familiar metaphors, icons and graphical features. Consideration of the socio-cultural backgrounds of the learners and their styles of learning ensured that the learning tasks and processes of instruction were embedded in culturally sensitive contexts that validated Indigenous ways of learning.

Apart from celebrating cultural diversity, the design of the Web site for Indigenous Australian learners shows how technology can be used to support contextualised design and enhance student achievement by explicitly acknowledging the learners' unique cultural perspective.

How Do Instructors Design A WWW-Based Course-Support Environment?

Wim de Boer & Betty Collis
Faculty Of Educational Science and Technology
University of Twente, PO box 217
7500 AE Enschede, The Netherlands
w.f.deboer@edte.utwente.nl, collis@edte.utwente.nl

Abstract: After one year (1997-1998) of working extensively with our instructors, particularly all of those responsible for our first-year courses, 17 courses required for all students and several senior elective courses (3) are now using their tailored-made Web-based course-support environments. In addition, during the 1998-99 academic year all of the second-year courses will be adapted to be delivered with their new course-support environments. In this paper we describe how a broad range of instructors, not only those who volunteer or have an initial interest in using WWW-based course support, but also those who are required to do so as part of a faculty-wide change process work through a design process based on rapid prototyping to evolve tailor-made WWW-based course-support environments. What are the options instructors choose for these environments and how popular are various types of options (for example, shared workspaces, WWW boards for computer conferencing, etc.) for course-support environments? Trends and implications in the set of options chosen by instructors in our faculty are discussed.

Introduction: TeleTOP at the University of Twente

The University of Twente in The Netherlands has national and international reputation in the field of telematics, the combination of information and communication technologies. Not only is there an extensive amount of research being done in the area but also the application of telematics applications to the teaching and learning process, what we call "tele-learning" (Collis, 1998) has a high priority. The most ambitious of the tele-learning initiatives at the University of Twente is the *TeleTOP* project in the Faculty of Educational Science and Technology. The overall goal of the project is to stimulate the innovative and appropriate use of telematics for learning purposes within the faculty in order to make the educational delivery more efficient, more enriched, and more flexible.

To achieve these goals a special system has been developed by a professional team of educational and technical designers and developers. The system is database-driven and Web-based and uses a variety of telematics applications, ranging from e-mail and Web pages to shared workspaces. The system generates WWW-based environments are meant as course-support environments for the instructors and students and not as replacements for face-to-face sessions and textbooks. Contact between instructors and students still is one of the essential aspects of a learning process (see Tielemans & Collis, 1998, for a further description of the educational and technical requirements for the system and how they have been realized).

However, no matter how elegant a system is, instructors must use it. Reasons that instructors in higher education do not make use of computer-based resources to support the instructional delivery of their courses are well known (see for example, Northrup (1997) and Collis & Pals, 1998). With respect to WWW-based environments, most current usage in mainstream programs in higher education is voluntary, and although there are an extensive number of examples of such voluntary use there are far many more instructors who are not making use of any of the instructional possibilities of telematics. There are relatively few examples of efforts to engage all the instructors in a faculty in the use of telematics applications in their courses. Merlic and Walker (1997) describe the *Virtual Office Hours* environment at the Department of Chemistry and Biochemisty at the University of California as one such example. Another is the TeleTOP Project at the University of Twente.

The decision (made by the faculty administration) to involve all courses in a re-design process, both pedagogically and to include use of telematics tools and WWW sites, involves the challenge of working with a wide variety of courses and instructors. To do this we have developed a WWW-based decision-support tool which we use as part of a rapid-prototyping process designed to maximize instructor involvement in the re-design of his or her course. Our situation has also given us an excellent opportunity to study what instructors actually want and use when given the possibility of a wide range of WWW-based tools and suggestions for using those tools. In the next section we describe the rapid-prototyping process.

Supporting Instructors in the Decision-Making Process when Designing a WWW-based Course-Support Environment

WWW-based environments to support all of the first-year courses in the Faculty of Educational Science and Technology were ready in a definitive form at the beginning of June 1998. How did this come about? Beginning in September 1997, a weekly instructors' session began in the faculty. These sessions were voluntary, and well attended. During the first two months of the sessions, instructors were introduced to a way of thinking about their courses, in terms of a matrix in which the rows are standard components of courses (course-organization aspects, face-to-face sessions, self-study and practice activities, projects and major assignments, testing, and general communication) and the columns relate to three motivations for change in each of the components (to make the component more efficient for instructors and students, to enrich the component, to make the component more flexible for different types of students). Links to examples of how telematics applications could support each category of change were demonstrated and discussed.

In November 1997 instructors were encouraged to consider their own courses and make a list of re-design options with could be facilitated by a WWW-based course-support environment tailored for their own particular courses. In December 1997 one-hour individual instructor sessions with the instructors of each of 21 courses were organised (all the first-year courses and a variety of other courses). The primary goal of the session was to use the especially made TeleTOP Decision Support Tool (DST) (Collis & De Boer, 1998) in order to interact intensively with the instructor whose course was being re-designed, trying to identify which WWW-compliant tools and associated pedagogical approaches are most likely to be acceptable and interesting to the particular course of the instructor and his/her way of teaching. For each of the course components a number of questions were asked relating to ways that a WWW site could be used relative to that component. Links to examples, primarily from courses already using the WWW in our own faculty, were provided for every question. Figure 1 shows a portion of the DST, with the overlay screen showing the example available from the link associated with a particular question. Immediately after the last of the questions in the DST was completed, a WWW page was generated for the instructor summarizing the choices that had been made, and providing the example links for those choices so that the instructor could further consider them via the use of an ordinary WWW browser at his or her convenience. This site generated by the DST served as the product of the first round of rapid prototyping.

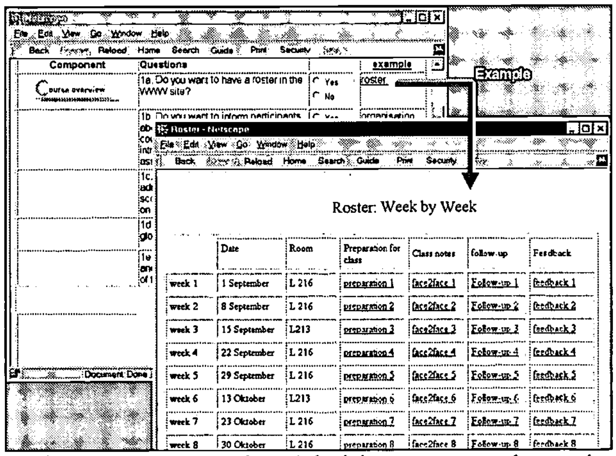

Figure 1. A screen dump of the WWW-based decision-support tool: questions and examples.

The second goal of the DST session was to respond to the instructors' reactions with ideas and suggestions, as well as to skip suggestions which did not seem like they would be comfortable for the instructor. The tool made it easier for instructors to make decisions with regard to making (some of) the components of their own courses more efficient, enriched and/or flexible in their new WWW-based learning environments. The instructor needed to decide what he thought was appropriate for his or her course. Twenty-one sessions, one per course, were organised in December and January 97/98 according to this approach, with one or two instructors participating and the authors carrying out the interview with the support of the DST at each session. A follow-up visit in the instructor's office one week after the DSST also occurred, to walk through the first site from their decisions with the DST, and make a second round of refinement of those decisions. Following this, a first prototype version of a course site tailored to the instructor's choices was generated, through the use of the TeleTOP database system. This process is being repeated in the same period in 1998-99 for all the second-year courses.

The next step for the instructors was to come together every week and practice with these prototype environments. The *Wednesday sessions* in which this occurred became an important part of the implementation process. Instructors had the chance to work together and exchange ideas. A few months later the instructors again went through the process of using a second WWW-based decision tool, choosing a final set of options for their course-support environments. As a result of this rapid-prototyping process, instructors not only are closed involved in the design process of the WWW sites that will support their courses, but also develop competency in handling those sites and the associated telematics tools and applications. The results of the process are tailored course-support environments, and also the creation of a sense of community among the instructors and a heightened level of awareness and literacy throughout the faculty with regard to the handling of telematics applications, network issues, and the instructional integration of telematics applications into regular courses.

Instructors thus had an extensive opportunity to try out a large variety of telematics tools and applications over the course of the rapid-prototyping process. What options have they actually chosen? In the following section, a summary of the options eventually selected by 21 courses in the 1997-98 cycle is given (see also Dijkstra & Collis, 1998, and Winnips, Collis, & Moonen, 1998, for discussions of two of the courses in detail).

Designing A Course Environment: The Options Chosen

During the second round (April, May 1998) instructors could make a final list of options for their course environment. Table 1 gives an overview of the options selected by the instructors for their environments.

Table 1. The options chosen for the WWW-based course-support environments

Component	Options	Description
General course information, self-study, lectures and support	News	A place for up-to-date information
	Roster	This is an important part of the environment and the ideas behind it. Here, instructors can put their study materials, assignments, sheets, notes and feedback related to the lectures.
	Quizserver	This option enables easy-to-make (self) tests.
	Course information	A course description can be put here. Think of goals, organisation, assigned text, which books, etc.
Communication	Email	In the mail-centre addresses of individuals and groups can be found. Mails can be send from here.
	Discussion	The discussion area can be used for a-synchronous discussions.
	Question and answer	Same as the discussion area, here with the focus on question towards the instructor.
	Chat	Synchronous communication.
Group-work	GroupWare	An easy to use file management area, for collaborative work.
	BSCW	A more advantaged file and communication management area, for collaborative work.
	Presentation	Presentations and other products can be presented in this part.
Resources	Glossary	Area where concepts can be explained. Relations with other areas can be made clear as well.
	WEB links	Resources: web pages on the WWW
	Multimedia	Resources: to the multimedia database.
	Search	A search centre: within the course environment or the WWW

The options *Newsflash*, *Roster*, *Course information* and *Email centre* were chosen by all instructors and thus are being strongly advised as the basic environment for the new round of courses being tailored during the 1998-99 academic year. The other options were chosen in various combinations by the instructors. Instructors with specific needs could get more tailor-made options. Figure 2 gives an overview of the percentages of the instructors who choose each of the above options. These numbers are based on the first 21 courses, of courses being offered between April 1998 through April 1999.

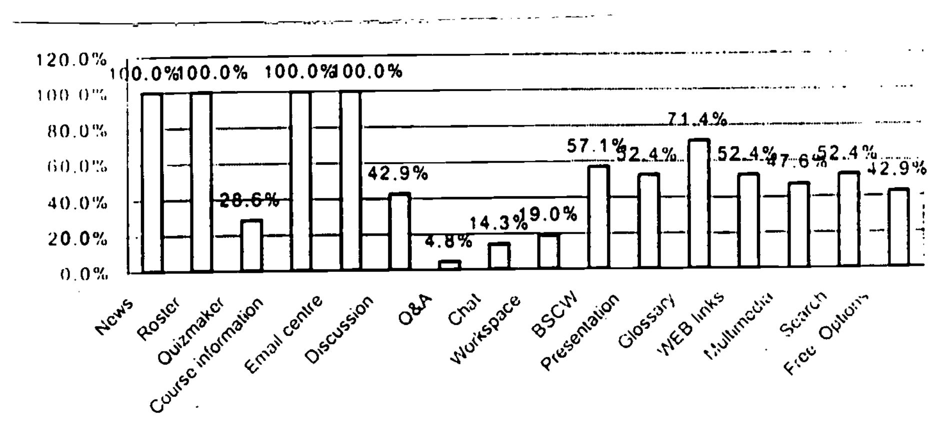

Figure 2. Percentages of instructors choosing various options (N=21).

Using the Course Environment

At the start of the academic year 1998-99 three courses had already used their WWW-based environments and seven courses were ready to start (timetabled in the first trimester). Participating in the courses are not only our regular students but also a new group of students participating mainly at a distance while remaining in the workforce. The latter group of students come one day every two week to thé University for a variety of face-to-face sessions. All the other courses that had been through the rapid-prototyping process were busy organising their environments, while learning from the experiences of their colleagues. Figure 3 is a screen dump of one of the course environments. At the left side of the screen the list of chosen options can be found. This is the menu area. At the right side all information will be displayed. All courses have a similar interface design, but differ in their chosen functionalities.

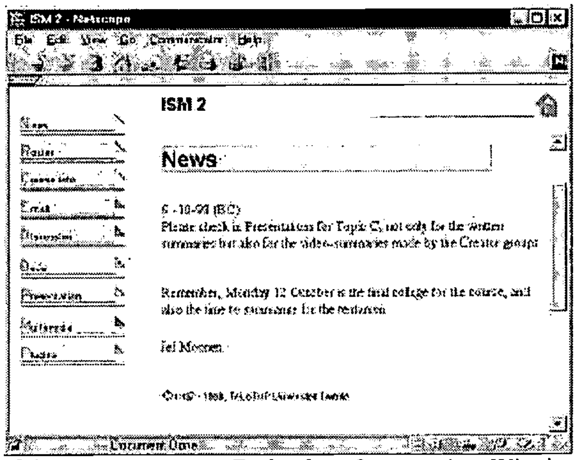

Figure 3. The Home page of the *Instrumentation Technology 2* course (see Winnips, Collis, & Moonen, 1998).

One part of the environment support the on-going organisation of the course. We call this the roster area. All instructors use the matrix-like rosters. This area helps them to place all organisational messages and materials needed before, during and after each contact session. Students can find the self-study materials or instructions in the roster. They can find the lecture notes and sheets and possible follow-up assignments, and can submit their assignments and comments directly via the roster. Instructors do not receive these submissions in their ordinary e-mail. All submitted materials are directly posted in the WWW environment, where the instructor can access them in a systematic way, whenever and wherever he or she chooses. The instructor needs no special software environment or tools; only a normal WWW browser and ordinary Internet access. Figure 4 is an example of such a roster, used in the *Instruction Design Theories* course, 1998 (see also Dijkstra, Collis, & Esryel, 1998).

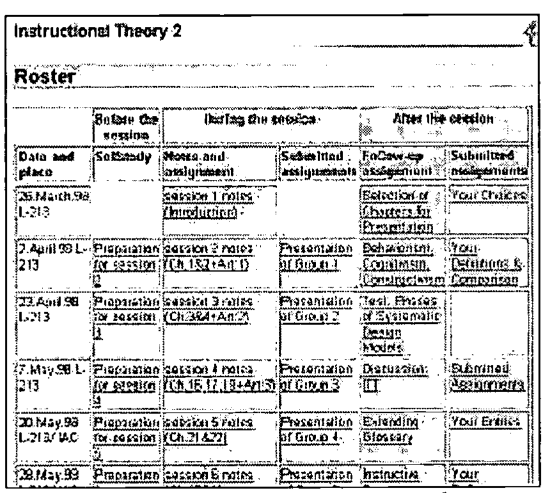

Figure 4. The roster of the *Instruction Design Theories* course

BEST COPY AVAILABLE

Conclusion

The TeleTOP rapid-prototyping approach, supported by two versions of a WWW-based decision-support tool, is a managable and effective way to involve instructors in the re-design of their courses, and at the same time in skill development at handling WWW-based tools and environments. The options chosen by the instructors build upon their existing ways of teaching, but extending these, primarily through opportunities for the students and the instructor to efficiently communicate and for students to add new resources to the course sites as follow-up assignments between face-to-face sessions. We believe this approach, building upon the instructional methods already familiar to the instructor, is a useful strategy particularly when instructors who would normally not consider making use of a WWW environment are involved. The approach also works for instructors already experienced with WWW environments as well. For more information, see http://teletop.edte.utwente.nl

Abstract : *This paper suggests a multimedia educational system which has the ability to extract intelligent instruction on the distributed environment. The proposed system is designed for supporting individual instruction and real time user interaction. As the system based on CORBA, it has ability for distributed computing facilities. Using MHEG standard, we can provide multimedia courseware and real time user interaction. To diagnose students' responses and generate evaluations, we use several linguistic variables and fuzzy theory.*
There are two major advantages for using this system. This system can provide dynamic generation of problems and the ability to provide a dynamic instruction strategy. And it can increase reusability of courseware material for using standard of multimedia representation and communication. We use CORBA and MHEG to overcome the disadvantage of the Web, passive protocol and poor interactivity, HTTP.

1. Introduction

The Web has been spread world wide as a standard of distributing multimedia/hypermedia information. There are many applications, include distance learning, based on the Web. The advantage of using distance learning on the Web is apparent. We can provide instructional information using a hypertext form, the same as students' cognitive structure[Cravener 98]. But there are some disadvantages using the Web: passive protocol and poor interactivity[Bolk and Britton 98]. These problems can be overcome with two models, that could be integrated in WWW. A uniform paradigm to encapsulate and structure web components can be achieved thanks to the OMG's CORBA[OMG 95]. And real time user interaction facilities can be achieved by international standard, MHEG[ISO 95].
Despite the WWW is able to access distributed information and services on Internet, it can not provide individualized information to students[Bolk and Britton 98]. In addition, unlike existing stand-alone ITS, students must have the ability to study freely and search related information easily. Therefore the system must overcome potential disorientation problems that could burden accessibility.
In this paper, we suggest an intelligent multimedia educational system that can make intelligent instruction and individual instruction on distributed environment. Our system can support concurrent learning and dynamic lesson planning for each student by using linguistic variables and fuzzy theory. In addition, our system provides instructional units in which students' response are diagnosed, and compared, thereby allowing dynamic instructional strategies to develop in step with the students' progress.

2. Consideration for Multimedia Educational Systems

In this chapter, we consider major problems for developing multimedia educational system on the Web.

2.1 Problems of the Web as educational infrastructure

Students do not require only delivering information, but learning altogether. The major problem when developing educational system on the Web, is very weak interactivity. For students to learn more effectively, they need a high degree of interaction. But most current Web material is represented as HTML, so the Web today provides only low level interaction[Bolk and Britton 98].

The second problem is poor ability for representing materials. Because the Internet depends on HTML, the materials seem to poorly designed books with hypertext capabilities[Bolk and Britton 98].
To increase interactivities and multimedia facilities, there have been many studies such as Java, CGI, ActiveX, and some extensions of HTML. But these methods are not fit for educational requirements. Most students need individual learning only for themselves. When considering difference among students, this is very important. But the Web lacks capabilities for individual learning.

2.2 The MHEG standard

The MHEG standard provides representation of multimedia objects on heterogeneous networked environment[ISO 95]. It can support real time user interaction when presentation. Multimedia information, which encoded by the MHEG standard, is the MHEG object. As using MHEG objects as inherited form in applications, we require an environment to present these objects. The MHEG standard defined such environment as "engine" [ISO 95].
The MHEG-5 standard is the fifth subset of the MHEG standard. It defines some classes in detail. Those classes are appropriate to some applications such as video on demand, audio on demand, interactive TV and hypermedia navigation [ISO 96].
So, we apply MHEG, the standard of multimedia information representation, when developing multimedia educational system on the Web.

3. System Design

In this chapter, we design multimedia system that has intelligent educational capabilities. Figure 1 shows the system configuration.

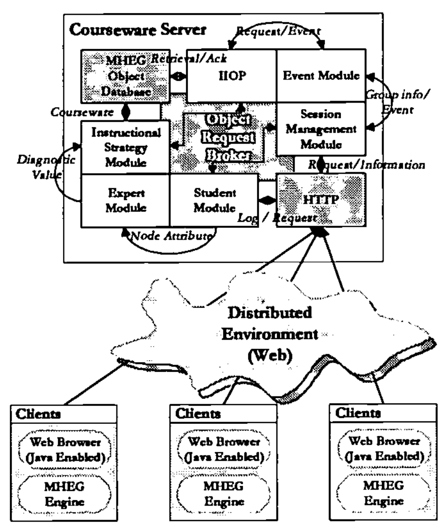

Figure 1. System configuration

When learning, students execute web browser that is able to run Java applet. Through log in process, courseware server sends materials to students in forms of MHEG objects. Client browser, include MHEG engine, presents those materials to them. The system logs student's learning history into student module, and diagnoses them in expert module, and decides student's next course in instructional strategy module.
When students participate in synchronous education program, such as video lecturing, session management module monitors students' activities. Event module processes happened user events, and interact with educational modules include student module.

3.1 Educational Modules

Educational modules consist of expert module, student module, and instructional strategy module.

3.1.1 Expert module
The domain knowledge will be used in coaching the students, diagnosing possible misconceptions after a student has made an error, and providing appropriate remedial materials. This domain model has dual representation network, the IUN(Instructional Unit Network) and the CN(Conceptual Network).

Within the IUN, each node represents a learning unit, and it includes the theme of units, learning aim, the link of the concepts related to the learning units, the links to the problems, and the links to the subordinate units.
There are two types of the instructional unit. One is the explain unit, the other is the problem unit. The explain unit has instructional materials that have various media types such as text, graphic, still image, sound, and moving picture. The problem unit has two major concept to diagnosing the student's state, difficulty and importance. These concepts are used when lesson planning and gradual instruction objective creating.
The CN is a knowledge network that piles up the knowledge of being contained in subject domain to be learned by the student. The CN is a data structure, which is a set of collected knowledge concerned with the declaring concept of domain knowledge, but independent upon the instructional knowledge. Each node within the CN represents the instructional concept, and the links between the concepts indicate the relationship of them. Using these relations, it is possible to generate problem dynamically, and to diagnose the student's error.
According to environments of the CORBA, expert module can access CORBA ORB to assist easy retrieval of materials, and URL indexing and caching demon to improve performance of system.
Unlike existing stand-alone ITS, user verification have to be supported so as to provide the individual learning according to the rate of each student.

3.1.2 Student module

The instructional strategy module uses the diagnostic result generated by student module in order to inference the basis for determination of learning progress, supplying advice, and selecting comments. In this paper, the student module is based on the overlay model. The diagnostic results of the student, problem type, and examples are saved at nodes in the student knowledge network. And the form of student knowledge network represents the learning path.
When the domain knowledge expert constructs the IUN and the CN by means of authoring interface, the two networks contain slots represented by linguistic variables for holding importance and difficulty that are the attributes of each problem and instructional unit.
The linguistic variables about the problem are used for diagnosing student's response. Using the linguistic variables, the domain expert can input at more user-friend environment because of being able to use linguistic variable and no need to decide special real number for attributes of all learning elements. The linguistic variable is the kernel of fuzzy theory that makes use of the fuzzy representation of human being in computer. Using the concentration and dilation in the fuzzy theory, we can define the function that diagnoses the student's current knowledge
The author can change the membership functions upon "Good", "Medium", and "Bad", and the diagnostic results can also vary according to the membership function applied. Hence, the author can control the diagnostic results by changing these three membership functions.
Normalization is defined as follows: suppose that all problem is correct, then, calculate the DV and divide into the result of calculation about correct answer. If the importance and the difficulty are applied at the same time to the same problem, select one that minimizes the membership degree and applies it.
To use more various values for representing the importance or the difficulty, we must consider modifiers applicable to the linguistic variables
regardless of its number of repetition. Hence, the inconsistency of diagnostic result caused by repeated applications of the modifier is removed. For example, "Easy" is never less than "Very Easy" in spite of the number of "Little" modifier's applications.
The calculation result by DV function for the diagnosis of student's response is a real number that ranges between zero and one. To execute fuzzy inference using linguistic variable, result obtained by the DV function has to be fuzzified. Fuzzified result is one of the linguistic variable that consists of Good, Medium, Bad, and the modifier $[Very]^*$, $[Less]^*$.
If we fuzzify the diagnostic results into the linguistic variables, then they can be used together with the inference rules using the linguistic variables.
If the author input the inference rule and there was conflicting among those rules, that is, different result is input at the same condition, the author is presented the condition and is asked what result should be used. The result of learning, whether well or poor, is determined according to what deterministic variable is input by the author. This shows that the author's intention can be reflected to inference rule.

3.1.3 Instructional strategy module

The instructional strategy module mediates and develops the learning of the students through the planning of a curriculum to order the domain knowledge that must be supplied to students, and the planning of teaching to decide the presentation method, re-planning to construct proper planning and monitor the action of students.
Among the contents of a lesson which are taught to the students, the total contents of a lesson are composed of the network of the main objectives of instructions that are relatively independent each other.
Lesson plan presents the evaluation problem and the instructional material of instructional unit, decided by the

curriculum planning to students in the proper level. The Instructional strategy module offers students the instructional material on the instruction unit and the evaluation problem by means of the method divided by the curriculum planning.
The gradual instruction objective must be created by considering the student level that has acquired the degree of difficulty of instruction unit and students' records obtained previously. For an efficient instruction, problem presentation order must be planned dynamically by according to the students' level. The instructional strategy module can create dynamically the problem about the concept learning and the discrimination learning using the CN. Also instructional strategy module can dynamically limit the number of links which the student can select, according to the level of each student. This module have functions which provide the students for advice when the students refer the irrelevant to the present learning content frequently or when disorientation problem occurs.

3.2 Activity Managing Modules

In this section, we design session managing module for providing time dependent group activities for synchronous learning/training. Table 2 defines operations for it.

Table 2 Synchronous learning/training operations

Operations	Functions
Basic Operations	Create Group
	Destroy Group
Group Management Operations	Join Group
	Leave Group
	Manage Applications
	Manage Time Event
	Control Token
	Manage Group Context
Data Transmission Operation	Support Unicast/Multicast
Information Management Operation	Manage and Retrieve User/Group Information

Figure 3 stands out session managing module configuration.

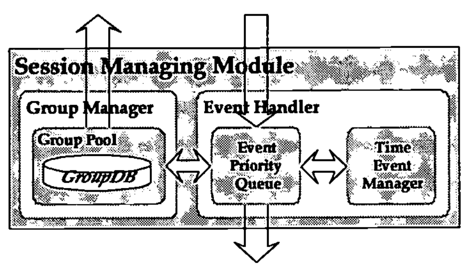

Figure 3. Sesssion Managing Module

Group manager creates groups as response for user requests, and manages them into group pool. Events caused at each group are sent to event handler, and processed using group managing interface.

3.2.1 Event Handler

Information sent to event handler consists of event data and consumer information. This information is managed as FIFO structure. Time event manager provides time dependent group activities. The creator can set lifetime of group, in this case, a group whose lifetime ended closed automatically. This facility is usable when lecturing has time dependency in educational system.
Time event manager manages information per group unit. Time event service process time event defined by user. When predefined event caused, it send it to group manager.

3.2.2 Group Manager

Group manager manages group context that consists of students information, operates for interaction among students. Group context includes student information who participate group currently, lecturer's information. Group manager maintains context recently processed event. When new event, such as participate and leave, caused context switching to appropriate context. When context switching caused, it notifies students of that case using event handler.

User can play a role of "Group Member" or "Inspector" and lecturer has a "Group Chairman" role. Lecturer as group creator has some privileges. Lecturer can give roles to students, close group oppressively, modify and manage group information.
A student must own token when transmit data to other students. When a lecturer requires token, group manager give token to lecturer immediately. But when a student asks token, group manager sends that request to the lecturer and then the lecturer arranges that. During context switching, such as changing token owner, participate or leave, group manager sends that to event manager.
Group manager provides "SendMessageToAll" operation when a student sends message to all participants. Session manager invokes it and group manager sends real data consists of student identifier and message contents using event handler.

3.3 MHEG Engine on Client Side

In this section, we design MHEG engine that can support real time user interaction and standard multimedia representation. Figure 4 shows the MHEG engine configuration.

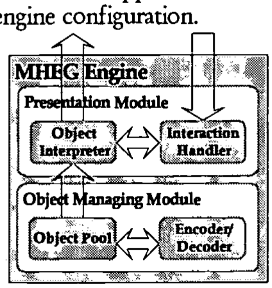

Figure 4 MHEG engine on client side

The engine consists of object managing module and presentation manager. The encoder and the decoder are based on class library. The class library serves converting between runtime objects and the MHEG objects. The presentation manager includes object interpreter and the interaction handler.

3.3.1 Object Managing Module

In our class library, we define the base class to inherit subclass. The MH5Object class, the base class, has method that can encode and decode one BER(Basic Encoding Rule) item. Each member variable of the MH5Object class is mapped into octets of the BER. The MH5Object class has methods for processing octets. It decodes the BER items, and provides decoded information to child classes. It also encodes information, which child classes specify, to the BER.
The root class is parent class of all other MHEG classes. The root class has an identifier of the application class. The group class includes the action object that must be executed after the MHEG application activated. Users can decode the application object by invoking member method. During encoding of the application object, we must add the BER lengths of lower level objects to length octet of higher level object. Thus, we need two encoding phases.
The scene class group defines the ingredient classes activated simultaneously. Unlike the application class, the scene class includes member variables that are required for presentation such as position and size. But, encoding and decoding of the scene object is same as them of application class.

3.3.2 Presentation Manager

The object interpreter analyzes internal object from decoder, converts them to object lists, and then stores in the object pool. The internal object from decoder is a tree-like structure whose root is the application class. The object handler extracts behaviors of presentable objects, and relocates objects.
When the object interpreter converts objects, we use temporal and spatial information. Since objects are relocated in accordance with spatial information, spatial synchronization and simple temporal synchronization in list structure are accomplished. The object pool contains lists of internal objects.
The purpose of interaction classes, such as hypertext, entry field, button, and slider, is supporting interaction with users. The interaction handler gathers and processes user inputs and events from presentable objects. The interaction handler analyzes transmitted events, and selects action objects. After that, it analyzes those action objects, and sends appropriate messages to message handling routine. Each interaction requires an action that selects certain object or modifies one or more objects.
All input has theirs own type in accordance with the interaction classes. The interaction classes are divided into real-time interaction classes and non real-time interaction classes. Table 3 shows types of user input for each MHEG-5 user interaction class.

BEST COPY AVAILABLE

Table 3 Types of user input

Class	User Input	Data Type	Processing Type
Hypertext	Select/not	Boolean	real-time
Entry Field	Text String	String	non real-time
Push Button	Click/ Not	Boolean	real-time
Radio Button	Press/Release	Boolean	non real-time
Hot Spot	X, Y Position	Integer pair	real-time/ non real-time
Slider	Value	Integer	real-time

Link class consists of link condition and link effect. Link condition is a condition that invokes a link operation. It can be a combination of other conditions. Link effect is an action list that is executed when a link operates. Link effect consists of event source and event data. Event data is a user interaction class that causes an event for link operation. The interaction handler compares event data to user input. If this comparison returns true, the interaction handler executes actions specified in defined condition. Link effect is to be an elementary action or action list. Action list can include an action list. In case of this, action size, the whole size of action list, is required. Action targets, which are modified or selected by each action, are also required.

4. Conclusion and Future Work

We design multimedia system that has intelligent education capabilities on the Web. Our system has several advantages than legacy systems on the Web. We provide individual learning facilities using linguistic variables and fuzzy logic. And we provide more interactivities using MHEG standard. We can distribute educational system on the Web using CORBA. Our system is flexible for distance learning and training that requires more specific and dedicated user interaction.
Of course, We consider introduce XML to our system for multimedia representation on the Web. It accomplished, we can provide more generalized education features on the Web.

Abstract: A performance support system provides a mechanism by which human skill levels within a particular task domain can be improved. This paper discusses the growing importance of distributed performance support systems and their use within the context of creating a 'learning organisation'. The design and development of a distributed performance support system called 'CLASS' is described. Its use as a performance tool is then compared with conventional approaches to aid provision within the context of creating supportive environments to facilitate the use of computer-assisted learning within an organisational framework.

1. Introduction

In their day to day activities, human beings are often required to perform a wide range of different tasks and jobs. These tasks vary quite considerably in their complexity. The successful execution of many of the more complex tasks often requires the use of some sort of tool, aiding facility or performance support system (PSS). The basic rationale underlying the use of a PSS is that individuals or groups of people (working together on a common project) are provided with appropriate tools and techniques to support the tasks that they have to perform. According to Barker and Hudson (1998), four major objectives of a performance support system are: (1) to achieve increases in productivity; (2) to improve the overall quality of task/job execution; (3) to improve the overall quality of the environments in which people work; and (4), from a human perspective, to reduce the complexity of the processes involved in executing a task.

Simple examples of performance support tools include: a typewriter, a telephone, a bicycle and an automobile. Increasingly, computer-based resources are being used to implement performance support systems. An electronic performance support system (EPSS) is therefore a facility which uses various types of computer technology to realise each of the four previously listed objectives within a given working environment or problem solving domain. Software packages such as word-processing systems and spreadsheets provide a good example of computer-based performance support systems.

Naturally, a fundamental requirement of an EPSS is that it should increase its users' on-the-job performance within a given task domain. This usually involves improving skill levels, reducing task complexity and/or providing appropriate training. These requirements can be achieved in two basic ways. First, through the provision of 'automation aids'; and, second, by providing various mechanisms to support 'on-the-job', 'just-in-time' (JIT) training which will enable users of any given system to 'learn as they do'. This latter requirement is an important aspect of building a 'learning organisation' (Lassey, 1998).

According to Malhotra (1996), a learning organisation is one which has *'an ingrained philosophy for anticipating, reacting and responding to change, complexity and uncertainty'*. Because organisations must adapt dynamically to the forces generated by change agents, ongoing learning and training activities are a fundamental requirement to their success. As has been discussed elsewhere (Gery, 1991; Beacham, 1998; Barker, van Schaik and Hudson, 1998), performance support systems are one way of realising this requirement within an organisational context.

Many of the early developments in EPSS have been described by Gery (1991), McGraw (1994), Varnadoe and Barron (1994), Raybould (1995), Banerji (1995) and Barker (1995a). Currently, there are two important directions of development for EPSS facilities. First, the creation of integrated toolsets that are able to meet the performance support needs of particular application domains (Barker and Hudson, 1998; Hudson, 1998); and second, a growing requirement to facilitate group working at a distance through the incorporation of network technology and the principles of distributred computing environments (Beacham, 1998). Indeed, the advent of relatively low-cost network technologies and the widespread availability of facilities such as the Internet and the World Wide Web has meant that performance support systems can now become highly distributed in nature - that is, different components can reside (or be replicated) at, and be accessed from, different geographical locations.

As far as this paper is concerned, we therefore regard a distributed performance support system (DPSS) as an integrated and globally accessible collection of electronic tools and data that can be used (as and when required) at particular points of need (within a workgroup or an organisation) in order to improve human performance within a given task domain. Because of their future importance as a resource for developing learning organisations, the remainder of this paper describes and discusses the evolution and future potential utility of distributed performance support systems. The design and construction of a single-site, multiple-server distributed performance support facility called CLASS ('Computer Learning and Support System') is then described and an outline is given of some the ways in which we have been using it. An attempt has been made to measure the potential utility of the system from the perspective of supporting its end-users' use of computer-assisted learning (CAL) packages. The findings from this work are briefly reviewed.

2. Case Study - The CLASS Facility

This section of the paper briefly discusses the background to the DPSS work that we have recently been undertaking. The implementation of the CLASS facility is then outlined. Finally, a description is given of the ways in which we have been using CLASS to support computer-assisted learning (CAL) and computer-based training (CBT) within the context of a learning organisation.

2.1 Background

Some of our early work in developing EPSS facilities has been described by Banerji (1995) and Barker (1995a; 1995b). Banerji showed how the performance of students using a file transfer program (kermit) could be improved through the provision of PC-based, online help and interactive aiding and training facilities. Similarly, Barker (1995b) has shown how the emerging principles of performance support can be used to apply EPSS techniques to the design and development of integrated support tools for use by students and staff in an academic setting within a university environment. Each of these applications involved the development of stand-alone EPSS tools. Our first attempt at building a distributed performance support system involved using a computer network system (the Internet) in order to access different forms of subject expertise that resided at different geographical locations (Barker, Richards and Banerji, 1994). This work has recently been extended and enhanced through the use of 'mobile computing' environments (Barker, 1996)

Many of the presently available distributed performance support systems that are now in use have evolved from conventional stand-alone EPSS facilities (such as those described above) in two basic ways. First, by providing 'dial-in' access; second, by implementing systems that can be shared in an in-house fashion through the use of local area networks. Current research in this area now seeks to incorporate activities of this sort within a more holistic approach that also involves the utilisation of global trans-world networks such as the Internet and World Wide Web.

In an attempt to rationalise activity in this area, we have proposed a DPSS taxonomy that incorporates two basic classification dimensions: first, the number of information servers that are involved; and second, the number of interlinked sites that make up the network topology. These dimensions permit a basic, four-class taxonomy to be proposed (Beacham, 1998). The classes within this taxonomy are: single-site, single-server; multiple-site, single-server; single-site, multiple-server; and multiple-site, multiple-server. The CLASS facility, that is described in the following section, is an example of a single-site, multiple-server system.

2.2 Implementing CLASS

The development of CLASS took place in three stages. The first stage involved conducting a needs analysis. Subsequently, in the second stage, a prototype system was built which was used for formative evaluation purposes. In the third stage, the prototype system was augmented and expanded into an operational DPSS. The needs analysis and implementation rationale are briefly described below.

The Needs Analysis

The needs analysis was undertaken within the School of Business and Management (SBM) at the University of Teesside in the UK. Its main aims were: (1) to identify the main limitations (if any) of current course provision within the SBM; and (2) to explore how CAL and PSS techniques might be used to make any improvements that were thought to be necessary. Both staff (teaching, research and administrative) and student (full-time and part-time) perspectives were studied using questionnaire-based techniques. In some situations, 'follow up' interviews were conducted in order to clarify issues that were not clear or in order to obtain more information about particular aspects of the study.

The results of the SBM needs analysis were compared with two other related surveys (one internal and one external) in order to look for similarities and trends. The internal (campus-wide) study was conducted by the University of Teesside's Library and Information Service (as part of its forward planning activities). The external survey was obtained from another UK university. As is discussed elsewhere (Beacham, 1998), the findings from both of these other surveys supported many of the findings of the SBM needs analysis.

Implementation Rationale

The findings from the needs analysis were used to 'steer' the design of the CLASS facility and also set priorities with respect to the order in which computer-based resources and online facilities were created and made available. As was mentioned above, the initial design and development strategy involved building a prototype system. This was based on the use of an in-house intranet facility and incorporated a virtual university metaphor (Barker, 1999). This allowed staff and students to use virtual offices, a virtual library and virtual classrooms. HTML (Version 4) was used as the development language and Netscape Navigator (Version 4) was used as the access and delivery vehicle. Extended interactivity within the system was achieved through the use of CGI scripting techniques, JavaScript and Java applets. Appropriate use was also made of 'helper' applications (primarily for Microsoft's PowerPoint, Word and Excel packages) and Netscape 'plug-

2.3 Using CLASS for Performance Support

This section of the paper briefly describes the main ways in which the CLASS facility has been used to support teaching, learning and administration activities within the SBM at the University of Teesside.

Once an intranet facility had been created within the SBM it became possible to use it to store, retrieve, deliver and maintain virtually all course-related documentation. By dispensing with 'paper' and providing electronic access to these materials through computer terminals, the productivity of staff and students increased substantially - in terms of ease of access to course-related information and the ease with which this could be modified and updated.

The basic rationale underlying our use of CLASS for the support of teaching and learning activities is similar to that outlined by Barker et al (1995) in their description of the use of a global performance support system for students and staff. However, the CLASS system goes much further, in that, it embeds a virtual university metaphor and allows various approaches to both synchronous and asynchronous teaching and learning activities. Some of the facilities that CLASS contains, or provides access to, include: online lecture notes; copies of lecture presentations (PowerPoint); problems and worked solutions; course-related CAL/CBT packages; details of project work; tutorial and workshop descriptions; email facilities; class schedules; conferencing facilities; electronic notice-boards; automatic marking of certain types of submitted work; and automated student self-assessment of progress. Although CLASS is by no means in its final form, the feedback that we have received with respects to its acceptance and utility provides significant motivation for its ongoing development. This feedback is discussed in the following section.

3. Evaluating Class

An extensive evaluation of the CLASS facility has been undertaken. Details of this are presented elsewhere (Beacham, 1998). This section of the paper provides an overview of the methods used and the results obtained.

3.1 Methodology

A four-step evaluation strategy was used. This involved assessing both staff's and students' attitudes towards four different approaches to the provision of support to facilitate the teaching and learning of a particular topic ***X*** within a given module ***Y*** of a degree course ***Z***. The four situations that were considered were: (1) minimal support; (2) conventional support with 'add-on' CAL; (3) conventional support with 'ownership' of CAL; and (4) the use of a DPSS. In case (1), a CAL package was used to teach the topic (X); no lectures were given and tutorials were organised in an ad-hoc basis, as and when they were needed. Case (2) involved a conventional teaching situation (with scheduled lectures and tutorials on topic X) with students using the CAL package as an 'add on' extra. Resource-wise, case (3) was similar to case (2) but involved re-organising the way in which the CAL package was used; in this approach the CAL program was used (by the lecturer) as a central resource (for demonstration and illustration purposes within lectures, tutorials and workshops) and by students (for the support of self-study activities). Case (4) was the same as case (3) but with the addition of a purpose-built DPSS facility (CLASS) to augment the course Z (in general) and the teaching of the module Y and topic X (in particular).

In each of the evaluation scenarios described above, questionnaires were used in order to obtain the opinions of staff and students with respect to pedagogic, technical, logistic, organisational and resource-based issues. Some of the results that were obtained are summarised in the following section.

3.2 Results

As was mentioned above, four basic evaluation scenarios were employed. These were used to gather feedback about the different types of support environment (for using CAL packages) and, in particular, the potential utility of the CLASS facility as a support mechanism for teaching and learning within an organisational context. Based on the various types of questionnaire that were employed in the evaluation, a set of six 'derived' attributes were identified as a basis for comparing the different modes of support. The six attributes that were used are listed in (Tab. 1) along with the attribute values that have been derived from the questionnaire data. Overall, 330 student volunteers participated in the evaluation process. All students were involved in studying the topic of '*Marginal Costing*' as part of a degree module entitled '*Introduction to Financial Decision Making*' (the total enrolment for this course at the time the evaluations were conducted was 549). The distribution of students over the different evaluation scenarios listed in (Tab. 1) was as follows: Case 1 (61); Case 2 (183); Case 3 (43); and Case 4 (43). Some members of staff also participated in two of the evaluation scenarios (Cases 3 and 4). However, the data derived from the staff questionnaires is not included in (Tab. 1); this is presented and discussed elsewhere (Beacham, 1998).

Attribute Assessed	Case 1 (Minimal)	Case 2 (Add-on)	Case 3 (Ownership)	Case 4 (CLASS)
Knowledge of topic after using CBL package	Low	Moderate	Very Low	High
Like using the CBL package	Very Low	Low	High	High
Factors limiting use (difficulty with package)	Low	Low	High	Very Low
CBL package easy to use	Low	Very Low	High	High
Environment contains features that are helpful	Very Low	Low	High	Very High
The range of sources available for practice	Very Low	Low	Low	High

Table 1: Summary of Evaluation Results

3.3 Discussion

As might be expected, the results shown in (Tab. 1) clearly reflect the apparent superiority of Cases 3 and 4 over Cases 1 and 2. Undoubtedly, this arises because the 'ownership' model of CAL usage and the integrated holistic approach provided by a DPSS (CLASS) each embed much richer teaching and learning strategies. Having said this, inspection of the results in row 1 of (Tab. 1) suggests that the topic knowledge transferred by CAL techniques using Case 3 seems to be less than that which takes place in Cases 1 and 2. This is indeed surprising since we would have anticipated that the knowledge transfer achieved using this approach to CAL package utilisation would be comparable with that observed in Case 4. We believe one possible reason for this anomaly is that the high level of knowledge transfer that took place in lectures and tutorials (using the 'ownership' model) reduced the need for students to make additional use of the CAL package themselves as a self-study resource.

As can be seen from (Tab. 1), the only approach which scores positively in all six attributes is Case 4. These results reflect that students felt that there were particular benefits to be gained by embedding a CAL package within the CLASS facility; namely, it was easier to use, it reduced the amount of difficulty experienced and provided a large number of sources from which to obtain information and practice skills. Bearing this in mind, we believe that these findings make a sound case for the more extensive use of the DPSS approach to the provision of aiding and support facilities.

4. Conclusion

Computers and electronic communications technologies are increasingly being used to provide mechanisms for the support of training, teaching and learning. These technologies make it possible to augment conventional approaches to instruction and, more importantly, provide mechanisms to facilitate 'education on demand' in a variety of different situations and contexts - such as, in the home, in the workplace, in libraries and in colleges. They also provide facilities for developing new approaches to skill and knowledge acquisition in the workplace through techniques such as 'on-the-job' learning and 'just-in-time' training. Within the context of creating 'learning organisations', an integrated, holistic approach to the provision of access to teaching/learning resources is now needed. We believe that this requirement can be fulfilled through the provision of distributed performance support systems similar to the CLASS facility that has been described in this paper.

Abstract: DVEs, along with the Internet in general, offer a number of attractive features for the education sector. However deployment in traditional educational environments, such as secondary schools, has not been achieved on a noticeable scale so far. In this contribution, we discuss technical and pedagogical issues, and specifically define possible scenarios of how this technology can be introduced to the school sector in a sustainable way.

Introduction

An accelerating factor in the use of the Information and Communication Technologies (ICT) is the recent advances in the fields of multimedia and telematics applications. Multimedia and telematics comprise the hard core of ICT. Multimedia can be considered as the combination of any two or more different media types (text, graphics, images, audio, and video). Furthermore, hypertext and hypermedia technology uses hyperlinks in order to represent in a structured way information that could be in various media types. This technology gives the user the ability to explore the information in a non-linear format that changes dynamically according to the user's choices. Additionally, virtual reality applications offer 3D interactive environments that can simulate real-life events and have great potential for educational purposes.

On the pedagogical side, new learning methods arise from the use of multimedia and telematics applications. These methods focus on the learner and allow an active, creative construction of his/her knowledge. New pedagogical models exploiting the potential of these technologies are emerging and new information or knowledge sources are now at the learner's fingertips. Informal access to knowledge through museums, science centres, libraries or browsing on the Internet is playing an increasing role in the learning process, but its impact is far from being understood. On the content side, the subject matters as the learning goals themselves are rapidly changing. On the software side, software agent technology enhances learning by providing intelligent assistance to learners in situations where direct manipulation interfaces are insufficient. Virtual reality techniques reduce the cognitive load in the use of some applications and thereby improve learning efficiency.

Today, most countries consider multimedia and telematics technologies as an educational tool and are trying to incorporate them actively in their curricula. The main concept is that the use of these technologies can significantly contribute to the educational process, supporting in parallel the role of the teacher.

Furthermore, many pedagogues have stated that multimedia and telematics applications could improve the quality of the offered education, because they can simulate many basic models of the learning process and the natural proceeding in which man assimilates knowledge. In particular, telematics technologies can simulate the learning by exploring and the incidental learning, while they could be used for the immediate access of learning materials and the collaboration among students.

Distributed Virtual Environments

A simple definition of a Virtual Environment (VE) is a computer-generated simulation, and the term usually implies the use of 3D computer graphics in the interface. VEs can in addition be multi-user, supporting multiple interacting users, and distributed, running on several computers connected by a network. It has become common to refer to a VE with both these additional properties as a DVE (Distributed Virtual Environment). A Distributed Virtual Environment (DVE) allows a group of geographically separated users to interact in real time. The environment in which a DVE user is immersed is three-dimensional to the eye and ear. Moving in the environment changes the userš visual and auditory perspective. Unlike a video conferencing system (where an attendeeš screen shows other attendees in their own video-conferencing rooms), DVE users assemble in a virtual world - they are all seen, for example, seated together around a conference table in one room, or walking together in a virtual building. Every user of a DVE appears in the computer environment as an avatar - either a customised graphical representation, a video of the user, or some combination of both -, which he or she controls. The user, besides interacting with one another, also deals with one or more computer simulations. While in use, a DVE can change continually, in every aspect. Further, a DVE can grow dynamically by accepting contributions of objects and structures from many sources. On one hand, interactivity is a basic requirement of all virtual environments. On the other hand, distributed virtual worlds require a certain level of persistence to achieve the impression of a single shared world. Persistence is realised by distributing and synchronising user input as well as user independent behaviour.

The role of DVEs in education

Implementations of DVEs, along with the Internet in general, offer a number of attractive features for the education sector:

- They may have cross-platform compatibility.
- Software for creating DVEs content can be downloaded for free.
- As some DVEs sit upon the World Wide Web, existing student knowledge is applicable, easing use.
- Pupils are used to DVEs from popular games, and expect immersion from innovative computer applications.

DVEs in education can be used in various ways but the most promising ones are either as mediums for education and research or as collaborative mediums.

As a medium for education & research

DVEs are being proposed as a means to facilitate both teaching and research in the educational sector. Indeed this is the most obvious role for DVEs. Three-dimensional content can be created and distributed to oneš own students, or made more widely available to learners across the globe. There are plenty of obvious applications for educational simulators in a number of fields: physics, planetary exploration, archaeology, biology, and chemistry all can benefit greatly from better visualisation technologies. The point of these systems is not necessarily the amount of things that can be done with them but the fact that students can have the power to create them on their own and can find it fun and motivating to do so. Any textbook or course materials that have 3-D graphics, such as architecture and engineering, may benefit from DVEs. If the course materials, or the research papers, require multiple drawing of a 3D object or space, then clearly DVEs will give benefits.

As a collaborative medium

One of the longer-term opportunities, but possibly the most exciting, lies in the educational use of the shared spaces for distance teaching and project collaboration. The communicative worlds, similar to those described above, would allow for students and stuff to engage in distributed meetings, seminars and tutorials. A number of trials using these existing technologies are being tried.

Collaborative virtual environments provide gathering grounds for new communities and types of interactions, and they give people a voice like they have never had before. We can share experiences and visions and learn to understand the other persons point of view. We can attend concerts, act in plays, and attend classes with an international audience. As long as people have something to say to somebody else, they can say it online.

Virtual European School

VES is a European project in the Educational Multimedia Sector, aiming to build up a comprehensive resource on teaching and learning material for secondary schools (pupils 10-19). The offer of the final VES system (ready in February 2000) will contain multimedia material, CBT products, and also additional background materials, such as passages from schoolbooks, or Internet resources. A major strength of VES is that a large consortium of educational publishers supports it. Over 20 publishers from 4 countries participate in VES providing content and designing the system in such a way, that VES fits into the working process of publishing houses. Therefore a smooth work-flow for delivery of material is guaranteed, and VES has the potential to become in short time one of the primary providers of on-line material in the major participating countries, that is Austria, Italy and Greece. However, in order to become a successful system, VES not only needs to fit the needs of publishers, but also the needs of its end-users, that is pupils and teachers in their role as multipliers. In order to integrate schools in the design process, VES has established a continuous feedback process in each of the three VES countries. In each country a regional school-network is collaborating with VES. Ideas are brought to the schools for evaluation and feedback is integrated into the design process. VES will be turned into a commercial system in the beginning of 2000. Billing and Copyright issues need to be implemented in a sustainable way. These topics will be essential for the success of the exploitation strategy of VES.

Deployment scenarios of DVEs within VES

Pedagogical issues

Using innovative technologies, VES aims to support new ways of learning. Providing students an access to the whole base of learning material gives them the opportunity to become more autonomous in their learning process. Students will no longer rely on only one source of information, but will be able to compare different sources and find additional information on their subject.

A typical example could be a DVE discussion platform on the various parliamentary systems in Europe. The DVE environment could provide the data, but the pupils can discuss on which voting or representation rules seem the most effective and democratic ones. For younger pupils a DVE on different climates throughout Europe would be more appropriate. A teacher can be present in such an environment, monitoring the cross-national discussions, and intervening only on specific open questions.

The key feature in these applications is immersion. DVEs can give a three-dimensional realistic view of an environment or situation. Therefore navigating within a DVE, learning is an active, explorative process. Views of the environment are individual, since persons are located in different positions in the environment

Scenarios of usage

Using DVEs in education encounters several obstacles. First and most important the limited bandwidth with which most schools are connected to the information infrastructure. However also more soft facts, as the missing of VR content, and the very limited experience of teachers with this sort of technology, need to be taken in account, when one designs a learning platform based on DVEs.

Within VES this problem was tackled, by defining several strategies, how to introduce DVEs to the target groups. More specifically there are three main scenarios envisaged:

- DVEs as Web site entry and navigation tool: A DVE used as main VES user interface, which leads, through objects allocated into that world, to other VES functionalities, such as search, compose or retrieve

content. These functionalities in a first development step can be traditional functions (chat, newsgroup, search, etc.).
- DVEs as learning units: VES will contain many individual learning units from different content providers. Some of those learning units could be DVEs, as fixed virtual worlds where objects in those worlds could be linked to specific content objects (such as texts, videos, and simulations). Further of course in such environments VR objects are envisaged. Participants can interact with objects, and gain access to the relevant learning units.
- DVEs as general content user interface: As a third development step, it is planned to provide a DVE tool set to teachers, containing several model worlds and a database of 3D objects to be allocated into these worlds by the teachers.

In sequel we present these scenarios in more detail.

DVEs as Web site entry and navigation tool

The Virtual Learning Centre represents an attempt to build a learning environment combining real life situations, educational principles, virtual reality features and WWW technology features. The development scenario foresees, that in a first stage the Centre, will be merely an entry point to traditional functionalities, such as search, browse content etc. in a two dimensional interface.

However the aim is to evolve this entry point to a fully functional Virtual Learning Centre. Within this Centre the participant will have access through familiar objects to typical functions. One example abstraction that we use for representing the stored material of the VES system is a building of an exhibition centre, where publishers have their own place to display their educational products. The centre is organised in halls, or thematic units. Each hall is organised around a learning subject, like natural sciences, art and culture, technology, foreign languages and others. Furthermore, each hall that represents a specific subject is divided in rooms, where each room represents a different learning age.

Every room of the centre offers different material, but the structure of the room is the same for all. In every room, there are kiosks that represent the publishers that put material in the VES system. Every publisher has its own kiosk in every room, where it displays the material that belongs to him. In the kiosks there are entities that represent the content material of that publisher. For example, a user can go to a kiosk, select a book, open it, see the metadata information about it that is stored in the database of the VES system and if he is interested in this item then he can view or download the relative content unit. There is physical representation of the most recently added items in the database, while the older items are inserted in a list, which the user can browse and select to view any of these. In this way there is no need to have physical representation for every content unit that is stored.

Having this hierarchical structure, the DVE environment becomes very easy for the user to navigate in it and find the material that he wants. In addition, the user can get used to the virtual environment after some visits and not get lost in it. Every room of the centre is a separate small file of a virtual world, reducing thus downloads times, and the user can go from one room to another through appropriate portals.

The Virtual Learning Centre comprises a number of other spaces characterised by function. There is an information centre where the user can get available information about the environment, the rooms and how to get there, latest news and others. Furthermore, there exist a conference room where predefined lectures, presentations, seminars and other events take place. As the VES system expands there will be and other rooms with specific functionality.

DVEs as learning units

DVEs are not at all common in the educational sector, and especially educational publishers have hardly any experience in this field. Building a comprehensive resource on learning material, based on VR techniques, is currently not feasible.

In the case of content production, it is possible to circumvent this problem by starting to develop single DVE content units, where a clear educational added value can be seen, and where content providers (in the case of VES publishers) are sustained by VR specialists in the creation of such worlds.

In the VES context these worlds are planned to be non-populated, but rather targeted at immersion properties of DVEs. An example could be the simulation of sewage treatment plant, where all the work cycles are shown, and the reaction of the system is simulated when different mechanism are being used. Limiting the DVEs to this scope not only facilitates the production and technical issues, but also gives a controllable way for teachers not used to this technology to adopt virtual environments in classroom teaching.

Within VES this development step is certainly not seen as an end-point, but rather as a first step towards deployment in school use. Once teachers, as multipliers get acquainted with this novel form of content, more interactive and open environments will be inserted.

DVEs made from collections of building blocks

The most advanced scenario, in terms of user integration is the one of DVEs as general content user interface. In this case it is envisaged that all content is allocated into virtual worlds. The working scheme would foresee that publishers and VR experts create an abundant database of basic DVEs and base objects, which can populate the environments.

An example of such a unit could be a VR timeline. The time-line indicating the years (or centuries) would present the basic DVE, while the base objects would be for example figures (e.g. an image of Napoleon), scenes and movies (a short video on life-style during French revolution period), but also more basic objects as dictionaries, notice boards, etc. Teachers would then take the empty world and populate it with the objects suiting their needs, associating to the base objects functions defined by them.

A user analysis performed within the project VES has shown that this deployment of DVEs is currently not sustainable in most educational settings. Therefore it is necessary to start out with the less advanced scenarios, in order to acquaint teachers to the new technology.

Design Issues

The design of a Virtual Learning Environment can be based on the idea of an exhibition centre, where the educational material is organised hierarchically according to a universal or subject-specific classification scheme for educational content. The exhibition centre is organised in thematic halls," each of them organised around a learning subject, such as mathematics, science, geography, art and culture, foreign languages, etc. Each thematic hall"representing a specific learning subject is further divided into rooms representing the subdivisions of each subject according to the classification scheme. Moreover, at the bottom level of the hierarchy there exist rooms representing educational content for different learning ages.

In order to have a user-friendly, integrated, and interactive user interface, the 3D environment of the Virtual Learning Environment can be combined with several HTML frames, each of them having its own functionality. Thus, one frame is used for embedding the Virtual Learning Environment, another is used for displaying status messages to the user and the rest display a console of buttons for interaction with the Virtual World. For example, there always exists a plan view representing the current users position at the Virtual Learning Environment and facilitating the navigation through different rooms. Also, the user can switch viewpoints, take predefined paths, or view certain simulations of specific tasks in the world. Finally, the content units that the user selects to view are displayed in a separate window so that the main console is always visible, avoiding in this way continuous back and forward actions.

Implementation Issues

An approach is to use VRML for the implementation of the Virtual Learning Environment. VRML is an acronym for the Virtual Reality Modelling Language. The aim of VRML is to bring to the Internet the advantages of 3D spaces, known as VRML worlds whether they comprise environments or single objects. The ISO/IEC 14772-1 international standard specifies the current version VRML 97. VRML offers a number of attractive features for presenting educational material including ease of use and cross-platform compatibility.

Another approach for the implementation of the Virtual Learning Environment is to use Superscapes VRT, which is an application for creating 3D environments. The file format of VRT worlds is SVR, which is a compressed binary file that contains all the geometry, textures, sounds and behaviours needed for the interactive 3D world, in a highly compact and encoded form, giving short download times and rapid set-up times. The 3D browser that displays VRT worlds is called Viscape and it is freely available. VRT has also a purpose-built behavioural control language, called Superscape Control Language (SCL) which is based on the C language.

In order to add the capability of, more than one, users accessing the same Virtual Environment at the same time and to create a Distributed Virtual Environment (DVE), a communication platform is needed for performing the interaction between the different users across the network. A DVE provides the users with access to a shared 3D environment. All participants are presented with the illusion of being located in the same place, such as in the same room, building, or terrain. That shared environment represents a common location within which other interactions can take place. The shared environment presents the same characteristics to all the participants. For example, all the participants could get the same sense of the temperature and weather, as well as the acoustics. Additionally, DVEs provides some way of communication between the participants by means of typed text, voice, etc. A DVE system consists of four basic components that work together to provide the sense of immersion among users at different sites. These are a graphic display, communication and control devices, a processing system, and a data network.

The main commercial platform for implementing DVEs from a VRML or a SVR world is the Blaxxun Community Server. The Blaxxun Community Server is a multi-user server that supports the operation, administration and usage tracking of virtual worlds that many users can inhabit simultaneously. It is an open system that supports all the relevant standards: HTML, VRML, Java, vCard, ActiveX, OCX, Direct3D and OpenGL to enable 3D multi-user interaction and it works together with the Blaxxun Community Clients.

Conclusions

The construction of Distributed Virtual Environments should be seen as a design problem in the broadest sense. VR projects with an educational remit should recall at all times the criteria of educational effectiveness. The drawbacks as well as the advantages of various aspects should be evaluated, including the effects of concretising information, of appropriateness of spatial metaphors and of the interface. Regarding shared worlds, they should be investigated to support distance tutoring and research, but with caution to ensure that the social grouping effect of actual meeting is not lost.

Abstract: Our aim is to describe and illustrate a theoretically based approach to the design of collaborative distance learning environments for complex domains. There is an obvious growth in the use of distributed, online learning environments. There is evidence to suggest that collaborative learning environments can be effective, especially when using advanced technology to support learning in and about complex domains. There is also an extensive body of research literature in the areas of situated cognition and problem-based learning that provides a theoretical perspective for the design of such learning environments. What is lacking is a clear articulation of design principles to guide the implementation of collaborative distance learning environments. We provide a description of such design principles, explicitly drawing on a socially-situated view of problem-based learning in technology-mediated environments. We conclude with a description of how this framework can be applied to the design of system dynamics based learning environments.

Introduction

Technology-based learning environments are growing in number and prevalence in spite of continuing debates in the academic literature with regard to their learning-effectiveness, impacts on organizations, and overall utility to society (Carter 1997, Clark 1994, Kozma 1994, Lengel 1997). There are many investigations into how people might learn using new technologies, and these studies are, in turn, causing much discussion with regard to foundational issues in learning theory and instructional design. One challenge is to make effective use of new technologies to support learning and instruction. It is our hope to provide a design framework for technology-mediated learning environments. This framework has implications for designing learning environments for complex systems. We proceed by briefly identifying and reviewing relevant theoretical perspectives. We then establish a unifying perspective with clear design implications in the context of these theories. This unifying perspective will then be used to describe our framework. We conclude with an illustration of the framework.

Theoretical Perspective

We begin by identifying relevant assumptions: (1) learning is a natural, human activity; (2) the unit of analysis for learning effectiveness is an individual human learner; and, (3) learners are rational. The prevalent research perspective is that instructional design is primarily a prescriptive enterprise forming a bridge between descriptive learning research and practical development of learning environments (Reigeluth 1983).

There is practical value in adopting this research perspective. By varying the instructional methods used in certain conditions, one can measure outcomes and study the effects of those methods on learning outcomes. If enough data is collected, one then hopes to be able to establish a strong argument for the desirability of a particular method given certain learning conditions, thus prescribing how one ought to design instruction to achieve desired outcomes. In this perspective, it is possible to identify how various types of learners engage in this process and then to take those differences into account in the design of instruction. Learners are rational in the sense that they are goal-driven, purposeful agents with the ability to identify and select reasonably efficient means to achieve goals. Typically, conditions are held constant and various interventions (instructional methods instantiated in particular learning environments) are investigated. Learning outcomes or effects are then measured on individuals.

Such a research paradigm has in fact produced many useful findings, so it should not be discounted. We refer to this as the atomistic perspective because it is characterized by an atomistic view of learning, both in terms of units of learning (very specific and discrete conditions, methods, and outcomes) and in terms of learners (typically focusing on individual learners). The atomistic perspective can be contrasted with what we call the integrated perspective (Spector 1995). The integrated perspective views learning as holistic and learners as members of a society or language community. The goals of a society or language community typically include a strong survival element, although this is quite often not made explicit. Living consists of working and learning, which are viewed as essentially collaborative efforts to achieve commonly held goals. From this perspective, individuals might manage to acquire extremely high levels of performance at particular tasks while the larger social group consistently falters. This would not count as effective learning from an integrated perspective.

Complex Domains

Complex systems can be depicted as a collection of inter-related items (e.g., stocks and flows in system dynamics), characterized by internal feedback mechanisms, nonlinearities, delays, and uncertainties (Sterman 1994). These systems typically exhibit dynamic behavior, especially in the sense that how they behave has an effect on the structure of the system, perhaps strengthening or changing the feedback mechanisms. This change in internal structure in turn has consequences for how the system will behave in the future (Davidsen 1994, 1996). Such complexity is difficult to understand, especially for newcomers to a complex domain.

Complex systems can be found in abundance at many different levels. Economics, ecology, epidemiology, project management, and training all typically involve complex, dynamic systems. People have difficulty in understanding and making good decisions about such systems (Dörner 1996). There are clearly individual exceptions, persons who somehow acquire a deep understanding of such systems. Typically, such deep understanding, characterized by effective decision making across a wide variety of changing conditions, takes years to acquire, and appears not to be easily acquired in spite of concentrated education and training efforts (Dreyfus & Dreyfus 1986). Why have we failed to improve our thinking skills in complex domains in spite of such persistent and serious efforts? In part, we have not fully understood relevant psychological and sociological factors. In part, we have not fully integrated relevant principles about human learning into design praxis.

People have difficulty in estimating the effects of accumulation over time, in predicting the effects of delays, and in calculating nonlinear outcomes (Sterman 1994). People tend to focus on local problems as opposed to whole systems, even when told that a holistic understanding is essential for solving particular problems. People become cynical and overlook possible solutions when initial attempts fail. People do not communicate effectively in crisis situations. People have difficulty inferring underlying system structures from externally viewed system behaviors (Dörner 1996).

We believe that instructional scientists have not fully understood the socially-situated learning perspective and its implications for human learning in and about complex systems. There is a great deal of discussion about situated, problem-based, and collaborative learning, but we are missing critical pieces of a design framework. Put differently, we believe that we lack a well-articulated design framework with sufficient detail to take us from a socially-situated, problem-based, collaborative learning perspective to the design of a particular learning environment for a particular subject domain. The closest such approach we find is cognitive apprenticeship (Collins 1991). We regard our work as an extension to that approach.

Situated Learning and Vygotsky's Cultural-historical Theory

The theoretical foundations for this effort come primarily from a socially-situated learning perspective (Lave 1988, Piaget 1970, Vygotsky 1978). Within this perspective, learning is viewed as an active process of knowledge construction in which learners are typically involved with other learners in authentic, problem-solving situations. The need to learn created by a realistic problem provides motivation, and interaction with other similarly immersed learners provides facilitation. We are favorably inclined to an attitude similar to Sfard's (1998) that emphasizes the need for both an acquisition metaphor (static knowledge objects with learners acquiring expertise) and a participation metaphor (dynamic knowledge objects with learners as active apprentices). Much higher order learning relies on knowledge and associated learning activities that might best be supported within the acquisition view. However, to progress beyond competent performance and become a proficient expert (Dreyfus & Dreyfus 1986), we believe that the participation metaphor with its emphasis on active learner participation in socially-situated and problem-oriented settings is crucial.

For Vygotsky (1978), human mental functions appear first as inter-individual and later as intra-individual. This process involves the use of socially developed tools. For Vygotsky, the unit of analysis for human activity and for human learning was the mediated action of an individual. This broadens the unit of analysis identified earlier from just the individual to include an artifact with which an individual interacts. Davydov (1988) developed a psychological theory of learning activity which focused on goal-oriented, collaborations within a social context. From this perspective, the aim of a learning activity is to teach study skills that enable learners to think on their own.

Collaborative Learning

Collaborative learning is based on the notions of *socially shared cognition* (Resnick, Levine & Teasley 1991), of *distributed cognition* (Salomon 1993), and of *jointly accomplished performance* (Pea 1993). In the latter, cognitive development is viewed as occurring though interactions between students, as well as between students and knowledgeable environments. Collaborative telelearning emphasizes collaborative interactions among students and between students and supporting actors in a distance learning environment (Wasson & Bourdeau 1998). Introducing collaboration into a telelearning situation raises new challenges related to the logistics and to the logistical support of collaboration. The majority of research into collaborative learning has focused on collaboration between physically present actors and has generally focused on whether and under what circumstances collaborative learning was more effective than individual learning. More recent efforts, however, have been directed towards a more process-oriented account of collaboration where the focus is on the role that variables such as group size, group composition, and communication paradigm play in mediating interactions. This is a clear indication that the unit of analysis has been appropriately enlarged beyond the individual learner.

We have now collected several design principles which form key features of a design framework, and we have shown their linkage to learning theory. These principles might be summarized as follows:

1. Provide support for the joint construction of knowledge objects and for the joint construction of problem solutions. This can be accomplished by providing learner-extensible databases, by providing learner-modifiable simulation models, by supporting learner-learner and learner-tutor collaboration in making changes and extensions to existing knowledge objects, and by supporting learner-learner and learner-tutor reflection on outcomes of those modifications.
2. Provide tools to support joint negotiation of alternatives. Commenting tools are a beginning. Allowing changes to be tested when appropriate is also important. It is especially important to allow learners to try out alternative simulation models, to observe results, and to support learner-learner and learner-tutor discussion and analysis of those results.
3. Provide both public and private feedback support mechanisms for learners while emphasizing to those intelligent agents providing feedback that it is important for learners to gradually improve their own ability to monitor and assess progress toward desired goals.

In short, this framework aims to support both individual work and collaborative activities, and it especially aims to support the development of collaborative learning communities.

Computer Supported Collaborative Learning (CSCL) & Telelearning

The important implications for CSCL that emerge from these theoretical foundations include a wide range of designs for computer-based learning environments, as well as the view that the computer is a mediating tool that needs to be seen in the context of the entire learning environment within which it will be used. That context includes the instructional setting, the presence or absence of a teacher, the role of teachers and tutors, the role of the learner and other learners, the curriculum, the organizational setting, etc.). Much contemporary research that falls under the umbrella term socio-cultural theory (e.g., Collins 1991) has been inspired by Vygotsky and his followers. CSCL requires thoughtful and careful design of learning scenarios and learning support. CSCL also requires technological design encompassing the telelearning environment configuration as well as the tools and services available.

The term *telelearning* is used to designate new forms of distance or of computer mediated learning, where the distance is not only distance in space or time, as in traditional distance learning, but distance in terms of culture and community, as well as distance in the mediation of learning activities and knowledge objects (Wasson & Bourdeau 1998). Distance learning evolved from an initial need to ensure equal access to education for all students. The most obvious feature of a distance learning setting is that students and teachers do not all meet at the same place or at the same time. Individual learning, individual tutoring and asynchronous communication are typical features of a distance learning situation, requiring extensive macro- and micro-instructional design, and a strong student support system. Variations of telelearning presence need to be taken into consideration, including the sense of telepresence in a virtual meeting, the sense of telepresence in interactions with rich multimedia environments, and the sense of telepresence in extensive human collaborations with online knowledge objects and virtual worlds (e.g., online microworlds).

A Design Framework for Collaborative Learning Environments

A relevant paradigm for the design of these learning environments can be found in the computer supported collaborative learning (CSCL) literature (Koschmann 1996). This paradigm focuses on the use of information and communications technology as a mediating tool within a collaborative framework (e.g., peer learning and tutoring, reciprocal teaching, project- or problem-based learning, simulations, games) of learning. This particular approach emphasizes an understanding of language, culture and other aspects of the social setting and can be traced in part to a socially-situated perspective of learning, as we have already indicated. While some suggest that these theories are not compatible, we suggest that they in fact provide an excellent theoretical framework for the design of online collaborative learning environments, especially for complex domains. The common and unifying notion of situated or shared cognition emphasizes the larger environment within which learning takes place; learning is viewed in part as entering into a *community of practice* with a shared language and understanding. The problem of establishing such a community of practice in distributed and online settings is a critical design aspect that has been poorly understood and not especially well implemented in practice.

The design methodology that we advocate is based on cognitive apprenticeship (Collins 1991), providing more learner support and facilitation for less experienced learners and gradually fading support and facilitation for more experienced learners. The learning setting is telelearning, as previously described. The overall learning approach is collaborative in nature, consistent with the theoretical foundations cited earlier. The specific view of collaboration is that tasks and activities should be realistically arranged and mediated in ways that naturally involve and recognize particular interests and skills of learners (Salomon 1993). That is to say that the collaborations should not be artificially enforced and that the sense of collaboration from the learner's perspective should be such that collaboration is viewed as necessary in order to complete the desired goals. In the marine bio-diversity example, students work in small groups of two and three and rely heavily on the assistance of graduate assistants and teachers to check their work. Nevertheless, they understand the significance of the activities in which they are engaged and recognize their contributions as valued and significant.

We conclude with an example to illustrate this theoretical framework. As we have already said, we do not believe that any large-scale, commercial learning environment has been designed with a systemic view of learning according to a theoretical perspective such as that presented here. Figure 1 is drawn from a learning environment designed according to this framework. Several such learning environments have been constructed and some data pertaining to learning effectiveness has been accumulated. That data suggest that this approach does promote learning and has been reported elsewhere (Spector 1998).

Exemplifying the Framework

We have thus far identified the following elements of an online learning environment for complex domains:

- Provide support for collaborative construction of components;

- Provide tools to support negotiation of alternatives;
- Provide both public and private feedback support mechanisms;
- Provide mechanisms to share and exchange information, objects, views, etc.;
- Facilitate a meaningful division of labor;
- Support joint, online thinking, commentary, etc.;
- Include meaningful learning scenarios;
- Design authentic problems and legitimate cases as the basis for learning activities;
- Take into account the entire learning environment;
- Support mediation among all the participants; and,
- Foster a sense of a collaborative learning community.

Figure 1 shows a screen from one version of a learning environment for resource management in large-scale instructional development projects. This screen shows that learners have multiple views of a complex domain. Consistent with our framework, this environment supports both learner-learner and learner-tutor interactions, as well as learner manipulation and modification of the underlying simulation, after learners have passed beyond the level of advanced beginner in this domain.

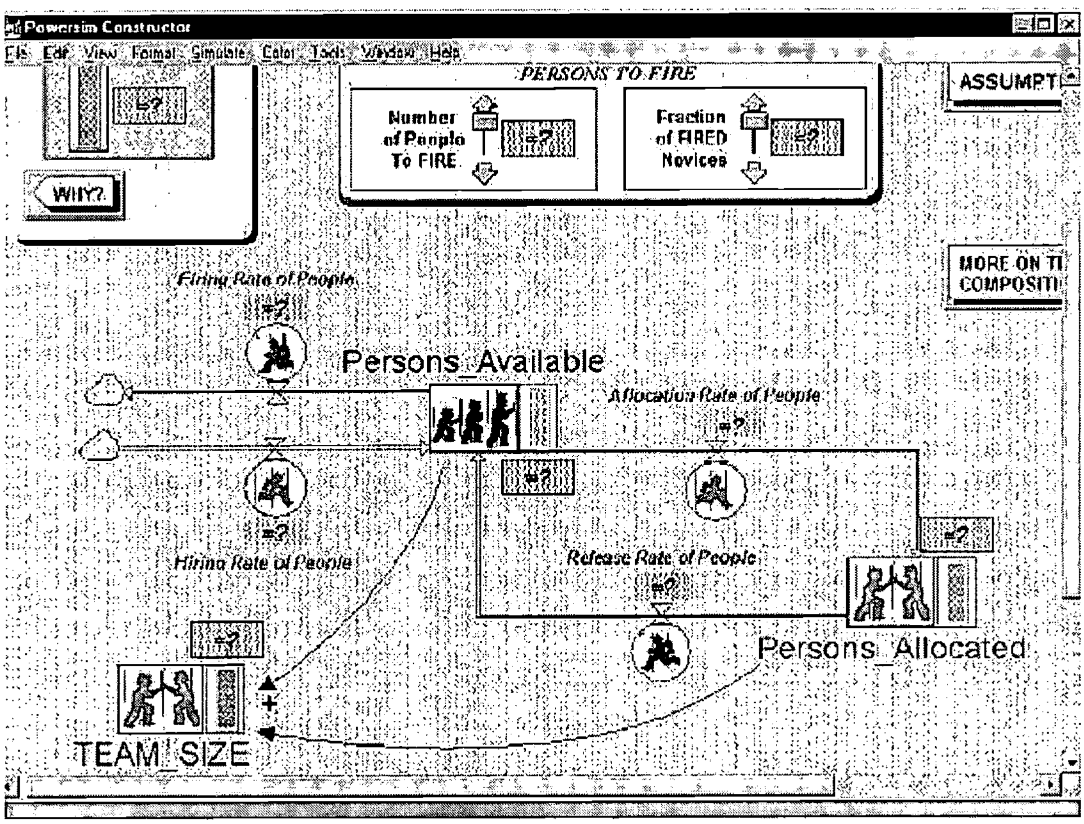

Figure 1: Websim for instructional resource management.

Concluding Remarks

It is premature to argue that this framework will produce significant, long-lasting, and positive learning effects in and about complex systems. Based on existing data collected on our learning environments and from data reported on some of those which adopt similar approaches (Sioutine, Davidsen, & Spector 1998), we believe that there is great promise in designing collaborative telelearning environments from a socially-situated learning perspective with heavy emphasis on collaborative learner participation in the creation and modification of knowledge objects and artifacts. We have been encouraged to learn that the system dynamics community is coming around to the view that it is not generally sufficient to provide only behaviorally oriented feedback about complex systems if one wishes to promote deep understanding of such systems. Learners should be encouraged to engage in model alteration, model construction, and policy and strategy design in a collaborative context if one expects lessons to transfer from the learning environment to real-world settings.

Abstract : Cyber university is a new field that can overcome the limitation of present education criteria. Student can receive learning in anywhere and anytime using information communication infrastructure. But, many researches in field of cyber university concentrate on development of solutions based application level. These solutions lack a flexibility and adaptability to be adapted in various environment of education.
In our research, we propose a framework that is not application level in solution for cyber university. This framework is designed using CORBA that is standard in distributed object middleware. The CORBA based framework can be integrated with other systems easily.
The framework is mainly composed by four components. Course manager maintains all learning materials using workflow concepts. Student manager maintains profile and conditions of learning for each student. Intelligent agent determines learning step and coarse using student's condition dynamically. Session manager maintains group activity between lecture and students.

1. Introduction

In advance of computing power and networking technologies, Many applications are developed by many corporations and institutes. Especially, Cyber university is a new field that can overcome the limitation of present education criteria[Ellis 1998, Dewy 1998, Lee 1997, Barajas 1998, Mittrach 1998]. In Cyber University, students can access training and performance supports via the Internet when and where they need it[Wade 1998]. And, it significantly reduces the cost and time requirements associated with more traditional types of training. Now, many research and solutions are provided for construction of cyber university[Dewey 1998, Lee1997].
But, the structure of cyber university is regarded as very difficult process because of diversity of educational environments. In spite of diversity, almost of solution and researches are concentrated on application level. Application level based solutions lack a flexibility and adaptability to be adapted in various environment of education[Barajas 1998, Mittrach 1998].
We proposed the framework-based solution for cyber university. Because of framework-based solution, the solution presents flexibility and adaptability to construction of cyber university in diverse environment.

2. Requirment for Framework

Cyber university can maintain a lot of learning contents effectively, and present contents to students by fit methods. Also, It is difficult for students to judge own state of learning and to determine subjects for achieve own goal. Because cyber university is less sufficient interaction between instructor and student than real university, functions that must determine student's coarse and monitor learning state are required. System can diagnose of the state of student and satisfaction of content presented to student, and determine learning step and coarse using student's condition dynamically. Also, because they would like to act on participants in group, group activity can supported by system[Manthe1996, Rezende 1995, Solyoll 1996].
Figure 1 describes the essence of education for cyber university. Cyber university allows students to access the

topics they need, when they need them. Students may choose to play entire chapters, or utilize the search function to answer a specific question. System determines the best course which student can approve to own goal using user requirement. After course is determined, system composes user's profile and prepares learning contents for student and presents it them. Then, students would learn learning contents by determined course. Result of learning is used by diagnose process. Diagnoses result is feedback to profiling.

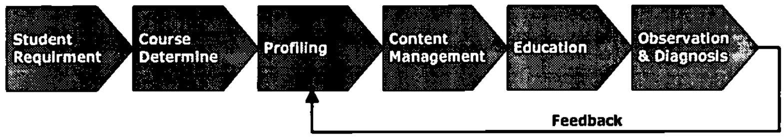

Figure 1. Essence of education for cyber university

- Student Requirements : It is goal which student want to learn through cyber university.
- Course Determine : System determine student's learning course using instructor's knowledge.
- Profiling : It maintains student profile that contains private information with requirement which student want to learn, and topic information which students access.
- Content management : Content management maintains learning contest and provides it to student.
- Education : Students can learn the course and contents decided matching functionality.
- Observation & Diagnosis : The process of learning is monitored continuously and result of student's learning and satisfaction are analyzed and returned feedback to students' profiling.

3. Framework Design

In this paper, we design CORBA based framework for cyber university. The framework is mainly composed by four components and they are designed using CORBA objects. Therefore, this framework is integrated with external application and database. And it is used in heterogenius environment.

3.1 Overview

[Fig. 2] shows overall configuration of cyber university using the CORBA based framework.

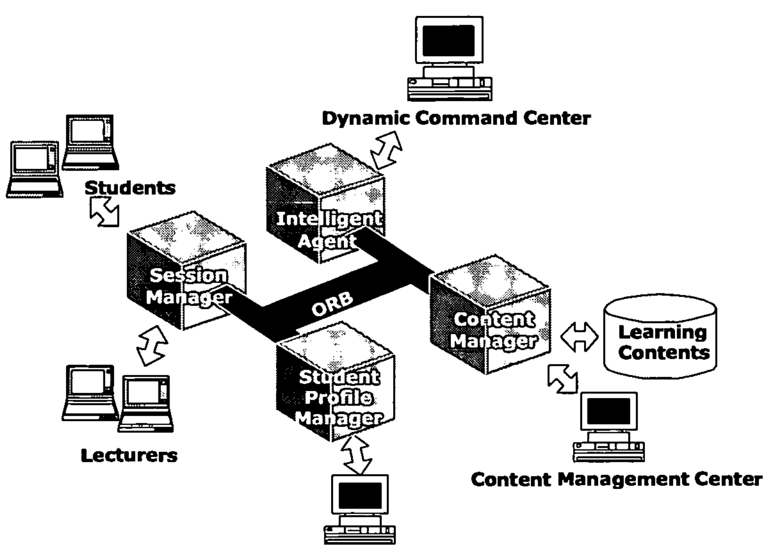

figure 2. CORBA based framework

3.1 Session Manager

In server side, session manager has group managing module and event handler. [Fig. 3] shows architecture of session manager.

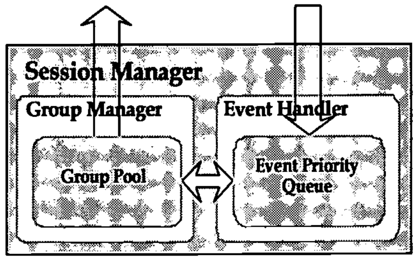

Figure 3: Session manager

Group managing module operates as gateway. It authenticates using information in student profile manager. And it manages group participated by students and lecturer. Event handler processes events that occur in each group. Group managing module creates appropriate group for user requirement, and manages those using group pool. Once event occurs, interaction handler catches that. If it cannot be handled, interaction handler sends it to event handler. Event handler processed that using group managing interfaces. Events handled by event handler require group-related operations such as create, destroy, join, and leave. Table 1 describes operation of Session Manager.

Table 1 Synchronous learning/training operations

Operations	Functions
Basic Operations	Create Group
	Destroy Group
Group Management Operations	Join Group
	Leave Group
	Manage Applications
	Manage Time Event
	Control Token
	Manage Group Context
Data Transmission Operation	Support Unicast/Multicast
Information Management Operation	Manage and Retrieve User/Group Information

3.2 Content Manager

Content manager manages learning contents using workflow concepts. Workflow based data management presents efficient routing of work from person to person or to groups and easy access to pertinent documents. Task is defined students and authors who use contents. Also, Detailed reports of all activities associated with a process. This manager has task manager and flow manager. Author designs the flow and task of learning contents. Task manager and flow manager control the learning content and monitor actions which is performed to contents. Authors and instructors design flow. And course manager maintains components composed in document and relationship among the components. The relationships are made up with update and delete relation. [Fig 4] shows Flow, Task, Task Manager object.

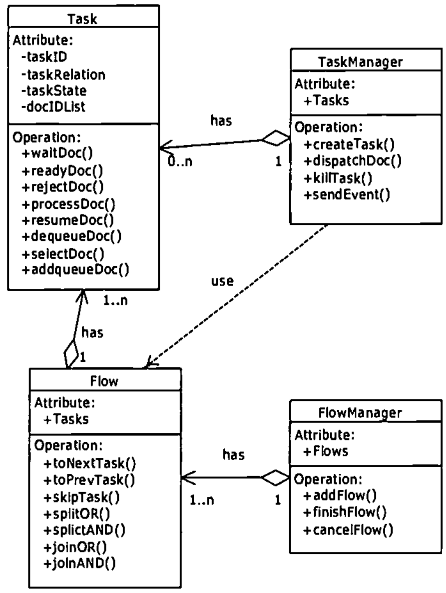

Figure 4. Objects of contet manager

For interface with database management systems, it uses persistence service in Common Object Specification Services (COSS). If we construct cyber university using the framework, this manager is connected to content management center. [Fig. 5] shows Course manager.

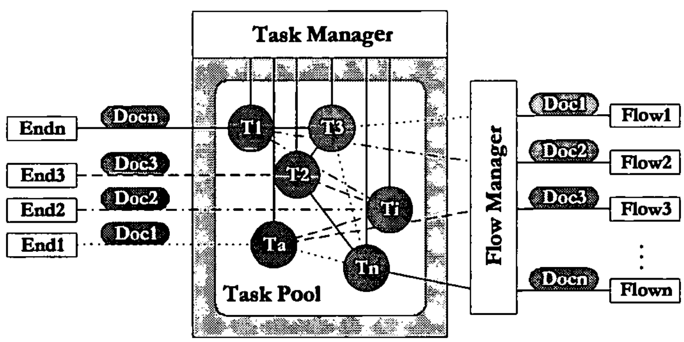

figure 5. Course manager

Content management center helps content professionals-creators, editors and site administrators- manage the full life cycle of content.

3.3 Student Profile Manager

Student profile manager maintains student profile, including student private information, result of learning, learning tendency. Profile manager presents operations described in Table 2.

3.4 Intelligent Agent

Intelligent agent determines student's learning course using requirements. Knowledge base is constructed by instructors. Then, determined result is used for designing process of flow of contents in Content manager. Intelligent agent has extract module and diagnosis module. Extract module extracts parameters for diagnosis of student from result of student's learning and return to diagnosis module. [Fig.6] is IDL(Interface Definition Language) interface for Extraction module.

```
struct Problem_Struct {
        string testNodeID;
        string type;
        string difficulty;
        string correctness;
};
typedef sequence<Problem_Struct> Problem_info;
interface Extraction {
        string Solving_Problem(in User_info user, in Problem_info problem);
        string Learning_Node(in User_info user, in string Next);
}
```

Figure 6. IDL interface for Extraction module

Diagnosis module diagnoses learning state using parameters from extract module. Diagnosed result is used for updating profile information. [Fig.7] is IDL interface for Diagnosis module.

```
struct Condition_Struc{
        User_info user;
        string condition;
};
typedef sequence<Condition_Struct> Condition_info;
interface Diagnosis {
        Condition_info Examine( in string User_input );
}
```

Figure 7. IDL interface for Diagnosis module

4. Conclusion & Future Works

Designed framework has several advantages. It can provide flexible and adaptable solution for construction of cyber university. Learning course is designed automatically using student's requirements and result of learning is analyzed and feedback for the bast fit education can be presented to students. Workflow based content management supports step-by-step education.

Also, because the framework is designed using CORBA objects, system expansion and integration can be done easily. There is an important feature to enhance educational values of this system. Currently, We plan to implement integrated distance learning system that using this framework.

Using the Internet in the Classroom: Variety in the Use of Walden's Paths

Abstract: Walden's Paths provides annotated guided paths over World-Wide Web pages. Designed as an approach for organizing classroom use of contextualized Web-based material, Walden's Paths provides a general mechanism suitable for use in implementing a range of different pedagogical strategies. This paper reports on some of the uses that teachers have made of Walden's Paths. One of the surprises for us in this project has been the range of ways in which Walden's Paths can be used in practice.

Introduction

Over the past three years we have been developing Walden's Paths (Shipman et al. 1997; Furuta et al. 1997; Shipman et al. 1998), software supporting the use of existing Web-based materials in elementary and secondary classrooms. This work has been motivated by the belief that as more information is made available via the Web, that there is a greater potential, and indeed need, for educators to make use of this resource.

The Internet is becoming an intrinsic part of society and the most effective method of distributing many types of information. Because of the relatively low publication cost of the Internet, economic pressures will favor increased use of it for information dissemination. Schools will have to find methods of making use of this resource or ignore a growing amount of content with educational potential. The question should not be whether to use the Internet in the classroom but how.

There are a number of problems with using the Web in the classroom. The Web is an unedited publication media and so there is information that is inaccurate and inappropriate for students. Web materials, when on topic, are most often authored for other purposes than education, leaving students confused due to their lack of vocabulary or context. Finally, browsing Web materials can reduce the student to being a "button presser", navigating from page to page as they might flip from channel to channel on television.

Walden's Paths represents one attempt to ameliorate these difficulties by providing teachers a way to focus student exploration, to add explanation and context to materials, and to integrate the Web resources in the existing classroom environment.

The next section of this paper provides an overview of Walden's Paths' functionality and interface. After this we present examples of how teachers have made use of Walden's Paths within the context of their existing curriculum. This leads to a discussion of issues for the use of Walden's Paths and, more generally, the use of the Web in the classroom.

What is Walden's Paths?

Walden's Paths, named after the paths Thoreau unselfconsciously created through the woods while living at Walden Pond, is a tool that allows teachers to construct guided paths using the information on the Internet. Like Thoreau's trails, guided paths provide structure through an otherwise unstructured environment.

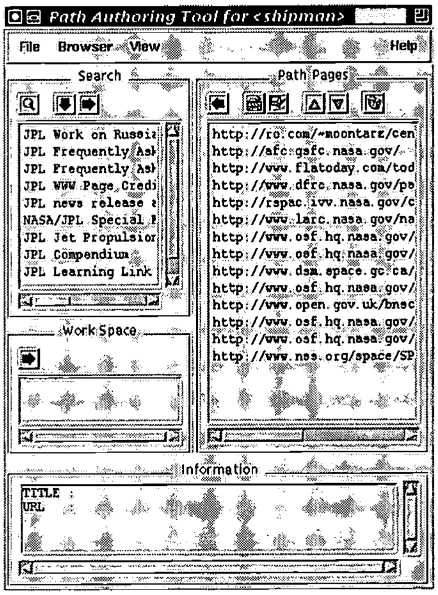

Figure 1: The Path Authoring Tool

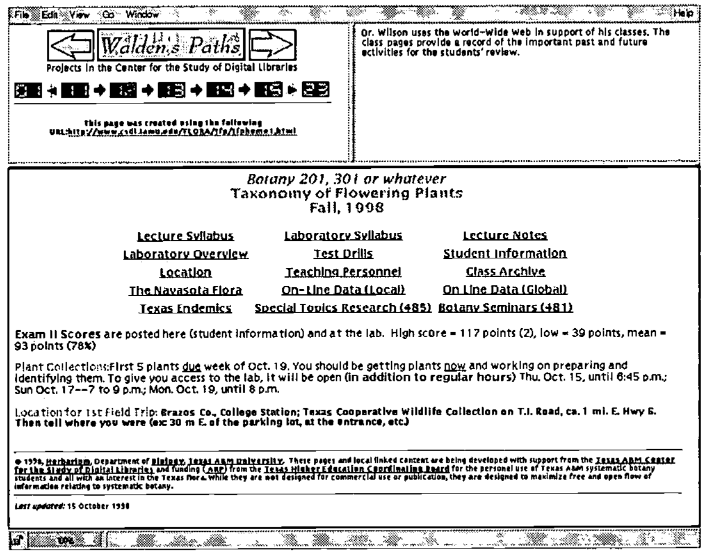

Figure 2: A path page created by the Path Server

The guided path as a concept goes back at least as far as Vannevar Bush's Memex (1945). Paths have been developed in specialized software environments and investigated with limited user communities in the late 1980's (Zellweger 1989; Trigg 1988). Paths in Walden's Paths are an ordering of Web pages with associated annotations. The pages used can be from anywhere on the Internet and their ordering in the path is independent of any existing navigational structure.

Walden's Paths consists of three components, a Path Authoring Tool for creating and editing paths, a Path Database for storing, retrieving, and sharing paths, and a Path Server that provides access to published paths.

The Path Authoring Tool, shown in Figure 1, is a Java-based interface that allows keyword searches for Web materials, the display of those materials in an external browser (e.g. Netscape Navigator), and the selection, ordering, and annotation of pages for the current path. The authoring tool also includes a "Work Space" for storing pages that do not fit into the current path but may be of use in the future.

Authored paths are stored in the Path Database. This database provides each authorized path author with a working area for storing paths. Paths stored here are not visible to the students and may be recovered for editing or continued work. When a path is ready for access by readers (here we are using the term reader instead of student to convey that the person accessing the path is not necessarily a student) it is "published" to the Path Server.

The Path Server is a Common Gateway Interface (CGI) program that creates the list of available paths and their presentation for readers. When a reader requests a path page, the Path Server constructs control-flow and annotation frames to appear at the top of the browser and requests the material from the source site on the Internet to appear in a lower frame (as shown in Figure 2). The reader can use the control-flow controls to step along the path. In addition, the links in the source page remain active. Following any of them takes the reader off the path, as shown in Figure 3. In this mode, further unconstrained browsing is permitted. The reader can return to the path departure point at any time by selecting the "return to path" button in the Walden's Paths navigation area of the display.

Use in the Classroom

The variety of ways in which Walden's Paths has been used to take advantage of Web-based materials in the classroom has been one of the surprises during the project. Our original conception of educational paths was that they would be created by teachers for use in the classroom as a convenient way for collecting widespread materials. We expected that teachers would then use the paths in ways similar to the use of traditional filmstrips—as an enabling way to direct their students' traversal of a sequence of related information items. In use, we discovered that

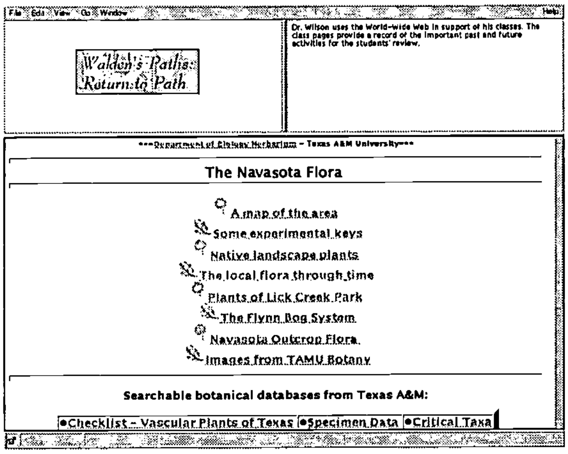

Figure 3: Off the path

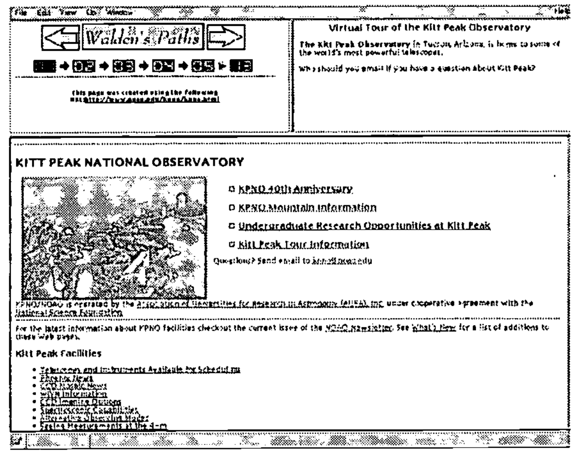

Figure 4: Kitt Peak Observatory path

this, indeed, did occur. However we also discovered that unexpected uses arose as well; uses that reflected a mixture of roles for both the materials and for the students. The following subsections will describe five separate uses of the system by teachers. For privacy reasons we do not identify the specific classrooms involved; some are located in Texas and others on military bases in Germany and Italy.

Embedded Assignments

A middle-school science teacher decided to use the path mechanism to create a virtual tour of the Kitt Peak Observatory. By collecting pages from different Web sites, he created a tour that not only described Kitt Peak, but also compared it to other observatories. A page from this path is shown as Figure 4.

The teacher made much use of the annotation feature of Walden's Paths, helping provide transitions between the information on the different pages and embedding questions for the students to answer on each page. The students, while traversing the path, were asked to answer (on paper) the various questions making use of the information provided on the pages.

The features are most interesting with this use of Walden's Paths are the mixtures of media—electronic and paper—used in achieving the teacher's classroom goals. Here, the teacher has blended Walden's Paths annotation feature with a paper-based assignment to focus and enhance the acquisition of information from the mixture of electronic information resources presented.

Modernizing Existing Practices

In a high school art and art history class, a teacher who had been using slides of paintings and sculptures for reviews and exams decided to use Walden's Paths to improve current teaching practices. Traditionally, during an art history review or exam, the students have to fill out a form as the teachers presents images in a 35mm slide show. Questions on the form might include the artistic period or style of the piece, the artist, defining characteristics of the piece, etc.

One problem with this approach is that each slide is available to the student during a short period of time. The student must quickly write down answers to the questions before the next slide appears. The teacher decided to replace the 35mm slide show with paths of images from on-line museums. In the revised exam each student could spend as much they needed on each image (within the time constraints of the class period).

The interesting feature of this use is the way in which a traditional teaching practice could be adapted and improved using the new medium. The updated solution preserves the familiar characteristics of the original situation while overcoming the technological limitations imposed by the equipment used previously.

Resources for Creative Work

A high-school computer music class teacher used Walden's Paths as a way to identify useful resources to students. Due to the technical nature of the computer music class there were few textbook resources available but much information on the Web.

The students, whose task it was to compose a new piece of music using MIDI, needed both explanatory and reference materials on the equipment and software they were using. The teacher created paths connecting sites with useful information on MIDI to act as a shared bookmark list for the whole class. Thus the teacher created a resource that enabled the use of Web-based materials in support of existing creative/constructive tasks.

The use of Walden's Paths to collect separate resources together to form a convenient package appears to be a common use of the system as we have observed it in other teachers' applications as well. In this use of Walden's Paths, the contextualization of information is not as important as is the coalescing of it in one place.

Class Projects

Another high-school music class used Walden's Paths in support of learning about musicians and music history. The unique aspect of this use is that Walden's Paths became an authoring environment for the students. The students had to form groups, pick topics, and author paths on these topics much like traditional group assignments to write reports on a particular topic.

Topics of paths ranged from specific composers and artists to areas of music (e.g., jazz). The students had to search and browse the Web to locate information on their topic and compose a useful path on the topic. The information selected by students included materials on music history, on the time period and context of the music, biographies of artists, and renditions of specific pieces.

A similar project was carried out in another high-school music class where each student had to suggest one or two pages for a class path on a particular topic. The students had to provide a reason why they thought their suggestion should be included in the path (why the reader would find it useful, or a description of the type of information it provided.) In this case, the teacher acted as a filter on what pages were included in the path.

While such an open-ended project could be given to students in this high-school classroom, there might be difficulties in such an assignment for younger students due to the challenges of locating information on the Web.

Extra-Credit

Another case of students authoring paths came in a high-school art class. In this case, an individual student, who was ahead of her fellow students, was given assignments for authoring paths that could be used by other students. This not only provided the student something creative to do that related to the course curriculum but also provided the teacher with assistance in developing materials for other students.

The positive feelings associated with seeing ones own work available to others helped drive much of the early publication on the Web. The publication of paths can be used as an incentive for students.

Discussion

The experience we gained from applying Walden's Paths in schools suggests some additional observations to us, which perhaps are less-related to the specific characteristics of our technology and more outcomes of Web-based projects in general. In this section, we discuss some of these issues.

Technological and social solutions

Paralleling the observations that we have developed earlier in this paper about incorporation of new technology into existing practices and association with existing artifacts, we were struck by the effectiveness of combined technological-social solutions in resolving technology-introduced issues. A frequent concern expressed to us during the development of the Walden's Paths project have been the issues surrounding identification of appropriate material for use by schoolchildren, particularly those in lower grades. The path allows the selection of suitable materials and the annotation associated with path material permits the teacher to provide contextualization of that material. However, off-path browsing remains unconstrained, as do general browser controls.

Our early assessment of the situation was that the commercial sector was likely to provide technological solutions that would ease this situation through the development of blocking software. To a good degree, this seems to be the case. However, we were impressed by the simplicity and effectiveness of the solution adopted by a middle-school teacher in one of our test sites—rearranging the classroom to place the newly-obtained computers in the center of the room, surrounded by the desks of the students.

Local and global path visibility

Addressing issues relating to intellectual property protection have been among the most interesting, challenging, and persistent topics faced by the Walden's Paths project. As we reported in a previous paper (Shipman et al. 1998), early concerns focused on reader confusion between content and container—between original source material and navigation/annotation material provided by Walden's Paths. We have carried out several redesigns of the reader's interface to make these distinctions stronger; the design shown in this paper's figures is the latest in this process. However, we have come to recognize that an interacting issue is that of path visibility.

Paths have been created for many purposes—to serve as a resource for an individual classroom, to communicate findings from a student to a teacher, to promote a class' efforts to the outside world, and to serve as a guide providing an overview of a Web site or organizational location. Implicit in each of these uses is an expectation of who the appropriate audience will be for the path—an individual, a localized group, or the whole Web. Our current path directory mechanisms do not allow the identification of the intended reader population, providing global access, but not localized access. This leads to confusion both by readers but also by content providers who notice unexpected changes in access patterns as the paths become more widely used.

One of our current project priorities, therefore, is the development of a richer directory implementation that will enable more fine-grained specification of the community of interest for paths. However a more comprehensive solution may require the development of a more flexible model of ownership and location for Web resources.

The Path Server is essentially operating as a proxy server—obtaining requests from clients and redirecting those requests to servers. The TranSend project at U.C. Berkeley (http://transcend.cs.berkeley.edu/), which provides a generally-available proxy service, noted an unexpected side effect of their service, namely the general availability of services site licensed to the Berkeley campus. This was because their proxy service runs inside of Berkeley's domain; special action was required to restrict access to licensed services.

In our current implementation, material is only redirected when on a path (off path material is obtained directly by the client computer and is subject to the restrictions at the client's site). Consequently we have not yet encountered a corresponding situation although the potential exists for a path author to take advantage of our architecture to allow outside access to restricted services. A comprehensive solution here may also involve reexamination of ownership for Web resources.

Conclusions

In this paper, we have described some of the unexpected uses of Walden's Paths that appeared during teacher use. Although we had specific pedagogical goals in mind when we initiated the project (Shipman et al. 1996), our current evaluation is that the tool created is relatively independent of specific pedagogy. Consequently, Walden's Paths can be incorporated into a variety of teaching practices. Furthermore, if specific pedagogical guidelines are to be supported, Walden's Paths provides an appropriate substrate for implementation of authoring filters that encourage following of those guidelines.

Distance Learning, the Internet, and the ADA

Sheryl Burgstahler, Ph. D.
Adjunct Associate Professor, College of Education
University of Washington
United States of America
sherylb@cac.washington.edu
http://weber.u.washington.edu/~sherylb

Abstract: The potential of the Internet to deliver instruction should not be underestimated. However, Internet use raises a number of issues, including equitable access. The Americans with Disabilities Act (ADA) requires that programs in the United States be made accessible to qualified participants with disabilities and the ADA accessibility requirements apply to Internet resources. Distance learning course developers should, therefore, take steps to assure that their courses are accessible to students with a wide range of disabilities. But, what does this mean for a course offered over the Internet? This paper discusses access issues and provides an example of an accessible course that is currently offered via the Internet.

Much has been written about the revolutionary impact that networking technology is having and will continue to have on all levels of education. Multimedia, simulations, real-time communications, interactions with artificial intelligence systems – the list of capabilities seems endless. Distance learning classes, once conducted using postal mail, FAX, and the telephone, are rapidly being converted to Internet-based delivery systems (Driscoll 1998; Garrison 1989; Palloff & Pratt 1999; Stewart 1995). Although the electronic delivery of courses is unlikely to completely replace traditional classroom instruction, this powerful option for the delivery of information and the facilitation of communication should not be ignored or underestimated by institutions of higher education, corporations, and other organizations.

One issue that should be raised when the Internet is used to deliver instruction is that of equitable access. The Americans with Disabilities Act (ADA) of 1990 requires that organizations in the United States that provide programs and services to the public must provide the same programs and services to people with disabilities that they provide to people without disabilities. According to this law, no otherwise qualified individual with a disability shall, solely by reason of his/her disability, be excluded from the participation in, be denied the benefits of, or be subjected to discrimination in program offerings. When people think of the ADA they usually think of accommodations such as elevators in buildings and lifts on busses. But, according to the United States Department of Justice, the ADA accessibility requirements apply to the Internet world also. A 1996 opinion letter ("ADA Accessibility," 1997) states that "Covered entities that use the Internet for communications regarding their programs, goods, or services must be prepared to offer those communications through accessible means as well." Specifically, if you offer a distance learning course via the Internet, to comply with the law, your offering must be made available to students who have disabilities.

Distance learning course developers should take steps to make their courses accessible to students with a wide range of disabilities. They can employ "universal design" principles to assure that their materials are not only accessible to the average student in a class, but to all students who might enroll, including those with disabilities. But, what does this mean for a specific course that you may wish to offer over the Internet? This paper discusses access issues and provides an example of an accessible course that I currently offer via the Internet.

The Students

With the rapid development of adaptive technologies that allow people with a wide range of disabilities to access computers, students with the following characteristics may be attracted to a distance learning class offered over the Internet.

- Trevor is blind. He uses a computer with voice output. Basically, Trevor's computer reads with a synthesized voice whatever text appears on the screen. He uses a text-only browser to navigate the World Wide Web. One of the challenges he faces when he accesses Web sites occurs when graphics appear and there is no text alternative for his voice output system to read. He may just hear "graphic" when a detailed picture of the anatomy of a frog is presented on the screen, "link" when no further descriptive text is provided in the link, and "image map" in place of the beautiful image map with linkable options that sighted visitors see.

- Maggie has low vision. She uses special software to enlarge all screen images. Even with her large monitor, she only sees a small portion of a Web page at a time. She is challenged when pages are cluttered and when the page layout is inconsistent from one page to the next.

- Mark is deaf. The Internet has been a great resource for him since, for the most part, the ability to hear is not required. Lately, however, he is running into more and more multi-media sites with sound clips that are not captioned or transcribed. He becomes totally lost.

- Sarah was an innocent victim in a drive-by shooting. Her brain injury has resulted in impaired fine motor skills. She uses one hand to operate a keyboard and track ball. She finds it difficult to select buttons on the screen when they are very small.

- Ryan, a bright college student, has a learning disability which impacts his ability to read and organize information. He has difficulty understanding Web sites when the information is cluttered and unorganized and when the screen layout changes from page to page.

How can you assure that these students will be able to access a distance learning class that you offer on the Internet? I will share what I have learned in teaching an Internet-based course for three years.

The Course

My *Adaptive Computer Technology* distance learning class (Burgstahler, 1997) is designed for teachers, parents, service providers, and computer lab managers. It is offered for three college credits in both rehabilitative medicine and education through the University of Washington in Seattle. The course surveys the field of adaptive technology as it impacts the lives of people with disabilities, including applications to employment, education, and recreation. Topics include interface devices, computer applications, compensatory tools, access to information technology, legal issues, and implementation strategies.

The electronic mode of delivery is an excellent choice for this course. Because of its specialized nature, few people in one locality are interested in taking it at any specific time. Students have participated from throughout the United States as well as from Canada, Italy, Germany, Japan, Australia, and Hong Kong. Being in the same place at the same time is not a prerequisite for participation. Students who have successfully completed the course include those who have visual and hearing impairments, mobility impairments, and specific learning disabilities. Design features of the course have made it accessible to everyone who has enrolled.

The Instructors

The first time this course was offered I taught it with a co-instructor who is blind and lives in New York. Since his computer is equipped with a screen reader and speech synthesizer, he required no special accommodation as we developed the course. We prepared materials and coordinated lessons via electronic mail. We "met" many times to discuss the progress of the course, but never in person.

The Instruction

Students in the *Adaptive Computer Technology* course purchase textbooks and videotapes before the class begins. They are placed on an electronic distribution list managed by standard ListProcessor software. The distribution list is used to send the syllabus and other course materials to the students. Lessons are distributed over a period of 10-12 weeks, but discussions continue for a total of six months. Students are required to read and respond to electronic mail at least once per week during the time that lessons are distributed. Class participation is required. To keep communications lively and prevent some students from just "lurking," I require each student to contribute at least one comment to each lesson discussion. Once distributed, the lessons are archived on the course World Wide Web site where students and instructors can easily access them.

Textbook reading and videotape viewing assignments are distributed via electronic mail with the weekly lessons. After an assignment is given to read material or watch a videotape presentation, the class discusses the content via the electronic distribution list. Small group discussions break off from full-class discussions from time to time as individuals find common interests with others. Participants also communicate individually with each other and with me via electronic mail. Guest speakers join in class discussions periodically. One regular guest speaker is the author of the course textbook. He lives far away from me and is an adaptive technology user himself. He usually joins the discussion list for two weeks.

In this distance learning course, all assignments are turned in to me via electronic mail. Students share summaries with their classmates via the course distribution list. The first assignment for students in class is to distribute an introductory biography to the class. Some of the required "papers" involve writing on a topic related to the course content using Internet resources, visiting a local facility and evaluating computer access for individuals with disabilities, and making recommendations regarding access to a specific facility or program. When ready, each student requests the final exam via electronic mail. Once it is delivered, he/she has several days in which to complete this essay test and return it to me via electronic mail.

The Accessibility of the Course

For the *Adaptive Computer Technology* course there is no meeting "place." This means that finding an accessible classroom to accommodate students with disabilities is not required. In this course, the primary vehicles for learning are a textbook, videotape, electronic mail, an electronic distribution list and the World Wide Web. Care is taken to assure that each delivery mode is accessible to all learners.

Textbook

The required textbook for this class is available in recorded form for students who are blind or who have specific learning disabilities. Recorded and electronic copies of books can be purchased from Recordings for the Blind and Dyslexic. On most campuses, the Disabled Student Services office can help instructors determine how a specific text can be provided in Braille, on disk, or on tape if such a request is made.

Videotape

Students in the course also purchase, as part of the required course materials, three videotape presentations which demonstrate key concepts covered in the course. Videotapes are open-captioned to make them accessible to deaf students. In addition, students who are blind can purchase them in audio-described format. This special format provides audio descriptions of videotape content that is presented visually.

Electronic Mail and an Electronic Distribution List

Electronic mail is highly accessible to those with disabilities. Media conversion and other customized accommodations are minimized since all participants are required to have access to computers when they enter the class. Whatever adaptive technologies they use facilitate access. For example, a blind student's computer output method (usually a screen reader and voice synthesizer) translates the course material available via electronic mail into an accessible format (e.g., speech). A student who cannot use her hands can command her computer to "turn pages." Similarly, a deaf student does not require interpreters or amplification systems since lectures and discussions occur on-line.

World Wide Web

A World Wide Web page serves as the course "library." Links to useful sites provide students with thousands of pages of resources for their papers, projects, and extended learning. The course Web pages are designed in such a way that people using a wide range of adaptive technologies can access them (Burgstahler, Comden, & Fraser 1997; Dixon 1996; Resmer 1997). Universal design principles are employed to maximize accessibility. They include simplicity, consistency and redundancy. A few key access issues are discussed below. More detailed Web accessibility guidelines can be found on the Web itself. The site maintained by the World Wide Web Consortium, at http://www.w3.org/WAI/, is a good place to start.

Simplicity

To make Web pages accessible, it is important to use a simple page layout. Buttons, navigational links and logos should be in logical places on each page. A simple page is particularly helpful to people who have visual impairments and to those with specific learning disabilities. In addition, large buttons allow for easy access for individuals with limited fine motor skills as they use mice, track balls, and other pointing devices. A high level of contrast between the background and the text on the screen and simple background designs ease access for people who are colorblind or who have low vision. Using universally recognized HTML (Hypertext Markup Language) tags allows all Web browsers to accurately display the content.

Consistency

Maintaining the same page layout from page to page within a Web site makes it more accessible. Buttons, navigational links, and logos should be located in the same places on each page. A consistent page layout makes navigating the site easier for everyone, but particularly for people who have visual impairments and for those with specific learning disabilities.

Redundancy

Some Web users cannot see images or hear sounds because of sensory impairments. Providing content in alternative formats can make information accessible to everyone. For example, blind Web users typically read the text at a Web site by using voice output systems. They do not have access to information presented in graphical form. Therefore, it is important to provide alternate text for each graphic so that those who cannot view the image can access the information it presents. Captions on pictures should be written in such a way that they are meaningful to visitors who cannot see the pictures. If manuscripts are displayed in an image format or video clips are used, text transcription should be provided. Image map choices should be provided in a text-based list in order to assure that the links embedded in the image map are available to those accessing only the text of the page. Tables, frames, forms, databases and special features should be used sparingly. They are difficult or impossible to use by blind students and, thus, require that an alternative format be provided.

Web pages for your distance learning class should be tested with a variety of Web browsers and monitors. One of the browsers used should be text-only, such as Lynx. In addition, a site can be tested for accessibility using "Bobby." Bobby, created at the Center for Applied Special Technology, is an HTML validator program that tests for accessibility and identifies non-standard and incorrect HTML coding. Bobby is located at http://www.cast.org/bobby.

"Way Cool" Technology

In my distance learning course I made a conscious choice to use simple software tools – electronic mail, distribution lists, the World Wide Web. But, what about chat rooms, specialized bulletin board and conferencing software, interactive video and other emerging technologies? When it comes to people with a wide range of disabilities, generally speaking, the simpler the software (e.g., text-based), the easier it is for them to access. For example, real-time chat systems are impossible to use by individuals for whom input and output methods are slow, whereas simple electronic mail is totally accessible. Video and audio interactions require that access barriers for visually or hearing impaired students be overcome. Whatever tools you choose to use, refer back to the descriptions of Trevor, Maggie, Mark, Sarah, and Ryan at the beginning of this paper. Make sure that they can fully participate in your course.

Conclusion

The Internet is a powerful, flexible, and efficient tool for the delivery of instruction. It provides new ways for us to teach and learn. Distance learning courses offered over the Internet attract people from all over the world. Some potential students have disabilities. A course using the Internet can reduce the necessity for special accommodations for students with disabilities, but only if it is designed with access in mind. Employing universal design principles will make your electronic resources accessible to people with disabilities and will also improve the access for people using older, slower technology. With a properly designed course, those with limited abilities to speak, hear, see, or move will not be limited in participation. In fact, your most "vocal" student may not even be able to speak in the traditional way.

Abstract: Based on long experience with educational software, both as developers and users, and with the use of telematics applications in educational settings, a team responsible for the implementation of more-flexible education within the Faculty of Educational Science and Technology at the University of Twente derived a set of requirements integrating technical and pedagogical principles for a WWW-based course-support system for the faculty. These requirements have been realized in a system built by the team and now is use across the faculty. The paper gives the system requirements, an overview of the TeleTOP system as realized to meet the requirements, and some indicators of the accuracy of the requirements based on experiences with the broadscale use of the system.

Introduction

Since the introduction of computers into education, there have been efforts to develop educational software that could replace the instructor. Despite extensive efforts to adequately model the critical variables in the learning process, the results have generally not led to software that has taken over from the instructor, with exceptions for what Draper calls "niche markets" (Draper, 1998). Within traditional higher education, the use of educational software as a replacement for the instructor, the textbook, the laboratory session, or the lecture, has not much occurred, especially at a faculty level where the scale would be large enough to make an impact on curriculum and program delivery. A number of analyses have studied the implementation problem and share the conclusion that the instructor is a critical variable in any use of educational software in school and institutional settings (see Collis, Knezek, Lai, Muyashita, Pelgrum, Plomp, & Sakamoto, 1996, for an international overview).

The availability of the WWW has brought a new wave of interest into the previous educational-software domain, particularly in higher education. However, we see in many cases a repeat of early ideas that accompanied computers in education, in particular the idea that a WWW-based course could provide a replacement for the instructor. The new variation of this is reduction of the instructor to someone who answers e-mails when students have a question. We believe the same problems will confront WWW-based courses as confronted educational courseware: problems related to not being able to anticipate all the sorts of human-human interaction and issues that arise in the regular teaching-learning situations which the good instructor handles based on his or her experience and intuition. That is why we endorse the use of WWW-based applications as tools to empower and extend good teachers, not replace them.

The Teletop Project

Since March of 1994 enthusiastic instructors in the Faculty of Educational Science and Technology of the University of Twente have been using WWW-based environments to support their regular courses (for a review of four year's evolution of one such course, see Collis, 1997). In these courses, the instructor was not less present or less involved with his or her students, but was empowered by the WWW-based tools to do more than before. Based on the experiences of these pioneer instructors, the reactions of the students, and the idea of extending and empowering, not replacing, the good teacher, the adminstration of the Faculty decided in May 1997 to commit substantial resources to the systemic support of change throughout the faculty: all courses to be re-designed to be more flexible and to embody the principle of extending the good instructor. WWW-based tools were to be the major technological instruments, while extensive work with instructors in a new approach to rapid prototyping of WWW-based course-support documents was a parallel emphasis (De Boer & Collis, 1998a,b). This initiative is called the TeleTOP Project. Along with the authors (who are responsible for the project) are five full-time instructional designers supported by the MediaLab of the faculty. Throughout the 1997-98, all of the courses of the first-year as well as a number of other courses have been redesigned, and are now in operation with a double-sized student group (the normal intake, and a new intake of about the same size of professional persons in the workplace wishing to complete a flexible version of our programme, primarily at a distance but coming to the campus one day every two weeks for intensive face-to-face contact with their instructors). Now, during the 1998-99 academic year, the majority of the other courses in the required program will be similarly adapted.

Requirements

While the original examples in the faculty of use of WWW environments to support courses were those of enthusiastic pioneer instructors, the TeleTOP Project has to deal with a more difficult target group: all instructors, including the less-interested, less-motivated, and sceptical, are to be supported in their re-design of their courses and their design of WWW sites to support their courses. Given these two basic aspects--empower, not replace the instructor with technology; and engage all instructors, with a wide variation in computer skills as well as a wide variety of levels of interest in the use of technology in their own teaching--we developed the following set of 12 guiding principles:

1. To make the threshold of use as low as possible for the instructors, the WWW-environments must be usable by the instructors without having to have a special training course and as easily as they handle a word processor. The TeleTOP team realized this principle by developing a database-generated system in which a flexible course-support environment is available to the instructor. The instructor chooses the features he or she desires to support the course, and only has to type into various types of fill-in forms to organize the notes and other material that is to be put into the WWW site.
2. Students also must be able to use the system without instruction, and no more than a small manual. Once they are familiar with the interface of one course-support environment, they have a consistent interface in other courses, reducing the need to learn to handle new environments with each new course. The environments are to be accessed through familar browsers; no new packages to learn, and nothing that requires them to come to the computer laboratory to use.
3. Similarly, the instructor must be able to do everything he or she wishes with the course through an ordinary WWW browser; no special authoring software, no special client. An instructor travelling out of the country can work on his or her course wherever there is access to the Internet via a standard browser. A guest instructor in another country can enter notes and materials directly into the course site, again without any special equipment and without needing to have access to the server. Thus the system should not be a server-client model, whereby the instructor in addition to the Internet browser has to install special software at the client side to get access to the learning environment.
4. By the principle "empowerment of the good instructor", the instructor must be able to choose for him or herself the way that a WWW site will be used to support his or her course. There is no standard pedagogical model that all are expected to follow. With this in mind, the TeleTOP Team developed a WWW-based Decision Support Tool (DST) (see De Boer & Collis, 1998a,b) to help the instructor get a systematic overview of examples of different ways WWW-based tools can be used within the organizational aspects of their courses, the aspects relating to lectures and face-to-face sessions, aspects related to communication with and among students, to the presentation of course-related materials, to file distribution and the addition of resources to the course site. After an interview session with TeleTOP Team members and the DST , the instructors have a more-informed idea of what is possible, and more importantly, what they will find appropriate to use in their own courses. Directly after the use of the DST,

a WWW-based framework of each instructor's new course-support site is available, to be tried out by the instructor via an ordinary browser. We believe the instructor must be the decision maker about the course site, but we know from our experience with authoring systems for instructors, that this principle often does not lead to any use of the authoring system or products made from it. This our approach involves continual contacts with the instructors.

5. We do not see the course-support sites as replacing the textbooks in the courses or making lectures unnecessary. Instead the course-support sites help the instructor add extra opportunities for student reflection, for communication, for student contribution of additional learning resources, for peer interaction and peer evaluation, and to add a "preparation for" and "follow-up from" each face-to-face session. Thus we conceptualize our course-support environments as information-communication exchange environments, that are also coupled with other information systems of the faculty such as the bureau responsible for student issues and administration.

6. The course-support environments must be capable of supporting a large variety of different types of instructional approaches, from courses focused on reading and written assignments with classic final examinations, to courses with complicated approaches to group work and project-based education. Tools to support any instructional approach must be available, including shared workspaces, test banks, and discussion boards.

7. The system must work will all other WWW products, for example Java applets and plug-ins.

8. The instructor must be able to put in and take out whatever is necessary in the course site without needing direct technical support (although we have student assistants who help out). Uploading and downloading attachments of a variety of types is particularly important.

9. The sourse sites must help instructors organize the information streams within a course; instead of student messages coming to the instructor's e-mail address, for example, they can be posted directly into the course site, either as private (only for the instructor to see) or public (for all in the course to see). Feedback from students or the instructor must follow the same principle. Also, there should be easy-to-set-up ways for messages to be sent to a group of students, or all the students in the course, or other groupings within the course, all from the same WWW environment.

10. Access to the system must be organized on the basis of inlog data which are used by the system database to tailor what can be seen and not seen to each individual. Also it must be easy to leave the system and go to an external site on the WWW and then return to the system, without leaving the browser. Privileges must therefore be regulated at the resource-document level, as to who has read and/or write rights to any item in the database. The author of an item should be able to decide him- or herself who has rights to a submitted item.

11. The system must be efficient to maintain, thus no labor-intensive hand-made HTML pages, but pages generated dynamically out of a database.

12. The system must handle multimedia resources the same as text resources. Video and audio must be streamed over the bandwidths available to the students.

Realizing the requirements: The TeleTOP sytem

On the basis of our prior experiences, a detailed market research of available course-support systems, participation in an international evaluation of several such systems, we came to the conclusion that none of the commercial products we studied met all of our requirements, even those still in the advertisement stage. We needed to proceed quickly; we realized our own system that meets all the requirements listed above. Fig. 1 on the next page shows the basic architecture of the system.

On the basis of a Web database that is optimized for free-format data (because we did not want to decide in advance what an instructor or student may want to include in a course environment) and that can support a large number of simultaneous users (a Domino server, 4.6), we have created an environment that from the instructor perspective is as simple as a great number of hierarchially ordered Web-based fill-in forms. If anyone with the login privileges of an instructor inlogs, he or she sees not only the site as the students see it, but also a number of extra edit-icons whereby on any page the instructor can make changes in the content and even the fill-in forms themselves, can make changes in text or HTML, can add links to external WWW sites (and also to other materials in the database), and can add files as attachments to any page. Anything entered by the instructor is placed on the server and in the database. This concept is carried out on all pages, for consistency and learnability, even the most-complicated pages.

As an example, an instructor can choose for a matrix, or roster model to indicate the organization of a course. Fig. 2 shows an example of the instructor's view of a roster page and of the student's view.

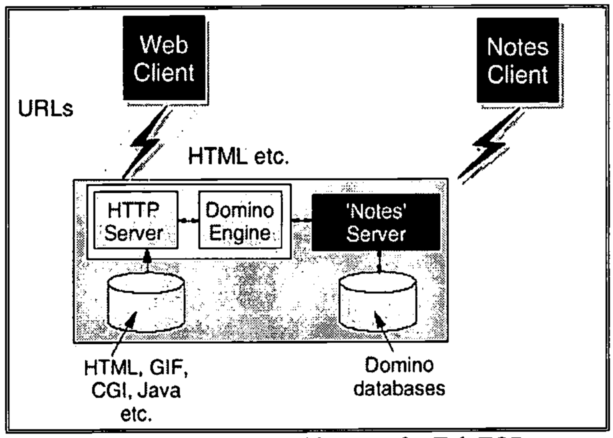

Figure 1. System architecture for TeleTOP

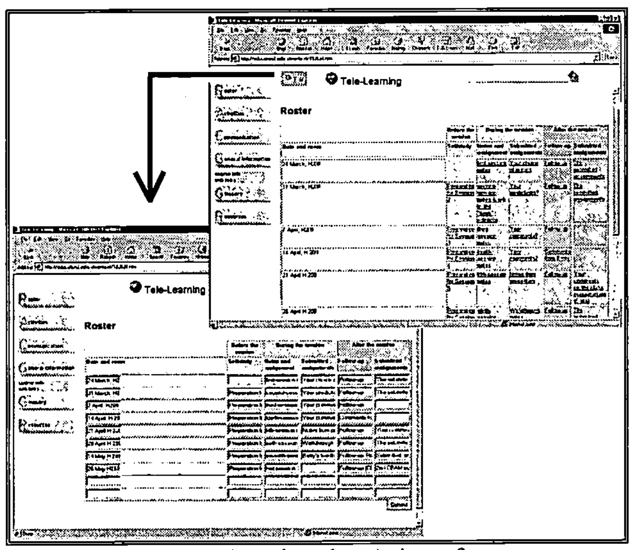

Figure 2. Instructor's and students' view of a roster page.

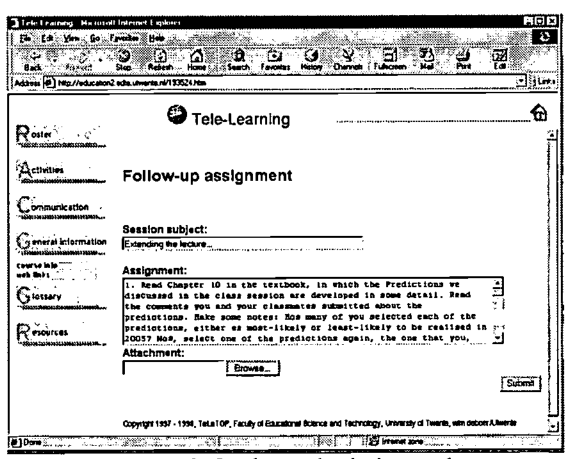

Figure 3. Student submission tools

In the edit view, the instructor can choose to add new rows to the roster, and can choose the labels for each cell in the roster. At the moment that the instructor types in a label on a previously empty cell, for example, a date indicating when a self-study assignment is due, a new page is associated with this link, with a basic fill-in-form and an upload button, so that the student can submit his or her assignment directly through this new page. Fig. 3 shows a page ready for the students to submit an assignment. The students can also decide if they wish their assignments to be readable by everyone in the class or only by the instructor.

Students can move through the course-support site pages, sometimes to submit assignments or ideas through the fill-in-form system, can add files to the site, and can use the e-mail tools for general e-mail communication (standard Internet addresses, sendable within the intranet or over the Internet).

Coupled with the database-server system is a video database, Mediabase, on a Silicon Graphics server. Via this system, video segments in whatever form and length and with whatever bandwide requires the user wishes can be also delivered to the TeleTOP WWW environments.

Experiences with the system

As the system is in use we are also carrying out an extensive evaluation study, led by persons external to our team. Students and instructors, again using fill-in-forms, are being asked to record the amount of time they spend on different aspects of a course and of using the course-support environments as well as many other aspects relating to the quality of the course experience. The first formal results will be published in November 1998 and the final evaluation results in June 1999 (in time for presentation at ED-MEDIA '99). We can say with our results so far that: Even for instructors who were sceptical or showed resistance initially about changing in their teaching, the use of the system is proceeding without real problems. All first-year instructors are using the system and many are coming to the Team to ask for help to try out even more new ideas. The students, and particularly the part-time students attending primarily at a distance, are not having any particular start-up problems (we did all we could to prevent this, by providing them with fully installed computers and modems at a low price, most of which they do not have to pay back if they maintain their grades). The instructors are particularly pleased with being able to make changes and last-minutes entries to their sites whenever they wish, even a few minutes' before a face-to-face session. They also appreciate being able to directly respond to what occurs in the course, by entering the site to make changes or add new materials at any time. Compared to the previous evaluation data from earlier years of using WWW-based environments, the students are finding the environments easier to navigate and use. And, we receive many requests for demonstrations for persons outside the university, who typically are enthusiastic about the system: "A simple to use, transparent system but one with which you can do anything you want in a WWW environment".

Further developments:

Evcn though the current system already consists of a rich WWW-based collection of learning environments, we still have plans to continue extending the system, particularly in terms of logistic management and supporting even more variety in instructional activities. For example, even though the roster approach gives the instructor considerable freedom and a great many possibilities for different types of student interactions, there are two further developments which we feel are important to our Empowering the Good Instructor principle:

1. First, we are beginning to research how we can use video to increase the quality of contacts and communication between instructor and student. We can support videoconferencing, but are particularly interested in capturing via video episodes of good communication during group activities or in a discussion session, and integrating these directly into the course site. This can be to the benefit of persons not at the class session (part of our flexibility principle), but more creatively, can be used to add the students' own ideas and comments, in spoken form as well as written form, to the resources in the course site (see Winnips, Collis, & Moonen, 1998, for an example). We see this as a way to support the Master-Apprentice idea that we believe to be part of good teaching, whereby the instructor and students together can easily access captured video for further reflection.

2. Secondly, we are working to further develop another aspect of the Empower the Good Instructor idea: how to help the instructor find and use small units of learning material such as instructional applets within the course site, not as a replacement for him or herself or the textbook, but as added value. The collection, classification, and use of "learning molecules" from via the roster or anywhere else in the course site, orchestrated by the instructor (or delegated by the instructor to the students) is another area we are working on.

Development and Administration of a Night Vision Goggle Training Course

DeForest Q. Joralmon
Raytheon Training and Services
United States of America
deke.joralmon@williams.af.mil

Abstract: The U.S. military's emphasis on night operations has made the development of night vision goggle (NVG) training increasingly important. The Warfighter Training Research Division of the Air Force Research Laboratory (AFRL/HEA) has been developing and distributing such training since 1990. This paper documents the development, evolution, administration, and possible future of multimedia-based NVG training courseware.

A videodisc version of the current NVG Training Course contains numerous motion video segments demonstrating various NVG effects. The videodisc provides high quality video and random access to various course elements. However, the videodisc cannot be revised without substantial effort and cost. Established digital video formats such as Video for Windows, QuickTime, and MPEG-1 do not provide the level of resolution necessary to adequately depict intensified imagery visual teaching points. Emerging digital video technologies such as MPEG-2 and DVD may be of sufficient quality to allow for distribution of the course in an all-digital format. Testing and implementation of these newer technologies for converting the course from analog to digital media is discussed.

The NVG Training Course is taught at numerous, dispersed facilities. Telecommunication technologies that are or could be used for course administration such as courseware distribution, user databases, and feedback on course content are addressed.

Introduction

Night vision goggles (NVGs) have been used by the United States Armed Forces since the 1940's. The technology has vastly improved since the first devices, using infrared illuminators and detectors, were mounted to sniper's rifles in World War II. Some current third generation NVGs have such improved resolution that one can see 20/20 under optimum conditions.

The increased use of NVGs by the U.S. Air Force (USAF), U.S. Navy (USN), and U.S. Marine Corps (USMC) aviation communities created an expanded need for NVG training. The Warfighter Training Research Division of the Air Force Research Laboratory (AFRL/HEA) has been developing and distributing such training since 1990. One product, the Night Vision Goggle Training Course, is the initial curriculum for USN, USMC, and USAF aircrew who fly missions with NVGs. The NVG Training Course is not specific to any one aircraft type as it addresses training objectives common to most tanker, transport, helicopter, fighter, and attack aircraft.

There is a standardized configuration for the physical layout of facilities used for NVG training in the United States. This configuration is known as a "NITE Lab" and can be housed in existing buildings, doublewide trailers, or new buildings. A large portion of the NITE Lab consists of the classroom. The classroom is normally configured to handle up to 15 students. Multimedia courseware used in the training and the equipment necessary to present the courseware are located in the classroom. A terrain board is also part of the facility. These boards are typically eight to ten feet square. The terrain board depicts a variety of terrain including an airfield, landing zones, cultural features, water, mountains, farmlands, desert, and forests. A light source is used to provide light levels ranging from overcast starlight to full moon. The light source can also be adjusted to emulate different moon angles. Students, viewing the board through NVGs, stand around the terrain board and observe various phenomena as presented and described by the instructor. Another important element of the NITE Lab is the eye lane. The eye lane is a light-tight room equipped with resolution charts and an illumination device. The eye lane is used to teach aircrew proper NVG adjustment and assessment procedures.

This paper documents the development, evolution, administration, and possible future of multimedia-based courseware used for NVG training in NITE Labs and other facilities.

Multimedia Technologies for NVG Training

Video examples of NVG effects as they happen in the real world are an excellent teaching tool. Such examples are shown to the students to make them aware of various NVG phenomena and the conditions under which they occur. Therefore, intensified motion video segments are an integral part of all NVG training courseware.

Six video programs were initially produced to support NVG training (Joralmon, 1992). These videotapes were used for both primary and refresher NVG training. Each program is approximately ten minutes in length and covers a different topic. The six video programs are entitled NVG Image Characteristics, Luminance Variations, Lighting Issues, Terrain Albedos, Weather Effects, and Navigational Issues.

The six videotape programs were replaced by the first version of the NVG Training Course published in 1994. This courseware is presented via an interactive videodisc. The videodisc is designed to be a multimedia-based instructor aid. All USAF, USN, and USMC NITE Labs are equipped with videodisc players. All of the graphic slides and accompanying motion video segments for the entire course are contained on a single two-sided disc. The videodisc uses Level II programming which allows the instructor to navigate through the various lectures. A Level II interactive videodisc contains all of the navigational programming on the second audio channel. Each time the disc is loaded into a compatible player, the navigation program is loaded into the player's on-board microprocessor thus allowing the courseware to be delivered. The presentation is presented to the class either on a large television monitor or on a screen via a video projector. The videodisc contains six academic lectures and three NVG adjustment and assessment lectures. The academic lectures are Introduction to the Course, The Human Visual System, Introduction to Night Vision Goggles, The Night Environment, Misperceptions and Illusions (specific to fixed wing and rotary wing aircraft), and Night Operations. The adjustment and assessment lectures cover procedures for AN/AVS-6, MXU-810U CATSEYE, and AN/AVS-9 NVGs. A printed instructor's guide is packaged with the interactive videodisc. The instructor's guide contains pertinent administrative information as well as the main course content to be delivered by the instructor.

An alternate way to deliver the initial version NVG Training Course was produced in order to provide the courseware to those units that might not have a compatible videodisc player. The alternate method uses 35mm slides as a storage medium for the graphic slides and a VHS videotape contains the motion video segments. Graphic slides with an accompanying motion segment have a prompt telling the instructor to play the appropriate motion video segment. The graphic slides can also be delivered via a number of different computer presentation programs (e.g. Microsoft PowerPoint). These alternate delivery methods virtually ensure that any unit can present the courseware to students even though there is a loss in image quality when presenting the motion video segments on VHS videotape.

Version 2 of the NVG Training Course was completed in early 1998. Again, the multimedia portion of the courseware is packaged on a Level II interactive videodisc. Revisions to course content were made based on instructor's recommendations. A printed instructor's guide continues to accompany the interactive videodisc. The alternate delivery method uses Microsoft (MS) PowerPoint for presentation of the graphic still frames and VHS videotape for the motion segments. 35mm slides of the still frames are no longer produced. A CD-ROM has been produced which contains the MS PowerPoint files, the instructor's guide (in Adobe Acrobat .pdf format), and other ancillary information.

This next section of the paper discusses multimedia technologies and how they might or might not be suitable for NVG courseware delivery. Current technologies will be discussed first, followed by an examination of emerging technologies. For purposes of this discussion, current technologies are defined as those that are prevalent in society (e.g. computers, CD-ROM drives, and videocassette recorders) and emerging technologies are those that have been recently marketed but have not reached the general public in large numbers (e.g. DVD drives, digital videocassette recorders, and advanced video compression algorithms).

Current Multimedia Technologies

Laser videodisc was chosen as the primary distribution format due to its superior video resolution and random access capabilities. The resolution of a videodisc is much better than that of a VHS format videotape. This is a critical issue in the production of night vision aircrew training multimedia. Video recorded with image intensified cameras has significantly lower resolution than what can actually be seen through an NVG. Therefore, it is important to first record the intensified image on a high-quality videotape format and then minimize the number of generations each scene gathers when it is being edited into a final production. A generation occurs each time an analog videotape is copied and results in some loss of quality.

The disadvantages of laser videodiscs are their high cost to produce and the inability to easily and quickly update the disc once it has been mastered and replicated. This is a significant problem since NVG technology and employment techniques are in a constant state of evolution. The need exists to be able to readily revise NVG Training Course materials. The challenge to date has been how to provide high quality revisions in a timely manner and at a reasonable cost.

The biggest hurdle in transforming the NVG Training Course into an all-digital format is digitizing the motion video segments.

Digital video formats available for use in computer-based training (CBT) and Internet (WWW) applications can be visually intriguing and of high quality. However, the demanding digital storage and processing requirements for full screen, full motion video can result in compromised image resolution. Digital motion video saved in a computer environment can also require enormous amounts of storage space. Hardware and software solutions are available to transform motion video segments into manageable file sizes. However, this transformation process often reduces the resolution of the motion video segment. How much resolution can be lost without negatively impacting the effectiveness of the presentation depends on the specific application. Computer playback of motion video is also demanding. Again, available hardware and software solutions are used to display the video. The quality of software-based playback is dependent on and limited by computer processing power. Hardware playback methods often include enough additional processing power such that full motion, full screen playback is possible.

How good digitized video needs to be is one consideration the courseware developer or educator should ascertain prior to using such presentation technologies. What makes video quality acceptable is dependent on the educational objective or content the video is supporting. In some applications, a low quality "talking head" scene playing back at 10fps may be sufficient. Low or medium quality digital video playing back at low frame rates may also be sufficient to show such items as control panels or displays. Other cases, such as those in which the viewer must clearly see visual details within the image (e.g. night vision aircrew training), require a higher-quality digital video format.

Current digital video formats are not of sufficient quality to support NVG training. Apple QuickTime (.mov files) and MS Video for Windows (.avi files) typically play motion segments back at 15 frames per second. The video is displayed in a small window on a computer screen. Increasing the size of the window can result in the image appearing quite pixelated. Video streams using the MPEG-1 compression standard play at 30 frames per second but again in a small, default-sized window of 352 by 240 pixels within the computer screen. MPEG-1 can be displayed full screen on a regular television monitor, but this requires using two screens for presenting course content. One screen displaying the graphic still frames and another displaying the MPEG-1 motion video segments.

Emerging Multimedia Technologies

Recently emerging digital video formats and computer media show promise that they are suitable for use in presenting NVG training courseware. Two of these technologies being tested by AL/HRA are MPEG-2 video compression and DVD media.

One of the most advanced digital video compression algorithms is the MPEG-2 standard. Full D-1 MPEG-2 video files play back at thirty frames per second on a computer screen in a native size window measuring 720 by 480 pixels. The quality is comparable to (if not better than) analog laser videodiscs. Interactivity and random access capabilities are possible using a variety of CBT authoring, WWW page development and computer programming techniques. MPEG-2 video files can be encoded using various software and, ideally, hardware solutions. The file sizes of MPEG-2 motion segments are large, but the ever increasing storage capabilities of desktop and portable computers as well as interchangeable storage media is sufficient to handle this large amount of data.

The MPEG-2 standard is currently being used in DVD[1] movie titles and telecommunications applications for the transmission of broadcast quality audio and video. DVDs are the same size as compact discs (CD), but can store much more data. A data CD has the capacity of 650 megabytes (MB) while DVDs can hold anywhere from just below 4 gigabytes (GB) to approximately 17GB. These capacities are sufficient to hold the entire NVG Training Course with the motion video segments encoded in the MPEG-2 video standard.

NITE Labs and any other site desiring to use an all-digital version of the NVG Training Course would require additional hardware to support DVD and MPEG-2 technologies. DVD requires a computer drive be placed into the computer supporting multimedia playback in the classroom. The price for a DVD drive is approximately $300. A DVD drive typically replaces a computer's CD drive since the DVD drive can read both DVDs and CDs. Playback of MPEG-2 files is best accomplished with an additional hardware board placed into the multimedia computer. The price for an MPEG-2 hardware decoder is about $250.

Testing of MPEG-2 and DVD technology is currently underway at AL/HRA. Prototype, all-digital versions of the NVG Training Course will be produced, demonstrated[2] and evaluated. Initial test versions will use MS PowerPoint to present the graphic still frames and the motion video segments. Those graphic still frames that have an accompanying motion video segment (not all do) will contain an element that allows the instructor to play the MPEG-2 video file. An example of such a still frame is displayed in Figure 1.

Figure 1. An example of an MS PowerPoint slide that contains an MPEG-2 format video segment.

The presenter clicks on the gray caption bar at the bottom of the photograph to begin playing the video segment. The gray bar is transformed into a video playback control bar and the area that was previously

---

[1]The term DVD is becoming the standard form of referring to this specific storage medium. The term was chosen to minimize confusion and ensure commonality between those who thought DVD meant digital video disc and those who thought DVD meant digital versatile disc.

[2]A demonstration of the digital version of the NVG Training Course (using MPEG-2 video files and DVD as the storage medium) will be made during the presentation of this paper.

occupied by the photograph is replaced by the motion video. The photograph and the gray caption bar return when the video segment ends. The presenter then has the option of playing the video segment again or moving to another slide in the presentation. Applications that allow the course to be presented using a WWW browser program will also be tested. There are no current plans to serve the NVG Training Course over the Internet since bandwidth limitations would significantly impede downloading of the large video segment files. Instead, if a WWW browser program were used for presentation, the course would be distributed in a format that would allow playback through the browser program via the host computer.

NVG Training Course Administration

The various NITE Labs are located throughout the United States and abroad. This presents, to course developers, the challenge of administering the course over distance. The NVG Training course has been taught since September of 1994 and several trends have emerged relative to its use. One such trend is that some instructors modify the course to fit their specific training needs. These modifications take the form of either deleting course content or supplementing the course with additional material. The ability to modify a course to suit a specific training need is one reason why having the course in a digital format is desirable. A digital format allows instructors to pick and choose or cut and paste what best suits the training requirements. However, course administrators should be aware of how the course is being altered lest any essential information be deleted or erroneous information be added. Both the deletion of critical information and the dissemination of false information could result in safety of flight issues. Therefore, investigating and reporting on course administration over distance issues could lead to recommendations suited to alleviating any potential problems and lead to better communication amongst those involved in NVG training.

Those involved in administering the NVG Training Course, AL/HRA for the USAF and the NITE Lab Model Manager (located at MAWTS-1 in Yuma, Arizona) for the USN and USMC, handle a variety of course administration-type subjects including course material distribution, NITE Lab hardware acquisition and maintenance, and instructor certification. All of these tasks are typically dealt with using some form of telecommunications (e.g. the telephone, e-mail) since the parties are geographically separated. Currently, there is no formal communication forum between course administrators and course instructors. Communication is primarily one-to-one with no means for one-to-many or group interaction. All involved would seemingly benefit if some system were in place that would allow for the easy exchange of information as it pertains to the NVG Training Course. The following are some efforts underway and recommendations that could assist in the administration aspects of the NVG Training Course.

Recommendations

An effort is being made to establish a comprehensive database that lists all current NVG instructors and their respective point-of contact information. This information includes a description of their teaching facilities (including telecommunications capabilities), the courseware they are using, and the type of NVGs and aircraft used at their location. Two software programs are being used to build the database. MS Access is one and FileMaker Pro 4.0 is the other. It is hoped that upon completion the database can be distributed and/or shared electronically. When the database is complete, it will be important to instill responsibility into the instructors to make sure they keep course administrators apprised of any changes, especially any changes to the course content and any instructor's changes in duty assignments.

At a minimum and as another initial step, an electronic mail broadcast group of instructors and administrators could be established. This would allow asynchronous communication within the group in the one-to-one and the one-to-many formats. An electronic mail group would also allow for attached files (e.g. courseware updates) to be transmitted.

NVG Training Course administration would seemingly benefit and improve if some form of computer-mediated communication (CMC) were implemented. A dedicated system, such as the FirstClass CMC software by SoftArc Incorporated or Lotus Notes, would provide a centralized system of communication for both administrators and instructors. Discussion threads could take place on a number of subjects such as NVG experiences (lessons learned), listing of course errata, technical updates and course materials distribution.

An Internet application could also be used to improve NVG Training Course administration and might possibly be the best solution. Current information could be posted, message boards and discussion groups established (though the author has found such web-based applications less than efficient), and the ability to download files included. A File Transfer Protocol (FTP) site could also be brought on-line. Security issues could be addressed by using Defense Information Security Agency (DISA) networks like Unclassified (but sensitive) Internet Protocol Routing Network (NIPRNET) and Secret Internet Protocol Routing Network (SIPRNET). NIPRNET would be the appropriate network to use for NVG training applications since (at the time of this writing) none of the information is classified. These networks provide certain degrees of controlled access to one's site and thus provide protection to sensitive and proprietary information.

Sophisticated messaging systems are being demonstrated that could be used for NVG Training Course administration (Bryant, 1996). The U.S. Navy X.400 defense messaging system capability allows users "to include all types of media (imagery, video, slide shows, etc.) as attachments to standard navy messages (p. 1). The author does not know the suitability, interservice availability, and full specifications of the X.400 messaging capability at this time but warrant further investigation.

Conclusion

This paper has discussed multimedia technologies that can be used to deliver aircrew training. Such papers serve as a benchmark in the timeline of technology development and implementation. It is interesting to look back at past conference proceedings, see what media technologies were being discussed, and now reflect on the degree of success those technologies achieved. This paper has also discussed course administration issues that are present when a course must be managed over distance. Future testing and implementation of various recommended technologies will hopefully improve upon the quality of continued night vision goggle aircrew training.

Designing Instructional Multimedia Applications: Key Practices and Design Patterns

Maia Dimitrova and Alistair Sutcliffe
Centre for HCI Design, City University, Northampton Square, London EC1V 0HB, U.K.
M.T.Dimitrova@city.ac.uk, A.G.Sutcliffe@city.ac.uk

Abstract: This paper is divided in two parts. The first part presents a study of the existing design practice in instructional multimedia organisations, and describes the stages of the design process. It reveals the major problems in design, which include complexity of the design process, which necessitates the involvement of a number of specialists from different professional areas, who need to communicate on a common ground, and the tight delivery deadlines against which designers have to compete. In part two, an approach to supporting the design process is proposed. In involves reusing previous proven design expertise through the use of design patterns.

1. Introduction

The effective design of instructional multimedia applications is an intersection of different scientific fields including pedagogy, cognitive psychology, computer science, and media design. The design of such applications is, therefore, a complex process that needs to take into consideration a number of interdependent factors. In a learner-centred approach to designing instructional multimedia, the primary focus should be on the learner and their existing knowledge and experience, as well as the learner's pre-determined learning style, and individual approach to learning (Wild and Quinn 1998). The characteristics of the learning material, and the tasks to be performed during learning also affect learning from multimedia (Najjar 1997). Thus, the media resources that satisfy the information requirements for each task must be carefully chosen while designing the presentation (Sutcliffe & Faraday 1994). To aid designers deal with the complexity of developing such applications, sound methodological support and guidance is required. In order to improve the design process, an understanding of the current approach to design is necessary. In the literature, a number of experiences of designing multimedia courseware have been reported, for instance the WinEcon (Soper 1997). These reports outline main design issues, and how multiple media was used to address the educational needs of that particular applications. Liu et al. (1997) also studied the multimedia production process. However, they emphasised mainly on the overall development process, and do not provide details about the design process. There is a need for more comprehensive studies of instructional multimedia design practices to inform researches of the design techniques used, and the major problems designers encounter.

This paper presents a study of the current design practice in instructional multimedia organisations. Section 2 introduces the designers and the projects examined. The results of the study are revealed in Section 3. A prototypical approach to improving the presentation design process through the reuse of previous design rationale is suggested in Section 4. Some example design patterns are also presented.

2. Study Background

2.1 Multimedia Designers

Eight designers from four educational multimedia organisations within the U.K. participated in the study. The instructional designers came from a variety of professional backgrounds, the majority of who had a mixture of qualifications, including fine arts and social sciences, electronics, electrical, telecommunications, sound and video engineering. Half of them also had a qualification in education or training. The designers' experiences with multimedia ranged from two to sixteen years, with a mean of five years.

The interview questions were divided in five main areas covering designers' experience on a recent multimedia project, the approach adopted to the design, the way of selecting and integrating representation media, any style guidelines applied, and finally the main problems encountered during the design process.

2.2 Design Projects

The projects represented a variety of application areas, which according to their learning objectives can be classified into two categories: training (including Captain Emergency Training, Call Handling, and Hotel Induction), and educational (including Innovation Process Management, Oil Lubrication, and Key Stage 2 Maths). In the training applications there was a well-defined set of learning objectives and skills that the learner had to acquire. The aim was not so much at teaching new knowledge in a subject matter, but at acquiring skills and applying knowledge. In contrast, the educational applications aimed to develop a deeper understanding in a subject matter.

3. Study Results

3.1 Design Process

Although the design methods varied across companies and individual projects, a 'waterfall' approach was adopted, including four main stages: Specification, Conceptual Design, Prototyping and Presentation Design, which are illustrated on (Fig. 1).

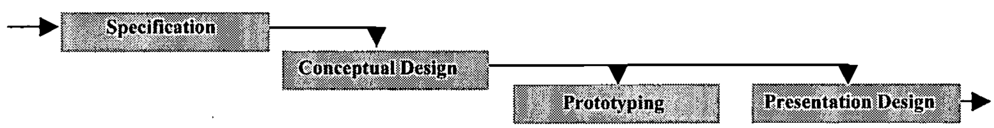

Figure 1: Instructional Multimedia Design Process

3.1.1 Specification

Every project commenced with setting up the aims and objectives of the courseware. This was done in an iterative process with the active participation of a subject matter expert from the client company, or qualified teachers. To be effective, the training material has to be defined in the context of the learner population. However, only in half of the cases the target user population was explicitly studied to identify their educational or professional background (3), computer literacy (2), prior domain knowledge (2), age (2), and job specification (2). There was no evidence that the individual learning styles of the target population were formally established.

3.1.2 Conceptual Design

During the Conceptual Design stage the courseware was specified in detail and the overall presentation style was determined. In five cases, every single training point was defined, including the material to be taught to the learner, and the interactions they had to perform. The content was divided into sections, which were structured in a logical way. In the other three projects, as the content was based on existing material, the content was already defined and structured. The subject matter expert was highly involved in this iterative process.

The learning objectives appear to have a strong influence on the choice of representation style adopted. According to the overall representation approach, the projects can be divided into tutorial, simulation, and game, as shown on (Tab. 1). Apart from the training objectives, other factors reported to influence the choice of representation style were the target learner population, and the budget available.

LEARNING OBJECTIVE	REPRESENTATION STYLE		
	Tutorial	Simulation	Game
Training	■ Call Handling	■ Captain Emergency ■ Hotel Induction (partial)	-
Educational	■ Oil Lubrication ■ Innovation Process Management	-	■ Key Stage 2 Maths

Table 1: Representation Styles According to Learning Objectives

In the tutorial applications, as the primary aim was to provide knowledge and make the learner reflect on it, the material was structured into topics and subtopics. At the end of each section the learner was given the opportunity to reflect on what was learned, by answering test questions, or engaging in activities. Simulation was selected to allow the learner to develop skills and strategies for dealing with certain situations. That was achieved by allowing the learner to interact with a realistic environment, giving them an opportunity to actively explore it (e.g. browse bridge of a ship), and interact with it in order to achieve certain goals (e.g. fight fire on board of a ship). In the Captain Emergency Training application the situation evolved dynamically depending on the user's decisions and actions, who then got to experience the consequences of those actions (e.g. decrease or increase danger of fire), thus providing learning by discovery. Assessment was based on effectively completing the tasks. At the end the learner's performance was assessed against company's standards, and they were provided with feedback as to how they could have reacted better. A game-like approach was chosen to encourage children to learn mathematics by engaging in different problem-solving activities. The system monitored student's problem-solving attempts, and provided them with an immediate feedback on their performance, with an option to look at help screens which provide deeper knowledge of the subject matter.

3.1.3 Prototyping

In all cases some kind of prototype was developed, which was presented to users for their feedback. The content and the level of detail included in the prototype varied from sample screens, images and artwork (4), through screens including partial functionality (1), to a pilot of a full module (3). The way the prototypes were evaluated also varied. Two of the screen prototypes were presented to some users for their comments and suggestions. In the latter four cases, the evaluation included observing users' actions to discover problem areas, as well as getting their feedback. As the evaluation was not done in a systematic way, the user feedback consisted predominantly of high-level comments regarding the colour scheme, or the look of the graphics. Only the pilot prototype resulted in clarifying functionality, verifying the accuracy of procedures to be implemented, as well as adding usability features.

3.1.4 Presentation Design

In the Presentation Design stage the abstractions of the Conceptual Design were mapped onto a real multimedia environment. In five projects scripting technique was used for designing the applications. However, the amount of details included in the scripts varied across projects. In three cases every single screen was defined, including a schematic layout of the screen, detailed description of the graphics and video sequences, as well as precise scripts of speech track and text. The relative position of media resources and their synchronisation were also specified wherever appropriate. Navigation controls were defined, as well as branching from one screen to other screens. In the rest two cases partial scripts were produced, specifying wording on screen, screen layout, questions to be presented, as well as branching to other screens. In the two full simulation cases a different approach to presentation design was adopted. As the material consisted of separate training exercises, each of which had different actions to be performed, first a transition state diagram was created for every possible action. After that the screens for each exercise were designed.

Media Selection

The designers were asked to define the reasons for selecting different media resources used in the applications. The answers showed that the factors considered in selecting the most appropriate media were high-level, and not based on sound pedagogical or cognitive psychology principles. Some factors considered were the learners' characteristics (e.g. reading abilities, computer literacy), and the type of information required. Other factors influencing the choice of media were client's preferences or expectations, limited memory space on delivery platforms, and limited budget. Some media selection heuristics were:

- Use speech as a primary instruction medium, because it is motivating to users.
- If the users are not very computer literate, use speech for instructions.
- Choose animation to represent concrete concepts and explain how they work.
- Select video for representing customer service and customer care skills, as the learner can observe reactions and body language.

Media Combination

For the user to extract the most important information from a presentation, it is vital to guide their reading sequence, as well as to aid them in establishing links between the information presented with different media. From the study, we discovered that very often the decision as to what media to combine and how was left to designer's creativity and aesthetic judgement, and no sound principles of human attention to various media were considered. It appears that there were four main reasons for presenting different media concurrently, which are:

- *Support*: When two different media convey related information, where one or the other medium can present additional information to the other resource. For example, display an image on the left-hand side with supporting text on the right-hand side.
- *Summary*: When one medium summaries and reinforces the chief points of the information presented by another resource. For instance, display bullet point text summarising the main points talked about in speech narration.

- *Explanation*: When one medium explains the information presented by another medium. An example is, where a complex interaction is presented by a set of graphics, speech or text can be used to explain the aim of the activity.
- *Redundancy*: When exactly the same information is presented by two different media resources. For instance, what-to-do instructions can be presented redundantly using speech and text.

Depending on the information requirement, a combination of the above could be used. However, there was no evidence of establishing explicit referential connections between different media presented concurrently.

3.2 Design Guidelines

To establish how much support designers used, they were asked regarding the guidelines and principles they applied in the design process. Five designers reported that their companies had developed presentation design guides. However, four of them suggested that these guides were used primarily to train new staff, and did not get referred to actively during the design process. It was pointed out that the design guides contained only high-level design principles regarding screen, interaction, and navigation design, as well as presentation of text, graphic, audio, and video. However, designers seemed to apply some interface design heuristics, examples of which are:

- Establish a uniform screen layout.
- Avoid using many hypertext links in one page as the user can easily get lost, instead use more rigid menu structure.

3.3 Design Problems

The major problems encountered by the designers fall in two categories: high-level constraints and design problems.

High-Level Constraints:

- *Client availability*: Client participation played an important role in ensuring user's satisfaction with the system. However, most of the designers reported that arranging meetings with Subject Matter Experts and obtaining clarification of content was quite often difficult. Getting hold of sufficient number of users for prototype evaluation, and receiving their feedback on time was another problem.
- *Available budget and delivery deadline pressure*: How sophisticated and interactive media can be created often depended on the budget available. In two cases tight delivery deadlines also resulted in reducing the time spent on usability testing.

Design Problems:

- *Creating workable designs*: In order to produce workable designs, designers had to establish a trade-off between the learning objectives, how feasible the ideas were within the time available, and whether and how easily they could be implemented using the available technology. To achieve that input from domain specialists, designers, graphic artists, and programmers was required. However, some of these specialists were unable to appreciate the multidimensionality of the design space, and therefore lacked common perspective in finding the best design solution.
- *Designing for users with different levels of abilities*: When the target population included users with different levels of computer literacy, finding the right balance between providing such navigation support, which would be sufficient for novices, and would not irritate experienced users, was a challenge. Structuring the training material to accommodate both, more and less technicality knowledgeable learners, was also not easy, as the first group required easy and random access to technical information of interest to them, and the latter group required more rigid structure and less complex terminology.

4. Presentation Design Patterns

The sections above identified three major problems with the current approach to designing instructional multimedia. These problems are: complexity, which necessitates the involvement of a number of specialists from different professional areas, who need to communicate on a common ground, and the tight delivery deadlines against which designers have to compete. One way of dealing with the complexity of design, and reducing the time and effort involved in the design process, without compromising on the quality of the software, is to reuse previous design knowledge when constructing new applications. One way of systematically reusing previous design expertise involves closely examining successful applications, and identifying recurring solutions to common design problems. These can be encapsulated in design patterns. Design patterns have been successfully used in architecture (Alexander et al. 1977), as well as in software engineering, predominantly in the object-oriented software design community (Gamma et al. 1995). A design pattern describes the core of a solution to a particular problem in an abstract way, which when used in a given situation can generate effective design.

In instructional multimedia, presentation design patterns can explore the interactions between the information and task requirements, and their external representation using different media, while explaining the pedagogic and cognitive implications of such compositions on the learner. Their focus on how the media representation can support learner's cognitive processes can ensure effective learning. As patterns can work at different levels of design - dialogue, content, screen layout, navigation - they can attempt to tie these levels together.

From the study, it emerged that five designers reused design rationale from previous projects. For instance, in one case, templates were used for presenting graphics and bullet point text together. In other two cases a uniform screen layout was set across a range of products. The designers found these templates time saving, and a good way of ensuring interface consistency within a product or across a range of products. However, reuse was not done in a comprehensive way. A coherent library of design patterns could potentially speed up the design process, provide professionals with a common lingua franca for communication, ensure interface usability, and pass design expertise to novice designers, so they can produce effective designs faster. Two prototypical design patterns are presented in the next sub-sections. Included are one content (4.1) and one screen layout (4.2) pattern. The patterns are described using a uniform format, comprising of the name of the pattern, the context or the situation which gives rise to the problem, the problem that needs to be solved, the proposed solution, and examples of existing systems, where the patter is implemented.

4.1 How-It-Works Mechanism Pattern

Context: Consider this pattern in representing the working mechanism of a physical object, where the behaviour of the aggregate object is determined by the collaborative behaviour of its components.
Problem: You need to explain how a complex devise works, which is composed of certain parts. There are two main forces that need to be resolved in such representations. Firstly, the user should be able to identify all individual components, and the roles they play in the mechanism, as well as the relationships between the components. And secondly, the user should be able to aggregate behaviour of the components into a semantic behaviour of the mechanism.
Solution: Structure the presentation into four parts. Firstly, present an exploded view diagram of the machine and a textual description of its overall function. Then, present a schematic diagram of the machine and its components, together with textual descriptions of the characteristics of each component. These two parts will facilitate the learner in decomposing the machine into its basic elements. To aid the learner in identifying the spatial relationships between devise components, present different views of the machine. Text and speech explaining component connections should accompany each depiction. Finally, present a realistic animation showing all component behaviours in actual order of occurrence. The animation should be synchronised with speech commentary describing the dynamics of the machine's operation. This will aid the learner in building a dynamic mental model of how the devise operates.
Examples: Microsoft Encarta – The Human Heart, DK Multimedia "The Way Things Work".

4.2 Interactivity Screen Pattern

Context: Consider this pattern in composing a screen allowing the user to perform a learning activity.
Problem: You need to allow the user to perform a learning activity, and to provide them with adequate task instructions at the same time. As the activity is central, and the learner will need to concentrate on it. Task instructions and learning support will have to be presented as well. However, although they are necessary for the successful completion of the activity, they should not obstruct the learner in performing the task.

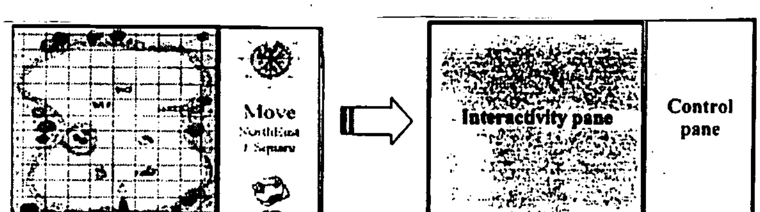

Figure 2: A Sample Interactivity Screen With Left-To-Right Visual Composition (Aircom Education ©).

Solution: Divide the display into two areas: interaction and control (see Fig. 2). As the interaction is central, place it at the left-hand or top side of the screen. Designate the smaller right-hand or bottom part of the display for task instructions and required learning aids. This will focus the user on the interaction. Use text for task instructions,

with redundant speech narration, which can enable the learner to familiarise with the interaction while listening to the instructions.
Examples: Aircom Education "Maths: The Journey to Swallow Farm".

5. Discussion

The study, although limited in size, provides insightful information about the current practices of designing instructional multimedia software. The findings show that the client is involved extensively in specifying the courseware, and reviewing the progress made at the end of every stage, which is important to ensure that client's requirements are met. However, this is not a sufficient guarantee for the usability of the user interface. The study revealed that although some learner characteristics were considered while making design decisions, that was not done in a systematic way. There is a need for a way of ensuring that learner's needs, learning styles, and individual approach to learning are addressed in the design, also suggested in (Soloway 1998; Wild & Quinn 1998). From the study, it became apparent that the selection of appropriate media resources is primarily based on high-level factors, such as selecting speech for motivating the learner. However, studies show that the information requirements for each task, and the cognitively relevant characteristics of the media are vital for allocating the media resources to be used (Sutcliffe & Faraday 1994), which has to be done on a moment by moment basis (Faraday & Sutcliffe 1997). In order to deliver the learning material effectively, designers should order shifts of user's attention according to the content being shown, and ensure that the elements of the presentation are integrated into unified propositions (Faraday & Sutcliffe 1996). However, the four reasons that designers stated for presenting different media concurrently although valid, are not comprehensive enough to ensure that the presentation will not overloaded user's attention, and cause difficulties with comprehending the information presented. Although the guidelines and heuristics presented can be of useful, they are of too high level, and need to be augmented with sound cognitive science and pedagogic principles. This evidence indicates that there is a need to further support the process of multimedia user interface design.

A library of design patterns can prove to be a better way of delivering design knowledge, as the patterns could provide the essence of proven solutions to common interface design problems, augmented with sound theoretical principles. Potentially, this could speed up the design process, provide professionals from diverse backgrounds with a common language for communication, ensure interface usability, and pass design expertise to novice designers. The proposed design patterns lay the foundations of a pattern library for multimedia presentation design. In our future work we will continue extracting design patterns, which will be integrated into a coherent pattern library. A systematic method of applying design patterns will also be developed. Finally, the validity of the patterns will be tested to ensure their benefit to the design process and students' performance.

Authoring Support for Adaptive Hypermedia Applications

Hongjing Wu, Geert-Jan Houben, Paul De Bra
Department of Mathematics and Computing Science
Eindhoven University of Technology
PO Box 513, 5600 MB Eindhoven
The Netherlands
Email: {hongjing,houben,debra}@win.tue.nl

Abstract: A hypermedia application offers its users a lot of freedom to navigate through a large hyperspace. The rich link structure of the hypermedia application can not only cause users to get lost in the hyperspace, but can also lead to comprehension problems because users read information in an order not foreseen by the author. Adaptive hypermedia systems (or AHS for short) aim at overcoming these problems by providing adaptive navigation support and by providing adaptive content.

We have developed a reference model for adaptive hypermedia applications: AHAM (for *A*daptive *H*ypermedia *A*pplication *M*odel), which is an extension of the Dexter hypermedia reference model (Halasz et al., 1990, 1994). The goal of AHAM is to describe adaptive hypermedia applications, especially from the point of view of authors designing such applications. AHAM divides an AHS into a *Domain Model* (DM), *User Model* (UM) and *Teaching Model* (TM). This paper describes support tools that help authors to create these three parts of an adaptive hypermedia application, and to assure that these parts together form a usable and consistent complete application.

1. Introduction

The rich link structure that is typical of hypermedia applications offers users a lot of freedom to navigate through a large hyperspace. However, it also causes users to lose their way in that hyperspace, and it leads to comprehension problems because users may read pages in an order which the author did not foresee and which may not even make sense. Adaptive hypermedia applications aim at overcoming these problems by providing adaptive navigation support and adaptive content presentation.

An *adaptive hypermedia system* (AHS) (Brusilovsky, 1996) is a special kind of hypermedia system that can adapt the contents and links of an application depending on *observed* user features. For building an AHS, the author has to provide two (related) parts: first of all the author has to write the actual hypertext; second, the author has to specify some dynamic adaptation control information. In practice it turns out to be necessary to provide authoring tools that facilitate the specification of both aspects. In existing AHS (Brusilovsky et al., 1996a, 1996b, De Bra et al., 1997, 1998, Calvi et al., 1997) authoring is often inconvenient, due to the mixture of (textual) content and diverse hints for adaptation. In Interbook (Brusilovsky et al., 1996b) the author must write structured, annotated MS-Word files. In AHA (De Bra et al., 1998) the author must write annotated HTML files. This mixture of content, links and adaptation makes it difficult for authors to maintain a clear picture of how *concepts* relate to each other. This implies that it is hard to define adaptation on an abstract conceptual level.

In (Wu et al., 1998, De Bra et al., 1999) we have presented a reference model for adaptive hypermedia applications, called AHAM (for Adaptive Hypermedia Application Model). In order to separate different authoring aspects, AHAM splits up an adaptive hypermedia application into a *domain model* (DM), *user model* (UM) and *teaching model* (TM). These three parts together form what the Dexter hypermedia reference model (Halasz et al., 1990, 1994) calls the *Storage layer*. Apart from this layer Dexter and AHAM also mention (but do not formally define) a Runtime layer which deals with sessions and the actual presentation and interaction on the screen, and a Within-Component layer which deals with implementation dependent representations of content and links.

In this paper we address operations of DM, UM and TM that are needed for creating (authoring) adaptive hypermedia applications. We describe these operations at the conceptual level, not the implementation level. The definition of these operations shows how the tasks of 1) creating content, 2) combining smaller pieces into composite (abstract) concepts, 3) defining relationships between these concepts, 4) verifying the consistency of these relationships, and 5) defining rules for the adaptation of content and links to each individual user, are separated. The separation of these tasks will make authoring of adaptive hypermedia applications easier than it is today. The separated tasks together form a description of the functionality of an authoring tool based on the AHAM model.

This paper is organized as follows: In Section 2 we describe the AHAM reference model, with its three parts (domain model, user model, teaching model). In Section 3 we show how authoring is facilitated by adding support functions to these three parts. Section 4 concludes and indicates future work.

2. AHAM, a Dexter-based Reference Model

In hypermedia applications the emphasis is always on the information nodes and on the link structure connecting these nodes. The Dexter model captures this in what it calls the Storage layer. It represents a *domain model* DM, i.e. the author's view on the application domain expressed in terms of concepts. In *adaptive* hypermedia applications the central role of DM is shared with a *user model* UM. UM represents the relationship between the user and the domain model by keeping track of how much the user knows about each of the concepts in the application domain.

In order to perform adaptation based on DM and UM an author (or AHS designer) needs to specify how the user's knowledge influences the presentation of the information from DM. In AHAM this is done by means of a *teaching model* TM consisting of so-called *pedagogical rules*. An adaptive engine uses those rules to manipulate link anchors from the Dexter model's *anchoring* and to generate what the Dexter model calls the *presentation specifications*. Like the Dexter model, AHAM focuses on the Storage layer, the anchoring and the presentation specifications. Figure 1 shows the structure of adaptive hypermedia applications in AHAM.

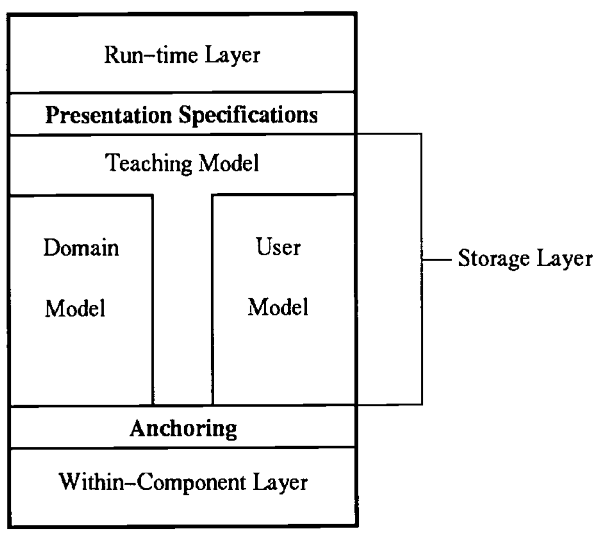

Figure 1: global structure of adaptive hypermedia applications.

In this section we present the elements of AHAM that we will use in Section 3 to illustrate the authoring functionality.

A component is an abstract notion in an AHS. It is a pair (uid, cinfo) where uid is a globally unique (object) identifier for the concept, and cinfo represents the *component's information* consisting of:

- A set of attribute-value pairs;
- A sequence of anchors (for attaching links);
- A presentation specification.

A *concept* is a component representing an abstract information item from the application domain. It can be either an *atomic concept* or a *composite concept*. An *atomic concept* corresponds to a fragment of information. Its attribute and anchor values belong to the Within-component layer and are thus implementation dependent and not described in the model. A *composite component* has two additional attributes:

- A sequence of children (concepts);
- A constructor function (to denote how the children belong together).

The children of a composite concept are either all *atomic concepts* (then we call it a *page* or in typical hypertext terms a *node*) or all *composite concepts*. The composite concept component hierarchy must be a DAG (directed acyclic graph). Also, every atomic concept must be included in some composite concept. Figure 2 illustrates a part of a concept hierarchy.

An *anchor* is a pair (aid, avalue), indicating the endpoint of a hypertext link. The avalue for an anchor in a composite concept is the identifier of a concept that belongs to that composite.

A *specifier* is a tuple (uid, aid, dir, pres), where uid is the identifier of a concept, aid is the identifier of an anchor, dir is a direction (FROM, TO, BIDIRECT, or NONE), and pres is a presentation specification.

A *concept relationship* is a component, with two additional attributes:

- A sequence of specifiers;
- A concept relationship type.

The most common type of concept relationship is the type *link*. This corresponds to the link components in the Dexter model, or links in most hypermedia systems. However, in AHAM we consider other types of relationships as well, that plays a role in the adaptation. A common type of concept relationship is *prerequisite*. When a concept C1 is a prerequisite for C2 it means that the user should read C1 before C2. It does not mean that there must be a link from C1 to C2. It only means that the system somehow takes into account that reading about C2 is not desired before some (enough) knowledge about C1 has been acquired. Figure 3 shows a small set of (only binary) relationships, both prerequisites and links. We treat links and other types of relationships in the same way in order to keep authoring support tools as generic and uniform as possible.

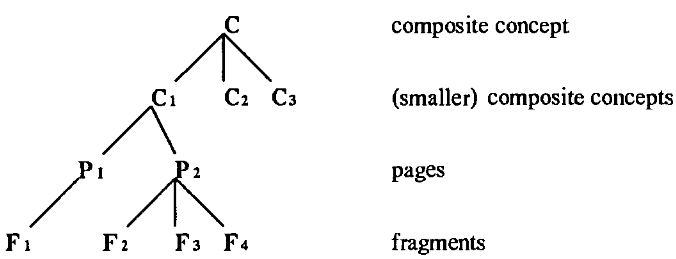

Figure 2: Example concept hierarchy.

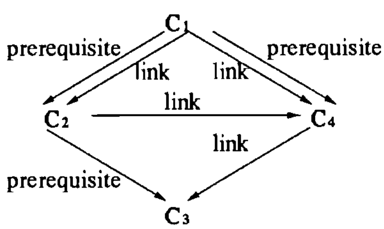

Figure 3: Example concept relationship structure.

The atomic concepts, composite concepts and concept relationships together form the *domain model* DM of an adaptive hypermedia application.

An AHS associates number of (system or author defined) user-model attributes with each concept component of DM. For each user the AHS maintains a *table* in which for each concept the attribute values for that concept are stored. The structure of this table is the *user model scheme*. The table for a specific user is a *user model instance*. If there is no confusion between scheme and instance we just use the term *user model*. One of the attributes of the user model is the unique (concept) identifier. Other attributes commonly found in AHS are the *knowledge value* and some "log" entry whether the user has *read* about the concept. The table below illustrates the (conceptual) structure of a user model, for a course on hypermedia. (In the example table the concepts Xanadu and KMS were at least partially learnt. The concept WWW, consisting of two sub-parts, is partially learnt because WWW-html has been read but WWW-http has not. One can see that WWW must be a composite concept that is not a page because it is already partially learnt while it has not been read at all.)

concept name (uid)	*knowledge value*	*read*	...
Xanadu	well learned	true	...
KMS	learned	true	...
WWW-html	well learned	true	...
WWW-http	not known	false	...
WWW	learned	false	...
...	...	...	...

A *generic pedagogical rule* is a tuple (R, PH, PR), where R is a "triggered" rule, PH is the "phase" for the execution of the rule and PR is a Boolean "propagate" field which indicates whether this rule may trigger other rules. The "phase" of a rule can have the value *pre* or *post*. The phase *pre* is executed before and during the generation of the page, while *post* is executed afterwards. These rules describe how an AHS works, but the AHS is not required to be rule based. In many existing AHS the behavior of the system is completely predefined. But in some newer systems, including AHA (De Bra et al., 1998), authors can add some kind of rules to the system.

A *specific pedagogical rule* is a tuple (R, SC, PH, PR) where (in addition to a generic rule) SC is a set of concepts used in the rule. The rule manipulates user-model attributes and "predicates" over specific concepts of SC.

An AHS may have predefined or implicit generic pedagogical rules. If these rules suffice there is no need for a language in which authors can write new rules. Author defined rules take precedence over predefined rules. Specific rules take precedence over generic rules, and are thus used to define exceptions to generic rules. The existence of the two execution phases makes it possible to do adaptation based on the "previous" state of the user model, and to update the user model to a "new" state afterwards.

A typical standard pedagogical rule for the *pre* phase is the rule that says that a link anchor will be *hidden* (or annotated as undesirable) if some prerequisite knowledge for the destination of the link is still not known. A typical standard rule for the *post* phase is the rule that says that a page-concept becomes *well learned* when the page is accessed and all prerequisite knowledge was present, and it becomes only *learned* when the page is accessed but some prerequisite knowledge was still not acquired.

The *teaching model* of an AHS is the set of (generic and specific) pedagogical rules. An *adaptive engine* (AE) is a software environment that performs the following functions (based on the rules):

- It offers generic page constructors.
- It optionally offers a (very simple programming) language for describing new page constructors.
- It performs adaptation by executing the page constructors.
- It updates the user model (instance) each time the user visits a page.

The adaptive engine thus provides the implementation dependent aspects while DM, UM and TM describe the information and adaptation at the conceptual level.

An *adaptive hypermedia application* is a 4-tuple (DM, UM, TM, AE), where DM is a domain model. UM is a user model, TM is a teaching model, and AE is an adaptive engine.

3. Authoring Support for AHAM

In this section we extend the (data) definitions of AHAM to include the operations that are needed for authoring. Because of lack of space we only give these definitions informally. We distinguish three main classes DM-Tool, UM-Tool, TM-Tool. These indicate which authoring functionality is needed for creating (and modifying) a domain model, a user model and a teaching model. When authoring (adaptive or non-adaptive) hypermedia applications it is difficult to verify global properties of the resulting hyperdocument. By separating domain model, user model and teaching model, the verification of properties becomes feasible and sometimes even easy.

DM-Tool must obviously offer methods to create and delete concepts and concept relationships. These methods may generate interesting side-effects that reduce the (manual) work for the author. E.g., when creating a new atomic concept, DM-Tool can show a dialog box to assign this atomic concept to a composite (which must be a page). When a page is deleted, DM-Tool can show a dialog box to let the author decide what to do with the fragments (atomic concepts) of this page. When a concept is added to a composite, DM-Tool can verify whether the composite only contains atomic concepts, or only composite concepts. We won't go into more detail here, but only describe support methods that work on a global level, and that can be used to verify the integrity of the domain model:

- "verify-hierarchy-is-DAG" checks that no (composite) concept directly or indirectly contains itself (as a child or a lower descendant). This check can be performed automatically each time a new concepts is added.
- "get-orphan-concepts" is used to find the atomic concepts that no longer belong to a page. It is not desirable to force the deletion of fragments when a page is deleted. The author may wish to keep some fragments and add them to other (new) pages later.

Each concept relationship type may have its own constraints. The combination of concept relationship types may introduce additional constraints. Whether DM-Tool can verify these constraints depends on their definition. Some methods for verifying common constraints are:

- "verify-connected-links" checks whether every composite concept (including pages) can be reached by following links from a given starting page.
- "verify-acyclic-prerequisites" checks whether no concept is a prerequisite for itself, either directly or indirectly.
- "verify-conditional-links" checks whether for every composite concept (including pages) there exists a path leading to that concept, from a given starting page, starting with the "default" user-model instance, and without visiting concepts for which prerequisite knowledge is missing.

The third method is a nice example of how the verification of constraints becomes difficult when different types of concept relationships are combined. Also, the verification is based on implicit assumptions about how the user model evolves. Indeed, this verification only works if we make assumptions about how the user model evolves based on the user visiting certain concepts. Figure 3 for instance shows a *sound* structure, only under the assumption that visiting a concept C_i implies that enough knowledge is gained about C_i to warrant that prerequisites that depend on C_i are fulfilled.

In an object-oriented view the UM-Tool can be considered as an object that contains DM-Tool as a part. When UM-Tool contains DM-Tool it becomes possible to model the interaction between the user model and the domain model as being part of the functionality of UM-Tool.

The authoring support of an AHS must include a method for propagating updates to the domain model DM to the user model. In our view this means that UM-Tool needs a method for importing all concepts from DM into UM. However, an author may wish to keep the user model simpler by only keeping some concepts in the user model. Therefore, we have an auxiliary method "verify-all-concepts-in-DM" to check whether all the concepts from UM are in DM, but no method to verify the opposite (because the opposite may not be desirable).

UM-Tool has different kinds of methods:

- "add/delete-concept" is normally available to the author, to manipulate the user model and eliminate low level concepts that exist in DM but are not of interest. (The author may wish to define the adaptation based on knowledge of high level concepts only.)
- "add/delete-attribute" is a method to add a user-model attribute to every concept. It means that the AHS is able to record values for this attribute about each concept. While the AHAM model describes the user model as a table structure in which all attributes are available for all concepts, a particular AHS may have a more restrictive implementation. In the AHA system (De Bra et al., 1998) for instance, there are some "concepts" that represent color preferences for links. These concepts only have a "color" attribute, while the other (real) concepts only

Whether authors can extend the user model with new attributes depends on the AHS. The limiting factor is the ability or inability to actually use new attributes. The *rules* in TM are the (only) means to use new attributes.

TM-Tool provides methods for creating *pedagogical rules*. In the object-oriented view TM-Tool contains DM-Tool and UM-Tool as parts. This makes it possible to describe the interaction between DM-Tool and UM-Tool as being part of the functionality of TM-Tool.

- "add-spec-pre/post-rule" are methods for creating *specific* rules. The author can add rules that work with *specific* concepts. The syntax of such rules depends on the AHS. An example of the use of specific rules in AHA (De Bra et al., 1998) is:

```
...
<!-- if readme and not intro -->
      This text only appears if "readme" is a known concept
      and "intro" is not yet known.
<!-- endif -->
...
```

- "add-gen-pre/post-rule" are methods for creating *generic* rules. Generic rules specify how the AHS should handle events and concept relationships of a given type. A *generic* rule about *prerequisite* relationships could say:
  - When a user visits concept C and all prerequisites are satisfied the knowledge about C becomes 0.8.
  - When a user visits concept C and not all prerequisites are satisfied the knowledge about C becomes 0.5.

  This rule applies to *all* prerequisite relationships, while the above example from AHA only works for a specific instance, with two specific concepts.

If TM-Tool lets authors create their own generic rules, possibly using their own attributes added to UM, it may not be possible to automatically verify the consistency of the rules. In the current version of AHA (De Bra et al., 1998) only specific rules are permitted, using a simple and not very expressive language. While this limits the power of

AHA it makes it possible to perform the verification that all concepts (pages) can be reached from the given starting page without violating any of the conditions.

An advanced AHS will let authors define their own (generic and specific) pedagogical rules. However, in the near future (and in our redesign of AHA) TM-Tool will most likely only let authors *configure* predefined rules. In the example above, the knowledge values of 0.5 and 0.8 could be author-configurable for instance.

4. Conclusion and Future Work

We have defined authoring support by specifying three main classes UM-Tool, DM-Tool, and TM-Tool. In the class definitions we have described the data model and the support operations for authoring. The division of adaptive hypermedia applications into a *domain model, user model* and *teaching model* makes the task of authoring clearer by separating different concerns. We have also indicated the main support functions that are needed to ensure that the three generated parts are internally consistent and also consistent with each other.

We are currently working on a redesign (and re-implementation) of the AHA system (De Bra et al., 1998) which is being used at the Eindhoven University of Technology for a course on hypermedia (URL http://wwwis.win.tue.nl/2L690/), a course on graphical user interfaces (URL http://wwwis.win.tue.nl/2M350/), and a kiosk information system for students who wish to do an internship or master thesis in information systems (URL http://wwwis.win.tue.nl/IShype/). AHA is also being used for the development of a course in language learning (Calvi, 1998). AHA currently offers authors the ability to specify *specific rules* for the inclusion of fragments or for determining the desirability of links. We hope to extend AHA with the ability to specify *generic rules* as needed by richer tools for creating user models and teaching models.

Abstract: In the rapidly developing area of User Interface Design (UID), the existing knowledge and understanding of UID serves as a basis for further research and study of factors affecting users as they interact with interfaces that utilize the technology of multimedia, virtual reality and intelligent agents. Color and navigation are two of the factors that are being investigated to help designers develop user interfaces that are effective and efficient for the users. This paper describes a color-coded navigation tool developed to support research about the effects of color on navigational decisions in a virtual reality environment. The tool, Color-Coded Virtual Reality Navigation (CVRN), allows the design and exploration of color-coded three-dimensional worlds and provides for navigational tracking. When using CVRN, the structure of the virtual world is a never-ending building composed of many empty rooms. CVRN enables researchers to customize experiments that allow for testing a subject's navigational behavior and color preferences in a virtual reality environment.

Introduction

Human Computer Interaction (HCI) especially as it relates to User Interface Design (UID) is one of the most rapidly developing subject areas in computer science and information systems. There has been a tremendous growth in interest about human computer interaction in the past two decades since the development of the personal computers, and subsequently, since the wide-spread use of computers by those outside the professional realm of computing. The study of HCI, a multidisciplinary area, has contributed substantially to the knowledge of how humans interact with computers. The results of such study have enabled the developers of computer systems to deliver products that are usable and that effectively support the user community.

Coupled with the development and discovery in the area of HCI are significant advances in technology that add to the complexity of the User Interface Design. In the last ten years, issues in UID have changed from those related to relatively simple text-based non-color screens to those related to interfaces which combine video and live images with text, sound, graphics and color. Furthermore, the user is now able to interact with the computer application system through these interfaces and UID also involves interaction issues. Currently, virtual reality and intelligent agents are also being incorporated into the user interface. Even though, the understanding of HCI has advanced rapidly over the same time span, technology has advanced to a greater extent. Consequently, HCI needs to consider the implications of new technology on the development of user interfaces. The basic knowledge and understanding that already exists regarding user interface design can provide a good foundation upon which to build a basis for research and study of factors affecting users as they interact with interfaces that utilize this new technology.

Color is one of the factors that has been researched and studied both as a physical property in the world of physics and as a factor in the two-dimensional world of user interface design. In fact many guidelines for using color in user interface design are available that aid the designer in developing user interfaces. Consequently, effective use of color in screen design has been increasing and is much more prevalent currently that it was at the beginning of the decade. Color is used to assist in formatting or organizing visual displays, to relate single elements into groups or to separate items from each other. It is used as a visual code to help the user identify or give meaning to items. It is used to attract the user's attention, to increase the display's appeal to the user and to portray natural objects. Experience with the use of color in many fields as well as that in user interface design has provided the user interface designer with much knowledge about what works well with colors and what doesn't and what the potential problem areas of color usage are. However, "There is a lot to understand about color in user interface design." (Shubin, et. al., 1996). This is especially true since the perception of color is highly subjective and is affected by both one's physical capability to perceive color and one's expectations about color use based on culture and learning or experience.

Navigation is another of the factors that has been researched in the two-dimensional world of user interface design. Interface designers have gained some insight into the navigational patterns of different groups of users based on user characteristics (Beasley & Vila, 1992; Beccue & Vila, 1992, 1994; Rendon, 1994). As designers work with three-dimensional worlds, they need to know whether the findings related to two-dimensions or to real world behaviors still apply. In reviewing literature related to navigation patterns in HCI, it was found that the research involving navigation in three-dimensional environments is concerned with research which focuses on navigational awareness, spatial ability or wayfinding (Satalich, 1995). The two-dimensional research on navigation patterns more closely aligns with wayfinding than with the other two areas.

Regian and Shebilske (1990) conducted a wayfinding study in a virtual reality environment. The environment was a virtual maze consisting of three stories with four rooms on each floor. Each of the twelve rooms contained a unique color-coded geometric object. Subjects were taken on three different verbally directed tours, then given one hour of free time to explore the environment. After this learning time, the subjects were given 3 wayfinding tasks each of which consisted of finding a specified object. They were instructed to take the shortest path to the destination. The authors found significant differences between the number of rooms visited by the subjects in each task and the number of rooms visited by a random walk algorithm for each task. While this experiment addresses the ability of subjects to learn navigational skills in a virtual environment, it does not indicate how they learn i.e. by self-exploring, by verbally guided tours or by a combination. The study did not investigate navigational patterns that might have been followed by the subjects.

Other research has shown that people do not make random decisions on which path to take at each decision point in wayfinding (Peponis, et. al., 1990). In fact, Peponis observed that people tend to avoid backtracking and to find visual vantage points or places that provide the best visual access to other areas of the environment.

One informal study investigated toolsets for wayfinding in virtual environments (Darken and Sibert, 1993). The following toolsets that were available to study participants: landmarks, flying, spatial audio markers, visual markers (breadcrumbs), coordinate feedback, grid navigation and either track-up map-view or North-up map-view. The use of the tools by subjects was examined for three different search conditions. One search condition was to explore and learn the environment. Another condition was to locate a known object. The third condition was to locate an object when information about its location was known. Through observation it was noted that the subjects used the different tools in a variety of ways and not always as expected. For example, breadcrumbs were used more often as landmarks than as a trail.

Satalich (1995) studied navigation and wayfinding in a virtual reality environment. The VR environment was a U-shaped building containing 39 separate rooms and over 500 objects. The building had some wide open spaces and other distinctive areas. Paintings and objects were located so that they could be used as landmarks. Subjects explored the building in one of the following ways: self-exploration; active guided where subject followed a pre-determined path; and passive guided where subject was moved through environment at a constant speed with no interaction. The control group only studied a map of the building; they did not explore the environment. In addition to the type of exploration, subjects either had access to a map for five minutes before entering the building or they did not. A third factor was whether or not subjects had a map during the exploration phase of the experiment.

The tasks assigned to the subjects in the Satalich study to investigate navigational awareness utilized the following three measures: orientation, route estimation and Euclidean estimations. The results indicated that having a map before entering the virtual environment improved performance but exploring the virtual environment did not. In addition subjects were given two wayfinding tasks. In the first wayfinding task, finding a room with a particular object in it, there were no differences between the control group and those in the different VR exploration groups. Those subjects who had access to a map prior to entering the VR environment performed significantly better than those who had had no access to a map prior to entering the VR environment. The results suggested that having a map during the wayfinding task may have interfered with wayfinding. Results for the second wayfinding task, finding a specific laboratory when the two main routes were blocked with fire walls, showed no significant differences across experimental conditions. However, the difference between the performance of the control group and those groups who had no access to any maps was significant. Satalich observed that the behavior of the subjects clearly indicated that decisions on which way to go were not random. Specifically she noted that "subjects, even when lost, would not backtrack without purpose."

The limited research into navigation patterns of users in virtual reality or 3-dimensional worlds raises many questions. The current research seems to indicate that navigation and wayfinding performance is not clearly understood and that more investigation is needed in order to gain a better understanding of the issues involved. Additionally, little research has been done on navigational patterns although what research is available seems to indicate that navigational patterns do exist. One factor which may affect a user's navigational behavior is color. In order to investigate how color may impact the way that users navigate in a 3-dimensional world, one needs to be able to control and change the color of the 3D environment and to track an individual user's movements through the color-coded virtual reality space.

This paper describes a color-coded navigation tool that facilitates researchers efforts in studying the effects that color may have on navigational decisions in a virtual reality environment. The tool allows the design and exploration of color-coded three-dimensional worlds and provides for navigational tracking. The structure of the virtual world is a never-ending building composed of many empty rooms. The tool enables researchers to customize experiments that allow for the testing of a subject's navigational and spatial behavior in a virtual world as color is changed.

Tool Use for Experiment Design & Methodology

In this phase of on-going research into navigational preferences of computer application users, a tool was designed and constructed that will be used to conduct research into the effect that color has on navigational decisions in a virtual reality environment. The Color-Coded Virtual Reality Navigation (CVRN) research tool will allow the user to explore a three-dimensional environment. The researcher can specify colors and track the user's navigational decisions when the user is performing an assigned task. Thus the study of color and user's reaction to it will be enabled through the use of CVRN to customize a VR environment and to track the user's actions.

The current version of CVRN incorporates the following components: the VR Environment Setup, the Demographic Survey, and the VR Experiment Interface.

The Demographic Survey enables the researcher to gather and record information about the subjects such as age, gender, level of education and national origin. The VR Environment Setup module permits the researcher to specify color distribution among the different rooms that compose the virtual world. The color distribution is determined by means of an RGB triangular model that permits multiple orientations and control for saturation and lightness. The setup module enables the researcher to place landmarks within the world to support wayfinding tasks. While the subject is navigating the environment and completing the tasks, his movements will be tracked and the time spent in each room logged. The VR Experiment Interface module is the world with which the user will be interacting to accomplish a specified task. Thus, CVRN will facilitate research efforts into the effect that color has on navigational decisions by providing a flexible tool that can easily be customized to conduct relevant experiments.

CVRN allows researchers to track navigational patterns of each subject when performing a task. Experiment designers can use CVRN to create various customized color-coded environments, to set landmarks and to prepare tasks and instruments to track navigators decisions. Analysis of data collected via the use of CVRN is still the responsibility of the researcher.

Researchers through their color-coded designs can evoke a subject's natural route decision making, if any. For example, a subject navigating the world of an achromatic design may choose a different navigational route than when navigating in a chromatic world. Within the chromatic world, a researcher could also use the tool to shed some light into the effect that hue, saturation and lightness may have on route selection.

The tool will allow the researcher to verify that color is the determining factor in route selection patterns since the color orientation or distribution within a world can be changed and controlled.

CVRN depicts a building with an infinite number of rooms, each having four doors. Each room can be set up with a distinctive hue, saturation and lightness. If the subject is free to explore the created environment, what would the navigation trail be? Are there any demographics that correlate to navigational decisions within particular color-coding (i.e., gender, age, right handedness, etc.)? Are there some color-coded designs that affect the sense of orientation more than others? In achromatic or chromatic designs, how many turns can a subject recall before complete disorientation occurs? The measures recorded by CVRN such as navigator location, time stamps, number and type of turns and landmark finding provides the researcher with electronically recorded information that will make organization, manipulation and analysis of data more efficient and accurate.

Technical Description of the Tool: Color-Coded Virtual Reality Navigation

The Color-coded Virtual Reality Navigation research tool (CVRN) is comprised of three modules: the *VR Environment Setup*, the *Demographic Survey*, and the *VR Experiment Interface*. All the modules are accessible by pull-down menus from the CVRN Main Screen. These modules were implemented using Microsoft Visual C++, Autodesk 3D-Studio, Microsoft Direct3D, Microsoft Visual Basic and Microsoft Access.

The *VR Environment Setup* includes the capability to select the color distribution based on a traditional RGB triangular color model and to place landmarks within the Virtual World. The VR Environment Color Distribution Setup Screen (Figure 1) includes the color orientation and the saturation and lightness control settings. The Landmark Placement Screen (Figure 2) includes drag and drop operation for landmark placement within the grid that represents the virtual world. The subject's starting navigation point in the world is represented by a red square in the middle of the grid. Originally, the landmark, which is represented by a blue square, is located outside the grid. This object can be placed anywhere within the grid. In Figure 2, it has been placed in the upper quadrant of the grid. One can use the arrows in the right hand side to show a path to the object. Currently, this capability is available only in the *VR Environment Setup*.

The *Demographic Survey* module is invoked from the CVRN Main Screen's Add pull-down menu. The *Demographic Survey Screen* is a form for the collection of demographic information from each subject who participates in the study. After completing the survey, the subject proceeds to the *VR Experiment Interface*.

The *VR Experiment Interface* depicts a virtual world consisting of a building with an infinite number of color-coded rooms in compliance with the *VR Environment Setup* parameters. See Figure 3.

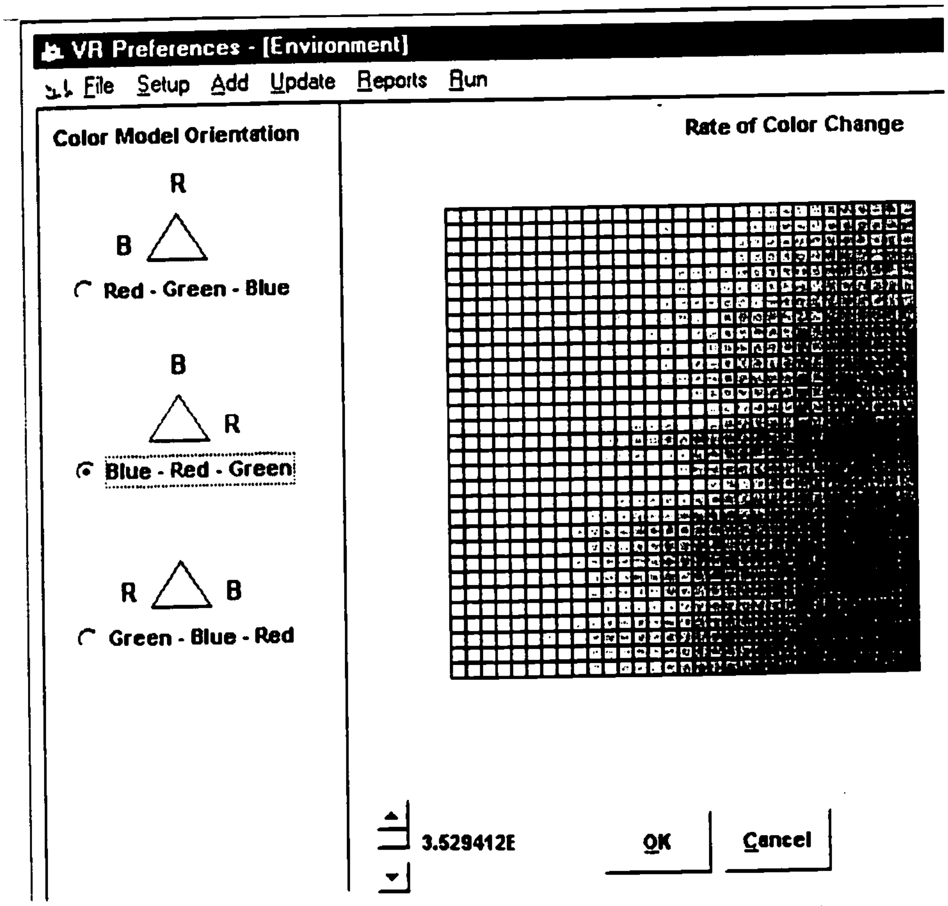

Figure 1: VR Environment Color Distribution Setup Screen

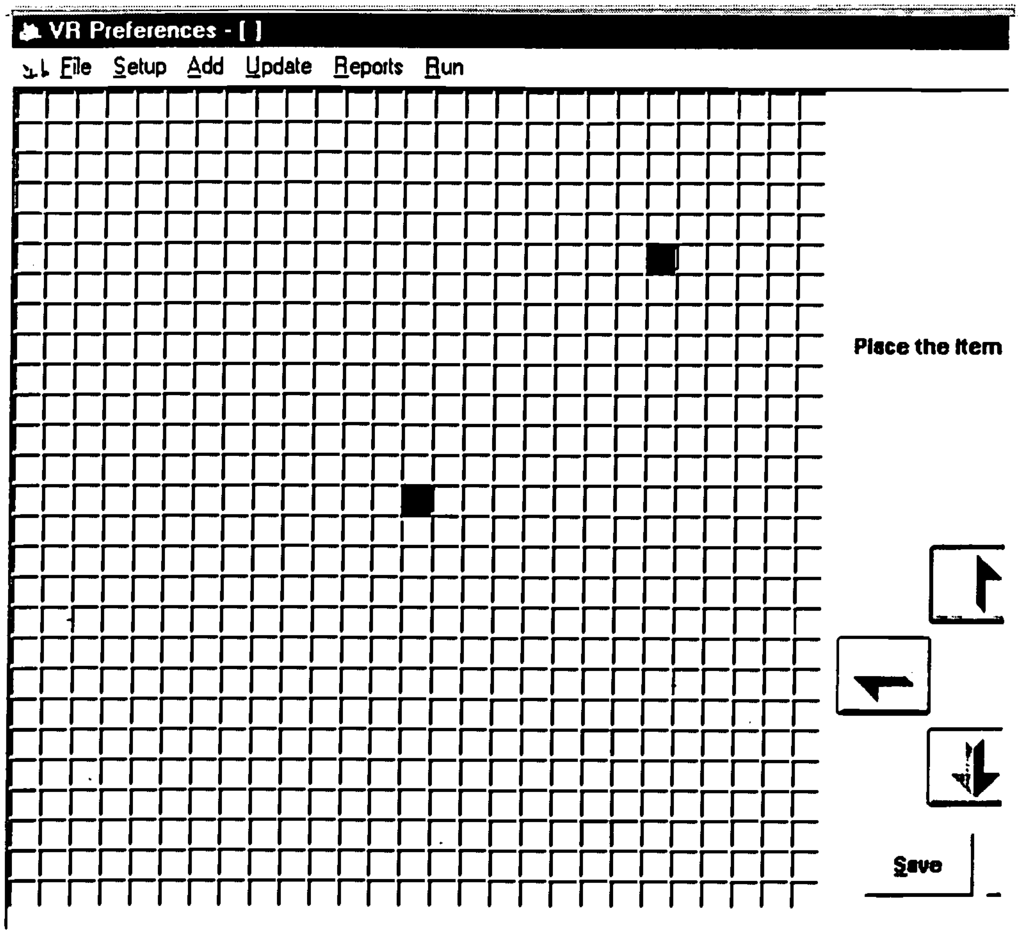

Figure 2: Landmark Placement Screen

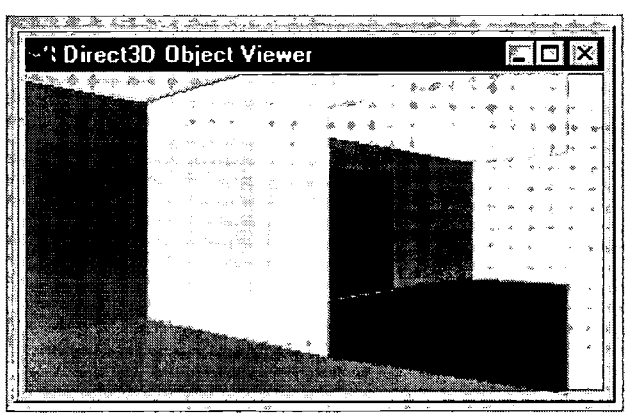

Figure 3: The VR Experiment Interface

The VR Experiment Interface supports two window resolutions: 320x200 and 640x480 pixels. The lower resolution of the VR environment can be used on less powerful machines to gain speed and provide for smother animation. The higher resolution can be used on more powerful machines to provide a larger VR field. The navigator can traverse the world using the arrow keys or look-around (rotate in the Y-axes) using the mouse. Once that the subject completes the specified task the experiment's data is saved in a database for future analysis.

Summary

CVRN was designed and constructed to support research about the effects of color on navigational decisions in a virtual reality environment. Research in this general area is hampered by the need to control or stabilize many factors while allowing the investigator to examine variables of interest and by the need to take or track many measurements of the activity generated during experiments. In order to investigate how users navigate in a 3D world, one needs to be able to track an individual user's movements through a virtual reality space when that user is attempting to accomplish a specific task. CVRN provides a template and data collection capabilities which enable the researcher to conduct such investigations in an effective and efficient manner.

Abstract: The Ohio University College of Business has been using problem-based learning approaches to instruction for the last 13 years. In March of 1997, the MBA Without Boundaries program was launched as a distance offering using a project-based action learning format. Participants progress through the program as a cohort and work on nine projects over the course of two years. Participants come to campus for 4 to 8 days between projects for debriefing on the project just completed and to be introduced to the next project.

Participants work in teams of four or five using Lotus Domino as the conferencing system for conducting their work. Faculty members monitor the participant work and offer two types of commentary. First, there are infrequent coaching comments offered if a team is seen to be particularly bogged down -- coaching focuses on the problem-solving tactics and group processes being employed. Second, faculty members offer project reviews offered to the entire class. This is a "how is the class doing" perspective -- commenting on similarities and differences in both strategies and the products that are being produced.

In this paper we will present an overview of the program and then focus on two issues: 1) instructor coaching and feedback and 2) participant interaction using Domino. Goals, alternative strategies, and problems in providing feedback will be discussed, with particular attention to the difficulty of balancing the felt need to "teach" the participants when they encounter difficulties with the goal of maintaining learner ownership. Participant conferencing strategies and the protocols they develop will be discussed. Both samples of their conferencing and data from interviews with the participants will be presented. For both participant conferencing and faculty coaching we will pay particular attention to how the strategies evolve across projects.

Program Overview

The Ohio University College of Business has been using problem-based learning approaches to instruction for the last 13 years. For more detailed descriptions of the evolution of the program development see Milter & Stinson, 1995 and Stinson & Milter, 1996. In March of 1997, the MBA Without Boundaries program was launched as a distance offering using a project-based action learning format. This followed over a year of development work between the core design faculty team and an external review board comprised of key individuals from corporations and learning centers. Selected participants must have at least 2-4 years of increasingly responsible positions and must be sponsored by their company. The actual average experience level in the first class begun in March 1997 is about 6 years. The average experience level for the second class begun in February 1998 is about 8 years.

The MBA Without Boundaries program uses an action-learning format with a theoretical base in cognitive constructivism, which places the learner into exactly the type of projects and work situations that he/she will face as a leader of the knowledge-age organizations of the 21st century. Participants learn basic business concepts in the context of their use, maximizing their ability to both recall and apply those concepts as they move back into the work world. Participants also develop the skills (communication, collaboration, teamwork) and the personal characteristics (initiative, creativity, personal responsibility) that are becoming so necessary for success. Participants develop a high level of comfort with information technology as they regularly access information through the resources of the internet, collaborate electronically over time and space, and develop and make professional-level computer-driven presentations.

The program targets 9 major projects. The projects tend to be large macro problems that address business holistically. Within each project are multiple smaller problems that participants must address to manage the total learning problem. Participants construct their knowledge of business practices by working their way through the problems. Participant learning is aided by the ability to access appropriate content on a just-in-time basis. Participants learn content at a time when it will be most useful to them in their management of the learning problems. While some of the problems are designed to challenge individuals separately, most of them are designed to be approached by collaborative learning groups.

While focusing on more macro problems and working with larger groups, the action-learning process employed is a derivative of Reiterative Problem-Based Learning, which was developed by Howard Barrows (Barrows, 1985), and follows closely the concepts of cognitive constructivism (Savery and Duffy, 1994) and cognitive apprenticeship (Collins et. al., 1990). (For a more complete description of our use of the action learning process, see Stinson, 1990, and Milter and Stinson, 1995.)

The program begins with an intensive one-week residency (Sunday 1pm through Sunday Noon). The participants then return to their homes and work assignments not to see each other again for 3 months. After 3 months of online interaction and collaboration, program participants meet for an intensive weekend (Thursday 1pm through Sunday Noon). Each project begins and ends in a residency. Participants progress through the program as a cohort and work on nine projects over the course of two years. Participants come together every three months during the two-year program; three extended weekends and one full week each year.

The faculty team, in regular consultation with the external review board, designs seven of the nine projects. Two of the projects are individual projects where participants design and implement projects of personal interest (these projects often benefit their company). Each project is developed to meet specific learning outcomes. In order to provide a foundation for the total program design, meta outcomes are developed by faculty members in discussion with executives and futurists. Content-to-action outcomes are more specific learning goals that participants need to learn in order to fulfill project expectations. The meta outcomes and content-to-action outcomes for the MBA program are as follows:

Meta Outcomes
(Approached through total program design)

A holistic understanding of business and the environment in which business functions.

A degree of technical expertise, but not a sub-optimal functional orientation.

Knowledge of current business practices and factors influencing those factors, but not knowledge alone. The ability to apply the knowledge effectively is critical.

A proactive orientation with the ability and self-confidence to take initiative and function independently.

The ability to tolerate ambiguity and the ability and self-confidence to clarify own role through normal interaction with others, internal and external to the organization.

The ability to manage self - time, resources, priorities, stress.

Communication skills, with particular emphasis on the ability to communicate ideas succinctly in oral form and electronically. While traditional report writing remains important, it will be less so in the future.

The ability to work effectively using electronic information technology.

The ability to collaborate effectively - the ability to influence others and be influenced, to listen and understand, to work out differences so they do not become destructive conflicts, to use diverse perspectives, cultures, and expertise to maximize effectiveness.

Content-to-Action Outcomes
(Approached through multiple projects)
Analyze an industry and develop a reasonable foresight for the industry.
Collect competitive intelligence, analyze emergent strategy, and determine competencies, strengths and weaknesses.
Analyze a company, identify important competencies and propose what the company should do now to compete effectively in the future.
Identify a market (customer value added) for a new technological development
Develop a proposal to a venture capitalist to obtain capital for a new venture.
Develop a business plan to effectively implement a new venture.
Select, from among alternatives, the most promising of new ventures.
Develop a program to develop and bring a new product or service to market.
Identify an appropriate manufacturing system and prepare a macro design of the system.
Analyze a process and propose a redesign that minimizes waste and maximizes quality.
Select from among alternatives, the most appropriate operational improvement techniques or programs, and design the implementation strategy.
Develop global sourcing strategies and programs.
Define a market, identify demand determinants for a product or service, and estimate demand.
Determine and appropriate price for a product or service.
Develop and implement a promotion strategy and program for a product or service.
Create, interpret, and use financial statements
Analyze cost structure and determine cost of products and services, using different cost accounting approaches (full, marginal, ABC).
Using ratio analysis and other appropriate techniques, determine the financial strength of a company.
Determine capital needed to support business activities and determine how to best obtain that capital.
Demonstrate sensitivity to the disparate cultures, values, and behaviors of non US business
Perform country analysis, determine potential for products and services in non-US countries, and identify appropriate modes of entry.
Operate effectively within the complexity of global, simultaneous domestic and international, business operations.
Identify and consider significant foreign trade issues, including laws, regulations, and currency exchange.
Perform basic business research, primary and secondary, using appropriate resources.
Incorporate ethical and social issues in process of making business decisions.

Each project has a set of "content-to-action" learning outcomes that are specifically linked to actions required during the projects. These outcomes are shared with participants and jointly agreed upon at the outset of each project during the reiteration on the first day. For the two individual projects participants develop a set of personal learning outcomes they wish to target.

Online Collaboration and Learning

During the 3-month span between the residencies participants, faculty, and outside resources collaborate online. Lotus Notes Domino is the software used to provide a platform for teams to work together and faculty to interact with the teams, individuals, and other faculty. Most faculty members initially believe it takes a lot of time to do it well. In actuality only 30 minutes per day checking on the database is usually sufficient to read entries for a class of 25 participants. It may take a bit longer to respond to many entries. Faculty members find that they must keep up or the entries can pile up.

Like other forms of groupware, Lotus Domino offers key enablers to assist with the collaborative work of learning. The elements of groupware as described by Lotus (1995) suggests that it must combine three essential elements to be viable:

- A reliable, scaleable and secure distributed document database. The database-centric model gives users the ability to assemble, share, and manage the rich variety of documents vital to conducting business --business plans, contracts, orders, product information, calendars and to-do lists, multimedia presentations, faxes, scanned images and video clips.
- An integrated messaging system. Groupware users must be able to take advantage of a messaging infrastructure to send and receive electronic mail and move documents through a workflow process.

- A rich application development environment. Developers must be able to rapidly build portable and scaleable strategic applications, which span document-oriented and structured database information.

Although most of the previous use of Domino has made use of its ability to serve as a document database, the integrated messaging system and application potential is being presently evaluated for future use. The present configuration of Domino for the MBA Without Boundaries program contains two major sections: common and project-specific databases.

Common databases are available on the Domino Intranet Homepage include:

- announcements (information about the program in general),
- address book (with pictures and information on participants and faculty),
- general discussion (about non-project matters or tangential issues),
- learning resources (collection of selected best of the breed for knowledge enhancement),
- technology issues (trouble-shooting area and FAQ items),
- internet resources (online knowledge adding items and skills enhancement areas),
- faculty/staff discussion (private area for faculty to work together in development and evaluation).

Project databases on the Domino Intranet Homepage include:

- project discussion (specific discussion regarding the current project),
- learning activities (learning issues and questions of the week assignments for individual assessment),
- database for each team (collaboration on the current project).

The Intranet Homepage also contains links to a help document, chatrooms, earlier project databases, and the College and University Homepages.

During some projects a database for "Question of the Week" is used. In this database each week a faculty member poses a relevant question for participants to respond to during a two-week period. Responses are evaluated on the basis of their ability to move the discussion forward by adding new insights or appropriate synthesis reflections. Participant evaluation for each project is split between 40-60% on team deliverables and individual performance. The individual performance is comprised of performance on learning outcomes, reports, questions of the week, and post-project assessments.

Instructor Coaching and Feedback

Part of coaching is the ability to offer new information as needed by individual learners. During the 3-month distance period of each project, faculty members provide learning module material via "streaming video" by placing 5-10 minute clips onto the Domino database. Participants use RealPlayer to play the video, audio, and/or the PowerPoint slideshow to view these "video connect" segments. This allows individuals with various learning styles to stay in their strong suit as they digest new information. Participants can question any module material online in the project discussion database. They can view the video connect as often as they wish merely by clicking on the icon for the clip.

Another element of coaching is the provision of feedback about the process or the content being dealt with by the learners. Faculty members react to the entries made by participants in the various individual and team databases and deliver feedback on a continuous basis. Each project has a faculty member serving as the project director. The project director is responsible for tracking individual entries required in the learning issues and "question of the week" databases. Each team is assigned a faculty mentor who is responsible for tracking the team's deliverables during the project. These activities also occur via the Domino databases.

Another area for coaching is in the learning issues database. As learning issues are defined, they are stated as questions. As participants find information and draw conclusions related to the learning issues they make entries in the database. These are reviewed and all participants and faculty members can express comments. These entries are one source of evaluation of participant learning.

Participant Interaction Using Domino

Participants use the various databases to submit information, ask questions of faculty and outside resources, discuss issues with colleagues and faculty, socialize, and collaborate in their project teams. After a couple of days most individuals become adjusted to using the asynchronous mode of interaction provided by the Domino database for these activities. There are, of course, times when synchronous discussion is preferred. When the team members need to reach consensus about a future direction or the value of a specific timely piece of information, it is advantageous to meet together at the same time. The database contains links to a chatroom (Microsoft's NetMeeting) that allows a team to hold a synchronous session. The chat software records these sessions and the chat log is placed in the team's database for tracking and archival purposes.

The Domino database allows participants to move quickly through various discussion, teamwork, data sources, chat, and other areas of collaboration. It allows participants to sort by topic, date, person, or category. It also allows for searching by key words. Because it is on the web, URLs that are entered immediately become hotlinks to the source sites. This makes it convenient for sharing detailed information on an "as needed" basis. The ability to function on an "as needed" basis is pervasive in the learning approach used by the MBA Without Boundaries program. The use of this web technology enhances the ability to deliver learning modules, information, tutoring, coaching, instruction, and collaborative space when the learner needs them. Recognizing the differences in learning and living needs among a group of learners, it would be difficult to offer such a program without the support of a software tool like Lotus Domino.

Reflections from MBA Without Boundaries Graduates

One recent graduate expressed the following reflections ... The MBAWB program has provided an opportunity to define and develop my individual and business competencies necessary to compete in today's challenging business environment. For the past two years a virtual relationship among twenty-one individuals has been established.

Sharing personal knowledge and experiences has provided a unique learning experience. It has changed my perception of how I learn. This was a struggle initially because of past industry and organizational cultural experiences. Being able to trust and share ideas on team projects that offer solutions to complex problems has been truly enlightening.

During the course of the program we have completed nine projects. Seven of the projects were team orientated and the other two projects conducted individually. These projects have provided the framework for a continuous learning process that will remain with me for a lifetime. The combination of participating in concept discussions, learning issues and assigned projects has enhanced my skill set and self-confidence to a level that will allow me to achieve my desired goals.

This can be best demonstrated by the project outcomes presented to third party clients involved with the Global Account Organization and Euro Currency. These dynamic learning experiences are unsurpassed and provided me with a tremendous amount of confidence.

Furthermore, the reflection process provides an opportunity to assess the past two years and quantify those competencies that were learned and will make me an effective business professional. First and most exciting to me is the development of my technical competencies. Turning on the computer was about the extent of those skills before entering the program. To elaborate, my ability to utilize MS Word, Excel and Power Point software is definitely a milestone. In addition, I am intimately involved in the startup of a computer product and service company with the purpose of positioning it to take advantage of the electronic business revolution transcending today's business and economic practices.

Another recent graduate offered these reflections ... The hard stuff is not the hard stuff. Actually, the soft stuff is the hard stuff. The hard numbers are scorecards documenting how well you managed the soft stuff. People are the ultimate challenge in business. How do you motivate them? How can you minimize distractions? How can you encourage them to adapt continuously? How can you persuade them to be loyal when the commitment is not returned?

Leadership still matters. The forest and the trees both matter. Even at the tree level, leaders must instruct, encourage and persuade. As information proliferates, someone must decide what is more important and which priority is next. Effective organizational leaders produce other effective leaders. Ineffective leaders stifle the entire organization.

Technology is a double-edged sword. Technology both raises and lowers barriers. Technology is a wonderful place to hide. Technology is a kind of wind tunnel. Whether one flies or crashes depends on how well one is designed.

Learning is the easy part. The challenge is in the doing. Asking the right questions is important. And figuring out what they are is no piece of cake.

Conclusion

We began working with this innovative and evolving platform for learning 13 years ago. At that time we made the commitment that if we ever thought we had it right it would be time to get out of the business. We do not believe we have it right. We have never offered the same program two years in a row. At each residency we hold a feedback session with the participants with the goal being to improve the program. We keep an open discussion in our databases for the same purpose. We are constantly searching for better ways to assist learning.

It is not easy to find faculty members willing to step out on such an ambiguous and often tenuous platform. When we do find them we cherish their involvement as much as they fully cherish the experience. Participants in the program, including faculty members, gain first-hand experience in what it takes to develop a true learning community. These experiences usually transfer immediately to other learning situations. It becomes a true spiraling of knowledge and learning how to learn.

Abstract: Over the last 3 years, the Open School, a service of the Open Learning Agency focussing on K-12 curriculum, has undertaken a comprehensive project to develop an end-to-end course development and delivery framework based on SGML/XML. This paper discusses the scope and direction of the project and outlines the processes involved in developing an Open School course, from Instructional Design to delivery in multiple media. Benefits of the approach and implementation issues are examined.

Introduction

Open School, a service of the Open Learning Agency focusing on K-12 curriculum, provides distance education courses and resources for students in the province of British Columbia, Canada. Traditionally, Open School has produced print-based correspondence courses. However, over the past five years, we have experimented with distributed learning technologies including proprietary client-server applications, web-based course delivery, online student collaboration, database-driven competency-based systems, and immersive virtual environments.

We have learned that to meet the needs of an ever expanding and changing client base, Open School must embrace new models of delivery and services beyond our core business as a producer of correspondence courses. Open School courses and resources need to be more flexible in their assemblage, customizable for individual clients, portable across different media, and accessible to as many students as possible.

The critical issues facing Open School with regard to developing courses for alternate media, different types of learners, and varied instructional contexts are cost and time. It is simply not practical to produce a unique course for every combination of learner, delivery environment and instructional context.

Features of a New Framework

In 1996 Open School began work on a new framework for course development and delivery. The initial list of desirable attributes included the ability to:

- create courses from Instructional Design to delivery
- create assessment types and mechanisms
- identify, associate and categorize resources within the course architecture
- create custom views of materials for different types of learners
- store and manage parts and pieces of course materials
- create a user-defined catalog of the parts and pieces of courses
- output to both print and web, as well as to other media

In 1996, there were no "off-the-shelf" products that could address this list in its entirety. Open School proceeded with an internal research and development project to create a solution.

One of the more important innovations in publishing and knowledge management today is structured information, specifically SGML (Standard Generalized Markup Language: ISO 8879-1986). In the summer of 1996, Open School's Research and Development team began work on an SGML-based course development and delivery framework.

This project was completed in 1998. As a result, Open School decided to pursue a structured information approach to course development and delivery. At that time, few educational institutions were moving in this direction. We saw this as a competitive advantage, an opportunity to innovate and inform. The emergence of the XML standard in late 1997 further validated our approach.

Structured Information Standards

SGML is an international standard for text and document processing. It is a *metalanguage* that provides a common syntax and notation to create specialized markup languages for specific domains—in our case, distributed learning. Any markup language that conforms to the standard can be used with a wide assortment of SGML/XML tools and applications.

A goal of an SGML-based markup language is to explicitly define the structure of documents. This allows computers to recognize structural components and metadata in a document, structures that traditionally have only been *implied* by presentational cues. For, example, in most documents, a **glossary term** might be identified by presenting it in bold or italics. To the human viewer, this convention is easily understood. But for a computer there is nothing significant about this string of characters apart than the fact that its is bolded or italicized, which may also be the style used to delimit an author's name or the title of a work. In an SGML document, the glossary term would be delimited by an explicit *tag*. This tag informs the computer that it has encountered a glossary term, which can then trigger specific processing of this data. For example, in print we may wish to collect all glossary terms and present them at the beginning of a lesson. If the same document is published on the Web, specific processing for glossary terms might enable hyperlinking each occurrence with its corresponding definition in a database.

The formal separation of content from presentation allows content to be presented in multiple media from a single source. The styles used in a specific medium are applied to the structural or semantic tags only in final presentation. The content is not bound to a specific presentational format and can be repurposed with greater ease.

Other emerging standards influenced the design of the Open School course development and delivery framework. Many Open School courses refer to or include various learning resources. In order to classify and categorize resources in our materials, we needed robust structures for managing metadata. We looked to and were inspired by the Dublin Core metadata set. We found, however, that local extensions were required to describe the wide variety of resources in our course material.

Similarly, the IMS Project's metadata work was another standard we looked to for insight. Although the IMS metadata standard is well thought out, it had yet to be realized in SGML or XML. We have and will continue to incorporate IMS metadata mappings to our own metadata structures.

Finally, the new XML standard itself promises those of us with SGML assets the ability to easily interchange content with others. But XML has drawbacks that result from its "newness"; parts of the XML family of standards are yet to be finalized. While this does not inhibit our use of XML for basic needs, it does restrict its use for the more complex requirements of our documents and overall system, which are better addressed today by the more venerable SGML and related ISO standards (like Hytime and Topic Maps). This will undoubtedly change in the near future and we are preparing ourselves to move entirely to XML when possible.

The Open School Graduation Program Project

The Open School R&D team spent much of 1997 and 1998 developing and prototyping the new course development and delivery framework. In 1998 Open School decided to implement the new framework with 14 grade 11 and 12 courses as part of a new initiative called the Open School Graduation Program (OSGP). The program is designed to provide high-school students with enough credits to earn a high-school diploma, working entirely online or in print.

The development group consists of 30 people: a management team, a collection of writers, production staff, Instructional Designers and a small technical team. We have identified and deployed software tools and environments for authoring, middleware processing, and delivery. Some of these tools include Adobe FrameMaker+SGML, AIS Balise, Microsoft Internet Information Server 4.0 and Microsoft SQL Server.

Process

The following outlines the basic process of bringing a new course into the SGML/XML framework, from Instructional Design through to delivery in multiple media. The process is composed of four overall phases, which are decomposed into a number of incremental stages.

Phase One: Requirements Capture and Analysis

For each course, a small team is gathered to address the business case, collect requirements, and prepare for the Instructional Design phase. The most important document we begin with is the British Columbia Ministry of Education's *Integrated Resource Package* (IRP). It is a document that outlines provincial standards for curriculum, assessment strategies, instructional strategies, prescribed learning outcomes, and recommended learning resources. Because its primary audience is in-classroom teachers, the IRP needs to be reviewed and localized for distance education. At this time we also review existing course material, technology standards, and feedback from the field.

Completion of Requirements Capture and Analysis Phase

The requirements capture stage provides the initial inputs to the next phase, the development of a highly structured Instructional Design Plan. Initial learner profiles are identified at this stage: baseline attributes of learner motivation, level of instructional support and technology access, informing the ensuing development by establishing determinants for alternate assessment and instructional strategies as well as providing criteria on which to determine the appropriateness of resources.

Phase Two: Instructional Design

An SGML Document Type Definition (DTD) supports each individual stage in the Instructional Design phase. An SGML DTD is the formal set of rules and element definitions that govern what structures are allowed or required in a document.

Stage One

The first stage of Instructional Design involves creating a robust outline of the course according to an SGML Document Type Definition (DTD). The course outline consists of a hierarchy of major subjects or topics, abstracts for content to be covered, and facets or themes (important subtopics that may pervade the course but are not represented in the major subject/topic hierarchies). The initial Instructional Design DTD requires a four level hierarchy of *nodes*: Course, Module, Section, Lesson. Learning Outcomes are positioned at the section and lesson level to serve as determinants for formal and informal assessment.

The Stage One Instructional Design Plan is an idealized mapping of subject/content and learning outcomes. It does not mean that this hierarchy is the only "view" of the course a student will see. It is however, a solid foundation on which to build materials that can be reassembled during presentation and delivery.

Stage Two

Stage Two of the Instructional Design phase involves resource identification and association. Relevant learning resources are identified and associated with the overall course architecture created in Stage One. Where appropriate, resources are further decomposed by annotation, describing their scope and relevance to particular nodes in the course hierarchy. This stage allows many different resources, textbooks, articles, online links, video clips and CD-ROMS to be appropriately situated within a course.

Stage Three

During Stage Three, assessment strategies are designed for both formal and informal assessment at the section and lesson level. Each assessment strategy is written for one or more learner profiles. They allow Instructional Designers to indicate resource dependencies and declare the type of assessment to be used in the activity or assignment.

Exit criteria for this stage requires all sections and lessons to contain assessment strategies for all learner profiles designed for the course. Designers are encouraged to develop multiple alternatives for each profile if the schedule allows.

Stage Four

An optional fourth stage (in development) of the Instructional Design process is intended to provide designers with the opportunity to develop alternate instructional strategies at each level of the course hierarchy. This stage facilitates:

- Alternate subject/topic hierarchies at all levels
- Custom sequencing of materials (requires existing structured content)
- Custom assembly of materials for specialized learner profiles (i.e. learners with special needs)
- Experimental approaches to learning

Completion of the Instructional Design Phase

The completed Instructional Design Plan, an SGML document, literally becomes the supporting framework for course authoring. All of the information in the design plan is included in the authoring environment. This ensures that the authoring process is tied directly to the original specifications laid out by the Instructional Design team.

Phase Three: Course Authoring

As with the Instructional Design phase, the Authoring phase is supported by an SGML DTD for every stage.

Stage One

Assignments and activities are developed in response to assessment strategies articulated in the Instructional Design plan. Authors create assignments and activities from standard architectures defined in the Authoring Document Type

Definition. Criteria for assessment (answer keys, marking rubrics, feedback mechanisms, etc) are required and therefore incorporated in the architectural template for activities and assignments.

Stage Two

In Stage Two, topic explorations are created based on the Instructional Design specifications for each lesson. Topic explorations are composed of text, graphics and multimedia elements appropriate for one or more learner profiles. Alternate topic explorations are encouraged for each lesson.

The result of Stage Two is a collection of peer topic explorations and activities written for one or more learner profiles. At this stage it becomes possible to select the appropriate topic explorations, activities and resources for an individual learner profile from the overall course architecture.

Stage Three

Overview material and front matter are created at this stage. This may include learner profile-dependent advance organizers, transitional components, and support materials.

Stage Four

An optional fourth stage (in development) provides authors the opportunity to address alternate instructional strategies described in Stage Four of the Instructional Design document.

Completion of the Course Authoring Phase

The completion of the Authoring Phase provides Open School with a highly structured representation of a course in its entirety. In fact it is a superset of all possible course instances that can be derived by individual learner profiles.

Phase Four: Delivery

The Fourth Phase of the course development and delivery framework focuses on producing course instances for delivery. At this point in the development process, the advantages of SGML/XML come to the fore. We bring an arsenal of SGML/XML tools and techniques to bear on the structured representations of the course materials to drive rendering for presentation. Each individual SGML/XML element and its attributes are leveraged by processing tools and associated with presentational rules. Using stylesheets and transformation rules, we produce both print and online instances of each course. It is important to recognize that this process is almost entirely driven by SGML/XML programming tools and very little hand tooling is required; a single set of stylesheets and transformation rules can be applied to all 14 courses.

Implementation Notes

Implementation of the OSGP project has not been easy. All members of the team have had to revisit best practices, "golden rules" and established "ways of seeing". The technical obstacles encountered during development were minor compared to cultural ones.

Never before has Open School simultaneously produced 14 courses, let alone in one year. The pressures and constraints of this rigorous timeline have been extreme. However, without these constraints it is unlikely we could have reached the consensus required to move forward. Constraint and compromise were crucial. A case in point: during the initial research and development phase, which preceded the OSGP project, it took many months to fully agree on an operative definition of learning outcomes.

The desktop publishing mindset has been hard to overcome. In the past, Open School authors had individual control over the presentation of the materials they developed. The new approach required them to forfeit some of this control to the larger team. Standard ways of presenting course components were developed through consensus and implemented post-authoring in the production phase. In the beginning, team members struggled with this separation of content and presentation. Once they saw the published results of the first stages and how their material began to take shape in print and online, much of their discomfort was alleviated.

Benefits of approach

As we enter the final stages of the development process, the benefits of the approach are beginning to be realized. Overall, we have gained a much better understanding of what is actually in our course materials and a more intimate appreciation of both their outstanding and not-so-outstanding qualities.

A major benefit of our approach is the structural consistency evident across all OSGP courses. This consistency allows the production team to leverage global stylesheets and transformation rules for delivery in print and online.

The increased efficiency in the production phase has provided more time to evaluate the overall quality and design of our course materials. Because we produce a published product at each stage of Instructional Design and authoring, the opportunities for formative evaluation and field review are many; no longer do these activities have to wait until the course is fully-formed.

A common vocabulary for course components and Instructional Design elements has greatly improved communication across teams. Instructional Designers, course authors, management, and production staff now have a common framework for workflow management.

We have yet to realize the full potential of our collection of structured course materials. In the future we anticipate being able to produce new products and services from this collection. The ability to repurpose will extend far beyond this year's print and online instances.

The Future

In the next year, we will be acquiring an SGML/XML object repository to manage and store our SGML/XML courses. This will provide us with all of the benefits of a database as well as an environment optimized for SGML/XML documents.

The advent of XML-enabled browser technologies like Internet Explorer 5.0 will allow us to deliver our structured content directly to the Web. In the coming year we hope to leverage this technology to provide an online environment for our clients to create customized instances of our courses tailored to their individual needs.

Work will continue on OSGP courses after delivery in September. The superset of course components will grow to accommodate additional learner profiles and instructional strategies. It is our intent to move to an evergreen revision cycle for the new course development and delivery framework.

In the coming years, we anticipate that the establishment of metadata and markup technology standards in education will allow us to integrate and exchange our structured course content with other institutions and organizations. We feel we are well positioned to take advantage of these opportunities.

Video Streaming Medical Grand Rounds: Convergence of Real Time, Any Time, WAN and Internet Delivery
(An early implementation of an important distance-learning technology)

Jonathon D. Levy, Amelia Ellsworth
Cornell University Office of Distance Learning
DistanceLearning@cornell.edu

Abstract: Distance-learning programs commonly characterized as being either synchronous (real-time) or asynchronous (on-demand), video or Web-based, traditional or non-traditional are now blending one into the other. A single word—"convergence"—now characterizes the cutting edge of distance learning, allowing pedagogy to fully drive the selection of technology and distance-learning formats. In the following pages, we will discuss the issues of interactivity, flexibility, integration, and isolation in the context of various synchronous and asynchronous technologies. We will describe the recent solution Cornell University has discovered by using NetShow video streaming software in combination with HTML Web frames and PowerPoint. By merging these media, Cornell can deliver Medical Grand Rounds over local and wide area networks in both real time and any time scenarios, combining video with Web-based presentation and a traditional format with a highly-unconventional delivery format. The presentation will feature a demonstration of Grand Rounds. Two of these demonstrations may be viewed on the Internet at: http://www.dl.cornell.edu (select "courses").

References

This is a report of an early implementation of an important use of technology; however, no empirical examination has been conducted. Only anecdotal evidence is reported herein.

This program may be viewed on the Web at

The Problem of Distance: spatial and temporal

Cornell's Weill Medical College is located on the Upper East Side of Manhattan. There are 4,500 doctors affiliated with twenty Cornell-networked hospitals within the five boroughs of New York who need to attend Grand Rounds presentations—updates in the various fields of specialty—at the Weill Medical College. Grand Rounds are traditionally conducted as a lecture presentation by top medical doctors. The lectures, accompanied by 35mm slides, focus on the latest developments and breakthroughs in medicine. It is very important that practicing physicians at these hospitals attend those Grand Rounds, but the physicians are scattered amongst the 20 hospitals, and it is difficult for them to attend the Grand Rounds in person.

For this particular application, time shifting proved far more important than space shifting. For most doctors, travel time plus presentation time results in a lost half-day of office and/or hospital time and very few are able to take advantage of the Grand Rounds opportunity. So Cornell began using the streaming components of the Windows Media technologies to deliver the lectures. The Microsoft Media Player software runs with any web browser on a Pentium machine with at least 32 Megs of Ram. A Macintosh solution is now available in Beta.

The Grand Rounds were initially offered live on the Internet to participating physicians and were archived for asynchronous access, so that physicians could watch them at a later time at their convenience. Interactive technologies were developed to allow doctors to "converse" with the presenter during the synchronous version, using a "mailto" button on the Web page for e-mail messages. However, initial experience showed that none of the doctors was interested in a synchronous presentation when an asynchronous alternative was available, so synchronous delivery was dropped, and the entire Grand Rounds series was offered only asynchronously.

Each Grand Round lasts about an hour. It is extremely important for the physicians to be able to see the 35mm slide image and to hear the presenter's voice very clearly. Cornell synchronizes PowerPoint presentation slides with the actual video. The slides appear in a separate window on the same screen. As doctors watch a presentation they not only see and hear the presenter, but as the presenter's image changes on the screen in the presentation room, the image changes on the computer screen of the person who is watching at a later time and at a distance. This allows Cornell to show very high-quality images accompanying the video, such as medical slides, cells, x-rays, photographs of patients, or other medical data that the doctors need to see as the presentation continues. The Media Player is configured like a video recorder, allowing doctors to stop the presentation if interrupted, and later restart it from the point where it was paused. The video, audio, and synchronized presented image (slide) all cue up and restart automatically.

One of the defining features of a learner in a distance scenario is their separation from the origin of information. This separation can be represented by a spatial or temporal distance. Learners in these scenarios sometimes find it challenging to motivate themselves and continue with the learning process. In this case the audience for this project is a highly motivated audience for whom delivery of the Grand Rounds using distance technology was, at first, solely for convenience. The project was developed with the idea that real time and anytime/anywhere presentations gave the audience the flexibility they desired. Presentation was intentionally kept as close as possible to the experience this audience was familiar with in a traditional lecture hall. Interestingly, many of the viewers reported that the Internet distance-learning programs not only accomplished the temporal objectives, but that the quality of the presentation actually was improved with the technology implementation.

Medical Grand Rounds: Background

The Cornell University Medical College is responsible for a lecture series referred to as Grand Rounds. These lectures provide continuing education for doctors in hospitals throughout the greater New York area by providing information about recent advances in their field of medicine. Traditionally, Cornell University delivered these grand rounds to medical staff in their twelve network affiliated hospitals by requiring the audience to travel to the Medical College and sit in their lecture halls. For reasons described below, this was not an optimal solution, but until recently there was no viable alternative. With the recent merger of the two teaching hospitals, New York and Presbyterian hospitals, the number of hospitals in the network rose to twenty, increasing the challenge for delivery of continuing medical education. When the Weill Medical College began to look for a new way to deliver Grand Rounds, distance learning communications technology was a natural place to turn.

The traditional Grand Round is an hour-long lecture given by a teaching faculty in a specific field of medicine. These presenters normally speak from behind a podium in very dim light with the focus of the lecture directed towards a front screen where 35-millimeter slides are projected as each point is made. In the normal course of a Grand Round, an average of 75 slides are used. These slides can be critical to understanding the lecture and are often high resolution graphics which depict the pathology or histology under discussion. There is very little interaction between the audience and the doctor making the presentation. At the end of the hour, there is a brief question and answer session and the audience files out to complete the review paperwork necessary for their continuing medical education credits.

The Proposals

Two methods for distance Grand Round delivery were considered:

- Purchase video-teleconferencing technology for each of the 20 network hospitals and deliver Grand Rounds in real time at 384kps to all sites. The presenter would be on camera and the slides would be sent either as an image taken off the projection screen or document camera (possibly an RS232 port) and the quality would be almost as good as that in the originating room. The rounds could be recorded and played back at a later time for doctors who missed the presentation.

- Stream the Grand Rounds over the Internet using Netshow 3.0 software. This program allows an audio/video file of the presenter to fill a frame in a web page and stream at speeds as low as 28.8 and as high as 500kps while the second frame flips the slide images synchronized with the presentation. Netshow provides the ability to capture, insert, and index time references in the video file to bring up a compressed digital image (most slides are usually no bigger than 400k) at the same time the presenter is changing slides in the traditional lecture hall. These images are scanned and cached ahead of time and are actually of a better resolution and quality than the ones projected during the traditional presentation because they are not distorted by projection. The rounds can be streamed real-time at the same time as the actual presentation, re-broadcast at a later time using multicast packets to conserve bandwidth, or accessed anytime on-demand at both 128kps and 56kps, allowing both LAN and dial-up access.

The solution:

In this case, the least-expensive solution also turned out to be the most effective solution. The Media Player is available to anyone at no cost (free download from Microsoft). All that is required to "attend" Internet Grand Rounds is a computer and an Internet connection. Because doctors valued their time more than higher bandwidth (the highest being attendance at the face-to-face presentation, followed by ISDN video), the lower bandwidth Internet solution was selected. Interestingly, this solution was also evaluated as "better than being there" by some of the participating physicians. This is due to the combination of technologies that allowed access to the video, audio, and synchronized presentation material at times most convenient to the physicians.

The lack of interactivity in this solution is atypical of Cornell's distance learning applications, but for this particular program it was deemed acceptable, since the face-to-face Grand Rounds offer only a short period for questions, and these are included within the Internet streamed presentation.

Innovation in Learning Methodologies for Adult Learners: Implications for Theory and Practice

Richard G. Milter
College of Business
Ohio University
United States
milter@ohio.edu

Abstract: This paper begins via a synthesis of theories targeted at innovative practices in the field of adult learning. Following a review of the current literature, the author discusses different strategies and methods used to enhance adult learning. Separation of teacher-centered and learner-centered methodologies are examined. Environmental conditions and use of technology are also items factored into the discussion. Comparative assessments of methodologies used at educational institutions and corporate learning centers are reported. The efficacy of both specific and generic theoretical constructs is examined in light of professional adult learners and the requisite skills demanded by their career positions. In other words, what theories are best suited to carry learning practices into the future to best suit the needs of active learning professionals?

Review of Adult Learning Constructs

To synthesize a field of theories is a fairly presumptuous task today. There are probably as many theories as there are stars, and we seem to be finding more of them every day. The purpose of this "synthesis" is to recognize the key elements displayed in several cogent theories regarding adult learning. Drawing on the thinking of Rorty (1991) as well as vonGlaserfeld (1989), Savery and Duffy (1994) describe the basic principles for learning. These include recognition that: 1) understanding is in our interactions with the environment, 2) cognitive conflict or puzzlement is the stimulus for learning and determines the organization and nature of what is learned, and 3) knowledge evolves through social negotiation and through the evaluation of the viability of individual understandings. Such principles are rooted not only in learning theory but also in innovation. Without innovative thinking our understanding would never be able to match the changing nature of the environment. All innovation must begin with an inquisitiveness that is grounded in personal cognitive conflict. And finally, innovation to be useful must at some point pass the tests of social negotiations.

Barrows (1997) has suggested responsibilities of the successful innovator beyond the creation and use of new methods for educating people. The most important of these responsibilities is that the innovation must provide a substantial contribution to the learning process for all those involved. In other words, the innovator must understand the learning outcomes (what is expected of the learner) and how the innovation relates to these outcomes. A second responsibility is that the innovator actively evaluate effectiveness of the innovation. It is not enough to get satisfaction scores from the users. The evaluation must target whether the learning outcomes have been positively impacted by the innovation. A third responsibility of the innovator is to promote the innovation through publication channels so that word gets out to other educators and learners. This activity matches the need to respond to social negotiations as mentioned above.

A final responsibility of the innovator is to remain flexible and open to change. By definition this means to continue to learn. It is too easy for innovators to begin to believe their innovation is the final piece to the puzzle. They believe that with their innovation, the light at the end of the tunnel can finally be seen as the sun on the horizon and not an oncoming train. Learning innovators must take special precaution to remain learning innovators. This means they must remain learners and not to close down channels for questioning. A colleague of mine involved in educational innovation and I made a commitment to each other about a dozen years ago that if we ever thought we were doing it right it would be time to get out of the business. When it comes to learning, the business focus concerning continuous improvement makes all the sense in the world.

Challenges for Educators

Continuous improvement suggests an unflinching drive toward flexibility and growth, or in a word ... learning. Educators might be best advised to follow Charles Handy's (1996) prescription for learning as we attempt to enhance our abilities to facilitate growth in others. His learning cycle suggests that all learning begins with an inquisitive mind (questions) that leads to the development of concepts (ideas) which must then be evaluated (testing) before a period of contemplation (reflection). This "questions, ideas, testing, reflection" process is not unlike that suggested in a more recent work, *The Power of Mindful Learning*, by Ellen Langer (1997). Langer presents methods for putting into practice a true learning focus that transcends rote memorization techniques typical of traditional teaching strategies.

Rote memorization, or learning out of context, is a way that many of us were weaned on education and learning. Some of us have gotten very good at it and have graduated into leadership positions in the education field. One question that arises out of this fact is whether we should have different learning strategies to facilitate learning in children than those we have for helping adults to learn. Although much research has been done to differentiate between the two, the verdict is still out. Although there are some differences between the learning processes of children and adults, such differences may pale when comparing the differences between adults' individual learning styles. It does appear often times that it is easier for children to learn new things (like languages and computer use). Perhaps the reason it appears more difficult for adults to learn new things is in part due to the ingrained process of learning out of context. Adults must attempt to unlearn not only substantive issues but also process methods in order to grasp new meanings.

Much of this can be attributed to the designs of educational institutions. According to James Botkin, co-author of *No Limits To Learning*, most formal schooling systems, with some notable exceptions, resist change in their objectives and style of learning and education. Botkin further suggests that "school, on a worldwide basis, is hopelessly out of date. In North America, despite widespread recognition of the inadequacy of K-12 and higher education, the response to date has been limited to 'more' for the future of what has not worked in the recent past. More hours, more homework, more science and math have been the guiding principles rather than new teamwork, focus on values, or holistic learning. No country in the world has been able to figure out how to divest itself of a system built for another age and another time and to start afresh in redesigning formal education" (Botkin, 1996).

New Learning Philosophies and Methods

Many educational institutions are doing an excellent job using an obsolete model for learning. Many leaders (including teachers) in these institutions "think of the mind as a storehouse to be filled" when they should be thinking of it "as an instrument to be used" (Gardner, 1965). Educational leaders might do much better to heed the edict of Plutarch that "the mind is not a vessel to be filled but a fire to be ignited." If educators refrained from considering the mind as a storehouse or a vessel to be filled, lifelong learning would take on a whole new significance. With it, the distinctions between learning in children and learning in adults would begin to blur. The major difference would become one of context, with adults having more experiences from which to draw ways for contextualizing learning. Of course, if educational institutions at the primary and secondary levels sought to develop learning skills in children, maturity would be measured by assessing a person's ability to refresh what they have learned and apply learning from one context to another. Adults who have experienced this approach to learning from the start might not be bogged down trying to unlearn the process methods of passive learning before joining in as an active participant in the learning process.

Some educational institutions at the K-12 and higher education levels have already begun to focus more on strategies for involving active participants in learning process in their design and delivery systems (see Barrows & Myers, 1993; Norman & Spohrer, 1996; Schank & Kass, 1996; Milter & Stinson, 1994; Schauble & Glaser, 1996; Duffy, 1994). The similarities between innovative programs in medical, law, engineering, and business schools and the innovation displayed in primary and secondary schools far outweigh the differences.

One of the key similarities exhibited in these innovative programs is a deliberate push for learner-centered methodologies over teacher-centered approaches (Stinson & Milter, 1996). This is not a recent development. In the United Kingdom in the mid-1980's business leaders and educators developed a plan to reform education which resulted in a report titled "Education 2000." Out of that report, a project was created to "shift the balance of teaching to learning; to provide a greater variety of learning experiences, and to make clear the responsibility of the learner for active participation in the learning process and for achieving successful outcomes."

With this shift comes acknowledgment that it is the individual learner (child or adult) who must claim responsibility for their own learning. No longer do these innovative institutions take on the claim for learning behavior in others. They attempt to provide an environment where a learning community can thrive. An environment where answers are not as important as questions; where getting to the answers is more important than the answers themselves. An attitude where the concern for learning outweighs the desire to imbed specific facts into the brains of others. Today, with knowledge doubling every 5 years and the half-life of most useful information being about 5 years, it seems silly to claim we can provide the requisite information for an individual's future needs as a professional or a global citizen. Today innovative institutions push for knowledge discovery, but not without also pushing for recognition of ways to apply the knowledge and the importance of updating knowledge.

The Processes of Learning

Another similarity of innovation in education across disciplines and age group boundaries is a concern for the design of educational methods. Whether you refer to it as pedagogy, andragogy, or learning methods, the question remains how to best develop ways to assist learners in their learning processes. In many traditional situations the designing of methods and processes is either done by some centralized mechanism (school boards deciding which texts to use) or "on the fly" while delivering the course (many university faculty discover creative ways to develop processes during the delivery process itself). Although neither of these approaches is suspect on the surface, the danger comes from acknowledgment that the design work is unimportant at the delivery stage.

That is, most educational institutions reward delivery of courses and programs and assume the design work is merely a precursor. Corporate learning programs, on the other hand, tend to place an equal (or sometimes even greater) emphasis on design of learning materials and procedures as they do on the systems for delivery. Such corporate learning programs will pay substantial salaries to in-house developers of learning materials and proposed delivery systems then will hire outside agents to actually deliver the programs. These external agents, though important, are hired for their abilities to facilitate learning environments, not for their expertise in the specific substantive domain. Attention to the learning outcomes and substantive domain is under the responsibility of the internal designers.

Although the design work tends to be performed within these innovative corporate educational programs, these developers make no presumption of total knowledge of substantive domain areas. Such programs regularly poll internal and external practitioners in the field to take a read from their expertise about what are the most significant learning elements for the future of their profession. In order to remain current, this development activity needs to be attended to on a regular basis. It is not a "once-and-for-all-time" procedure. It is also critical as designers seek to synthesize input from current practice that they also give consideration to what the future holds for the particular professional domain. Sometimes this means going outside the view of current practice which might have a tunnel vision perspective.

Use of Technology in Learning

Use of technology is an area that tends to be engendered outside the specific practice domain. People tend to resist change until they see the benefits. Most times the introduction of a new technology causes short-term drops in performance. This tends to be temporary but nonetheless frequently dissuades full acceptance of the technology by practitioners. And yet the use of technology is clearly linked to the development and implementation of innovative learner-centered educational programs. Recent publications give substantive examples and suggestions for inclusion of more technology in learning environments in primary through secondary schools as well as professional training programs (Hamalinen, M., Whinston, A., & Vishik, S., 1996; Schank, R.C. & Cleary C., 1996; Wilson, 1996). It is not a passing fad that there is a convergence of new learning environments and new technologies.

Although universities have often led the way to development of new technologies, they have frequently lagged in response to their full utilization. This is, unfortunately, the case as well in use of new learning technologies. According to Botkin (1996), the most promising action in reforming education and modernizing learning is to be found not in universities but in the international business community. He attributes much of the reason to the fact that schools and universities still do not have the "financial or innovative human resources" to carry out the fundamental changes required by the challenges of the future.

Impact of Corporations on Learning

Business organizations, on the other hand, have begun to see the value in investing in education for the future. As reported by Botkin in 1997, corporate universities in Europe and North America now appropriate more funds to support learning than all the world's universities combined. They are growing 100 times faster than the university world, and the lifelong adult learning they support is 25 times larger than the traditional university student market (Botkin, 1997).

Corporate sponsored programs have begun to make tremendous impact in the world of learning at the primary and secondary levels. Motorola has for years pumped money into the school systems that supply its plant in Chicago with employees. But as important as the dollars, Motorola has also formed a sensitive and reciprocal relationship with the people who lead these school systems. They are facing the changing nature of the world together and have invested time and energy as well as money into the development and learning of young people who will be the leaders of tomorrow; a few of them leaders working for Motorola. And Motorola/Chicago story is not the only example of this type of collaboration. According to a report filed in 1992 by the Committee for Economic Development, there were in the US over 140,000 corporate-academic partnerships involving 30,000 elementary and secondary schools (Dickson, 1992). Today this figure is even larger and clearly not limited to partnerships in the US.

Universities, steeped in bureaucracy, tend to be one of the last organisms to experience needed change and often get dragged kicking and screaming into the future. People in universities frequently become defensive in relationships with business people, even though it is business that awaits the products of university programs. The fact is that the business world is experiencing rapid and constant change. Organizations in that world are learning to cope, or are disappearing. University leaders must realize this fact and take responsibility for the future of either coping to survive or helping to lead our students into the world that is becoming.

A Wake-Up Call for University Leaders

Leaders in university settings must begin to appreciate the fact that they do not have a corner on the education market of the future. It comes as a surprise to traditional educators to learn that fully one-third of professional educators are at work not in universities but in corporate institutes of education or learning centers. Another one-third are in church-related education, and the balance in conventional public and private educational institutions (Botkin, 1996). It is time (in fact it may soon be too late) for university leaders to begin to find new ways to bridge learning relationships with educators in these different segments.

By "university leaders" is meant anyone associated with a university setting who is involved in adding value to the delivery of learning programs in the future. By definition, therefor, this would not include administrators busy about the job of keeping the university on a steady state following outdated mechanisms and teaching methods. It is time that professional educators in university settings act like professionals. It is time to take our mission seriously. If we are to assist in developing lifelong learners in the turbulent and uncertain world of tomorrow, it is important that they not only know things but that they are also able to act using their intelligence. Being intelligent no longer means scoring high on some quantified psychometric. Being intelligent connotes that an individual has "the ability to learn and to apply what has been learned to adapt to the environment, or to modify the environment, or to seek out or create new environments" (Sternberg, 1997). University leaders need to act intelligently as we prepare for our futures and help ready others for their futures.

It is time that we begin to question, develop and test new ideas, and reflect on the processes that we use to assist others to learn. It is time to heed the challenge of Malcolm Knowles, author of *The Making of an Adult Educator*, in that "we must become able not only to transform our institutions in response to changing situations and requirements, we must invent and develop institutions that are 'learning systems,' that is to say, systems capable of bringing about their own continuing transformation" (1995). In this way we must realize the importance of the age-old adage to "practice what we preach." But first we must reconsider what it is and how it is we are preaching. Only in this way will we be able to truly assist others in their search for learning.

Abstract

The quest for lifelong study opportunities is expected to become one of the main characteristics of the rapidly evolving information society. Members have to be able and equipped to acquire knowledge and/or skills in ways that fit their personal situations. To help fill this need we developed a coherent design approach of educational instrumentation as a solution. This approach is named E-study. The E-study concept refers to a socio-technical infrastructure for life long learning. Herein we will describe the 'technical' and the 'socio' parts of this infrastructure. The technical site implies the Internet, while the socio site implies situated learning. Then, we describe the project ComMedia in which we bring the E-study approach in practice. We have embedded the E-study environment in the context of Communication Studies, University Twente, Enschede. Therefore, we feel that we can speak about the application of the E-study concept in a university education context.

Introduction

As the World Wide Web grows into a serious educational medium, learning will no longer be restricted to classrooms, or in the case of companies, training institutes. The Web enables a form of flexible and interactive learning that can be very valuable. This style of learning is illustrated in Collis (1991) where it is concluded that the Web and its associated technologies may possibly become the "killer application" for "tele-learning". In our research we use the concept E-study to refer to learning and training by means of the Web (de Vries, 1997; de Vries, 1998-a). We are especially interested in the design of online study environments based on the cognitive apprenticeship approach as described by Collins, Brown & Newman (1986) and Collins (1988). In other words, we want to train students to solve cognitive problems by providing modelling, coaching, and fading in online study environments. In this paper we describe first the concept E-study, which is the basis for our design. Secondly, we will describe four key design guidelines and, as an illustration, we have provided an example of a developed online situated learning environment based on these guidelines.

The concept E-Study outlined

The E-study concept refers to a socio-technical infrastructure for life long learning. The concept of life long learning is used in a Tele-learning sense. In short, 'making connections, among persons and stored resources, through communication technologies for learning-related purposes' (Collis, 1996). In this definition, an emphasis is laid on the use of information and communication technologies. To enable life long learning the need for a socio-technical infrastructure, that is a hardware and software infrastructure embedded into an institutional infrastructure, must be filled. The E-Study concept will stand for life long learning by means of the Internet. On the Internet, teachers or study guides, are expected to prepare study tasks, guide study processes, and evaluate the study processes and results. Students, or lifelong learners, will carry out relevant study tasks in ways that fit their task contexts. The context for instruction can be a university setting, an in-service training, a specific on-task performance support, and a short training at home, etcetera. Educational instrumentation is needed for study guides and lifelong learners to carry out their tasks. Figure 1 illustrates the E-Study concept.

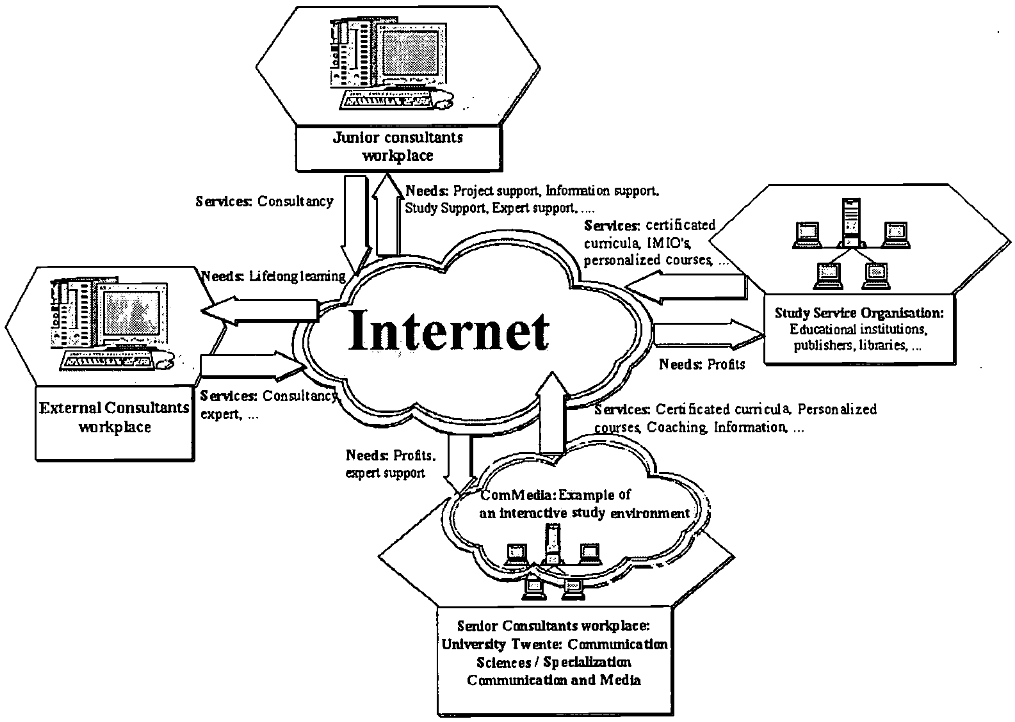

Figure 1 **An illustration of the E-Study concept**

We describe four leading principles for the design of educational instrumentation for e-study. These principles are flexibility, integration, instructional interaction, and information-enriched. We refer to flexibility as the freedom for teachers and students to determine: what to study, why to study, where to study, when to study, how to study, and who will be involved in the study process. The second principle is integration. This principle is related to flexibility. While flexibility implies diversity, integration means unity. Integration refers to consistency and coherence in the provided educational instrumentation. By instructional interactivity we mean interaction, as an input/output process between one or more users and a software program, purposefully intended for knowledge acquisition and incorporation in a broad sense. The fourth principle is information-enriched, which basically means that all relevant 'curriculum' information is provided. The information society provides members with an enormous amount of information. Members must be able to find applicable information and make use of it in a proper way. Informative as a design principle implies that users are enabled to find and use applicable information locally as well as globally. We use the concepts Interactive Study Environments, Interactive Study Systems, and On-line Study Services to describe the E-study concept (Vries, 1997, Vries & Vogel, 1997). These concepts refer only to a technical infrastructure. In the start we referred to a socio-technical infrastructure for life long learning. The described technical infrastructure has to be embedded into an organisational infrastructure. In this paper we will further discuss the 'socio'-part of the infrastructure.

An educational organisation as a context for situated learning

Our main interest involves the design of online study environments which enable situated learning. We see situated learning as 'learning knowledge and skills in contexts that reflect the way the knowledge and skills will be useful in real life' (Collins, Brown, & Newman, 1986) and as 'learning tailored and tuned to a particular situation'. If we combine both descriptions we have a clear view of life long learning. The first part refers to learning in an educational organisation, while the second refers to learning in non-educational organisations. Such learning is from the learner's point of view continuing education. The main issue for both kinds of organisations is that they consider themselves as a learning organisation, 'an organisation that is continually expanding its capacity to create its future' (Senge, 1990). Clearly, situated learning reflects our ideas of the 'socio' part of the E-study concept. Here, we will discuss situated learning in educational organisations. In de Vries (1998 b) we describe design guidelines for online study environments for non-educational organisations.

We took the cognitive apprenticeship approach from Collins, Brown, & Newman (1986), or to be more specific, their framework for designing learning environments as the starting point for the design of online situated learning environments. Their framework describes four characteristics of such environments: content, sociology, methods and sequence.

In the project known as ComMedia, we designed an online 'virtual learning company' as a 'real life context' for study projects. Figure 2 illustrates the design of ComMedia. These study projects were for students who desired to become specialists in the design and implementation of interactive media applications for corporate communication. ComMedia is part of Communication & Media, one of the six specialisations of the study program Communication Studies, University Twente, Netherlands. A specialisation it is the subject in which a student specialises in the final period before graduation, comparable with a major. The field of interactive media and corporate communication is the subject of Communication and Media.

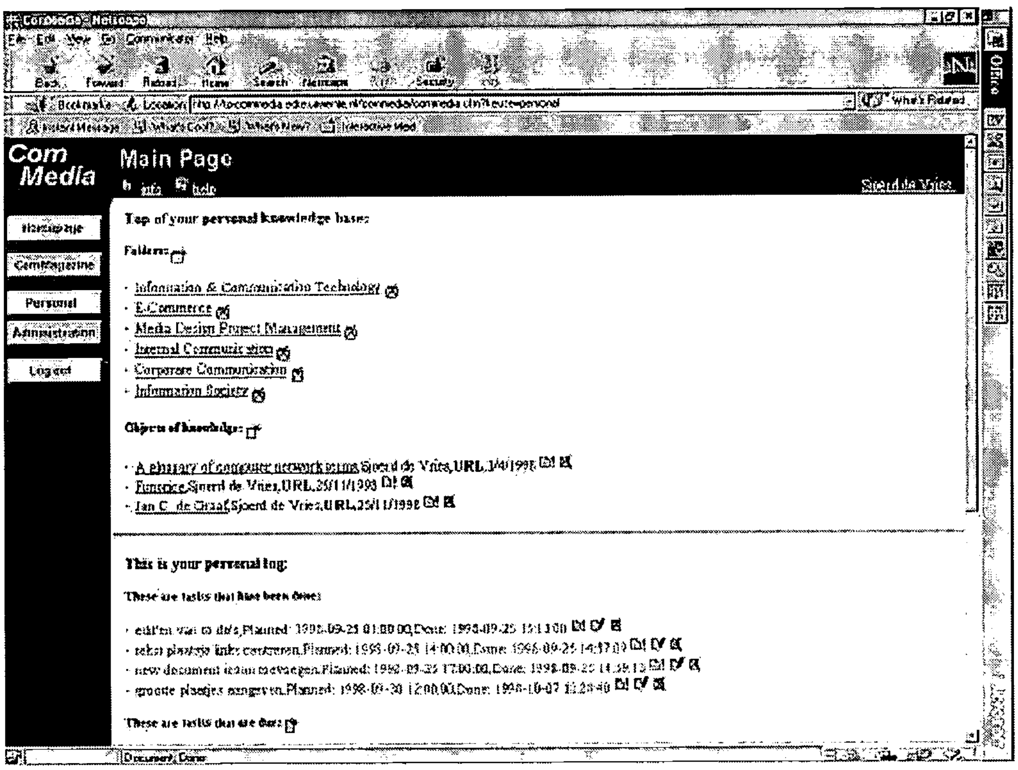

Figure 2 The personal workspace of a student in ComMedia

ComMedia as a technical system, is a website on a Microsoft NT Server. We are using Cold Fusion from Allaire as the development platform. Cold Fusion is a rapid application development system for professional developers who want to create dynamic Web applications and interactive Web sites. It provides a fast way to integrate browser, server, and database technologies into powerful Web applications. ComMedia can be considered as an infrastructure for project education. Almost all the information is stored in a database. For our database platform we are using Microsoft Access . We use the term infrastructure because ComMedia can be easily adapted and configured for another educational context, for instance for the knowledge domain 'management' in higher education. We will now discuss examples of how we applied the framework of Collins. Brown, & Newman for the design of ComMedia.

Content

The characteristic content refers to domain knowledge, heuristic strategies, control strategies, and learning strategies. ComMedia is comprised of insight, knowledge, and skills in the design and use of interactive media for Corporate Communication. The basic design guideline is that relevant 'domain' content has to be stored into a knowledge base. This knowledge base must enable the internalization, externalisation, socialisation, and combination of four modes of knowledge conversion described by Nonaka & Takeuchi (1995). In ComMedia we call this knowledge base the Cabinet. The Cabinet is a repository or in other words a mine of information. Basically we distinguish five knowledge objects and identify five knowledge object types. These knowledge types are information fragments, persons, groups, projects, and competencies. Information fragments are media products containing distinct messages. Examples include documents, links, multimedia files, and WebPages. Persons are the members of the expertise center. Examples of member roles include junior consultants, senior consultants, external consultants, editors, managers, and maintainers. Projects are dedicated workspaces, for example personal, design, research, and consultancy workspaces. Groups are people who share a certain interest without a distinct project goal, specific resources or deadlines. Examples of such groups are newsgroups, discussion groups, and special interest groups. Competencies are sub knowledge-domains. Examples are divisions, competence centers, and courses. Each knowledge object is described by a profile. The profile characteristics we describe are for instance: identification, domain themes, domain keywords, applicability, and accessibility. Identification describes generic, ownership, and author information of objects. A domain theme describes the main subject areas to which object are related. In general, there is a hierarchical order of themes. Domain keywords describe the central concepts in a knowledge domain to which objects are related. Generally, there is a network of central concepts. Applicability describes the usability of objects and refers to the forms in which objects may appear, for instance in an online magazine, portfolio, showcase, project, or internal report. However, applicability also refers to peoples' opinions about the value of objects. They can grade objects and present their opinion in words. Accessibility describes the availability level of objects. We make a distinction between the individual, project, competence, internal, and external level. A specific object available on the individual level means that it is part of a personal archive. However, that person can make the same object part of a certain project archive, etcetera. Based on these characteristics, it is possible to create a characteristic profile for each individual knowledge object. In the very near future, it is expected that these profiles will be 'built' dynamically, based on the persons behavior. That means that for instance, persons' profiles, and more specific the description of the persons' competencies, are updated continually. This update will be based on the study activities a person performs. The strategies are translated into task objects and a set of these objects form workspaces. Task objects are for instance: archive, personal management, design, and study. Examples of workspaces are the personal workspace, the study project, and the design project workspace. Each workspace is formed dynamically, based on the personal profile.

Sociology

Sociology is characterised by situated learning, culture of expert practice, intrinsic motivation, exploiting cooperation, and exploiting competition. The basic design guideline is that the learning of knowledge and skills happens in contexts that reflect the way the knowledge and skills will be useful in real life. This characteristic is made concrete by a 'company' metaphor. ComMedia is designed as a company that enables members to prepare, guide, carry out, and evaluate a wide variety of projects. As a company, ComMedia has the following mission: to offer consultation and design services to (non-)profit companies facing corporate communication media problems or companies interested in communication opportunities made possible by information and communication technology developments. These companies wish to offer a usable information and communication platform to students and teachers to set up, look after, pass through, and evaluate study projects. ComMedia is designed as a virtual learning 'knowledge company'. It is a knowledge company whose primary tasks concern knowledge about the design and use of interactive media for corporate communication purposes. It is a virtual, imaginary profit company that only exists online. Last but not least, it is a typical learning company. It's major task is to enable 'junior consultants' to become 'senior consultants'. ComMedia is a typical adhocracy. There is a strong need for innovation and creativity. There is no middle management and consultants have a lot of freedom in carrying out their tasks. We identify four major roles: administrator, senior consultants (teachers), junior consultants (students), external consultants (former students) and visitors. Tasks are carried out in (study-) projects. Each project team has a lot of freedom in completing the project, as long as they meet standard preconditions, set by teachers.

Methods

Methods refer to the ways students are supported in acquiring and integrating cognitive and metacognitive strategies for using, managing, and discovering knowledge. The basic guideline is that for each study project, students and teachers need to have the opportunities for modelling, coaching, scaffolding, fading, articulation, reflection, and exploration. The applied 'study method' is a project-based education. In our view we consider the senior consultants, the teachers, as mentors for the junior consultants, the students. Furthermore we have a balanced structure in student responsibility. For instance, students have to meet stated deadlines in the first two course projects, while they have their own freedom in setting deadlines in the last two course projects.

Sequence

The characteristic of sequence refers to the way integration and generalisation of knowledge and complex skills can be achieved. The basic guideline is one in which the study profile of a curriculum has to reflect increasing complexity, increasing diversity, and global before local skills. The study profile of Communication & Media is: C&MTheory (7 sp): a theoretical introduction in the design and use of interactive media for corporate communication. In this course the main assignment for students is to put together a so-called 'webfolio', a personal C&M information website, and to make use of each others websites to write a 'scientific' article; C&MDesign (7 sp): a practical introduction in methods, techniques and instruments for the design of media for corporate communication. Here the main assignment for students is to write a project proposal for solving a communication design problem -- for instance a website for marketing ends, and to design a simple prototype with the function of a scale-model in the building industry. C&MResearch (8 sp): a media product design research assignment where students have to carry out 'state of the art' research concerning design guidelines for, for instance, 'the corporate image on the web' or 'marketing websites that sell'. C&MProblem-solving (20 sp): a final assignment where students must solve a communication design problem in a real life context. Students must design a prototype as a 'proof of concept' and write a thesis about their work. One sp stands for one-week study, so the whole specialisation concerns 42-study weeks full time study.

Some final remarks

The design framework of Collins, Brown, & Newman although described in 1986 is still very useful for designing online study environments. We consider ComMedia as a useful proof of concept. It is successfully applied in the study program of Communication and Media. Our main experience is that students appreciate our educational approach. The students evaluations are very positive, as they stated 'we really work hard for the first time in our study'. ComMedia as an environment is only a tool. The 'socio' approach or the organisational infrastructure is in our view crucial. Based on experiences, we are further working on the design of ComMedia. Our aim is the development of a generic online platform for situated learning, which is applicable as a university expertise center for interested persons from educational and non-educational organisations. Our ultimate goal is a knowledge community for life long learning. There is much work to be done.

Discussion

We believe that the cognitive apprenticeship approach is still one of the foundations of education. Trends in life long learning and the upcoming information society only strengthens our belief. The Internet provides us with the means of designing attractive and powerful situated learning environments. We think that our design approach offers practical concepts and guidelines for designing such environments.

Abstract: Navigating the Web has its difficulties. If some of the user disorientation originates in the practical operations for navigation and is reduced when the browser provides a map of the visited space, we argue that the main difficulty arises with characterizing Web contents. We propose a new approach to Web navigation support coined "constructive navigation support". We present the main features of NESTOR, a browser implementing this approach and we discuss the results we obtained during a first experiment in the educational domain.

1 Introduction.

In today's information society, information gathering and use constitute a major activity. The two main information access modes, query and navigation, correspond more or less to the extent to which the researched information spaces are « moderated » i.e. « the extent to which the space structures have been coordinated and controlled » (Jul & Furnas 97). Query is the access mode appropriate for moderated data bases, having a known structure: query software can incorporate features which are based on this assumed structure. Navigation is more appropriate for accessing low-moderated information spaces which don't result from a unified design process - such as the Web. Browsers, which implement the navigation mode, can hardly assume that the diverse documents they link to, have a given structure on which the design of navigation aids can be based (except the node and link structure which is inherent to hypermedia). However, some attempts have been made (Pirolli et al. 96) . On the Web, even though it is not a moderated space, query is used jointly with navigation : the space is so huge that information gathering cannot but begin with querying. However, this cannot be as successfull as it is -sometimes - with databases. The search is then pursued through navigation. It has been assumed much too prematurely that the two modes navigation and query, would add up, and, with the use of search engines on the web, provide a convivial and at the same time efficient way of finding the information sought. But information can be very hard to locate and sometimes not even found at all, although it can be there, in the very documents that are being screened. Almost all the media that have been used until now have a content which is strongly structured and controlled: think of newspapers, TV, libraries. While there are large subspaces on the Web which are in fact moderated (electronic libraries, on line news, institutions official websites), there are also numerous websites which are maintained by individuals outside of standard, official or academic information structures. And this is new: individuals have produced documents for years, but never till now have they be able to reach so quickly a large public. This might account greatly for the success of the Web, but it clearly put the cognitive load of information filtering on the user shoulders, while this load was previously mainly assumed by people acting as moderators.

At least two aspects of electronic navigation lead to navigation difficulties : at the practical level , navigating is circulating with a vehicle : a matter of locomotion (Jul & Furnas 97). Maglio and Matlock (Maglio & Matlock 98) found that "people naturally think of the web as a kind of physical space in which . At a more conceptual level, navigating is mainly a matter of decision making : selecting links to follow. Overall, it seems that the model of Navigation In-Real-Life is still valid : "orienting in the environment, choosing a route, monitoring the route and assessing that the destination has been reached" (Hook et al. 98) – except that in information gathering tasks, the destination is not a location but rather a goal. In fact, this happens too In-Real-Life as people move in a vehicle to achieve a goal. And as In-Real-Life, the two levels of activity - practical and conceptual - lead to different problems and call for appropriate support.

Users disorientation in closed hypermedia corpus (i.e. moderated information space) has been known for sometime now. Several Webmap-based new browsers are under construction (see for example http://www.cybergeography.org/atlas/web sites.html). After all, graphical user interface (GUI) and Hypertext User Interface are to date the major human-computer interaction modes that prevail on the Desktop and on the Internet and there is no reason why they should not be combined. Like others (Ashmore 97), we observed that providing a map of the visited information subspace can "ease inadequacies in Web navigation" (Cockburn & Jones 97). Still, we observed that navigating with a map-enhanced browser in the non-moderated Web brings about much disorientation. User difficulties in making navigational decisions seem to appear at a more conceptual level : identifying documents, delineating pertinent materials, organising the information into categories, pro-actively selecting links through contextual navigational cues - referred as "residue/scent" by (Jul & Furnas 97).

Just as it happens in the world of cinema, orientation deals with expectations about the "off-screen space" i.e. that space which is not visible on the screen, but which is still part of the scene (Persson 98). As noted by Harper (Harper 98) : "Interpreting information is not only a matter of what happens during reading : it is an activity that occurs within a broader institutional practice ... an academic journal for example does not just convey information: its meaning is wrapped up in such things as what is known about the status of the journal". Knowledge of such things provides the context for reading. Reading Web documents requires that users develop a specific system of interpretation through which they build the off-screen context. Because the contexts of production of the Web documents are so diverse, there cannot be easy expectations. There exists many cues about the off-screen context which can be collected along the navigation process in order to ease the interpretation task. But it remains that reading Web documents and thus navigating across them relies - more than in the case of other media – on a *personal construction* of what is meaningful.

We propose then that a software tool with the aim to support navigation should be a *constructivist environment* i.e. an environment which provides means for manipulating and working with self experience. Constructivism implies that knowledge stems from a process of interactive restructuring and transformation of personal experience. This implies - in the domain of electronic navigation - that the tools provided allow for gathering, representing, structuring and creating navigational objects - "externalizing" in the wording of Vygotsky. In this way, in constantly re-structuring the dynamic graphical representation of the browsing activity, users construct mental knowledge spaces (Zeiliger et al. 97). Structuring self experience with information requires conceptual skills as well as external "cognitive" tools (Norman).

This point is even more valid in the educational domain : indeed learners are used to access info spaces (such as libraries) which are not only strongly moderated but whose categories are also close to school categories. It is likely that when learners explore the Web they have to face a new problem : it conveys categories which conflict with the school categories (because Web categories are linked to the diverse *intentions* of the information providers). These were the types of problems that we focused on during studies - part of which are reported here - that were conducted the educational domain with a specific navigator named NESTOR. We implemented this new Web browser to test the constructivist approach to Web navigation support.

2 Implementing the Approach: the NESTOR Browser.

NESTOR is a Web client which runs on Microsoft Windows 95/98/NT platforms. It is a standalone Web browser, however the basic browsing and HTML editing features are provided through Microsoft's Active X components (TwebBrowser and THTMLEd) which means that NESTOR takes advantage of InternetExplorer 4.01 retrieval motor, options, popup menus, dynamic HTML and so on. NESTOR browsing interface is very similar to that of IE4 – except perhaps that it has been skimmed a bit ! The NESTOR left-window interface - which is specific - deals with the construction of maps and of a personal information space. In that view, NESTOR implementation can be considered as constituting an add-on to standard Internet browsers.

The main screen of NESTOR is divided into two windows : a standard browsing window (to the right) and a map window (to the left). While both windows support a range of navigational activities, the map window has been designed to facilitate information-structuring activities. Direct manipulation prevails in the map window while hypertext navigation is the standard mode in the browsing-window. Graphical user interface (GUI) in general and direct manipulation in particular are interaction modes which are more adequate for constructive tasks : tasks which require re-arranging collections of objects. The map window can be thought of -at first- as a dynamic map representing the visited Web subspace. Most navigation operations (such as backtracking) are available in both windows and provide a crossed feedback. NESTOR also records the raw navigation history and allows for re-constructing a map from a selection of this history. As "re-visit" accounts generally for more than 50% of users' operations, the map and history features (and their combinations) are very useful. There is a special mapping of search motors (representing queries in order to facilitate the exploration of the filtered documents) and some handy features which facilitate directed searching like a "breadth-first" mechanism (Newfield et al. 98). Further more, NESTOR has been designed to promote the *construction* of a personalized Web space. For that purpose, the map-window is interactive : it allows for re-arranging as well as *creating* new objects : documents, links, annotations, sub-maps, tours, search keywords and conceptual areas. It is best viewed as a sort of note-taking tool which is consistent with the Web structure : notes take the form of a personalized web which is inter-weaved with the public WWW.

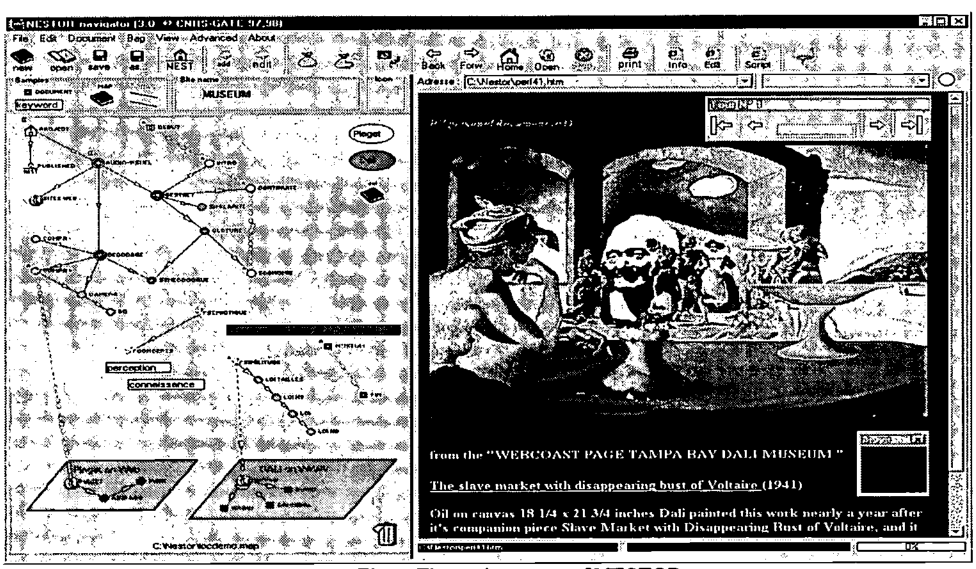

Fig 1. The main screen of NESTOR.

We now list the main features of NESTOR with more details and outline how they implement the constructive navigation approach.

2.1 Representing Self Navigational Experience : while the user performs navigational operations with the Web browser, NESTOR automatically draws a graphical representation of the Web subspace which has been visited. Every visited document is represented as a circle whose size depends on the number of outgoing links. Visited links are represented as arrows. There is an automatic layout which favours the point of view of the user's self experience (as opposed to an overview map based on a network centred representation) : as long as the user traverses to a new document, objects and arrows are posited along a straight line figuring a "user's route"; the object corresponding to the currently displayed document is highlighted providing situational cues for the user's position in the visited subspace; when the user navigates using the back or forward buttons the corresponding objects are highlighted; when the user starts browsing again, a new straight "route" is drawn. This graphical representation is dynamic and interactive : users can re-arrange the layout through direct manipulation; any visited document can be accessed directly by double-clicking on the corresponding graphical object. The use of such maps increases the visual feedback in *practical* navigation operations and facilitate orientation.

2.2 Constructing a Personal Web space: at the beginning the map reflects the visited subspace, i.e. public documents and their public links. But then, users can create personal documents and personal links, and inter-weave them with the public network. Personal links are created through direct manipulation on the map: i.e. simply drawing an arrow between to objects on the screen - either public or personal - creates an hypertext link. Personal links are represented as dotted arrows while public links appear as solid arrows. Public documents need not be aware they are linked. Personal links appear as hotwords in a separate window jointly with the document they are attached to but their anchor is not incorporated to the document itself. Building thematic maps and creating personal hypertext are activities that promote directed Web searching.

2.3 Note-taking : The process of inter-weaving the public and the personal network can be thought of as a sort of note-taking mode which is consistent with the hypermedia structure of the Web: i.e. notes include not only text but links as well, so that the Web network is annotated with a network of notes. Additional features are available in that line: annotations can be attached to every visited document be it public or personal. Annotation content is HTML-formatted so that it can include text, links or even questions in a "CAL fashion" as well. Whenever an annotated document is re-visited, the corresponding annotation is displayed jointly in a separate window. A visible clipboard - "the bag"- is also available to allow selecting and gathering of information along the navigation process; when pasting information into the bag, NESTOR includes a return link to the source document. The information gathering and note-taking activities help user structure their thoughts and construct meaningful information.

2.4 Creating Keywords Objects and Conceptual Areas: keywords, conceptual areas and sub-guides can be inserted in maps. User created keywords are automatically searched for in the visited document's text and highlighted when found (both on the map and in the document): this is especially useful when navigating across a set of documents which have been selected by a search engine. Keywords object are also extracted from the search motors queries. Web maps and keywords appear in the same window so as to allow different combined layouts. Conceptual areas help structuring the maps with object clusters.

2.5 Creating and Saving Navigational Objects : all objects created by users (maps, keywords, conceptual areas, annotations and routes) can be saved to a file and retrieved. Those objects are considered as "navigational objects" in the view that they can serve to initiate new navigational operations: for example navigating from the links in the annotations. "Conceptual orientation" is facilitated through creating, arranging and capitalizing on such objects (using their navigational properties and methods). We use the term "map" to refer to such collections of navigational objects.

2.6 Sharing Maps : NESTOR allows navigational objects to be published and shared by a group of people. Simple URLs as well as whole maps can be published. NESTOR users are warned whenever they navigates to a URL which has been previously published by one of their colleagues. In that case, annotations attached to the document (by the publisher) are available, as well as the map in the context of which the publisher has accessed the document. Bags can be published too. Computer mediated communications and collaborative navigation can help users construct meaningful information : a process Harper describes as "collaboratively defining institutional matters of relevance" or in short a "world-known-in-common" (Harper 98).

3 Evaluating the Tool and the Approach.

3.1 Educational context. We chose to evaluate the use of NESTOR in a real life setting (i.e. in the school computer room, in cooperation with the school teachers) with students knowledgeable in the use of computers and already familiar with WEB navigation. Groups of high school students (aged 15-16 years old), having prior experience with the Netscape navigator, were given a pedagogical task which consisted in finding information on the Web in order to answer questions relating to economy (Task 1) and to ecology (Task 2). They had for each task a maximum of two hours. The task was completed when they had found the relevant information and written or recorded it in the "bag" file. Task 1 dealt with a *curriculum topic* in economy: the students were each given a paper document presenting the task, with 2 questions to be answered, and a list of Web URLs where the required information could be found. The students were also each given detailed written instructions on how to connect to the main academic server where the Web addresses were already available. The students worked in dyads with NESTOR, one computer for two students. Task 2 had to do with *a topic loosely related to the curriculum*: ecology. The procedure was the following: the students worked individually (5 min.) and then in a group session (25 min.) with the aim of setting up a list of their own keywords on pollution of air and water. In this way the topic was addressed not only with an academic label but by a thematic envelope as well (the list of chosen keywords). The students were then shown and explained NESTOR keyword features and given three written questions to answer. They had 2 hours for their work and were finished when they had found and annotated 5 relevant URLs.

Having already experimented that visualizing of self navigational experience facilitates users' practical orientation (Zeiliger et al. 97) we were here interested in understanding why a user does so many revisits (more than 50% in our observations) of the same sites, even when a map is available. The first task was framed in order to provide information on this recurrent problem. The question content was labeled in such a way so as not to reproduce the exact labeling to be found on the sites indicated. This refers to the hypothesis that searching for information in low-moderated information spaces such as the Web requires greater categorization competency on the part of the user. We wanted to explore how students would succeed in matching a curriculum question with Web information. The second task was more open. We hypothesized that students have difficulties because they do not recognize the information they are seeking when the information is displayed and contextualised in categories different from the "school" categories. We therefore wanted them to use their own categories. This was achieved by having them prepare their keyword list.

3.2 Evaluation results. We discuss here information gathered on the use of NESTOR by three groups of students (two groups of eight and one group of ten). After eliminating repetitive operations due to retrieval delay (still a frequent source of disorientation in academic use), we ended up with 1061 operations within a period of 1033 minutes (17 hours and 22 min). We are concerned here strictly with the navigation operations, which were recorded on each computer.

		Task 1	Task 2	
Total operations				1061
Navigating by use of hotwords	HOTW	49 %	48 %	49 %
Navigating by use of map objects	MAP	21.5 %	19.5 %	20 %
Using BACK button	BACK	18 %	5 %	14 %
Using NEXT buttton	NEXT	1 %	1 %	1 %
Typing an URL and pressing OPEN	OPEN	1 %	1 %	1 %
Going back home	HOME	1 %	7 %	3.5%
Miscellaneous				11.5 %
Revisiting		53%	55%	54%

As expected, the percentage of re-visits is very high. Use of the map is high (about 20%, to be compared with the low use of BACK around 14%). Because NESTOR map represents only the visited subspace and because – unlike BACK – it provides a direct access to any visited document, we can assume that students were aware of re-visiting URLs in at least 20% cases . We have here situations where students revisited the same documents several times, looking for information that they were not finding, although they knew that it was there. During interviews conducted after the sessions, students spoke of their disorientation caused by the way the information was presented in the Web documents. When analysing the individual traces, we find that much revisiting also involves going along already traveled paths (among which we observed numerous to-and-fro cycles). We think we can frame this in terms of *conceptual disorientation*, not to be confused with the *practical disorientation* which has been reported when users navigate in closed hypermedia corpus using map-free browsers. More experiments are underway on a larger scale : 72 university students at Ecole de Management de Lyon (http://www.em-lyon.fr) have been given NESTOR to complete a 3 month information-gathering task on the Web and collaborative navigation features are being evaluated within the framework of the LEARN-NETT European project (http://tecfa.unige.ch/proj/learnett).

4 Conclusion and Future Work.

We found that navigating the Web even with a map-enhanced browser causes much disorientation problems. We hypothesized that much of this disorientation arises at a conceptual level, because in non-moderated information space the context for reading is often lacking. In the educational domain, when the researched information is presented in a context different from their academic context or yields novel perceptive and lexical data, learners cannot attain its meaning through surface scanning. To grasp the meaning behind the linguistic units, they have to go to the level where lies the information necessary for semantic categorizing. NESTOR maps and their navigational objects provide basic means for gathering cues along the navigation paths and structuring them with the aim of building a context for deep reading. In this perspective, future Web browsers should not only provide maps, they must tend toward full environments engaging users looking for "information that counts" into more constructive activities. Quite the contrary to surfing.

Abstract: The World-Wide Web has the potential to significantly change the ways in which students interact with texts, making them more active participants in their reading. Unfortunately, while many see the Web as promoting interaction, most pages provide relatively passive modes of interaction, only permitting students to click on one of a series of links to select what to read next. In this paper, we present one step toward making pages more interactive: a system that permits students to *annotate* arbitrary Web pages with notes, glosses, questions and comments; to *share* those annotations with their colleagues; and to develop *discussions* through those annotations.

1. Introduction

The World-Wide Web (Berners-Lee et al. 1994). is revolutionizing the ways in which we share information. In particular, it is affecting the ways in which we teach and learn. Unfortunately, while the Web is often seen as making students more active learners, most students can only interact with pages passively, by reading and clicking links. Some educators suggest that this is no more active than flipping pages or looking through the table of contents or index in a book.

In fact, paper provides many opportunities for active interaction with the material being studied. On paper, students freely mark the pages in their texts, underlining words or phrases, jotting notes in the margins, summarizing key sections, and even folding down corners to remind themselves of particularly important points (see, e.g., (Marshall 1998)). While some of these aspects are included as core Web technologies (e.g., the lists of bookmarks provided by most browsers are similar to the folded corners of printed texts, and perhaps more usable), others are less available (e.g., it is difficulty to jot notes electronically and keep them on an existing page).

In this paper, we describe a system we have developed to support *annotations* to pages on the World-Wide Web (WWW) Our system permits learners to add comments, notes, and glosses to existing Web pages, thereby helping students become more active learners. While our system does not provide all of the mechanisms suggested in (Marshall 1998) (e.g., we do not support highlighting), our system provides an appropriate starting point for developing richer systems.

We have developed a system that permits selected *annotation* of arbitrary Web pages. Our system permits students to annotate pages with public and private notes, glosses, questions, answers, and discussions. We expect that as students have increased ability to interact with Web pages, they will become more active learners.

There are other annotation tools (or Web-based systems that include annotations) available, such as ComMentor (Röscheisen 1995), CoNote (Davis 1996), the Group Annotation Transducer (GrAnT) (Schickler et al. 1996), HyperWave (Maurer 1996), Medium (Lapique and Regev 1998), and WebCT (Goldberg 1998). We distinguish our system from by supporting annotations of both local and remote pages; permitting annotations at author-defined and automatically-generated positions on the page; supporting annotations on changing pages; and providing multiple protection levels for annotations.

We developed this annotation system to serve multiple purposes. First, an annotation system would provide a way for a student to take personal notes. Given the increasing number of course pages available, and the increased use of computers in the classroom, it may be possible for students to take online notes on course pages during class. For example, (Rebelsky 1998) reports that in a computer-equipped classroom in which daily course outlines were available online during class, some students opened the daily outline in an HTML editor to add their own notes. Second, an annotation system is also an appropriate way to share notes. For example, one might post questions about an assignment or suggest followup readings. Third, students can use sequences of notes to provide a discussion (similar to a typical threaded bulletin-board, but with focus on a particular point on a Web page).

For an annotation system to be successful, it must not only accommodate the needs, preferences, and habits of its users, but also predict and shape them. A student or instructor new to hypermedia authoring and usage may understand the ability to add notes to a page, but may not think about other issues, such as *protection* (who should be able to see an annotation), selection of *annotation points* (where annotations should go in a document), or *appearance* and *positioning* of annotations. We report on these design issues and the user testing that guided our design choices in the subsequent sections.

2. Architecture

Among our primary goals was to design an annotation system that could be installed and used widely. This led to a number of core requirements, including

- a teacher should be able to install and use the annotation system without making modifications to the Web page server;
- students and teachers should be able to use the annotation system with current Web clients; and
- students should be able to annotated a wide variety of pages, including pages on different servers and pages that neither teachers nor students had direct control over.

These requirements led to an architecture based on a centralized annotator and an extended version of the core of Project Clio (Becker and McLaughlin 1998) (Becker et al. 1999). A single CGI script is used to coordinate all annotation activities. A page request is routed through the CGI script. The CGI script

1. retrieves the page from a server (or from the file system, if the page is stored locally to the CGI script),
2. adds *annotation points* (described in section 2.2),
3. identifies the annotator (including group permissions),
4. fetches annotations from an annotation server,
5. inserts the annotations or links to the annotations into the page,
6. updates the links on the page so that the CGI script is used for further page fetches, and
7. returns the modified page.

In a future version, we expect to be able to use a form of proxy server for the same purpose.

The retrieval of original page, identification, link update, and return are handled by Project Clio. The addition of annotation points, fetching of annotations, and insertion of annotations were added for this project.

Because the annotation system is based on a CGI script, it is relatively easy to install (some servers may need a flag set to permit use of CGI scripts). Since it does not require modification to the underlying pages, it permits annotation of pages that neither teachers nor students control. Since the determination and fetching of annotations is done at the server side, and not the client side, it requires no extensions to clients. However, the current mechanism for displaying annotations does require JavaScript, which is supported by both of the most popular browsers (Netscape Communicator 4.0 and Internet Explorer 4.0). The display mechanism is described in section 3.

A settings file can be used to customize some aspects of the CGI script. In particular, it can be set to accept requests from only certain domains or certain accounts. This permits instructors to limit access to annotations. (The protection system described in section 2.1 provides additional forms of access control.) The settings file can also influence which pages can and cannot be annotated. For example, some instructors might wish to limit annotations to their own pages, or to a particular set of pages they have already identified.

2.1. Protection

There are three trends for protection of annotations: annotations are either private (accessible only to the user), group/semi-private (restricted to a group of users), or public (accessible to anyone reading the page). Many systems permit only one type of annotation. For example, CoNote provides only group annotations. Similarly, systems treat the different types of annotations quite differently. For example, WebCT (Goldberg 1998) separates annotations, which are private, from discussions, which are semi-private, using different interfaces for the two.

We chose to provide all three "types" of annotations with a consistent interface. When a user creates a new annotation, (s)he may choose to make it private, group, or public. Because we could foresee different groups of people using the same page (e.g., faculty, teaching assistants, and students might all have discussions on a course page), group protection also includes a note as to which groups may view the annotation. When browsing annotations, readers can see the headers of all the annotations, but may only view the bodies of annotations for which they have appropriate permissions.

2.2. Annotation Points

An annotation system for the Web must accommodate the differences between the Web and paper. One particularly important difference is that while paper remains fixed (and any errata are separate documents), Web pages often change. This means that annotations cannot be conveniently tied to a particular piece of text. Where should annotations appear?

Some annotation systems, such as the original NCSA Mosaic annotations (NCSA 1997), place annotations at the page level, with one annotation per page. Such placement seems overly course given the more typically fine-grained annotations students typically make. Discussions with faculty and students suggested that there is need for more specific placement of annotations. For example, a question about a particular problem in a homework assignment best belongs near that problem. More importantly, an instructor interested in having students gloss a work (i.e., add commentary) will not be satisfied with annotations that are so coarse-grained.

A finer-grained ideal would be to permit users to select the text to be annotated. Such a solution is used in the Multivalent Document system's markup system (Phelps and Wilensky 1997). Unfortunately, standard HTML browsers will not easily support this choice. One alternative, used in the Group Annotation Transducer (Schickler et al. 1996), is to allow users to specify the text that will be tagged. Unfortunately, entering the appropriate text requires more effort on the part of the user and also suggests difficulties if the page changes or if the same phrase appears multiple times. Both of these fine-grained solutions may lead to annotations at awkward, confusing, or otherwise inappropriate points on the page.

Another alternative is to allow authors to specify the annotation points in a document, as in CoNote (Davis 1996). The disadvantages of such an alternative is that it places all the burden on the author, and provides little freedom for the annotator. An advantage is that it permits annotations to remain through changes of the document (something particularly difficult in phrase-based annotations).

We chose a hybrid solution, in which annotation points can be added by the author, but are also generated by the system for "natural" points in the document. At present, these points are currently set to be section headings, which often designate a logical break from one thought to another. For typical documents, section headings are fine-grained enough to permit annotation at a reasonable level but coarse-grained enough that the document is not over-croweded with annotation points. We use heuristics based on approximate text matching to determine the (re-)placement of annotation points in changed documents.

3. The User Interface

A similarly interesting problem was where to put the annotations themselves. A number of alternatives suggested themselves (many of which have been used in other systems). One might make links to the annotations and bring them up in the same window when clicked. Such a solution is easy to develop, but makes it more difficult for the novice Web user to view both text and annotations. One might make links to the annotations and bring them up in the same window. One might insert the annotation text into the same page. However, this can make the original text more difficult to read, as the annotation interrupts the flow of the text. One might use popup windows, in which the annotation appears over the annotated text when one moves the mouse over that text or clicks on it.

3.1. Surveying Potential Users

We decided that this was not an issue we could approach in the abstract, after the system was constructed. Hence, we surveyed potential users about the strengths and weaknesses of a variety of designs. We developed eight different prototype interfaces for an annotation system and surveyed students with a variety of computer background. The examples varied in appearance and technical design issues. One example displayed annotations in a separate pop-up window. Another brought the user to a new page which displayed the annotation and the corresponding paragraph (the annotated text). In a third design, the annotations were visible on the page, within the document. For another the annotations were in the margin. The colors and icons changed from example to example, while the text and annotations were constant. Since we worried about interrupting the flow of text, a few examples permitted the users to turn the annotation feature on or off. We did not test the interface for entering the system (in which students enter their account and password) which is taken from Project Clio (Becker and McLaughlin 1998) (Becker et al. 1999).

Most participants preferred a pop-up window to view and add annotations, since they did not want to disrupt the page they were on. Annotations directly on the Web page seemed to add clutter and make the page less readable. Also, the less obtrusive the annotation buttons were, the better. At the same time, many found the ability to hidc and show the annotation buttons (or the annotations themselves) confusing.

Based on this feedback, we developed a hybrid of the eight used in the survey. We chose to use two small buttons to indicate the annotation points. One button is used to add annotations and appears at every annotation point in the document. The second button is used to indicate the presence of annotations at that particular point in the document, and is only used if there are annotations for that annotation point.

3.2. Interacting with the system

If one clicks on the **View Annotations** button, a separate window appears showing a collapsible tree of annotations corresponding to that annotation point. There is a tree of annotations because we permit readers to write followups to other annotations, and found a tree the most natural way to represent the many discussions that may come from one annotation point.

If there is only one annotation available for a particular annotation point, that annotation is used as the "alt text" for the annotation button. In modern browsers, such as Netscape Navigator 4.0, this provides a quick pop-up view of the annotation. If multiple annotations are available for a particular annotation point, the number of annotations is used as the "alt text".

When the user selects the **Add Annotation** button or the **Followup** button, a new window appears. The annotator can enter a name, title, and the annotation. Annotators can also select permissions: self, selected groups, everyone on system, world. Finally, an annotator can choose to make an annotation anonymous (so that, for example, students can post comments without fear of appearing less confident or successful they wish to appear).

While the annotations do not preserve text formatting (e.g., whitespace), they can be written in HTML, the HyperText Markup Language (Raggett et al. 1998). This gives authors freedom to format their comment or question by adding emphasis, tables, lists, and other structure.

3.3. Followup Surveys

After the new interface was complete and the underlying system implemented (so that subjects could add their own annotations and not just view existing annotations), a second group of subjects was brought in to test the new interface. This group of subjects included some of the first group, but also some new subjects.

While participants were generally satisfied with the structure of the implemented annotation system (e.g., the pop-up windows), many identified some technical problems that would not be obvious in a prototype. For example, many pointed out that the windows should auto-reload, so they can see the changes they made immediately. It was also noted that a close button was needed in the annotation window. Finally, many subjects needed more ready access to a help system.

4. Future Work

We have developed and begun testing of a system that we expect will enhance the effectiveness of course pages by permitting students to add notes and questions to Web pages in and out of the classroom. Our initial user-testing suggests that this will be a usable system, but we do not yet know how much or how it will be used. Because the system depends on parts of Project Clio, we must wait until Fall 1999 for our initial course trials. Based on feedback from those trials, we expect to make extensions and modifications to the system.

We also expect to refine the interface for the "annotation tree" (the set of annotations for a particular point in the document). While we conducted regular testing of the placing and appearance of annotations relative to the page, we were able to do less testing of the appearance of this tree.

Finally, we intend to provide alternate "views" of the annotations so that, for example, a student who wishes to print a document with annotations may conveniently do so. We expect to test at least two alternates for this "all in one" view: one in which the annotations are placed near the text they annotate and one in which they are used as footnotes (with footnote numbers places in the text).

USING A THEORETICAL MULTIMEDIA TAXONOMY FRAMEWORK

Rachelle S. Heller

Diannem@seas.gwu.edu

Abstract: An expanded multimedia taxonomy is proposed to provide a framework for understanding and conceptualizing interactive multimedia for the purposes of teaching, research and project design. The taxonomy is an especially helpful tool for the generation of evaluation materials. Specific examples of how to generate evaluation categories and concerns is included.

WHAT IS MULTIMEDIA?

Multimedia is a polysemous term - a term with many definitions and in this case many roots. In this paper, multimedia is defined as the seamless integration of two or more medium. A multimedia taxonomy is proposed to help organize the discipline based on a previous media taxonomy (Heller & Martin, 1995). The taxonomy helps to classify the space called multimedia and helps to draw attention to difficult issues. Whilc multimedia is an emerging field, the fact that we can provide a taxonomy indicates that it has reached some level of stability and maturity to be reckoned with.

THE TAXONOMY

The multimedia taxonomy can be visualized as a three dimensional matrix (Heller and Martin, 1998). Media type, the rows of the matrix, pertains to the various media involved: text, sound, images, motion and combinations. Media expression, the columns, refers to the level of abstraction portrayed using these media: elaboration, representative and abstraction. Context, the third dimension, portrays the various roots in multimedia: disciplines, interactivity, audience, aesthetics, quality and usefulness. As originally expressed the taxonomy had 90 cells in three dimensions to be defined (Heller and Martin, 1995). In the beginning work, it was observed that evaluation or design questions often repeated themselves, regardless of the medium form or expression format. For example, questions about text size are appropriate no matter the format of textual presentation. Based on this observation, the taxonomy was expanded to provide a category in the format called general - this category is used for questions that are constant over the format space. Hence there are 120 cells provided by the taxonomy and each can be expressed as a series of questions that can be used as a development or evaluation guide. The newly expanded taxonomy becomes a floor, not a ceiling, for a series of guidelines that can be used to generate a series of questions about an application.

Media type is arranged as a series of individual medium of increasing complexities (i.e. storage). The various media should be clear. Text is the presentation of information using an alphabetical symbol system. This includes prose is various languages as well as presentations in such forms as mathematics or other symbol systems. Sound is the inclusion of spoken word as well as generated tones forming music or other audible information. Images include photos and hand drawn items while motion can be motion pictures or animations. Multimedia, as defined above, is the inclusion of any two or more of these.

Media Form	General	Media Expression Elaboration	Representation	Abstraction
Text	Math functions were correct Is it clear which input device to use Word choice was unclear/clear Grammar was correct Reading characters on screen (very hard to very easy) Spelling was correct (No to Yes)		Font for bold and italics is readable	
Sound	Sound quality (unclear to clear) Sound speed (too fast/slow..just right) Sound volume (too loud/soft..just right)	Speech is Captured without stutters	Sound effects are recognizable	
Graphics	Quality of image (low to high) Size of image (too large/small to just right)			Icons are clear Iconic Metaphor is sharp
Motion	Quality of motion (jerky to smooth)			
Multi media	Media Integration (Uncoordinated to coordinated) Media technical synchronization			

FIGURE 1: Sample Questions from the Quality Dimension

Contextual categories that are not applicable to the specific product being evaluated can be eliminated from the protocol. The questions (Figure 1) are framed either as a Likert scale question with five gradations or an open ended questions requiring a free form user response. Those that are intended to be considered using a Likert scale are presented with the categorical extremes listed in parenthesis. For example, to evaluate the item listed as use of motion one can generate a question for the form:

	Jerky				Smooth
Use of motion	1................	2...............	3...............	4..............	5

The Multimedia Taxonomy is best understood in its application. The new media space is 6x4x5, where each cell can be used to address specific aspects of media design or evaluation. For example, the aesthetics category might encompass the following concerns: In the general expression of text, we might ask, is the font size appealing, while in the elaboration expression of text, it is appropriate to ask the aesthetic question concerning the richness of the literary expression on the continuum from dry to poetic. In representational expression of text, we might ask whether the format of the outline is logically well-structured and in considering the abstract expression of text within the aesthetic categories, we could ask if the textual image as an icon is pleasing.

Similarly, when considering questions of audience in the general category for text we might ask if the instructions are clear, while in elaborative or representational expressions of text we might ask evaluative questions about whether the feedback to the audience is appropriate or if there is a compatibility between the reading level of the audience and the level of expression of the textual description. The usefulness category prompts us to assess the value added by a medium type or expression. The extended Multimedia Taxonomy elicits questions about sound quality as well as sound impact.

Under the category of Usefulness, the evaluation protocols contained questions about whether a medium like sound was functional, by asking users to rate the sound on a Likert scale that ranged from annoying to helpful. The protocols also contained open-ended questions about what the user remembered about the sound in the application being evaluated. Thus, the newly expanded Multimedia Taxonomy becomes a floor, not a ceiling, for a series of guidelines that can be used to generate evaluation questions about a multimedia application. Parts of the taxonomy not relevant to the specific product being evaluated can be ignored when developing the evaluation protocol and data-gathering instruments.

AESTHETIC

The guidelines in this section are intended to examine the appearance, artistic look or impression of the IMM. Questions related to design, rather than function, are the focus in this section Figure 2 is an example of questions for aesthetics.

AUDIENCE

Audience guidelines are intended to direct the evaluator to address issues of how the IMM relates to the audience and how the audience members might be able to process the medium form in a specific medium format. For example in the area of text as elaboration, it is necessary to ask whether the text is at the reading level for the intended audience. On the other hand, while text as representation does require the user to read, there tend to be fewer words and grammatical constructions in this category but the representation (e.g. outline) might not be familiar to the particular audience. This section requires the evaluator to know to whom the IMM is intended. Before preparing an evaluation protocol for a particular IMM, the evaluator should know who the intended audience is.

DISCIPLINE

Guidelines in this section are intended to identify the content specific material in each of the media forms within a specific medium format. For example in reviewing text that is presented in representational form (outlines or lists) is necessary to ask here whether the lists are complete and accurate within the content area. This section is often best evaluated by experts in the content area rather than by IMM designers or members of the intended audience.

Media Type	General	Elaboration	Representation	Abstraction
Text	Font size is appealing Free from stereotypes Media overuse? Overall impression Screen design Screen spacing Use of color	Literary Expression (Dry to Poetic)	Format (i.e. outline) is well placed Position of messages (appropriate)	Metaphors are consistent within the application Text image or icon
Sound	Sound (annoying to helpful) Sound (noisy to tuneful) Volume (too soft/loud to just right) What did you think of the sound?		Background sound (pleasing)	Sound effects (not pleasing to pleasing) Sound effects (unclear to clear)
Graphics	Still images attractive? Use of color pleasing?		Background images (too faint)	Icons pleasing?
Motion		Video or animation (not pleasing to pleasing)		

Figure 2: Sample questions based on aesthetics issues

INTERACTIVITY

In this category, evaluators should be addressing aspects of control, navigation and linking. Aleem (1997) is examining the relationship between the attribute of interactivity to the media type and expression. He has further subdivided the attribute of interactivity into four categories: Passive, Reactive, Proactive and Directive. With the Passive aspect of interactivity, the user has no control, but instead, all control is embodied in the application (i.e., a PowerPoint presentation) Reactive interactivity provides limited response for the user within a scripted sequence. Proactive interactivity allows the user to play a major role in the design and construction of situations, typically by manipulating values for valuables. Multimedia that has interactivity at the Directive level allows the user both to respond to and to initiate actions within the application as well as to tailor aspects of the environment, such as selection of color choice, feedback choice, and so on.

QUALITY

This section refers to the technical, reproductive aspects of the IMM. Quality issues relate to clear images, correct synchronization and timely delivery.

USEFULNESS

This category refers to the value of the material presented in the IMM as well as the ease of use of this material. Since Interactivity covers the navigational issues and Usefulness covers the ease with which a user can operate the application there seems to be a muddy ground between the two categories. But there is a distinction. Usefulness also includes whether the user can operate the equipment necessary to make the application run. For example, questions such as can the user operate the head tracker or the roller ball as well as is there a need for external devices to run the IMM are appropriate in the ease of use category.

As can be judged from the foregoing paragraphs, not all of the 120 cells contained within the three-dimensional Multimedia Taxonomy are completed. Some are being examined in detail, while others are still to be developed. Students in courses in the Seminar on Multimedia Evaluation in the Department of Electrical Engineering and Computer Science at The George Washington University (Heller, 1994) have been successful in designing evaluation protocols using the Multimedia Taxonomy as a guideline. Figure 3 represents a sample of the survey comments developed from the formative evaluation of Ada Mentor, an online web site for the study of the Ada programming language. The Multimedia Taxonomy helped pinpoint such problems as too many forms within the web site and the inability for a user to see the entire page. They were able to suggest on the bases of the evaluation, that the Ada Mentor developers reduce the navigational capabilities and clarify the functionality of navigational icons.

CONCLUSIONS

We believe the multimedia taxonomy is a reasonable organizing framework. Admittedly there is room for extension of the multimedia taxonomy if new ways of thinking about multimedia are presented. The extensibility of the taxonomy is demonstrated by the ability to take a cell or series of cells and, using them, form new detailed sub-taxonomies. This is demonstrated by the work presented by Aleem (1997).

The multimedia taxonomy is a solid framework - the details of each of the cells needs to be completed. Currently we are beginning usability studies using the taxonomy. Specifically, we are interested in whether evaluators can use the taxonomy as a guideline to improve the coverage of their existing evaluation protocols or does the fragmentation of the taxonomy interfere with, or distract from, the evaluation. In continuing efforts to establish quality evaluation products we are also beginning to review the use of object oriented design techniques and metaphors as a possible format for expressing multimedia evaluation. As a beginning we are considering each medium (text, sound, stills and motion) as a specific object and each object has its specific attributes (size, color, form declaration, representation and form) and behaviors (interactions). Objects can form clusters and it is these clusters that can have different relations and interdependency. Investigations into the use of cluster analysis as a methodology for multimedia evaluations is just beginning.

As an organizing principle the Multimedia Taxonomy presented here can be used to understand both design and content messages. The next step is to review the taxonomy in light of various studies in the psychological and cognitive aspects of understanding of multimedia applications to determine whether this taxonomy can shed light on these areas. Questions such as how we come to understand an image and how that understanding is different from our understanding of text can be answered in part by using the taxonomy. We have presented a few examples of the impact of the Multimedia Taxonomy on the design and implementation of evaluation protocols for multimedia products. More work in this area remains to be done. Finally, however, the Multimedia Taxonomy represents an attempt at the formalism that is needed to provide the both a theoretical and practical framework for the new and rapidly growing field of interactive multimedia.

The Design and Development of a Web Site to House National Accreditation Documentation

Caroline M. Crawford
University of Houston – Clear Lake
2700 Bay Area Boulevard, Box 50
Houston, Texas, USA, 77058-1098
crawford@cl.uh.edu

Abstract: The design and development issues surrounding a World Wide Web-based site to house documentation for a national-level accreditation of a College of Education is daunting, to say the very least. Many different facets introduced themselves through out the design and development of such a Web site. The Web site in question concerns a national accrediting body, National Council for the Accreditation of Education (NCATE), that has led a "bleeding edge" push towards the design and development of a Web site that houses pertinent documentation concerning the professional education unit that is undergoing the accreditation process. Although numerous possible future questions and concerns within the design and development process were thoroughly discussed and responses were decided upon, there were numerous occurrences throughout the design and development process that were not expected. These occurrences are the primary focus of learning and should be discussed through a much larger audience so that others working through such a process will be familiar with any concerns that may arise within their own situation.

Introduction

Accreditation has become a primary concern within the professional education units over the previous fifteen years. Although quality standards have been in place within the educational realm for well over a fifty-year period, recent events and publicity have caused the strengthening of accreditation through out the United States of America. The accreditation process is built upon clearly defined standards that each professional education unit must delineate through out the accreditation process. As stated by the National Commission on Teaching and America's Future,

> Setting Standards is like building a pyramid: Each layer depends on the strengths of the others. Students will not be able to achieve higher standards of learning unless teachers are prepared to teach in new ways and schools are prepared to support high-quality teaching. Higher standards for students must ultimately mean higher standards for teachers and schools. Otherwise, the end result of the standards movement will be more clearly documented failure rather than higher levels of overall achievement. (1996, p. 27)

Due to this stated desire to raise the standards of the educational units within the United States of America, a focus has been placed upon accrediting bodies. Interestingly, accrediting bodies at different levels through out the educational realm. From specialization areas, such as Spanish through instructional technology, through overarching accrediting bodies, such as the National Council for the Accreditation of Teacher Education (NCATE).

Herein lies an interesting element. Due to the strong feelings of necessity towards an overarching, professional education accreditation, Roames (1997) describes the national conference of 1951 wherein the efforts of at least four representative council organization bodies came together. As a result of these efforts, the National Council for the Accreditation of Teacher Education (NCATE) was approved. Although NCATE was developed almost fifty years ago, the numerous reforms that NCATE has worked through have developed a stronger, living organization that spearheads accreditation processes. Herein lies the focus of this article; NCATE developed a task force, the NCATE Task Force on Technology and Teacher Education (National Council for the Accreditation of Teacher Education, 1997) which noted the desire to "establish pilot projects with a few institutions to implement and evaluate state-of-the-art uses of technology in the current accreditation process .... These pilot projects should be conducted both by institutions seeking initial accreditation and those pursuing continuing accreditation" (National Council for Accreditation of Teacher Education, 1997, p. 19). This statement not only indicated the desire of the NCATE organization to further discuss the implementation of technological innovations within the accreditation process, but it seemed to be an open invitation to professional education units to establish pilot projects to introduce technological innovation into both the initial and continuing accreditation process.

Purpose of the Study Statement

The purpose of the study was to qualitatively describe the design and development of a professional education unit Web site to integrate the unit's applicable documentation concerning the units anticipated NCATE continuing accreditation.

Design

Instructional Design Model

The Four D Instructional Development Model (Thiagarajan, Semmel, & Semmel, 1974) was implemented as the instructional design model due to its clarity and linear nature. However, the interesting aspect of this instructional design model choice was the choice of a linear model to develop a nonlinear learning environment, which may also be described as ill-structured landscape environments (Wittgenstein, 1953). Questions were raised concerning the positive as well as detrimental effect that a linear model would have upon a nonlinear learning environment and, after numerous discussions, a clarity of thought between a linear instructional design model and a nonlinear learning environment was reached. Although a linear instructional design model may be implemented to develop a product, this linearity has no impact upon the final product due to the developmental structure versus the product structure; although a linear model is decided upon due to it's clarity of process and ease of use on the part of the designer and developer, this would not impact the product of a nonlinear learning environment.

Nonlinear Learning Environment

The nonlinear learning environment, clearly displayed through the possible use of the World Wide Web environment, is one which offered the ability to link multiple areas of pertinent professional education unit documents together within one Web site. This linking ability offered a nonlinear environment through which the NCATE Board of Examiners (BOE) members who would ultimately view the documents. This nonlinear environment would offer a clarity of though and information to the NCATE BOE members and, theoretically, ease the strain placed upon NCATE BOE members who are required to traverse this documentation over a short time period. Another positive aspect to the implementation of a nonlinear learning environment for the pertinent professional education unit documentation is the ability of the NCATE BOE members to have the option to view the pertinent documentation before ever stepping foot on the university campus. The NCATE BOE members had the ability to view relevant documents before visiting the campus that would offer more time during the visit to interview and view areas, persons, and places of interest.

Qualitative Data Collection

During the initial components of the research process, as well as through out the design and development of the professional education unit's NCATE Web site, certain aspects were clearly articulated as having relevance towards the importance of the process and, therefore, were clearly stated as areas of data collection. The researcher implemented a qualitative data collection so as to obtain necessary, relevant, and descriptive data pertaining to the design and development of the Web site. The three areas through which data was collected through out the design and developmental process were the areas of historical research, participant observation, and interview.

Historical Research

Historical research describes the location, obtainment, development, and digitization of the documentation that was integrated into the Web site. Through out each of these processes, perhaps the most difficult would be the location of the historical documentation. Although the faculty and staff within the professional education unit were clearly helpful and went beyond their duties, the difficulty in merely locating the historical documentation was a timely venture. The historical documentation was available to the Web site developer without question; however, the location of the documentation and the ability to actually "put hands upon" the documentation was another matter. Yet, as previously stated, the faculty and staff within the professional education unit were of the utmost help through out the location, obtainment, development, and digitization of the documentation process.

Participant Observation

The ability of the researcher to become an integrated member of the professional education unit was of utmost usefulness through out the design and developmental period. As an "insider" within the professional education unit, the faculty and staff were comfortable with the researcher and were willing to offer personal thoughts and beliefs concerning the design and development of the Web site, with little to no concern as to the trustworthiness of the researcher. The integration within the professional education unit was a helpful part of the design and developmental process, and offered numerous instances of thoughtful reflection and discussions with the faculty and staff of the professional education unit; without such an integrated aspect, the researcher would have most likely missed instances of clarity and breakthrough discussions pertaining to the Web site.

Interview

The Web site was continuously appraised through out the design and development periods. There were two groups of appraisers; the first group being technical and interface usage experts, with the other group being Texas members of the NCATE BOE organization. The reasoning behind the use of the NCATE BOE members from Texas was the desire to eliminate any chance that the NCATE BOE members chosen for the professional education unit's BOE visiting team could possibly have been a member of the Web site design and development research; in other words, NCATE BOE members from Texas would be ineligible to act as NCATE BOE visiting team members for the professional education unit that was designing and developing the Web site, because no BOE member may examine a university within their own state. This structure is in place to ensure any form of in-state bias would be extricated. The willingness of the Texas NCATE BOE members to act as appraisers through out the design and developmental periods is a strong indication that the collegiality and desire towards excellence within the education profession ensures the quality of our education profession's future.

Development

The development of the Web site consisted of three main elements: the developmental process, the integration of documentation, and quality assurance. Within each of these areas, the desire for appraiser feedback to aid in the developmental process was clear.

Developmental Process

The process through which the Web site development progressed was steady and streamlined. Through out regenerative periods of development, appraisal, reflection, and significant redesign, the Web site focused upon quality assurance and the integration of documentation. The appraisers offered reflective, significant input through the interview process that aided in the development of the Web site.

Integration of Documentation

The steady integration of documentation through out the developmental process offered numerous instances of nonlinear integration of documentation as well as the hyperlinking of specific subject areas within and between the documentation. The hyperlinking process between the specific subject areas within the documentation was perhaps the most time-consuming aspect of the integration process, outside of the location, obtainment and digitization of the documentation.

Quality Assurance

The quality assurance was an element that was felt through out the design and development of the Web site. Without the quality aspect as an integral part of the Web site, the researcher felt that the design and development was a useless exercise in futility. Therefore, the quality assurance was felt through the design, development, appraisal, redesign and redevelopment. Quality assurance can not be overemphasized as a primary aspect through out the design and development of the professional education unit NCATE Web site to house pertinent documentation.

Results

To address the previously stated purpose of the study, the methodology chosen was of a qualitative nature, specifically ethnography. Within the ethnographic areas, a triangulation between historical research, participant observation, and interview was implemented. A further consideration within the research was the limitations of the study, which are integral to the complete understanding and significance of the research.

Historical Research

The historical research was an integral aspect within this developmental research. The documentation offered the ability to not only integrate and delineate numerous aspects within the professional education unit, but also to develop a nonlinear hypertext environment through which the documentation would offer the ability to display further understanding of the knowledge available. Although the location, obtainment, development, integration, and digitization of the historical documentation was of primary concern through out the design and developmental periods, the careful development and thoughtful appraisals were essential to the quality assurance of the Web site.

Participant Observation

The use of participant observation through out the design and development of the Web site offered an unstructured viewpoint through which to obtain thoughtful responses and viewpoints without the strict question-answer protocol that would underlie the interview process. The ability of the researcher to act as an "insider" within the professional education unit allowed both faculty and staff the comfort zone through which to impart important comments concerning the design and development of the Web site, as well as to verbalize any concerns or questions that arose.

Interview

The interview process consisted of structured question-answer sessions that were made available through a Web-based form that would ensure the appraiser a comfortable environment to offer input, reflect, and further comment upon requested information as well as outside areas that were important to the appraiser. Instances of outside e-mails also occurred through out the appraisal process; although without any form of incentive on the part of the researcher. The appraisers seemed to require an outside, personalized mode of connection with the researcher that perhaps fulfilled a deep-seated desire to connect on a more personal note, as well as offer further insightful information to the researcher. Through such interviews, whether through the formalized question-answer Web forms or more informal e-mail communications, the quality assurance of the Web site was ensured.

Limitations of the Study

The limitations of the study were few; however, each limitation was a significance consideration through out the study. The first limitation was the appraisers might have answered the stated questions so as to please the researcher. This is a possibility whenever human subjects are used in research situations; however, a considerable effort was put forth through the deliberate working of the Web site feedback forms so as to not influence the appraisers. A second limitation as that the appraisers would interpret the stated questions differently than the intended meaning. Due to this possibility, the researcher gave each question careful consideration so as to reduce the interference of questionable grammar or verbiage. A third limitation is the danger of generalizability of the study. This study can not be generalized beyond the professional education unit for which the Web site was developed. However, certain aspects of the design and developmental process may be useful for future endeavors and are offered as a modest component towards future efforts.

Conclusions

The occurrences through out the design and developmental periods of the Web site offer numerous instances of thoughtful reflection, learning, and growth. Such experiences must be conscientiously considered so that future endeavors will gain from such experiences. Although the observations and experiences attained through this research are considerable, future endeavors will offer significant possibilities towards the establishment of further defined and delineated facets of learning.

Human/Computer Interface Issues for a National Accreditation Web Site

Caroline M. Crawford
University of Houston – Clear Lake
2700 Bay Area Boulevard, Box 50
Houston, Texas, USA, 77058-1098
crawford@cl.uh.edu

Abstract: The use of the World Wide Web as a tool to disperse information for national accreditation has been severely underutilized. The ability to offer informational documentation concerning the health of an institution, such as a university, in a non-linear hypertext format is one which could offer a healthy, severely needed element towards the accreditation process. The ability to ease the accreditation process towards a more flowing sharing of information has been a long time coming, but one which is on the brink of exploding. The National Council for the Accreditation of Teacher Education (NCATE) is one national accrediting agency that has realized the Web's vital use and has begun the process of implementing this underutilized tool.

Introduction

The use of the World Wide Web (Web) towards the development and integration of information for a national accreditation structure is in its infancy. However, the utilization of the Web as a tool to disperse information has presented itself as a primary area of interest to one national accrediting body, the National Council for the Accreditation of Teacher Education (NCATE). NCATE is an accrediting institution that has stated their desire to pull technology into their accreditation process. NCATE developed a Technology Task Force (National Council for Accreditation of Teacher Education, 1997) that stated the desire as well as the need for the ability to integrate technology into the accreditation process. One such request was the desire of piloting the development of a Web site through which the integral documentation pertaining to the accreditation process that would be available. This would allow for the accreditation Board of Examiners (BOE) to view the documentation before stepping foot on the campus, as well as the ability to link documentation in a hypertext format within the Web site.

The importance of human/computer interface issues through out the Web site developmental process can not be underemphasized. Although the main focus of the developmental process was the placement of documentation on the Web and the interrelation of the documents within the site, the appraisers for the Web site focused upon the human/computer interface issues to a large extent. Although the appraisers were asked to comment upon structural strengths and weaknesses, the appraisers consistently focused upon the interface issues as being of primary importance. The issues, concerns, and comments concerning the human/computer interface are integral to the development of a national accreditation Web site to house pertinent documentation.

Human/Computer Interface

The World Wide Web (Web) is a medium with the capacity to display nonlinear structures in a hypertext environment, which in turn leads to a further understanding of ill-structured knowledge domains on the part of the user (Wittgenstein, 1953). These ill-structured, nonlinear, hypertext environments offer a cognitive flexibility to the documentation, therefore the knowledge, that is obtained by the user (Spiro & Jehng, 1990). Although the constructivist theoretical structure embraces such an environment, certain aspects must still be thoroughly, reflectively considered through out the development of a learning environment. Due to the direct parallel between the learning environment theories and the NCATE accreditation Web site through which pertinent professional education unit documentation is made available to the NCATE BOE team, careful consideration of the human/computer interface issues must be a focus within the design and developmental process. Reflections pertaining to human/computer interface issues, concerns, and comments must be thoroughly considered so that the future endeavors will have a basis upon which to build.

Issues and Concerns

Several noteworthy human/computer interface issues and concerns were raised through out the design and development of the professional education unit's NCATE continuing accreditation Web site. Only the thoughtful, reflective consideration of each issue and concern offered useful, creative ideas that could be implemented in real-world environments that could, in turn, address the discussions surrounding each subject.

Instructional Design Model

The first of these issues was the questionable use of the Four D Model (Thiagarajan, Semmel & Semmel, 1974), a linear instructional design model, to develop an ill-structured, nonlinear, hypertext Web environment. Concerns arose surrounding the use of this model because, as the argument was delineated, the linear instructional design model may impact the ill-structured, nonlinear, hypertext Web site that was to be developed. However, after further discussion and theoretical underpinnings were discussed, the realization that a linear instructional design model does not necessarily lead to a linear product was agreed upon. A linear instructional design model, as the Four D Model clearly is, can indeed offer a product the defined requisite step procedures outlined in the Four D Model to attain a nonlinear Web environment. The basic parallel understanding between the two, descriptively the model and the product, is that the model leads the progress through out the design and development of the product; however, the product demands to be developed while focused upon its own specific goals and objectives. Therefore, the importance of a tight parallel between the instructional design model and the product goals and objectives is obvious; yet the underlying theoretical structure of the instructional design model does not drive the underlying theoretical structure of the product. The theoretical underpinnings do not necessarily have to be the same to produce a strong product.

Intellectual Property and Ownership

A second issue was the placement of faculty vitae and syllabi on the Web site. At the beginning of the developmental process, the desire to offer the professional education unit documentation and information as a freedom of knowledge endeavor drove the location and obtainment of historical information. However, as the developmental process became more engrossing, the faculty raised questions surrounding the idea of placing course syllabi on the Web for anyone to view. This concern arose due to the knowledge, history, research and reflection that was apparent through out the course syllabi; many faculty had built their prestigious careers upon the subject matter contained within the course syllabi and the faculty were not inclined to place these course syllabi on the Web for anyone to view, borrow, or use towards someone else's own personal end. Although the faculty were eager to offer their aid to anyone that may ask for information and would most likely offer their course syllabi upon request, the perceived lack of control, when placing information on the Web, was a concern. The control that was apparent through the personal contact between faculty member and the person requesting the aid was a workable situation; however, when the information was placed on the Web, it became a question of intellectual property and ownership. Anyone could take this information and do whatever they wanted to do with it. This was the concern of the faculty.

After numerous discussions and the support of the faculty, the decision was agreed upon to place password protection upon the NCATE Web site that would house the course syllabi, as well as any other documentation that the faculty agreed to include for the Web site. The question of intellectual property and ownership pertaining to the placement of course syllabi on the Web site offered faculty the opportunity to clarify the gray area of intellectual property and ownership within the professional education unit environment and, on a larger scale, the university environment.

Copyright

Within the same thought pattern as the intellectual property and ownership, the question was raised concerning copyright issues and concerns. The question of copyright, both of the historical documentation placed on the Web site and the Web site itself, was discussed through out the developmental process. The university administration is still working on the final documents pertaining to the copyright legalities; however, the concerns over copyright issues pertaining to this Web site are quite clear. If the documentation was developed for any part of the university environment during the employment of faculty, usually described as research, service and teaching, then it is the property of the university and the university will receive at least a percentage of the proceeds. However, anything is worthy of discussion and copyright may be one of these discussion topics. Therefore, the question of copyright when discussion the historical documentation that was placed on the Web site was the sole copyright of the university. Also, the Web site itself was the sole property of the university and copyright went to the university, although the theoretical underpinnings and learned lessons were the knowledge obtained by the researcher.

Template

The template structure of the Web pages within the Web site was areas of discussion through out the developmental process. The strong feelings of the appraisers pertaining to the template structure that the Web pages would follow were consistently questioned, discussed, commented upon, and complimented. The Web page templates consisted of a title bar along the top of the page, with higher-level navigation buttons directly below the title bar, listing left to right. Along the left side of the page were same-level navigation buttons that offered the ability to quickly navigate through out other relevant Web pages without the difficulty of moving within the Web site, losing the place within the Web site navigation structure, and forgetting the information of importance during the navigation process. However, one significant template structure addition that was offered by the appraisers was the desire to have an area along the right-hand side of the screen that would offer textual links to areas of related importance within the document that the user was viewing. This aspect quickly led to an innovative aspect within the Web pages that offered easier, quicker nonlinear, hypertext availability within the Web site. Although this was an obvious addition to the Web page templates, the clarity of thought on the part of the appraisers led to this innovative use of the nonlinear, hypertext environment.

Comments

Several noteworthy human/computer interface comments were raised through out the design and development of the professional education unit's NCATE continuing accreditation Web site. Only the thoughtful, reflective consideration of each comment would aid in the development of the professional education unit's NCATE continuing accreditation Web site.

Interface Format

The interface of the Web site was the first consideration within the initial design and developmental process. The desire of the developer to integrate a useful, smooth interface into the Web site that would seamlessly aid the user towards the documentation of importance was an issue that was constantly in the developer's thoughts. Interviews were conducted with the appraisers requesting feedback upon the template color(s), template text size, and overall template aesthetic appeal. Specific questions were asked concerning each templates:

- Attractiveness
- Unattractiveness
- Obvious and Easily Viewable/Readable Links
- Positive Aspects
- Negative Aspects
- Distracting Aspects
- Annoying Aspects
- Personal Thoughts Concerning the Template
- Which template(s) were preferable for the Web site

Through these overarching questions, numerous insights were gained from the appraiser responses. The appraisers, as an overall desire, found the simplistic, straightforward templates to be most attractive; the reasoning behind this was that the appraisers felt that the "busier", less simplistic templates would become more of an eyesore as the user traversed through out the Web site. Although the less simplistic templates may have been attractive for a one page template, the consistent use of the template would become difficult for the user; as one appraiser noted, the template should be an appealing backdrop for the documentation, not the other way around.

Web Browser Inconsistencies

A comment noted most loudly through out the developmental and appraisal processes was the inconsistencies between the Web browsers Netscape Navigator or Netscape Communicator (Netscape, 1997; Netscape, 1998) and Microsoft Internet Explorer (Microsoft, 1997). Although the Web site was developed for consistency in viewing across platforms and browser types, the difficulties that became apparent when developing the Web site made the simplistic aspects of a Web site more intriguing and desirable. The Web site became a streamlined structure with very few outside inconsistencies not taken into consideration. However, although all inconsistencies between Web browsers were thoroughly discussed and reflected upon, instances of inconsistencies will always arise when developing a Web site; the structure must be flexible enough to work within these inconsistencies and aid the user in the user's quest for information.

Conclusions

The importance of human/computer interface issues through out the Web site developmental process can not be underemphasized. Although the main focus of the developmental process was the placement of documentation on the Web and the interrelation of the documents within the site, the appraisers for the Web site focused upon the human/computer interface issues to a large extent. Although the appraisers were asked to comment upon structural strengths and weaknesses, the appraisers consistently focused upon the interface issues as being of primary importance. The issues, concerns, and comments concerning the human/computer interface are integral to the development of a national accreditation Web site to house pertinent documentation and must become central to the development of the Web site. Through trial and error through out the design and development process, the thoughtful, reflective nature of the appraiser feedback offered numerous instances of insight and developmental aids.

Houston, Texas, USA, 77058-1098
crawford@cl.uh.edu

Abstract: The use of technology within the PreK-12 classroom has been steadily increasing within the previous ten-year period. However, teacher training has not kept a similar pace. The training available for the teachers, as well as the administrative-level school district employees, has lagged desperately behind the technological hardware integration. For this reason, school districts are looking towards training the personnel in the district. Universities are continuously developing such training for their students at the undergraduate level as well as graduate level, so the universities are the logical answer to the school district needs. Within southeastern metropolitan, semi-rural and rural areas within the State of Texas, several districts and universities have developed partnerships through which the training of school district teachers and administrators can occur.

Introduction

Training school district Instructional Technology Coordinators in the use, development and implementation within instruction of multimedia is an area that is only recently being addressed. The school districts have received extensive amounts of money for networking and hardware integration within the PreK-12 classrooms; however, the training that must be implemented has lagged behind the networking and hardware. The school districts have begun looking towards outside entities through which the training of the school district personnel can occur, whether through business or educational arenas. Within the southeastern metropolitan, semi-rural and rural areas within the State of Texas, several school districts have turned to the surrounding universities to develop partnerships. The universities have answered the school districts with an energetic response and are eager to offer instructional technology training to the school district personnel.

The universities are developing a pyramidal, top-down structure through which the persons trained will in turn train others, until each of the district personnel are trained. However, this training begins at the university level. The desperate need of the school districts are being met through the thoughtful integration of not only technological training, but also the modeling required to use technology as an integrated tool within the classroom environment. This modeling begins with training the independent school district Instructional Technology Coordinators. The Instructional Technology Coordinators are persons that are responsible for training the other district personnel on the use of computer software and hardware within the district. One of the primary areas in which the district personnel are to be trained is the development, instruction, and use of multimedia.

Training Modules

The first consideration when training the school district personnel is deciding upon the information that needs to be addressed. A needs assessment clearly is indicated at this stage of the process; only through a needs assessment will the desired, needed, or required subject matter be indicated and offer the ability to be addressed. Multimedia is one area that was indicated as being not only desired, but also a subject area that would be necessary for future endeavors. Therefore, multimedia was an area that would be necessary to develop a training module.

Training modules are merely clearly articulated curriculum that offers training, information dispersal, hands-on activities, and packets of information for the trainer and the learner. Such information is necessary to develop, unless a quality training module is available. For the needs of this situation, a training module was developed by the university faculty and students to aid the school district personnel in the attainment of the necessary information.

Training the Trainers

Once the needs assessment has occurred, with results leading to the development of a multimedia training module, the next area of concern would be the question of who would train the learners. The university faculty would logistically be unable to facilitate each training session, so the question follows as to exactly who would facilitate the trainings. The logical answer actually consists of two responses: school district instructional technology coordinators and university graduate students.

School District Instructional Technology Coordinators

The school district Instructional Technology Coordinators have perfect logistical positions through which to train the school district personnel. Therefore, the Instructional Technology Coordinators would be the primary focus of the university faculty. Once the Instructional Technology Coordinators are trained upon the integration of multimedia, the information dispersal would again focus upon multimedia, but upon the training towards the facilitation and integration of multimedia; in this way the trainer has the experience of being on the receiving end of the instruction as well as on the facilitating end. This two-sided experience allows the facilitator to not only empathize with the learner, but to also have the experience necessary to foresee possible problems or questions that may arise during the training sessions. However, the school district Instructional Technology Coordinators have positions which pull them in numerous different directions all at the same time; therefore, it may be impossible to solely train the Instructional Technology Coordinators as trainers due to the possible inability of the Instructional Technology Coordinators to act as sole trainers for the school district personnel. With the majority of Instructional Technology Coordinators having numerous duties, as previously stated, one simplistic answer would be to train the university graduate students as trainers.

University Graduate Students

Training university graduate students as trainers for school district personnel offers a multitude of experiences for the university graduate student. Not only will the graduate students receive real-world experience training adults in educational settings and the possible monetary compensation that would be available; but, the graduate students would have the ability to further develop one or more training modules that would be beneficial, further their knowledge of learning environments and curricular events, and develop mentor/mentee relationships with university faculty as well as school district Instructional Technology Coordinators. The graduate students could work parallel to the school district Instructional Technology Coordinators, contract their services through the university to the school districts, or numerous other combinations which would offer the experience that graduate students may desire to obtain real-world experience and develop surrounding school district contacts that may aid them in future ventures. The possibilities for the university graduate students to work with university faculty and district personnel towards the development of multimedia offer a well-rounded experience to university graduate students.

Technology Integration

The development, instruction and use of multimedia in a classroom environment open the world to numerous instances of technological integration into the educational curriculum. Through this integration of multimedia, the curriculum can be largely enhanced and the learners will have the ability to develop further knowledge and experiences that would have previously been unimaginable. For the purposes of the training of school district Instructional Technology Coordinators in multimedia development, instruction and use, three focuses of technology integration will be considered: teacher-centered technology, student-centered technology, portfolio assessment.

Teacher-Centered Technology

The development of training modules to focus upon the teacher-centered aspect of technology integration into the curriculum and, therefore, into the educational environment, offers numerous opportunities for multimedia to be integrated. Multimedia can be used as a linear or nonlinear lecture device for the facilitator, which would enhance the lecture through the integration of pictures, videos, sound files, animation, and other such facets of multimedia. The ability to integrate such enhancements into a lecture-style situation offers the ability to maintain the motivation of the learners, emphasize numerous integral aspects of subject matter, or merely display an innovative curricular entity.

However, the teacher-centered multimedia technology must not merely be used for lecture-style purposes. The ability of the facilitator to develop multimedia products that would enhance prior knowledge, develop conceptual frameworks for the learners, act as knowledge-checking experiences, or an even more advanced multimedia package can offer the ability to develop teacher-centered multimedia drills that the learners would work through as a class. The primary aspect of the teacher-centered technology is the innovative uses of multimedia within the experience. Numerous facilitators may already understand the fundamentals of a multimedia package; however, the true skill is displayed when the facilitators display their knowledge towards developing a teacher-centered or a student-centered multimedia package.

Student-Centered Technology

Student-centered technology can be further defined as instructor-created or student-centered technology. Within the area of multimedia, the ability of both the facilitator and the learner to equally develop multimedia programs for distinct purposes is an integral part of the curricular and instructional situation.

Instructor-Created Multimedia

The development of multimedia for the learner is an experience that opens a multitude of environments to the learner. The facilitator may create mere drill and practice environments through the higher-learning situations that would request critical analysis on the part of the learner. Although the facilitator must carefully decide upon the curricular integration and introductory environment through which to engage the instructor-created multimedia, the possibilities are endless.

The facilitator must have the capability to develop multimedia products that will facilitate the learning process while engaging the learner until the requisite goals and objectives are obtained. This is no easy feat, and one that must be considerably touched upon through out the training of the school district personnel.

Student-Created Multimedia

The student-created multimedia is another aspect, altogether. The ability to create educational environments through which learners can create multimedia products that have educational relevance is a carefully learned ability. The training of district personnel to have the foresight, comprehend the capabilities of the student-created multimedia products, and open the curricular and learning environment to this option is one which must be facilitated in a forthright manner. The ability of learners to create their own multimedia package of their learning opens the learning environment to one of control on the part of the student, as well as creates a collegial attitude on the part of the student. This type of environment is one that closely emulates the business, professional environment of today and one that must be carefully integrated into the learning environment for our students to emulate. Of interest is the close parallel between student-created multimedia and portfolio assessment within the educational environment.

Portfolio Assessment

The development of student-created multimedia products, and the integration of these products within a larger structure, emulates a digital portfolio. The creative, developmental work that is brought to a portfolio entails numerous hours of difficult thought patterns and critical analysis of numerous high-level situations. The difficulty within a digital portfolio, which is what is being addressed, is the assessment factor. Once the learning occurs and the multimedia product is developed and integrated into a portfolio structure, how will the portfolio be assessed?

As with numerous paper portfolio assessment structures, A reflective piece is included by the learner for each product that is included within the portfolio. Through this reflective piece, the portfolio assessor has the ability to attain a working understanding of the learner's thought process through out the developmental period and to assess the learning which took place. On a larger level, a rubric or a matrix is viable options through which to assess a portfolio. Through a matrix or a rubric, clear delineations are presented to the portfolio developer and assessor as to the criteria through which to obtain the desired grade within an organized grade structure.

Although there is a lot of information pertaining to portfolios and portfolio assessments available, the integration of technology into the portfolio environment should be openly addressed within the multimedia development, instruction and use training sessions for school district Instructional Technology Coordinators.

Conclusions

Training school district Instructional Technology Coordinators in the use, development and implementation within instruction of multimedia is an area that is only recently being addressed. The desperate need of the school districts are being met through the thoughtful integration of not only technological training, but also the modeling required to use technology as an integrated tool within the classroom environment. This modeling begins with training the independent school district Instructional Technology Coordinators. One of the primary areas in which the district personnel are to be trained is the development, instruction, and use of multimedia. Through the development of training modules, training the trainers, and technology integration, the introduction of multimedia into the educational environment is becoming a reality.

Applying Constructivist Learning Principles in the Virtual Classroom

Abstract: In recent years, much has been written on the philosophy and theory of constructivism. Only recently, however, has it become feasible to consider constructivist principles within the context of adult distance education. The participant interaction that is central to most constructivist theory has become possible primarily because of advances in communications technologies that have become an integral component in an increasing number of distance education environments. There remain a number of barriers to full implementation of constructivist principles within the context of higher education. This paper will address some of these barriers and describe how instructors in a technology-mediated distance-delivered undergraduate program designed a learning environment based on constructivist principles.

Introduction

Academic discourse relating to the value of collaborative learning appears to be based on the distinction between the individual and social nature of human cognition. The former position reflects the work of Piaget (Wadsworth, 1971) where the focus is on individual cognition. In this view, the function of the group is to provide social pressure to solve problems. This pressure stimulates the individual to resolve internal conflicts which, in turn, leads to cognitive growth. The latter position is based on the Vygotskian model, wherein the group plays an integral rather than peripheral role in cognitive growth. Knowledge is created through social interaction, and then, primarily through language (Frawley, 1997). Young (1997) illustrates the full continuum of epistemological stances relating to how humans create knowledge, the relationship between the individual and social context, and their relative impact on the process of knowledge creation. He identifies six schools of thought, each of which can be placed in one of three categories: *Category 1* in which social context and interaction are irrelevant (i. Radical, Material constructivism, ii. Critical, Final constructivism); *Category 2* in which the social environment may or may not play a role in the construction of knowledge (iii. Existential constructivism, iv. Efficient, Objective constructivism); and *Category 3* in which the social nature of knowledge construction is central (v. Social, Formal constructivism, vi. Co-constructivism). Although Young's categories are useful for describing the different epistemological positions, learners themselves are not restricted to employing any one position in their construction of knowledge. From both a developmental and contextual perspective, learners will naturally move fluidly from one knowledge construction mode to another, unless something impedes this movement. In traditional distance education, the learning environment has acted as such an impediment because it could not support the movement from cognitively oriented to socially oriented knowledge construction.

Another central tenet of constructivism is an emphasis on process. Learners should participate in authentic, active learning experiences. This presupposes a complex learning context, which reflects the ill-structured nature of real-world problems. In this learner-centred environment, the teacher functions as facilitator of learning, rather than dispenser of content. Reflection is part of the process of building knowledge, as is articulation, both internal and social. Jonassen et al. (1995) refers to these attributes as: context, construction, collaboration, and conversation. Zahorik (1995) categorises them as activating knowledge, acquiring knowledge, understanding knowledge, using knowledge, and reflecting on knowledge. The emphasis accorded to each of these facets by proponents of the different constructivist schools of thought varies. There exist a number of theories, perspectives and approaches to constructivist learning including: situated cognition (Brown, Collins, & Duguid, 1989; Lave & Wenger, 1991), cognitive apprenticeship (Duffy and Bednar, 1991), and cognitive flexibility (Spiro, Feltovich, Jacobson & Coulson, 1991). Increasingly, theorists are addressing the ways in which technology can be used to support constructivist learning environments (Duffy & Jonassen, 1992)

Barriers to Incorporating Constructivist Principles

With so much importance placed upon interaction between and among learners and instructor, and the difficulty of achieving that interaction within the traditional distance education environment, it is not surprising that distance educators found it onerous, if not impossible to reconcile constructivist principles with the reality of their working environments. The adoption of communication technologies by the distance education community has substantively removed one barrier to participant interaction, but there are a number of other factors that limit the extent to which instructors apply constructivist principles. While these are not exclusive to the distance education environment (Carr, Jonassen, Litzinger & Marra, 1998), their impact may be felt more strongly in that context.

Instructional Design

The prevalent instructional design models tend to impede the application of constructivist principles (Wilson, Teslow, & Osman-Jouchoux, 1995). The linearity of most instructional design models, coupled with the objective-driven development process, acts as a major constraint, one that is more evident in the context of distance education than it is in the traditional face-to-face higher education context. Most post-secondary instructors develop their courses with complete or near complete autonomy, but this is seldom the case when courses are developed for distance delivery where planning and development are frequently a team effort. This supports instructors whose experience with distance delivery is limited, or provides technical resources, thus freeing the instructor to focus on content. The number of proprietary software programs that have been developed to replicate this environment by providing 'course development toolboxes' for use by instructors who do not have access to instructional design teams indicates the prevalence of this development model. While taking a template approach to instructional design may ensure efficiency and consistency, it is seldom conducive to supporting constructivist principles.

Institutional Constraints

The institutional barriers to implementing constructivist learning principles identified by Carr et al. (1998) are essentially the same for both face-to-face and distance delivered courses and programs. Any differences tend to be of degree, with the distance context subject to somewhat greater constraints. The three institutional barriers we will discuss are those of textbook focus, time constraints.

The textbook focus evident in the face-to-face classroom is reproduced in the virtual classroom, but with the inclusion of an additional element—the World Wide Web. Now, instead of, or in addition to, providing printed packages of readings and study guides, these materials are often posted on course web pages. This reliance on text material may be one of the most difficult barriers to overcome, because is it is based on not only an institutional bias, but also a cultural one. There is also a possibility that because interaction within the context of computer-conferencing is mediated through text, i.e., the written rather than the spoken word, such interactions are regarded more highly by the learners than are discussions in the face-to-face classroom. Learners routinely print the comments of fellow students for future reference (Technology in Higher Education (T.H.E.) Study Group, 1998). Essentially, they treat what would be a conversation, had it occurred in a face-to-face environment, as if it were a textbook.

Time constraints place a serious limitation on constructivist learning. It takes longer to design an authentic learning environment. Complex, ill-structured activities where learners must experiment and negotiate naturally take longer to complete than do activities designed to transmit information. The time factor becomes even more of an issue when working in a text-based, asynchronous environment. It takes longer to compose a message that will be subject to scrutiny than it does to make a similar comment in class where a large portion of the message is transmitted visually using paralinguistic clues such as body language or intonation in ways that are denied to the writer. In addition, when conducted asynchronously, discussions and negotiations may be attenuated over a considerable length of time.

Learner Resistance

Adult learners are very often self-directed and independent learners. These characteristics are particularly evident within the context of distance education. Even within technology-mediated environments, many learners express a preference for content-delivery facilitated by instructional design models (Technology in Higher Education (T.H.E.) Study Group, 1998). Communication technologies can provide an opportunity for interaction between and among learners and instructors, but while many participants enjoy the interaction, fewer view it as an essential component of learning. Wells (1993) notes that "Students who are 'socialized' to the *isolation* of self-study may even need to be 'resocialized' to the educational benefits of interaction!" (p. 83). Ensuring that on-line activities are meaningful may help overcome the learner resistance that results from exposure to not only new ways of learning, but also new technologies. Interaction should not be merely an add-on to course content, but rather, an integral component of the learning experience.

Lack of Role Models

Instructors as well as learners have been socialised into a culture of information transmission as opposed to one of knowledge creation. The industrial model of traditional distance education has provided even fewer models of constructivist principles than has traditional face-to-face education. Communication technologies, however, can provide the means for distance educators to move beyond the industrial model by supporting constructivist learning principles in a post-industrial distance education context (Garrison, 1997).

That potential notwithstanding, distance educators have few role models for designing and facilitating constructivist learning environments. Teaching is an activity often conducted in isolation from other practitioners, and this is even more of a factor for distance educators. Pre-service teacher education rarely addresses the context of distance education and many, if not most, distance educators have little or no context specific instruction. Courses and programs that are available generally focus either on features of the technology or on instructional design models. There is a need for professional development activities predicated upon constructivist principles where distance educators can both observe and practise collaborative interaction.

Incorporating Constructivist Principles

The question remains--how can distance educators incorporate constructivist principles into their on-line classrooms? Over the past two years, we have instructed several sections of a technology-mediated distance education course for adult educators who were either beginning to work in distance education environments or expected to. Faced with the constraints previously identified, we have tried to create complex learning environments, facilitate learning, foster collaboration between and among the course participants, and encourage reflection. Using the six learning principles of mulitiplicity, activeness, accommodation, authenticity, articulation, and termlessness identified by Koschmann, Myers, Feltovich & Barrow (1994) as a framework, we will describe some of our activities and their outcomes.

Mulitiplicity

The principle of multiplicity refers to the multiple perspectives inherent in any authentic, ill-structured learning environment. Knowledge construction is a complex activity and the learning context should reflect this complexity. When planning for learning, the instructor needs to focus on the *complex whole* rather than on the *discrete parts* of tasks and problems. This is especially true in distance education where breaking a problem into subsections, or a series of discrete steps is a common instructional strategy. At the same time, it is essential to distinguish between a learning activity that reflects the complex nature of knowledge and a needlessly complicated learning activity. If an activity does not lead to the desired type of interaction, it is possible that the activity itself is overdesigned and interfering with or restricting interaction. The simplest of activities can provide an opportunity for a rich learning experience (Carr, et al. (1998).

The concept of multiplicity was integrated into all of the learning activities used in this course. Since one of our goals was to have students challenge their assumptions about what it means to teach and learn in a technology-mediated environment, students were expected participate in and critique course activities from the perspectives of both instructor and learner. Initially, even though the participants are themselves instructors, many were reluctant to relinquish their role of student, and we found that it was frequently necessary to actively encourage participants to experience the activities from alternative perspectives.

In order to provide students with an opportunity to assume multiple roles and perspectives, we attempted to create as authentic an environment as possible. It has been our observation that many experienced instructors new to technology-mediated distance education attempt to transfer teaching and learning strategies directly from their previous context, whether that be face-to-face or traditional modes of distance education. Since this is seldom effective, we wanted to provide course participants with an opportunity to experience, within a risk-free environment, the disequilibrium or frustration that comes with moving from the familiar to the unfamiliar, so that they would be compelled to question both their attitudes and practice. To accomplish this, we first analysed the way certain activities were typically implemented in face-to-face adult education courses and then moved them in their entirety into the virtual classroom. By dividing these activities into a series of discrete steps, we could have ensured that learners experienced greater 'success' in the class, but that would have inadequately prepared them for the process of adapting and transferring their teaching methods to the virtual classroom.

Activeness

This principle refers to the process whereby learners assume ownership of the topic or problem and explore it in ways that are most relevant to their needs. This precludes an emphasis on content (the traditional objective, information, measurement model that guides and limits discussion) in favour of the creation of authentic tasks. Since adult educators have more than a passing familiarity with the use of icebreakers, students were asked to work in groups to develop an icebreaker suitable for use on-line. We did not want to force participants to curtail their explorations of the topic in order to submit a product or to direct their focus toward receiving a grade, so no marks were assigned to the product. We also had, and still have, reservations about the tendency to assign grades to on-line activities in order to stimulate participation, when similar 'in-class' activities would not be graded in a face-to-face environment.

No two groups approached the problem in the same way since the members of each group were influenced by different factors, ranging from their experience with distance education to their attitudes toward icebreakers and the characteristics of their students. Those groups where some members had prior experience in distance education spent much more time discussing the rationale and associated problems and processes in advance of designing an icebreaker activity. Those groups whose members had no first-hand experience with distance education jumped right into the development stage, but as they experimented with different icebreakers and encountered an assortment of unforeseen problems, they began to question their initial assumptions. It would have been impossible to predict the variety of factors and resources that influenced each individual's contribution. Nor would it be possible to condense their negotiations and conclusions into a series of steps that could be used to 'instruct' another group of learners.

Accommodation

The principle of accommodation is based on encouraging learners to become aware of and challenge their assumptions at the most basic levels. One of the ways we try to help participants to accomplish this is to expose them to difficulties experienced by many distance education instructors. This enables them not only to enhance their knowledge and skills, but also to question their attitudes and beliefs about distance education and what it means to be a distance educator.

At the outset of the course, we explain the learning context to the participants and try to prepare them for a certain amount of frustration and discomfort. It should be noted here that this course is part of a program of study and that the students have already completed several courses using the technologies before beginning the one described here. In spite of our warning and their earlier experiences, or perhaps partly because of the guided, highly structured nature of those earlier experiences, the ill-structured nature of this course came as quite a shock to some participants. Since the course has a strong affective component, participants were encouraged to discuss their feelings of disequilibrium.

One activity that encourages participants to challenge basic assumptions is introduced at the beginning of the course. Again, students are asked to replicate a routine in-class activity. In this case they are asked to "get themselves into groups" and "brainstorm" a particular topic. They have one week to accomplish this before reporting back to the class. This activity brings to the forefront assumptions about group dynamics. Students compared the on-line process with what takes place in the face-to-face setting, debated the rights of adult learners to autonomy, discussed factors that influence the success of self-selection, and suggested possible alternatives for group formation. Throughout the remainder of the course, we applied these suggestions, and they were then subjected to the same critique.

It must be noted that students are not the only ones to experience a certain amount of turmoil. Even instructors who are proponents of experiential learning generally want those experiences to be positive ones. It can be difficult to let students make 'mistakes'. Instead, we have attempted to foster a culture of adventure rather than one of successes or failures. In support of this, we facilitate frequent debriefings allowing learners to discuss the process. Applying the concept of accommodation requires the instructor(s) to be prepared to adapt to the unique characteristics of each group of learners. Just as each class makes different suggestions for group formation, so they suggest creative, innovative variations on other aspects of the course. And, as the learners confront their assumptions, we too must continually identify and challenge ours.

Authenticity

An essential component of constructivist learning is the emphasis placed on the learning context. The rationale for offering this course hinges on the learning context, that is, making the transition from the face-to-face classroom to the technology-mediated environment. To this end we encouraged participants to be as descriptive as possible about their working environments, both face-to-face and virtual. What were the similarities in content, educational goals, learner characteristics, and institutional characteristics? What were the differences? This not only helped the group members understand the unique circumstances of the others, but also highlighted conflicting expectations resulting from the change in context. The process of painting these detailed pictures provided the class with a far richer context than could be provided by any individual.

At another level, we created a context for learning that encouraged risk-taking and experimentation. We wanted learners to be innovative within the virtual classroom. We also wanted them to gain enough experience that they could make sound instructional choices. Through the process of active experimentation and the discussions that ensued from these experiences, we hoped to provide a model learners would continue to use to analyse and evaluate their practice.

Articulation

Learning within a constructivist environment should be a collaborative rather than a competitive experience. To this end, students are encouraged to work together to solve problems and negotiate solutions. Participating in this way not only helps them to integrate their learning into their prior experience, but also helps them to develop communication and interaction skills that they can apply to their own instructional contexts. For learners who have been socialised to be independent learners, it can be difficult to make the adjustment to collaborative activity. And since this type of interaction goes well beyond product-based group work, it is not only the independent learners who must learn new skills. The instructor should be prepared to model collaborative dialogue. This can include, but is not limited to questioning, interpreting, elaborating upon earlier comments and synthesising the discussion. Comstock and Fox (1997) refer to this as the social process of making meaning. We should note here that using a team-teaching approach can be advantageous when attempting to model collaborative interaction.

Termlessness

At the same time that students are participating in any given activity, they are encouraged to engage in a parallel discussion about the process. In a face-to-face class it would be necessary to halt the learning activity in order to discuss the learning process or to explore one or more of the assumptions contributing to the development of the activity, but computer conferencing allows us to transcend temporal barriers. This parallel processing illustrates one of the strengths of computer-conferencing where the technology acts as a cognitive tool that supports metacognitive activities. Parallel discussions also take place in order to help participants process the affective component of the course.

Conclusion

In this paper, we have described how we apply constructivist learning principles in a technology-mediated distance delivered course for adult educators. We identified and addressed the barriers faced by adult educators who would like to apply constructivist learning theory to their distance education courses. Using a model developed by Koschmann et al., 1994) as a framework, we illustrated some of the approaches used to create a constructivist learning environment within a very specific context. Distance educators can use communication technologies to facilitate the application of constructivist principles to the on-line environment by increasing the opportunity for interaction between and among students, overcoming the temporal barrier that impedes parallel processing, and encouraging the development of authentic learning activities. If the technologies are to meet their full potential, however, researchers and practitioners must direct their attention to evaluating and implementing the principles of constructivist learning theory in order to bridge the gap between theory and practice.

Abstract: The use of graduate students to train surrounding independent school district Instructional Technology Coordinators is an important aspect to each of the entities involved in the situation: the graduate students obtain opportunities to display their strengths and to introduce themselves to the surrounding professionals within their area; the university obtains positive feedback concerning the strengths of their students, as well as the positive public relations displayed at such times; the independent school district Instructional Technology Coordinators are offered opportunities to learn cutting-edge technology from the university, the use of university resources, as well as the opportunity to view possible future recruits in an "on the job" real-world situation. Each of the entities has positive situations through which to explore future possibilities.

Introduction

Graduate students not only desire but also need the help of their university faculty to present learning situations to them. These learning situations are not only to aid the university in its pursuits but also, more importantly, to expand the students' opportunities to learn new situations and environments. However, the graduate students must be mentored so as to produce a positive experience within the three primary groups involved. This is where the faculty must step in and facilitate the development of the course curriculum and instructional situations. The previous experience of the faculty member can help guide the graduate students towards a positive experience for all members involved.

Hardware and Software Issues

Although the graduate student may have everything ready to walk into a training situation and successfully lead a training of district coordinators in multimedia development, last-minute issues consistently arise. Two last-minute issues have consistently been questions pertaining to software versions and computer security issues.

Software Versions

The graduate student has diligently worked to produce an awe-inspiring training module and can't wait to jump into training the District Coordinators. However, the software versions of the tools they will be using for the training that can be located on the computer hardware lag behind the version for which the graduate student has developed the training module. Although the graduate student has considered absolutely all conceivable situations that may arise and are secure in the fact that they are unquestionably ready for anything, this problem has arisen time and again. Although the graduate student has the latest versions of every single software title available on the market today, the university may lag behind. Unfortunately, this consideration may not cross the faculty member or the graduate student's mind until faced with such an issue. For the sake of all concerned with the training, especially to offer a stress reduction to the graduate student that may be faced with such an issue, it is a hard-learned lesson to always check with the institution, whether university or field-based organization, that will house the training. Not only will this offer a positive environment through which the graduate student can begin the scheduled training, but also the graduate student will feel more secure when developing the training module.

Computer Security Issues (Windows NT)

A second consideration when dealing with such basic issues as hardware and software is the question of levels of computer security. This is not usually a problem with the Macintosh operating system (Apple, 1998), unless another level of software is added to the operating system that adds a computer security issue. Yet the administrator of a Windows operating system, whether Windows 95/97 or Windows NT (Microsoft, 1995; Microsoft, 1997a; Microsoft, 1997b), can delineate the level of computer security on each computer in a training classroom. This must be discussed before the training is developed and ready to facilitate; without such discussions, surprises will occur. The computer administrator can offer numerous suggestions to the facilitator, but the suggestions are only available if the computer administrator knows there are concerns or issues that must be resolved. Therefore, the forthright inquiries and discussions between the faculty member aiding the graduate student, the graduate student, and the computer administrator where the training will occur is a strong suggestion to waylay any training-morning tragedies.

Insecurity and/or Nervousness of the Graduate Student

Whether the graduate student has made it a career to facilitate training sessions or is a novice in this realm, the insecurity and/or nervousness that any facilitator feels before the beginning of a training sessions is a natural experience. However, the extent to which a graduate student can experience this insecurity and/or nervousness may be multiplied due to the added pressure of the faculty member's expectations and the district coordinator's expectations. For these clear reasons, the faculty member may be inclined to be extra sensitive to the graduate student's needs throughout the design, development, and facilitation of the training module. For the majority, graduate students have a familiarity with trainings and professional presentations; however, there may be certain aspects of the facilitation of the training modules that may require extra sensitivity and discussion between the faculty member and the graduate student.

Interface Between the Graduate Student and the Learners

The interaction between the graduate student and the learners in the training session is of the utmost importance. Although the graduate student may be nervous, it is important for the faculty member to mentor the graduate student to present a professional demeanor. This is a "safe" situation through which the graduate student can learn their own personal training style and have the ability to try different aspects with the security of the situation readily apparent.

Become Easily Flustered

Although all presenters become flustered at one time or another in their careers, the impact of early presentations on the psyche of presenters can have long-lasting effects. Therefore, the importance of the faculty member acting as a mentor and guiding the graduate student is of the utmost importance. The graduate may become easily flustered due to the intense pressure they are placing upon themselves to do a good job. The ease with which a novice presenter may become flustered is quite higher in probability than a more experienced presenter; therefore, the graduate student must be carefully guided and aided through the first, most important, facilitation of training experiences. As the old saying goes, 'what can happen will happen', and this is doubly true when a novice presenter has taken the helm.

In spite of the fact that it is never an easy situation, when a graduate student is indeed flustered and needs assistance, the faculty member should be available to step in and offer assistance without breaking the flow of the training session. The careful assistance that the faculty member offers during the first few training sessions that the graduate student facilitates will develop the graduate student's ease and confidence for future presentations. For this reason, it is of major importance for the faculty member to carefully consider the point at which to offer assistance, as well as the subtle way in which the faculty member flows in and out of the training environment; if too obvious, the faculty member will develop a sense of insecurity within the graduate student and may impact the future presentation ease of the graduate student. Through thoughtful consideration on the part of the faculty mentor, the ability of a graduate student to become flustered may lessen.

Pace of Presentation

A difficulty that presents itself for novice presenters is the ability to check the rate at which the presentation is flowing to ensure the learners are gaining knowledge. Many novice presenters speed the training to such a point that the learners obtain very little from the presentation; yet some presenters, already mentored to take a longer period of time to ensure the knowledge is obtained by the learners, moves at too slow of a pace. Each presenter, whether novice or expert, must gauge the learner's needs and pace the presentation towards the learners in the educational environment. Although this may be an obvious presentation rule, novice presenters may need guidance to ensure the learners will be able to attain the knowledge they desire.

Vocal Range and Intensity

Many people become easily excited by a subject that they are discussing or become so wrapped up in their own nervousness that it is difficult to gauge the vocal range and intensity that is being presented. Much of this comes with experience; but much of this can be mentored and discussed with novice presenters. The vocal range of a presenter may have the tendency to reach higher octaves during presentations, especially at the beginning of a presentation. The voice range should be practiced and become a conscious part of the presenter's internal checks during professional situations. Lowering the voice merely one or two octaves offers the presenter the ability to appear calm, centered and knowledgeable even if the presenter is about to lock their knees and faint in front of the crowd.

The intensity of the voice is also a consideration worth noting. Some presenters have a naturally "soft" voice that rarely can be heard above a conversational tone and some presenters have "booming" voices that can be heard across a grassy knoll. Although both of these situations have their place in civilized company, the difficulty is gauging the desired effect for the situation one finds them in. The graduate student may particularly affected by the question of vocal intensity due to the amount of professional presentations that have been presented. The faculty member mentor can offer particularly helpful advice in this situation; although this must be carefully done. If the graduate student is presenting a training in a computer environment, the noise from the machines will add to the intensity of the student's voice; however, if the graduate student is presenting at a round table discussion, the intensity of the graduate student's voice will significantly drop. Gauging one's vocal intensity to fit the desired situation is an area in which a faculty member can mentor a graduate student.

Presentation Style

Each presenter has their own distinct presentation style; whether energetic or demure, loud or soft, structured or less structured, handouts by the ream of paper or no handouts. There is a certain format through which the presenter finds a comfort zone. Once this comfort zone is found, the presenter engages the learners in a consistent manner; however, this comfort zone is not usually yet discovered by the novice presenter. Herein the faculty member mentor has the ability to aid the graduate student.

Respect the Learners

Although this is an obvious area, sometimes people become so involved in their own insecurities that they feel the need to present themselves as the most knowledgeable for the subject they are teaching. Only they could possibly have the answers that the learners are seeking. This develops beyond the training areas of multimedia and sweeps across any subject area that is available; it seems to be a natural human reaction to insecurity. However, the learners have their own prior knowledge that they bring to any endeavor and this prior knowledge and expertise must be respected. An area of considerable concern is the way a presenter may talk to a learner; sometimes the lack of experience or security within themselves may develop into a way of talking "down" to a learner in order to feel that the presenter is the sole person in the room with the ability to offer any kind of knowledge attainment to the learner. This must be carefully watched and the faculty member mentor should work towards developing a sense of respect towards the learners within the graduate student.

Speak to the Whole Group

When nervous, it can be a natural reaction to only focus upon a specific section of the room or a certain select few members of an audience. This can sometimes make the presentation of information much less daunting to a novice presenter. But this must be discussed and the graduate student must be made aware of these faults; only through the careful integration of all learners in all areas of an educational environment will the successful attainment of knowledge be accomplished. However, the difficulty lies within the timing of mentoring the graduate student: if discussed before the presentation, the graduate student may focus too heavily upon this area; if discussed during a presentation, the graduate student may become more nervous and insecure; if discussed after the presentation, the graduate student may harbor greater insecurities concerning their presentation abilities. This is an area that the faculty member mentor must address on a student-by-student basis.

Handouts

Learners enjoy having something that they can physically hold onto, whether it is paper handouts or a CD-ROM that includes further information or merely a Web page that the learner can download at a later time. Handouts tend to give a sense of security to the learner that is felt beyond the mere presentation by the graduate student. This is an area in which the graduate students should be mentored; the format of the handouts, the inclusion of information within the handouts, and the inclusion of graphics within the handouts are all important lessons. The faculty member mentor can help guide the graduate student while learning such issues, as well as aid the graduate student when difficulties arise during the design and development process.

Write Difficult Points on a Large Board

During the presentation, questions and issues may be discussed that are easier to note or present through the use of a blackboard or similar type of writing situation. Sometimes, graduate students tend to shy away from the use of a large board on which to write important aspects of the discussion, yet this type of visual display can aid a discussion. Therefore, the graduate student should be encouraged to use a writing board when it will aid the discussion or attainment of knowledge.

Positive Feedback

Humans enjoy positive feedback if in a complimentary, sincere manner. This is an important aspect of any presentation, whether complimenting a learner on a question raised, complimenting an innovative attempt at developing multimedia, or requesting aid when a difficult part of the learning process is reached, positive feedback is important in the motivation and success of the learner. However, the majority of graduate students has been on the receiving end of the positive feedback for an extended period of time and may not have made the connection between positive feedback and the success of the presentation. The faculty member mentor can aid this situation by mentoring the graduate students in the use of positive feedback.

Move Through Out Class to Check for Understanding

The movement of a presenter through out an educational setting offers the presenter, as well as the learners, numerous advantages. For example, the presenter can check for understanding, can keep themselves from becoming a part of the "talking head" syndrome, can aid learners that may not be exactly where the presenter hopes the learners will be in the educational situation, as well as numerous other positive outcomes. The learners receive support from the presenter moving through out the educational setting through the ability to ask specific questions of the presenter in a more informal setting, become psychologically more on task with the goals and objectives of the educational setting, and make the educational setting one of a more collegial attitude. Through such simplistic actions as the presenter weaving his or her way through out the educational setting, the feeling of the environment can drastically shift to a more positive structure. This is an area that a novice presenter may not necessarily be comfortable with or be aware of, yet the faculty member mentor would strongly be urged to make mention of this simplistic addition to a presentation.

Closure to the Learning Situation

Unless previously educated as a presenter, many presenters may not be aware of the necessary closure to a learning situation. Smiling, throwing their hands up in the air and loudly stating "we're done!" is not an appropriate closure to a presentation; however, after hours upon hours of developing presentations or training modules the novice presenter may be so overwhelmed by being at the end of the presentation that they may forget their closure. However, this is an area of the presentation of which the faculty member mentor should be way and guide the graduate student. A closure, as in all presentations, is of the utmost importance and must be carefully developed.

This is the point at which most learners will remember the presenter; therefore, the closure must not only be included, but must have the strength to endure.

Conclusions

Graduate students have a multitude of abilities and strengths to offer within many situations; however, the knowledge that the graduate students bring to an educational situation may not be couched within presentation experience and training situations. The thoughtful mentoring on the part of a faculty member mentor can aid the graduate students in the development of presentation experience and training situations through the thoughtful, reflective guidance that is necessary to develop into strong presenters. Through the experience of training district coordinators in multimedia development, the graduate students have the ability to learn such important aspects of their graduate-level work as presentation and training skills.

Abstract: Evolutions in education lead to an increased use of problem-based learning and a variety of technologies. This contribution discusses the issue of support in technologically rich, problem-based and collaborative learning environments. Five dimensions of support are identified: amount of support, topical object, formal object, delivery system and timing.
In the ParlEuNet-project, an European project, four different support models will be investigated in a rich technological, problem-based learning environment. Two models relate to access to a dedicated database, the two others relate to the role of the teacher.

Introduction

New information delivery and communication technologies open a whole new world of opportunities and possibilities to access information and to communicate on an international level. These technologies are entering schools, which generates questions on how to use these effectively in regular class situations.
At the same time, new insights in learning and instruction have resulted in a shift from teacher-oriented towards student-centered education and from encyclopedic towards problem-based instruction by presenting ill-structured tasks and supporting learners. Teachers become facilitators of learning in the process of gaining knowledge.

The question on the amount and kind of support to be provided is becoming of paramount importance to integrate new technologies as valuable tools in powerful learning environments. How the question on support is answered depends on the theoretical stance that one takes with regard to learning. In this contribution a moderate constructivist view on learning is adopted.

In this contribution first the issue of support is analyzed theoretically. Next, it is discussed how support is dealt with in the ParlEuNet-project. In this implementation and research project the issue of support in a technologically rich, problem-based and collaborative learning environment is addressed directly.
In the conclusions it is specified how the ParlEuNet-project studies the support issue.

The Issue of Learning Support

Given the acknowledgement that not all learners are willing to execute all necessary learning activities (Elen, 1992; Jonassen, Mayes & McAleese, 1991), it is accepted even by constructivist that instruction has primarily a supportive role (Elen, 1992; Lowyck & Elen, 1991). Support aims at enabling the learner to engage in appropriate learning activities.

[1] Part of this research is sponsored by the European Commission 'Targeted socio-economic research', Directorate General XII, Science research and development, Directorate G, as part of the Joint Call for Educational Multimedia under contract number MM 1022.

Quality of instruction is dependent on the choice of the tasks and the adaptation of support to what is actually needed by individual learners and/or group of learners. In view of deciding about support, an analysis of different dimensions of support is required.

Dimensions of Support

Decisions about support can be situated on different dimensions (Elen, 1995). Each of them will be discussed.

1. Amount of support: the learning process is seen as an active, constructive, cumulative and situated process. The learner should determine his/her learning goals, select appropriate activities and find a way to fulfil them. The necessary amount of support will depend on the extent that the learner is able and willing to construct his/her own knowledge. Consequently, the amount of support has to decrease with increasing knowledge, ability and motivation. Indeed, research demonstrated that the relationship between amount of support and learning is curvilinear, both insufficient and excessive support is detrimental (Clark, 1989). Support has to be adapted to the specific needs of individual students. A gradual withdrawal of support is generally advocated. After a period in which cognitive activities are modeled by the instructional agent, the learner is gradually more and more activated to execute cognitive and metacognitive activities. Finally, all explicitly-designed support is removed and support is to be actively requested by the learner (Dillemans, Lowyck, Van der Perre, Claeys & Elen, 1998).

2. Topical object of support: the second dimension relates to the topical object of support. This topical object especially relates in rich technological, problem-based and collaborative learning environments to different levels. With respect to problem solving students will need support on both the process of solving a problem and the content of the task.

Collaborative learning increases the need for support on the group and the individual level. Students working in group will benefit from guidance on the process of working in group, role division, work distribution and balancing individual and group needs. A technological environment adds a fourth level. Students may require support to use the technological tools. Students need to know how the tools work and what can be done with them for solving the task.

3. Formal object of support: Support has also a formal object that relates to the student characteristics targeted by support. Support may be directed towards students' prior knowledge, (meta-)cognitive skills or motivation. Each of these learner variables, sometimes combined in a 'learning style', may be the formal object of support (Dillemans, et al., 1998). If lack of motivation is the major problem or prior knowledge is, support will differ.

In the research, attention has shifted from prior knowledge as the formal object of support to metacognition and motivation. This parallels the shift from encyclopedic to problem-based learning.

4. Delivery system of support: A fourth dimension pertains to the system through means of which the support is delivered. Decisions relate to the extent to which support is embedded in technology, made available through means of textbooks, or delivered by peers or a teacher. In rich technological, problem-based, collaborative learning environments support can be delivered through a variety of means. With increased technological possibilities, support can be easily embedded in the technology or delivered through the technology rather than by a teacher.

In a problem-based environment, support is partly embedded in the task. The task must connect to the prior knowledge of students as to trigger interest and motivation. In a collaborative environment, other members of the group may also deliver support (explaining, solving problems).

The question of what delivery system to use for what kind of support is basically a question of efficiency. Some support may be more easily provided by technology, other by teachers or peers.

5. Timing of support: The last dimension, timing, has several aspects. First, given the curvilinear relationship between learning and support, one may expect the need for support to decrease with growing prior knowledge, cognitive ability and motivation (Vermunt, 1992). Secondly, in the 4C/ID model, van Merriënboer (1997) has suggested that in order to be effective some support (e.g. explanatory information) has to be delivered up-front and some support just-in-time.

In a rich technological, problem-based and collaborative learning environment, support on the different topical levels must be delivered at different times. Technology enables to build just-in-time support systems. However, technology itself also requires just-in-time support. Students need support immediately if technology fails. For solving a problem and working in group, support can be given in advance by for instance explaining the principles of group work and the different steps in problem solving. Similarly, moments of orientation and reflection during problem solving can be well-suited for up-front feedback, by anticipating problems based on passed experiences.

The Role of the Teacher in these Different Dimensions of Support

Teachers in rich technological, problem-based learning environments are no longer the 'experts'. Rather, the role becomes one of providing resources and managing mediating interventions in order to enable learners to achieve learning goals (Devine, 1994). The teacher becomes a coach or learning facilitator (Elen, 1995; Roblyer, Edwards & Havriluk, 1997) and delivers support in accordance to this role. In a problem-based student-centered learning environment support is aimed at helping students to perform optimally. The teacher can temporarily provide adequate support in order to enable students to function within their 'zone of proximal development'. Through this support students may perform on a level just above their current level of performance.

The topical object of teacher support in rich technological, problem-based and collaborative learning environments is directed to all levels. Teachers support use of the technology, problem solving, working both in group and individually. The formal object of this support may differ; and is to be adapted to the specific needs of the students.

The ParlEuNet-Project

The ParlEuNet project aims at creating a problem-based, student-centered rich technological learning environment in which students from 12 secondary schools in 7 countries may learn about the European Parliament. With the following three main pillars, the educational use of technology is focussed upon:

(1) A problem-based learning environment is offered in which students work on a multi-dimensional problem. In view of acquiring problem-solving and information-processing skills, the task constitutes a real and ill-structured problem. Moreover, motivating to students and allowing them to apply a variety of information-processing and problem-solving skills.
(2) In the ParlEuNet-project students work in groups with peers from their own classgroup and from classes in different countries. The task has to allow for meaningful and international collaboration, sufficiently complex and encourage co-operation in view of cognitive load distribution (Hmelo, Guzdial, & Turns, 1997). In the ParlEuNet-project students receive a problem related to the world of work from a member of the European Parliament. Students are requested, together with students from internationally spread schools in other countries, a functional policy document on employment by following the regulations of the European Parliament. A minimum of structure must enable students to finish this ill-structured problem within 32 hours.
(3) In order to solve the above described task, students get access to a variety of information and communication tools: a dedicated database with information on the European Parliament and the task, word processing, spreadsheet and presentation tools, access to the Internet; free access to telephone and fax, an e-mail based communication tool with white-board facilities and finally access to video-conferencing once a week for communicating with their peers in the other schools. Students themselves decide on the use of these tools.

Support in the ParlEuNet-Project

An important question in the ParlEuNet-project addresses the issue of support. Some of this support will be equal for all students and some will be variable. All students will get support on the level of solving the problem; they will get the same task and sub tasks; collaboration and working with technology. For solving the task students may rely on a project booklet, containing a description of different problem solving steps. The booklet also contains help for working in group (roles and work division) and some explanations on the use of the tools are given as well.

Four support delivery systems can be identified: booklet, teacher, technology and peers. While the booklet is identical to all students, support delivered by teachers and database is not. Both delivery systems have two modes (Tab. 1). First, access to the dedicated database is 'open' or 'scaffolded'. In the 'open' mode, students have access to all the information in the database at any time. In the 'scaffolded' mode, students can get hold of all the information, but access to the information is structured in line with the specifications of the 4C/ID-model (Van Merriënboer, 1997) and accommodates the specific role of the student (for example, a student with an 'expert' role will be oriented towards using the information on the specific topic whereas a student with a 'liaison officer'-role will be oriented to the information on publication regulations of the European Parliament).

With respect to the teacher as a support delivery system two models will be studied: a pro-active and re-active model. The teacher models in the ParlEuNet-project do primarily differ as to who takes the initiative to deliver support. In the case of pro-active support, the teacher is part of the group that works on the task and may –as any group member- take the initiative to assist the students in their work on the task. In the re-active support group, however, the teacher is not part of the group but functions as an independent process-oriented consultant. In the re-active support mode, teachers will assist students only upon their request.

		Database access	
		Open	Scaffolded
By teacher	Pro-active	6 schools / 72 students	6 schools / 72 students
	Re-active	6 schools / 72 students	6 schools / 72 students

Table 1: Four types of support in the ParlEuNet-project.

The Pro-Active Teacher

Support in the pro-active mode will be primarily cognitive apprenticeship-like (Collins, Brown, & Newman, 1989). Apprenticeship originally pertained to the process where novices are acculturated in an industrial setting by means of externalizing or verbalizing the internal processes or activities involved in expert problem solving (modeling), coaching, and scaffolding (Mandl & Prenzler, 1991). In a cognitive apprenticeship-environment, the acquisition of cognitive skills is focussed upon. Students are encouraged to engage in complex problem solving, collaboration and reflection in view of the development of cognitive skills. A teacher may model a cognitive skill, coach learners in their attempts to execute the skill and execute sub tasks learners are not yet able to execute successfully. In the ParlEuNet-project the students are acculturated in the process of international collaborative problem-solving. The pro-active teacher will be part of the working group and will help students while identifying problems, organizing the work, communicating with students in other countries, retrieving information, drafting a report, ... by modeling, coaching and scaffolding. This support by the teacher is not product-oriented (finishing the task) but primarily directed towards the development of cognitive skills and, hence, more autonomy of the students. The students themselves remain responsible for executing the task.

The pro-active teacher is a full member of the problem-solving group. Together with the students, teachers work towards realizing the task. As any pro-active group member would do, the pro-active teacher may anticipate the needs of the students and make suggestions on how to solve the problem. For instance, the pro-active teacher may, even before the student asked for it, suggest places where relevant information can be found to a student who is looking for information.

The Re-Active Teacher

Support in the re-active mode is based primarily on discovery learning ideas and insights, with an emphasis on self-direction and intentionality in learning (Bruner, 1966). Discovery learning starts from the idea that cognitive skills, like problem solving, emerge gradually as a consequence of successful coping with the environment. These cognitive skills can be brought on their optimal level by sensitization and activation through repeated experiences of their successful use (Crutchfield, 1966). This implies that, in order to experience success, students will explore and experiment with the environment, without real guidance of the teacher. The impulse for exploring and experimenting in the environment lies in the task. Two sources will make students intrinsically motivated to work on a task (Bruner, 1966), curiosity and the drive to achieve competence. An 'authentic' and challenging task that can be achieved and appeals to the curiosity of students will be motivating to students and reduces the need for extensive teacher support.

In a discovery learning approach, the teacher extends the student's range of experiences, by providing the students with opportunities to explore a situation and by encouraging students to generate and test multiple hypotheses. The teacher is part of that environment, as an information resource (Bruner, 1960). But, the students will be enabled to 'discover' everything themselves. Students take the initiatives. The teacher only provides an environment and challenges the students in order to promote reflection (Jonassen, 1996).

In line with these principles, the re-active teacher will wait until the students ask something, his coaching is based on past experiences of the group. The re-active teacher acts like an independent, process-oriented consultant to the collaborative learning group. On technical and organizational questions, direct answers may be provided, in all other cases answers of the teacher will aim at encouraging students to reflect upon their activities and explore alternatives.

Conclusions and perspectives

As previously indicated, the ParlEuNet-project is both an implementation and a research project. In the above the support and its implementation in the ParlEuNet-project has been presented. The project enables to study the issue of support in depth. The effects of the four 'support models' are investigated. As such, the ParlEuNet-project constitutes a real example of a design experiment. At least 72 students will receive support in line with each of the four support models (Tab. 1). The project aims at identifying the effects of these four support models on:

- quality of the policy document produced by the students;
- knowledge of and attitudes towards the European Parliament and its operations;
- attitude towards the educational use of technology; collaborative learning, and problem-based learning;
- students' use of technology during the project sessions, and
- students' use of cognitive, meta-cognitive and collaborative strategies during the project sessions.
- change in epistemological beliefs of the students

Student characteristics (prior knowledge, interest in the task, cognitive ability, gender and cultural background) will be taken into account as co-variates. With respect to teacher support the two main research questions are:

1. Can differences in epistemological beliefs, attitude towards technology, problem-based and collaborative learning after the project, be explained by (interaction between) the amount and kind of support on the one hand an students characteristics (prior knowledge, (meta)cognitive skills, attitudes) on the other hand?
2. Can the patterns of cognitive information processing and communication activities be explained by (interaction between) the amount of support on the one hand and student characteristics on the other hand?

In order to answer these research questions a classical pre-test, post-test research design has been opted for. During the actual work on the task students' activities are monitored in order to identify differences between groups in the use of cognitive, meta-cognitive and collaborative strategies. Additional data will be gathered through means of the log-files that will keep track of students' use of the database and of the communication tools. As much as possible, readily available research instruments are used. In some cases, however, (e.g. measuring prior knowledge of and attitude towards the European Parliament) specific instruments have to be developed. For measuring the prior knowledge and attitude towards the European Parliament a questionnaire has been developed, which will be administered three times: (1) at the start of the project, (2) at the end of the project and (3) 10 weeks after the project. This will give us a better view on the evolution that students went through and whether there are differences between the different conditions.

Computer Mediated Communications: Changing Patterns Of Academic Research In The Uk

P.Fung
Institute of Educational Technology
Open University
UK
p.fung@open.ac.uk

Abstract: The use of Computer Mediated Communications (CMC) has brought change in our ways of communicating with others. This is self-evident in the world of commerce and it seems intuitive that this should also hold true within any community whose use of CMC has become widespread. This paper considers the nature of change, if any, that CMC has brought about within academic research communities. A pilot study with groups of academic researchers is used as the focus of discussion. Some 'changes' brought about by the use of CMC in academic research were obvious and unsurprising. Other changes, though less obvious, may be more significant in bringing about change in approaches to academic research. The paper concludes by touching on what was seen by participants as not only the enabling aspects of the use of CMC but also ways in which CMC must develop in order to be used effectively in academic research.

Introduction

The development of Arpanet in the USA and subsequently of university academic networks in Europe such as JANET and EARN has contributed to Computer Mediated Communications (CMC) being available in British universities for the last two decades. It is in recent years, however, that easy access to CMC has become more generally available to academics of all disciplines in British universities. Patterns underlying the increase in CMC use within UK research groups during this time span are discussed in (Fung & Weerasinghe, 1998) and can be situated within the literature of innovation adoption (Rogers, 1995). While research into the speed and manner of adoption of CMC within communities (Kerr & Hilz, 1982, Lea et al, 1995) is in itself an area of research interest, the focus of this paper is on the implications and potential effects of the widespread and increased adoption of CMC in academic research. Discussion of these is based on the outcomes of a pilot study undertaken in the spring and early summer of 1998 as a first investigation of how UK academics perceive the use of CMC in their research work (Fung, 1998).

The term CMC covers the transmission of computer mediated data over a wide range of communication channels, from computer text, through audio to visual and possible combinations of each. In this pilot study the term was used with reference to electronic mail. This particular means of CMC was chosen for investigation because it is the medium which has been available to academics over the longest period to date and is arguably still the medium most widely available to academics in the UK. This being so, looking at the use of email in academic research seemed a promising way of beginning to track any changes in approaches to research due to the influence of CMC.

In the following sections of this paper, a brief description is given of the study that was undertaken. The outcomes of this study are then used as the basis for a discussion of email as a research tool and areas of change in academic research which the increased use of email may influence. The paper concludes by summarising what participants in the study saw as the most effective use of this type of CMC and aspects of its use which merit further research.

Overview of a Pilot Study and Outcomes

The aims of the pilot study briefly overviewed in this section were threefold. They were to gather the perceptions of academics concerning the use of CMC in research; to identify any areas of change in approaches to academic research brought about by its use and to make a first assessment of its perceived effectiveness as a research tool. Six academic research groups were approached and invited to participate. Four of these groups are based at the Open University, Milton Keynes, UK, while one is based at Leeds University, UK and one at the University of Surrey, UK.

Participation in the study was voluntary and in each of the six research groups taking part in the pilot study, email facilities were well established and available to group members. A self-completion survey was distributed to members of each participating group and seven participants took part in individual face to face interviews, during which aspects of their use of CMC were explored in more depth.

A Broad Picture

The purpose of the self completion questionnaire was to establish a picture of email usage among the researchers surveyed, their perceptions of its use in research, the advantages which they saw this technology brought to their research and what they saw as problematic in its use. In total 84 researchers were surveyed and completed questionnaires were returned by 54, representing a response rate of approximately 64%.

In establishing email usage, responses showed that, as expected, most participants had easy access to email at work, though there were two exceptions. Most used it on a daily basis, though again, relating to access, there were two exceptions, both of whom used it less frequently. In all groups surveyed responses indicated that the bulk of administrative messages in their institutions came via email.

In investigating the role that email played in participants' communications with colleagues, over 80% indicated that the statement 'I usually use email rather than the phone to contact colleagues' was true for them, while only 7% agreed with the statement 'normally the phone is my first choice for contacting

Participants were asked to rate their perceptions of the use of email in helping to establish research contacts 'that they might not otherwise have made'. Broadly speaking, the role of email in making research contacts that would not otherwise have been made, was seen as 'definitely' helpful. At an international level, by 33 (61% of respondents), at a national level by 31(57% of respondents) and within their own institutions by 19 (35%), i.e. it was seen to be more instrumental in establishing research contacts in proportion to the geographical distance of potential contacts.

Perceptions of the usefulness of contacts which had been made in this way followed the same pattern in that those made at an international level were seen as 'extremely' useful by 21 (39% of respondents), rating higher than the usefulness of email-instigated research contacts at national and institutional levels.

A common feature of many email systems is the facility to subscribe to groups or lists of users with specialist interests and to participate in discussions within those groups. The majority of respondents subscribed to lists or conferences while there were relatively few who did not subscribe to any. Reasons given for not subscribing to lists or conferences were lack of time to 'get round to it', given by one respondent and a feeling that the contents rarely proved to be useful, given by four respondents.

The majority of those surveyed only skimmed messages from lists or conferences (61%) and rarely participated directly in discussions or information exchange. For many, however, 59% of respondents, an important use of list or conference subscription seemed to be one of information dissemination, redirecting any messages considered as being of interest to other colleagues.

Of the 46 respondents who did subscribe to email lists or conferences, 9 people, almost 20%, indicated that they did not find them useful. An explanation given by three of those respondents subscribing to email lists or conferences but reporting that they did not find them very useful, was 'a lack of time to read the contents'. This lack of time was seen as current but not meriting unsubscribing. These respondents shared the view of another two respondents who did not find 'lists' very useful but still subscribed to them in the hope ' that one day a really useful message that was highly relevant would arrive' and that this made continued subscription worth while.

Participants were asked what importance they attached to email as a research tool at three stages of their research, i.e., planning, information gathering and dissemination. Overall its role was seen by respondents as most important at the information gathering stage (39 respondents - 72%), less so at the stage of dissemination (33 respondents - 61%) and least important at the stage of planning research (30 respondents - 55%).
Nevertheless 39 respondents, i.e. over 70%, felt that email had changed how they planned and carried out their research. In addition to that percentage, six respondents (13%) indicated that email had not changed how they carried out their research, since email had always been available to them and had always been used by them as a research tool.
Responses given to the question 'What sort of differences do you feel email has made to the way you carry out your research?' showed that the principal ways in which respondents felt that email appeared to have made a difference. These were that; it had helped them widen and increase the number of their research contacts; assisted academic collaboration and was a practical help in planning and implementing their research. The category of 'other' ways in which email had made a difference included two threads. In one, three respondents noted the way in which email had changed the pattern of relationships between researchers as supervisors and their research students. In the second, two respondents commented that requests for information and replies to these requests could be sent off with too little thought so possibly encouraging a 'lazy' attitude to research.
Participants were asked 'What do you see as the biggest disadvantage of email as a research tool?' and 'What

Of the 50 participants who replied to the question 'What disadvantages do you see?', 10 respondents (20%), saw no disadvantages, while from the other 40 responses, it is clear that the sheer volume of information and communication is seen as the biggest disadvantage.
Replies showed that the speed and immediacy of email and the scope it allows for widening research contacts is clearly viewed by most (27 participants - 50%) as its biggest advantage, followed its use as an information resource. Its use in establishing collaborative research and in facilitating document exchange as a part of collaboration and the benefits of its asynchronicity were noted by 9 respondents (17%).

In Summary

This broad picture of the 54 researchers responding to the questionnaire shows that while all but two have easy access to email on campus, 60% see it as useful for making and establishing research contacts at an international level. 70% feel it has changed the way they carry out their research and 85% of those replying subscribe to email lists or conferences (though the principal activity in relation to these is to forward items to colleagues). The biggest advantage of using email as a research tool is seen to be its speed and immediacy, the biggest disadvantage is felt to be the volume of communications that it generates. Looking in a little more detail at the data which contributed to this broad picture, however, showed some responses which were not quite so in line with what might have been expected and which indicated areas that would be interesting to probe further. To some extent this was done within the framework of the personal interviewing which took place. In other areas it was change which is not taking place which was of note and this too will be discussed in the following section.

Discussion

As one participant did, it is perfectly legitimate to ask the question 'what does it mean, to use email as a research tool?' Within the context of this study, the answer to that question is 'to use email to facilitate the processes involved in carrying out academic research'. All six groups who participated in the pilot have good email facilities and all are active research groups. As results showed, using email in academic research work, as a research tool, is well embedded practice within these communities. The majority of participants (82%) recorded that they usually use email rather than phone to contact their colleagues. Over 75% find it useful for making research contacts, approximately 70% feel that email has to some extent changed how they undertake and carry out their research, while another 13% have always used email in their research and as one researcher noted, 'couldn't imagine doing research without it'.

In most areas of questioning the results given in the previous section were similar across all groups. Since the groups participating in this pilot were relatively small in number, comparisons among groups could, in any event, only be made on a tentative basis. In practice, there were only two areas in which different 'group' responses might be interesting to consider further.

The first related to the preference for email contact with colleagues. Here, within a humanities research group, there appeared to be a much lower preference for email as first choice of contact with colleagues. Only just over half of respondents in this group (5 out of 9) agreed that they usually used email rather than phone to contact colleagues, the lowest proportion in all groups. It is possible that this may be an indication of a discipline difference in adoption of CMC, as suggested by (Alsop et al 1997), but would obviously need to be investigated with larger samples.

The second apparent difference between groups occurred in importance given to the role of email in research dissemination. Here, in one group, 7 out of 11 (over 60%) saw email as of major importance at the dissemination stage of their research, in comparison with a much lower proportion in all other groups. This, too, may relate to a 'discipline' difference, since many of this particular group's activities focus on development of communication technologies. However, though they may appear interesting, differences within groups of such small numbers have to be treated with caution and can only serve to highlight areas of further investigation.

These possible group differences apart, overall the outcomes indicate that these researchers see email as an essential and integral part of research work. The importance of email in making research contacts is seen as considerable and outcomes indicate that it does facilitate research processes and is seen as having effect on the processes involved in research.

Some of those effects are unsurprising. In many ways the role that email plays in facilitating contacts is simply to do what the phone and the letter previously did, but more efficiently and faster. To recall those advantages, asynchronicity removes an element of uncertainty that exists with phone calls. Messages may be composed, revised and sent, regardless of the recipient's presence at the expected location and can contain a detail and amount of information that would be impractical to leave on an answering machine. Messages that have the equivalent status of hard mail can be sent over distances and at speeds that could not be matched by traditional postal services. The effect on the research process appears to be one of speeding up and widening the scope of research contacts.

Similarly, some effects on research methodologies employed in the research process can be viewed as allowing the same processes to be carried out with more efficiency and to reach a wider audience. Respondents mentioned the fact that, as noted by (Foster, 1994), research surveys can be carried out with one electronic posting and qualitative data obtained via email is by nature of the medium 'on-line', thus eliminating the need for transcription. Only one participant in the study, however, reported having used email as a means of carrying out research surveys. This may relate to the relatively small number of participants whose research would encompass that research method. It may also relate to the fact that within the UK, as yet, for other than very specifically targeted populations, survey sampling using this medium would be affected by level of email access and usage (Selwyn & Robson, 1998).

Since inevitably the ease and breadth of transmission result in more research surveys reaching more people, no less surprising is the disadvantage, noted by two respondents, of more people receiving more unwanted surveys via email.

While the effects mentioned above could be classed as unsurprising, there were two areas in which results from the pilot study indicated effects on research processes that seemed more surprising.

One of these was the effect of email on the process of postgraduate research training. Research into the use of email in teaching and learning at undergraduate level is not new (Wild & Winniford, 1993; Pitt, 1996) and is ongoing, particularly in institutions where distance education is the principal teaching mode, as in the Open University, UK. Less researched is the effect of using email in postgraduate research training. An essential and integral part of practising research is sharing and passing on research knowledge and knowledge of research methods from skilled to apprentice researchers. This is principally achieved in the tutor/supervisor relationship and by research training courses offered as part of the 'research training' package to postgraduate student researchers.

Communication between supervisor and student researcher, i.e. mature and apprentice researcher, plays an important part in this process and it is here that email may be bringing about a subtle change. Responses from participants indicated that one of the advantages of email was improving research student/supervisor communications. This was investigated further during interviews with seven of the participants. Discussion with both mature and apprentice researchers suggested that the use of email could be instrumental in bringing about change in the nature of the student/supervisor relationship.

At base this seems to relate to the asynchronicity of email and to the perceived greater informality of the medium. At one level, email means that student and supervisor are able to be in more frequent contact than would traditionally be practical. The asynchronicity of email allows messages to be sent, replied to, without imposing or requiring a 'physical' presence as would happen if the question/information was delivered in person or conveyed via a phone call. At another level, interviewees referred to the ease with which they felt they could communicate by email within this student/supervisor relationship. This suggests that, perhaps, the perceived informality of the medium may encourage a more spontaneous communication between supervisor and student than would traditionally exist. To quote one interviewee 'the relationship is more like one of

This perceived informality is also shown in the way in which respondents felt that it was an 'easy' way of making contacts with other researchers. No relevant interviewees spoke explicitly of 'training' students to use email to approach and make contact with leading experts in their research field. In two cases, however, it was clear that it was expected of students that they would do so. Students were encouraged to read, as part of research training, material which summarises and explains to apprentice researchers how best to make use of email's potential in making research contacts (Agre, 1997).

The other area in which, from the survey responses, email appears to be effecting a change of approach is in academic research writing. Changes email had brought about in collaborative academic writing were mentioned both in replies to the questionnaire and in discussion in interviews. Changes were principally seen as positive, though some misgivings were expressed.

Email was seen not only as widening the scope for collaborative writing, but also as a way of allowing a greater freedom in collaboration, since documents could be so easily exchanged, amended and added to among collaborators. One interviewee expressed it as the opportunity to incorporate ideas and revise documents in a way that would have been impractical before electronic communications were available.

It was also noted that using email to transfer documents and to discuss current writing meant that it was easier to obtain peer feedback more easily at an earlier stage and on a wider basis, thus making a positive contribution to the quality of papers.

An aspect of this greater freedom afforded by the speed and ease of document exchange and editing, however, that aroused some misgivings from another interviewee, was the fact that this could and did mean that sometimes collaborative research writing could be more difficult to bring to closure.

It appears from the pilot survey that it is in these two areas, research apprenticeship and in academic writing, that email seems to be bringing about or have brought about, changes in research practice.

In contrast, there appears to be one change, which email might have been expected to bring about, but which, according to data from the pilot, it has not. List and conference membership, while very common, does not seem, for the majority of respondents, to have instigated its frequent use for scholarly discussion. Work by (Berge & Collins, 1995) indicates that CMC has great potential for promoting scholarly discussion, but, with one exception, this was not apparent from the pilot data. Rather than an opportunity for increased scholarly discussion among specialist groups, participants in the pilot appear principally to use these groups as 'information sources'. Responses indicate that the majority of participants see access to lists and to conferences as an indirect means of disseminating research information. Certainly, in one sense this is contributing to scholarly discussion, but not in the direct way that one might have supposed.

Conclusion

Considering the outcomes discussed in the previous sections, there are aspects of email use that have 'changed' the way in which research is carried out. In some areas this change is simply one of moving to a medium that facilitates faster communications and allows more widespread and varied research contacts than was previously possible using paper-based and telephone communications. This type of change will continue, as the technology develops and is seen as positive and enabling. A number of comments were made about the problems of 'incompatibility' of mail systems, the difficulties of attaching documents, of downloading documents and of the 'overload' of information. To increase the effectiveness of email as a research tool these issues must be addressed and given time these technical 'challenges' will no doubt be resolved. Academics too, will presumably in time become more adept and at home with the technology, employing information 'management' techniques and making more use of information 'filters' as they become available, to maximise the efficient use of CMC in their research.

In other areas, changes being brought about by CMC could be more significant since data indicates that the use of email may well be influencing the ways in which research is planned and carried out. In the study reported here, email has been taken as the medium to investigate the use of CMC as a research tool. There are possible indications (and given the scope of a pilot investigation these can only be interpreted as possible indications), that its use is influencing the researcher / student researcher relationship, the process of research apprenticeship and that it could be contributing to change in the process of academic research writing. If this is so, then the increased use of CMC, widening access to the Internet and greater availability of new computer based technologies is likely to hasten and highlight those changes. The pilot study undertaken indicates that these are areas that merit investigation in more detail and on a wider basis. Doing so would contribute to incorporating the most positive aspects of change that CMC is bringing about or likely to bring about in academic research.

To the Institute of Educational Technology Research Committee, Open University (UK), for granting funding to enable this research to be undertaken. In particular my thanks to colleague Terry di Paolo, for his extremely efficient management of data collection and processing of postal survey data, which was greatly appreciated. To all those colleagues in the six research groups who took time from busy schedules to complete and return those surveys. A special thank you to those colleagues who spared time to take part in face to face interviews.

Implementation of Hypermedia System for Helping Teachers Teaching Method of Mathematics with Real Classroom Video

Suk Hee Wang
Daelim College, Computer Science Department, KyungKi Do, Korea
Technology Based Learning & Research, Dept. of Educational Media & Computer
Arizona State University

Abstract

The demand of developing educational multimedia systems has dramatically increased. Especially web-based hypermedia systems can be valuable for the public to use. However it is very complicated to develop large hypermedia web-based systems with big capacity. This paper will present math•ed•ology™ system, an interactive, hypermedia, web-based professional development program. I will also explain instructional, technical and interface design as well as the implementation of math•ed•ology™ system from a developing and programming point of view.

I *propose the effective method of programming for large hypermedia systems to reproduce using basic templates with naming conventions and alias (dummy) media files which contains file pointers only.* And also evaluation of the math•ed•ology™ system is given by using Gagne's Nine Events of Instruction.

1. Introduction

The demand of developing educational multimedia systems has increased enormously recently. Especially web-based hypermedia systems can be valuable programs for the public to use. However it is very complicated to develop large hypermedia systems including all the different types of media files such as text, image, graphics, audio and video. Many program developers have asked themselves "Which developmental tool is the best if the size of the multimedia systems is large?" and "What kind of developing method of huge size of hypermedia systems is the most effective?" and "How can we evaluate the systems once they are developed?"

We had the same types of questions at the beginning of math•ed•ology™, which is an interactive, multimedia, web-based professional development program, at the developmental stage. TBLR (Technology Based Learning & Research at the Arizona State University, Educational Media & Computer Department) team made an effort for more than two years to develop math•ed•ology™. This paper will highlight the following points from the vivid developing experience. Section 2 will present overall constitutions of math•ed•ology™ system. I explain instructional design, technical design and interface design. In section 3, I present implementation of math•ed•ology™ system from development and programming point of view. Section 4 shows evaluation of the math•ed•ology™ system is according to Gagne's Nine Events of Instruction. Nine events are the follows: Informing the learner of the objective, presenting the stimulus material, providing learning guidance, eliciting performance, providing feedback, assessing performance, enhancing retention and transfer, stimulating the recall of pre required sites capabilities, and gaining the user attention[1]. Section 5, presents a conclusion and future work. The full twenty-five lessons of math•ed•ology™ are now available on the web site **http://mathedology.ed.asu.edu.**

2. Design of math•ed•ology™ system

math•ed•ology™ is an interactive, multimedia, web-based professional development program. It is designed to increase student achievement by increasing educators' knowledge of the NCTM(National Council of Teachers of Mathematics) discourse and curriculum standards, as well as, bilingual and ESL strategies. The user is identified as in-service and pre-service mathematics teachers, staff development personnel, and professors of mathematics methodology for pre-service teachers. The program is a comprehensive resource that includes a database of twenty-five elementary school mathematics lessons on a variety of topics. 'Solving an array problems', 'Symmetry', 'Multiples with Calculators', and 'Perimeter Search' are the examples of the lesson titles. These lessons are taught in English, Spanish and bilingual formats.

The lesson provides a rich environment within which educators can see live lesson video of actual classroom instruction, and are accompanied by analytic commentary from: Mathematicians, Mathematics Educators, Language Specialists and Classroom Teachers. Each lesson is preceded by a set of focus questions, a list of user outcomes, a description of the setting and context, a lesson plan, language and teaching strategies, and applicable discourse and curriculum standards. A section on mathematical concepts accompanies the lessons and details the concepts addressed in the lesson. And also illustrative animations are given to help understand concepts. Language

Environment explains how the classroom students constitute in terms of the language they used. A pre-interview and post-interview with the classroom teacher provides insight into the perspective of the actual classroom instructor. The teacher describes expectations and objectives for the students and reflects on what has happened and whether the expectations and objectives were met.

The sitemap section is a graphic overview of the program's overall organizations. Users can click on any item to directly navigate to a particular content area they want to jump. The Help section provides users with a brief overview of the interface of the math•ed•ology™ project and offers trouble-shooting advice. A chat section, which is online discussion forum, allows user to consult with experts and fellow teachers. A notes section provides users with an opportunity to record thoughts and ideas. It is recommended that users carefully consider each question and then open their favorite text editor (such as Microsoft Word™, WordPerfect™, Notepad, WinWord™, or SimpleText, etc.) and write down and save their comments there. A complete listing of NCTM Curriculum Standards and Professional Teaching Standards, and Bilingual resources are included for reference. An Assessment section allows the user to practice identifying curriculum strategies and identified language strategies, reflect and extend section on the lesson taught, and consider additional methodologies for teaching similar lessons. <Figure 1> shows the sitemap of math•ed•ology™.

FIGURE NOT AVAILABLE

3. Implementation of math•ed•ology™

The web browser has become a uniform interface for users to archive multimedia information over the internet. The convenient uniform user interfaces is a major characteristic of the web. To enhance the functionality of the web browser, it is definitely worthwhile to incorporate the visual programming into the browser. The visual programming tool and Frontpage Explorer & Editor are useful for this purpose in the project. Hence the system is developed as an embedded module to reproduce programs. Some multimedia data such as graphic, animation, video and music have inherent hierarchical structure[3]. Multi-structure information is useful for handling hypermedia documents[4]. Basic idea of dealing with thousands of audio and video icons for huge hypermedia system efficiently is that separating generic and specific audio and video files as a first step. The next step is making a basic template including all different types of generic text and image icons that specify image source, default hyperlink location for audio and video icons.

To make basic template program, we use FrontPage Explorer and JavaScript. On the top header frame file, we include main 11 section icons, Home, Sitemap, Introduction, Bilingual/ESL(English as a Second Language), Lessons, Help, Chat and Notes. Each icon has hyperlink so users can navigate any time they want to make jump. All different teacher's lesson contents are in the Lesson Section. From the Lesson, user can watch all twenty-five lessons' database. Each lesson has overview, part 1 through part 3, (some of the lessons have 2,4,5 or 6 lesson parts), and assessment. Make separate teacher's image folder to put all kinds of images which are graphics, classroom pan image, student work image and icon images. And also, make separate teacher's media folder to put all audio and video files.

The followings are the steps to prepare audio and video files. Take video camera for the real classroom teacher's lesson. From this analog tape, convert it to digital master tape using AVID and MC Express system software. And export video files to avi file format. Record all voice over of the teachers, mathematicians, mathematics educators, and language specialist's commentaries for the lessons. Digitize the audio and export to wav file format. Next step is using SoundForge to edit video and audio files. And save files as real audio and video(rm file type). To make animation files, which are in sub menu mathematical concepts on overview screen, we use 3D Studio Max.

At this point we need to think about reproduce the application with different contents and same types of basic template program. It is necessary for developers to operate multiple programs with same format on the network. An ideal reproduction system must allow the developers to manage huge size of programs as simple as possible. It is important not to change every file and every multimedia icon to reproduce the application. It is natural to build applications on the top of the web client to maintain the same interface platform. In order to use efficient way to reproduce same types of hypermedia system, it is recommended to take naming convention, and to make dummy(alias) media files which have only file pointers pointing the location where real audio and video files exist[10].

<Figure 2> shows the inherent hierarchical file structures to reduce efforts when we reproduce the same types of applications.

FIGURE NOT AVAILABLE

<Figure 2> File Structure of math•ed•ology™

The summary of developing stage in order to reproduce application program is as follows:

1) Separate files into general (generic) and specific audio. Media folder has plenty of audio and video files, including generic and specific files. Dummy media files have file pointers only. To reproduce new lesson, it needs to change the real audio and video files instead of changing whole html files, file properties and default locations of every audio and video icons. All audio and video icons have specific image properties from generic image folder in the template program.
2) Use the same naming convention to make file names for all audio and video data.
3) Make dummy audio and video filé, which has corresponding file pointers using same naming convention.
4) Change only real audio and video files in real media folder.

Developers do not have to change all image properties, audio properties, image source, or image location at all. Once change real audio and video files in media folder, that is all developers have to do reproduce multimedia application which has the same types of format.

4. Evaluation of math•ed•ology™

This self-evaluation of math•ed•ology™ is completed using Gagne's Nine Events of Instruction. It is based upon the survey result of graduate students and educational professional who reviewed math•ed•ology™ several times. math•ed•ology™ was reviewed from the teacher standpoint, and viewed as a teacher learning strategies to teach mathematics.

1) Informing the learner of the objective: The objectives can be found throughout the program. The focus questions help to bridge the user from learning to actually doing. The user can create their own lesson plan by following the focus questions. And also user-outcome section shows what the user will learn from this program.
2) Presenting the stimulus material: Through the use of video, it is possible to learn from some of the best teachers, and listen commentary from the experts from various fields. For the novice teacher can watch how the real classroom will it be and what will the student reaction be.
3) Providing learning guidance: math•ed•ology™ provides guidance through the use of real classroom video, transcripts, and all different kinds of commentaries for teachers that are learning to teaching methods and strategies. For the programming point of view, the sitemap section shows overall view of this program and every spot has hyperlink to corresponding pages, so users can navigate easily.
4) Eliciting performance: The focus questions are a way to elicit performance. The teachers are asked to start thinking about the materials and applying it to their work.
5) Providing feedback: There is no feedback. The program is interactive in the sense that user can push buttons to navigate as user chooses, but there is no real feedback given. Using chat section can solve this problem. The chat section is online discussion forum allows user to consult with experts and fellow teachers.
6) Assessing performance: The assessment is a good tool to see what the learner has learned. It is important to see what the user is able to identify from the lesson, reflect on, as well as extend the knowledge, and applying it. math•ed•ology™ provides the assessment section includes overview, identify, reflect, extend and apply[8].
7) Enhancing retention and transfer: The assessment provides a forum for students to plan different activities based on the information that they have learned. For the technical point of view, one lesson is completely programmed, then all twenty-five lessons programmed with same basic templates. It gives benefits and cost reduction to develop effort reduction to use the programs.
8) Stimulating the recall of pre required sites capabilities: Identified curriculum standards and discourse standards are given with complete lists of those. So user can refer to write new lessons. Users are asked to recall the section required in the assessment section.
9) Gaining the user attention: Overall, graphic icons, live classroom video, and animation are enough material gaining user attention[9].

Overall math•ed•ology™ gives most of the items needed except feedback section. The program does not evaluate the learner performance at the end, so the user does not know if the objectives were achieved and to what degree. There needs to be a component that will provide feedback to the user on how well s/he did.

5. Conclusion

The demand for development educational hypermedia system is remarkably increasing along with the developing time and cost because the size of multimedia resource files is huge. In this paper, I introduce math•ed•ology™ system from my efforts and experience when I worked on the project for developing the system. I propose a method, which supports not only dealing with a large number of multimedia files efficiently, but also reducing developing time in the same types of multimedia application programs. The main contribution of this paper is to propose the efficient method of programming for large educational hypermedia systems to reproduce using basic templates with naming conventions and alias (dummy) media files, which contain file pointers only. I present self-evaluation of math•ed•ology™ system, so other developers can refer to the view on the designing stage on their own.

The math•ed•ology™ system can be extended with new contents for middle school and high school mathematics education materials. A feedback section can also be added for future research to orient the user on the system's development stage.

Abstract: This article deals with the use of computer-aided tools for teaching Operations Research/Management Science. We describe two of them, ORWelt and ClipMOPS, and show how we use them for teaching purposes. ORWelt is a hypermedia learning environment covering the subject area of Operations Research on an introductory level. ClipMOPS is a dedicated tool for modeling and solving optimization problems. Students can use these tools in addition to the lecture. The long-term goal is to change the way of teaching towards application-oriented learning while basic content can be learned with ORWelt and ClipMOPS.

Introduction

In this paper, we discuss approaches of learning the interdisciplinary subject area of Management Science/Operations Research. Management Science (MS) is closely related to Operations Research (OR) and summarizes the application of the modeling approach for managerial decision support. The objective of OR is to find practical solutions to operational problems of all kinds, often within tight time constraints. The models are usually built using quantitative methods, such as linear programming, mixed-integer programming, network models, decision analysis, discrete and continuous simulation, queuing models, and so on. OR methods often facilitate an in-depth understanding of the problem.

Operations Research (OR) is a very complex subject matter to teach. As indicated above, a wide range of quantitative methods is applied to practical problems. Typically, realistic problems are often unstructured, it is not obvious at first glance which method is appropriate. Students learning the subject matter are not perfectly prepared to handle the complicated, often messy problem situations. The usual teaching methods such as lectures are not suited to transfer the problem context beside teaching basic algorithms. Moreover, the traditional, method focused way of teaching management science does not leave much time for case studies, discussions, and student presentations in classroom.

The ability to apply mathematical modeling techniques can be trained with case studies. Then methods are bound to a situated context and students have to analyze the problem and find out which method should be applied in which way. This requires far more elaboration than merely applying a given algorithm on a clearly defined problem. In our point of view, learning emerges from an active construction process and knowledge must be integrated in the learner's mental models to make it accessible in the long run. This process can be supported by situated learning, e.g. by discussing case studies. Moreover, situated learning is more fun, thus increasing students' motivation to learn because they can feel an immediate success after constructing a solution themselves. In most cases it is not possible to present rich case studies in a lecture due to time limits. Furthermore, because there are often more than one hundred students with varying backgrounds and interests (majoring in business studies, business computing, industrial engineering, computer science, or business education) in a university class, it is not possible to adjust the pace so that each student can easily follow a teacher-centered lecture.

These were the reasons why we decided to provide students with a tool which helps them to learn quantitative methods also outside the classroom at their own pace, thus leaving more time for discussions, presentations and teamwork during the classes. We believe that an interactive, computer based tool is better suited to achieve this goal than a conventional textbook.

Our thesis is that traditional lectures can be enhanced but not substituted by computer aided tools. In the subsequent sections of this paper we present two approaches on how this can be done. First we introduce the hypermedia learning environment ORWelt, second the specialized tool ClipMOPS which serves as a modeling tool for optimization models.

ORWelt

The ORWelt project started in February 1996 with the intent of providing a hypermedia learning system that would cover all standard introductory OR material, supplemented by tests. Furthermore, case studies were provided in order to support different approaches to the same content. The purpose of ORWelt is not to replace the lecture but to give the lecturer more time to discuss real-world case studies with the students. We do not expect that computer based learning approaches will replace face-to-face communication in real-time between students and lecturer. The personal contact between teacher and student is still important because goals such as motivating students for the subject matter, i.e., providing input which affects the student in a positive manner, can hardly be achieved by a computer-based system alone.

Currently, ORWelt comprises 19 subject and 15 test modules covering the main subject areas of MS/OR on an introductory level. Content can be directly accessed through a graphical browser or the learner can visit a predefined guided tour. Besides standard navigational tools such as footprints, bookmarks and history, guided tours can be defined in order to avoid the 'lost in hyperspace' effect. The contents covered by ORWelt are shown in (Fig. 1). Shadowed nodes labeled in italics denote subject modules supplemented with test modules. In addition to the subject modules, ORWelt includes test components to allow students a self-assessment of their comprehension. The tests are usually not multiple choice, but a wide range of interactive methods is used in order to allow the exploration of the test. Our goal is that students get engaged in learning instead of merely receiving information.

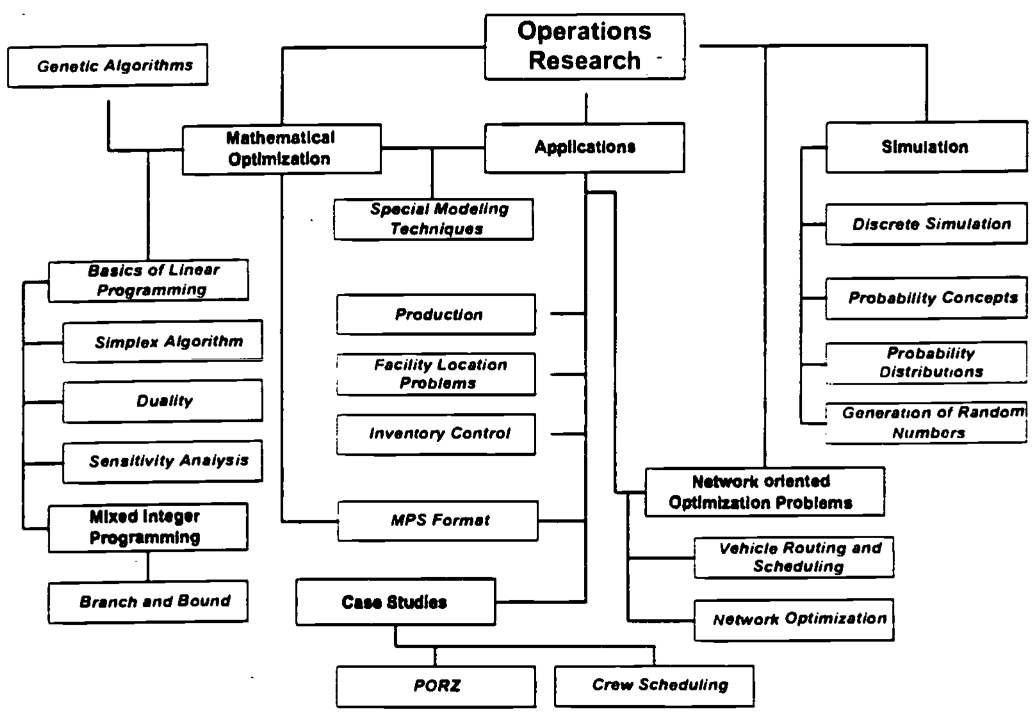

Figure 1: Content covered by ORWelt

A key feature of ORWelt is the integration of the professional optimization code *MOPS* ® (*M*athematical *OP*timization *S*ystem, see (Suhl 1994)). MOPS is an all purpose optimization code library which can be accessed from many programming environments, on condition that Windows Dynamic Link Libraries (DLL) are supported. The utilization of MOPS allows the user to solve predefined optimization models while varying parameters of the model. The solver itself resides in the background, and the output has not necessarily to be formatted as a tabular report. It is left up to the developer how to visualize the results. Most optimization models in ORWelt visualize the resulting solution graphically, for example using pie charts, indicating a way to interpret the solution. It is important to direct the learner's attention to the critical point of the solution shown. Empirical studies in the field of illustrations indicate that general instructions to pay attention to a specific illustration are ineffective, the learner needs calculated hints pointing out the important aspects (see (Weidenmann 1997)). Transferred to the field of OR, graphical visualization offers much more possibilities to direct the learner's attention into a certain direction than a simple tabular report. This way OR concepts such as sensitivity analysis can be explored in a very vivid way. 'Dynamic' optimization models which can be solved on the fly by MOPS add a new quality of learning and teaching that cannot be achieved by means of a normal textbook. The dynamic representation allows the learner to interact with the model: he or she can alter parameters, compare solutions and explore the structure of the problem formulation.

The project ORWelt started with an experimental phase followed by iterative refinements of the development process. We use teams of typically 2-3 students attending a project seminar with a total of 2-6 groups per semester. The seminar is supported by a group of two knowledge domain specialists and one or two programming specialists. The authoring environment we use is Asymetrix Toolbook®, currently version 6.1 (Instructor II). Writing hypertext is not intuitive and requires certain skills in structuring information. On the one hand, it is quite demanding for students to develop educational material while, on the other hand, they get a very valuable experience out of it. Intensive coaching of students is necessary but it is possible to achieve high quality software. See (Blumstengel, Kassanke 1998) for a detailed description of the development model.

At the moment, ORWelt is a supplementary offer for students, they can use it but they do not have to. The long-term goal of the ORWelt project is to change the way of teaching towards application-oriented learning (Blumstengel, Kassanke, Suhl 1997). Lecture time should be used more efficiently to discuss real-world problems while teams of students learn parts of the material, especially basic algorithms, supported by the learning environment. ORWelt can also be used as a reference and for exam preparation. For a more detailed description of ORWelt see (Blumstengel 1998). ORWelt can be downloaded at (ORWelt 1999).

The optimization code MOPS is also used in the next example 'ClipMOPS'. In ORWelt, students have the possibility to solve optimization models in the so called MPS format. Students can use ORWelt as a tool to solve self formulated models without having to worry about formulation syntax of other solvers because the MPS format is an industry standard for optimization models. Although they can solve these models using MOPS, the model representation is not interactive in the sense of direct manipulation. Modifying a single coefficient requires altering the MPS file and reloading it. In ORWelt it was not possible to provide an interactive model representation due to technical restrictions of Toolbook. The second tool discussed here is dedicated to modeling purposes.

ClipMOPS

ClipMOPS was developed in close cooperation with the Free University of Berlin in 1998. ClipMOPS is intended as a students' tool for modeling optimization models and was introduced to students in Berlin and Paderborn in the winter term 1998/99 for the first time.

Traditional optimization software is typically run by a cryptic command language. Students cannot fully concentrate on the real task (modeling an optimization problem) but have to cope with learning a specific command language. Graphical user interfaces are not very common in this field of software and an easy-to-use software was not available. Currently we use two software packages – AMPL® and LINDO® – in teaching OR. Both are based on the DOS/Windows operating system and have few graphical visualization abilities. Furthermore, AMPL is a powerful but not easily mastered modeling language. AMPL is not a beginner's tool, the learner has to have a clear understanding of the model's structure. The problem is that we teach a broad variety of students majoring in diverse studies. They usually have problems to use the optimization software currently used due to their different mathematical background and algorithmic training. Although, the Microsoft Excel® solver add-in solves optimization models, it has some drawbacks. Namely defining models with the solver add-in is not very intuitive and, more important, the resulting solutions provided by Excel's solver are not necessarily reliable (in the case of mixed integer programs and degenerate solutions, see (Thiriez 1998)).

We wanted a tool which encapsulates the formal description of an optimization model in a graphical, intuitive way and additionally offers reliable solutions. Due to these reasons we considered a spreadsheet platform to be ideal for our purposes. At this point, we started to develop a solution ourselves with Excel in combination with MOPS. Excel is very common, most of our students use the Microsoft Office suite for word processing etc., thus students have a basic understanding of how to operate Excel in general (e.g. cell editing). Furthermore Excel meets the technical requirements for using MOPS (linking Windows DLLs).

Optimization models can be represented in a two-dimensional matrix of decision variables and restrictions. This matrix can be directly transformed to a spreadsheet representation of columns and rows where columns represent decision variables and rows are shown as constraints. Although this way of defining a model is only appropriate for small scale models and does not reveal the model's structure, students seem to prefer this representation (see (Fig. 2)). Especially beginners favor a matrix representation to the very compact mathematical formulation or a model definition in the MPS format, respectively.

Figure 2: ClipMOPS model representation of the diet problem in Microsoft Excel

ClipMOPS has an easy-to-use interface and allows an iterative refinement of optimization models. This way students can concentrate on modeling the optimization problem and waste no time to figure out how to tell the system what they want to express. The model size is restricted to a maximum of 100 decision variables and 200 restrictions but this model size is sufficient for teaching purposes. Existing models in the standardized MPS format can be imported and exported. Additionally the seamless integration into the Excel environment allows to make use of Excel's built-in graphical abilities. A student version of ClipMOPS can be downloaded at (ClipMOPS 1998).

Using ORWelt and ClipMOPS for Teaching

ORWelt and ClipMOPS may be used by students and teachers, as well. As a teaching resource ORWelt may be used by the lecturer as a high-level visualization tool, e.g., to visualize algorithms stepwise and to give further explanations on each step. This way he or she can attract the students' attention to crucial points in the animation. Algorithms are dynamic while the traditional methods used to teach them are not. An animation accompanied by a lecturer's comments fits the dynamic nature of an algorithm much better and adds a presentation quality which normally cannot be achieved by traditional means. Although developing multimedia animations is expensive, the development effort for additional animations decreases, since ORWelt contains a set of all purpose animation routines which is permanently enhanced and can be used repeatedly. The presentation of case studies can be enriched by sounds, photos, videos, etc., thus giving a more vivid impression on what the case study is dealing with. Students are not just passively receiving but actively constructing a solution themselves. As a hypermedia environment ORWelt integrates all types of media in one environment, a laptop and a projection device such as a video beamer or LCD panel are sufficient. Additionally, the hypermedia structure fits the manifold relations between different concerned subject areas better than a linear one.

Students profit from the benefits of self-directed learning as well. They can choose the location (where), time (when), and duration (how long) they spend with the learning environment, that means the availability of the learning environment is enhanced, there are no fixed times or locations for learning. However, to accomplish the engagement of students in the learning environment, a simple transformation of a book to a linear, electronic form is not sufficient. To achieve this goal, one has to use interactive elements, e.g., simulations or dynamic optimization models, in the learning environment. The degree of interactivity is a crucial factor for the success of a hypermedia learning environment (see (Haack 1997, p. 152, Schulmeister 1996, p. 388ff)). Preliminary questionnaire results indicate that students consider interactivity, animations and tests to be the most important advantages of ORWelt compared to traditional education material.

There is no comfortable way to define optimization models within ORWelt (except MPS files), this gap is filled by ClipMOPS. We consider ClipMOPS as a high-level tool which should be used in a way similar to a calculator. Our students are required to gain modeling skills, the final calculations can be done by optimization software. Although it is important to know how optimization models can be solved without the help of computers, no one will try to solve a problem of realistic size without optimization software due to the amount and complexity of the necessary calculations. The computer is an authentic tool and should already be used during students' education.

ORWelt and ClipMOPS will be extensively employed for teaching purposes in the future. Both tools have reached a reliable degree of stability and will be permanently improved. We intend to add a world wide web (WWW) based component to ORWelt, thus enabling learners to access it over the internet. The long term goal is to change the way of teaching towards application-oriented learning in the lecture while basic content can be learned with support from ORWelt. Our Students need OR modeling skills to tackle the problems of the future. ORWelt and ClipMOPS are two examples how we try to improve the quality of teaching OR.

Animations in Physics Educational Software

Richard R. Silbar, William C. Mead, and Robert A. Williams
WhistleSoft, Inc., 168 Dos Brazos, Los Alamos, NM 87544, USA
E-mail: silbar@whistlesoft.com

Abstract: In the process of learning how to create effective computer-based training modules for accelerator physics, we have come to believe that simple two- and three-dimensional animations are often the most valuable multimedia tool for presenting technical material. This talk demonstrates a number of the animations we have developed for our tutorial series *Accelerators and Beams* and discusses why we think they are successful. Examples range from illustration of the right-hand rule for vector cross products to demonstration of the so-called "vertical betatron oscillation" that is used for ensuring stable beams in accelerators.

Introduction

Four years ago WhistleSoft, Inc., began developing a set of computer-based multimedia tutorials for accelerator physics under a Small Business Innovation Research grant from the U.S. Department of Energy. At the time we began this project our expertise was not in multimedia but in science. Company personnel consists mainly of Ph.D. scientists who were at one time associated with the Los Alamos National Laboratory. We considered ourselves as domain experts in the subjects for which we were about to develop tutorials. On the other hand, we had a lot to learn about user interface issues and how to create multimedia. Even more important, we also had much to learn about instructional design and pedagogy.

We originally designed the *Accelerators and Beams* tutorials for the academic market.[1] However, we have always had the idea in mind that we could later customize its separate modules for laboratory and/or industrial usage. This would extend the use of these modules to a non-traditional student audience, such as the technicians and operators employed at large accelerator facilities. We are therefore targeting a broad audience – from lower undergraduates and technicians up to graduate students and professionals in science and engineering. Most of our work so far, however, has been at an elementary level, for end users who have taken, say, an algebra- or calculus- based introductory physics course.

The modules comprising *Accelerators and Beams* use all the usual multimedia techniques: interactive On-Screen Laboratories,™ hypertext, line drawings, photographs, two- and three-dimensional animations, progressive disclosure (at the student's choice of pace), and video and sound. The multimedia enhances the student's rate of learning and length of retention of the material.

This paper discusses what we have found to be arguably the *most* effective multimedia technique for learning physical concepts: two- and three-dimensional animations.

---

[1] Our publisher, Physics Academic Software (see http://www.aip.org/pas) released *Vectors*, late in 1997. The *Forces* module became available in August of 1998. *Motion in Electromagnetic Fields* recently began shipping, and PAS has also accepted *Dipole Magnets* for publication. We expect to publish two other modules in this series.

The Textbook Approach

A typical modern physics textbook contains many figures and pictures. The diagrams are almost always two-dimensional and static.

There are a few exceptions. Some textbooks, such as the classic text on mathematical methods by Morse and Feshbach, have experimented with doubled, offset pictures which, when viewed with special glasses, give a three-dimensional "depth" to the drawing. Others, such as Max Born's *Restless Universe*, give crude animations by utilizing an old "flip book" technique predating even Walt Disney's cartoons.

These exceptions, however, are quite rare, despite the fact that many concepts in physics involve both motion and all three spatial dimensions. We suspect that one reason why there are fewer physics majors than, say, psychology majors is this: there is a particular aptitude that only a few people have for being able to visualize motions and depth from the two-dimensional figures the texts and lecturers can present.

We also suspect that the non-traditional student, such as the accelerator technicians we are also targeting, have a much more "hands on" approach to learning. Two-dimensional diagrams, while a staple of their trade, are probably secondary to their understanding of a circuit or a device.

The Computer Advantage

A computer-based tutorial is *not* a substitute for a good textbook. It is hard to read extended text on a computer screen. However, the personal computer has many advantages over a textbook, one of which is that it can easily present a moving picture of a three-dimensional concept.

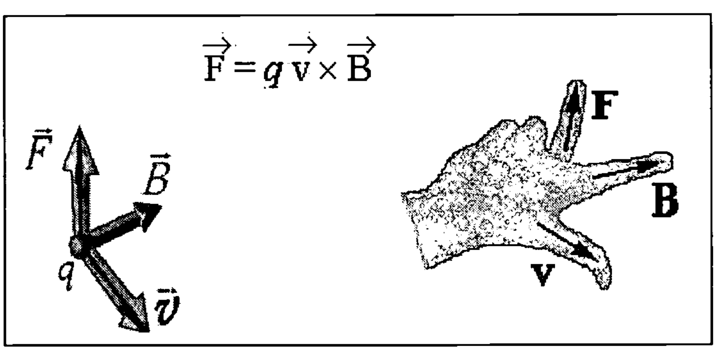
In what follows, we will discuss some of the example animations we have incorporated in our tutorials. The reader should bear in mind that this abstract is just like a textbook, namely static and two-dimensional. We will try to impart the flavor of the animations, but there is no substitute for seeing them "live" on a screen. The presentation of this paper will demonstrate these animations, projected from the computer.

Most of the examples we will show below are three-dimensional animations dealing with concepts involving electromagnetic forces. That is because of the nature of the main theme of our modules, *Accelerators and Beams*, where the electromagnetic force is the important one. We believe that similarly effective animations would be helpful in many other core physics courses, such as classical and quantum mechanics.

Animation Examples

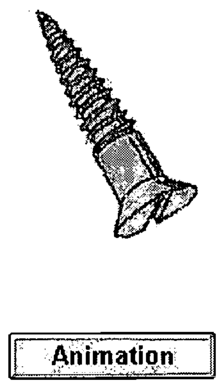
Right-Hand Rule

An important (and often difficult) concept for many students is to understand the direction of the force felt by a charged particle moving in a magnetic field. This Lorentz Force is expressed as a vector cross product of the particle's velocity with the magnetic field vector, as in the following:



This figure is a snapshot of a portion of a page from our *Vectors* module. The equation and the photo of the hand are static. The colored arrows at the left, however, are shown as they appear in the last frame of an animation which shows how one "swings" the velocity vector **v** into the magnetic field vector **B** to get the force direction. This is then followed by a moving camera view of the three vectors that shows them from a number of points of view, ending up in the position shown. The student can repeat the animation as often as he or she needs by clicking on a button labeled "Animation."

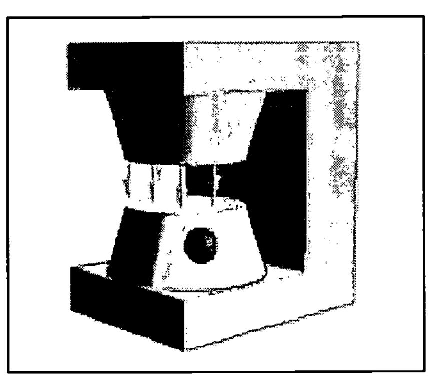
Another, related animation in the *Vectors* module shows the motion of a right-handed screw, a concept difficult to describe in words or in static pictures.



The page on which this animation occurs first shows the (static) picture of the wood screw shown on the left. When the student clicks on the animation button, the screw is replaced by the corkscrew-like spring that then rotates and winds its way up from the lower right to the final position shown.

Bending Magnet

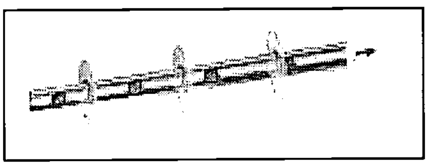
The concept of motion of a charged particle moving through a bending magnet is a direct consequence of the Lorentz Force Law illustrated above. An animation showing this is represented by the following:

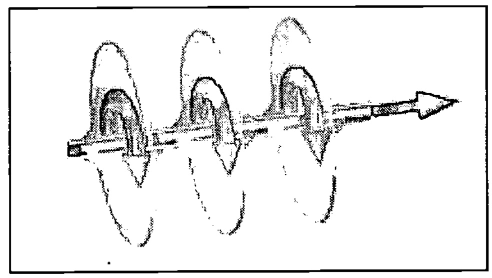


Here we see the animation in its initial frame. When the student clicks the button, the red ball (representing a charged particle) moves into the magnetic field of the dipole magnet and bends to the left. Again the student can repeat the animation as often as necessary. One reason why that might be necessary is that, in this case, our tutorial poses a question to the student: is the red ball negatively or positively charged? (You can figure it out from the right-hand rule.)

Magnetic Field Around a Wire

The *Forces* module also illustrates how a current-carrying wire builds up a surrounding magnetic field. The following shows the animation associated with this a few frames after its start.

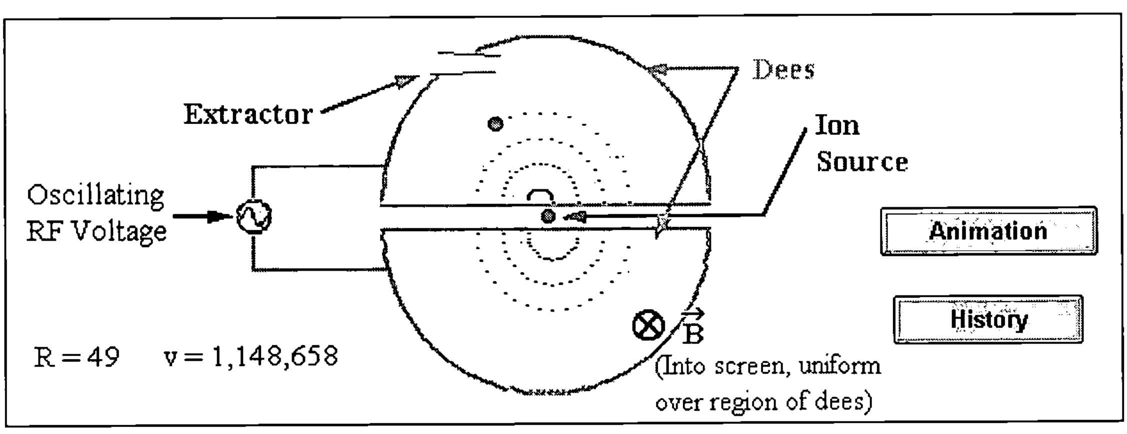




Here the "red charges" start moving through the wire to the right (as shown on the left), building up the blue magnetic field lines looping around the current. When the current reaches a steady state, the magnetic field stops growing, i.e., reaches its steady-state condition shown on the right. As usual, the animation is repeatable, as necessary.

Cyclotron

Our *Motion in Electromagnetic Fields* module contains a section on cyclotrons. The "How It Works" page has a useful two-dimensional animation, shown on the next page. Here the screen snapshot shows the situation partway through the animation. You can "see" the acceleration, which occurs, across the gap between the Dees from the spacing of the dots (and the increasing speed of the red charged dot). The display continuously updates the values of the radius of the arc and its (increasing) velocity at the lower left as the particle advances outward.

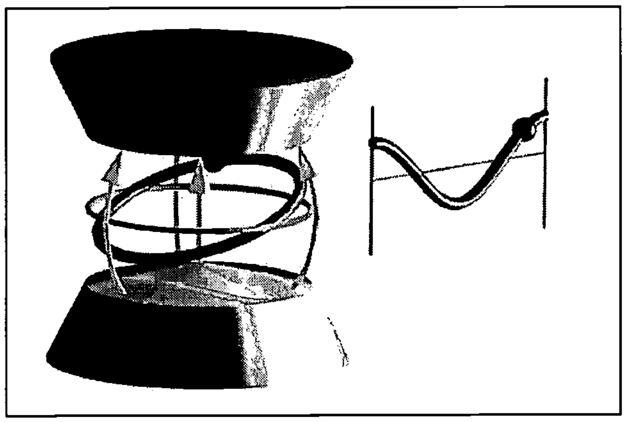


Eventually, the particle radius grows to the point where it leaves the upper cyclotron Dee through the extractor port. For the physicists among us, the resulting particle beam then can be used for a scattering experiment or production of a radiopharmaceutical isotope.

This two-dimensional animation, by the way, was done entirely within the authoring framework we use for our tutorials. We use a built-in scripting language to move the red charge dot and to leave its trace.

Vertical Betatron Oscillation

Moving on to a somewhat more advanced module, the *Dipole Magnets* tutorial discusses how these magnets bend and focus charged-particle beams. One of the topics considered is betatron oscillation, the use of restoring forces to keep the beam within the accelerator while it is being accelerated to its final energy. The animation for the vertical case looks like this:



The student is most likely to see this perspective-view animation after having first viewed a two-dimensional animation and another three-dimensional animation looking at the motion from the side. The green circle represents the "reference trajectory" and the red circle that of the red particle which is slightly "off" that principal path. The restoring force that keeps the red particle moving along the canted red circular path comes from the non-uniform-magnetic field. (The pole piece shaping, which makes the non-uniformity, is better seen in the side-view animation.) The moving red charge (ball) also simultaneously traces out the sine wave graph shown on the right side of the figure.

Lessons Learned

We began the *Accelerators and Beams* project without much appreciation of the power of a good three-dimension animation. Clearly, the more we learned about how to make them, the more we came to appreciate their pedagogical value. As we stated in the introduction, we believe that, for many purposes, this is the most valuable multimedia tool for presenting technical material.

Acknowledgments

We prepared the three-dimensional animations discussed in this paper using Macromedia's Extreme 3D and Calgary's TrueSpace applications. The animations are embedded in tutorials created using Macro Authorware. We want to acknowledge support for this project from the Department of Energy. We also thank Prof. John S. Risley, editor of Physics Academic Software, for his continuing advice and criticism of our software modules. Further information about this project can be found at http://www.whistlesoft.com/~silbar/. In particular one can download a white paper from there detailing the latest status of the *Accelerators and Beams* project.

Using Learning Protocols to Structure Computer-Supported Cooperative Learning

Martin Wessner, Hans-Rüdiger Pfister & Yongwu Miao
GMD - German National Research Center for Information Technology
Integrated Publication and Information Systems Institute (IPSI)
Dolivostr. 15, D-64293 Darmstadt, Germany, E-Mail: {wessner, pfister, miao}@darmstadt.gmd.de

Abstract: A common problem of CSCL (Computer-Supported Cooperative Learning) is addressed: How can we coordinate goal-directed, effective interaction in a group of learners? We introduce the concept of *learning protocols* which originates in script theory. We then discuss which dimensions of cooperative learning can be supported by learning protocols and propose how learning protocols can be integrated in a CSCL environment.

1. Introduction

Consider the following two examples:

- A trainer asks his/her students a question. After some seconds without response he thinks that nobody understood or could answer the question and re-phrases his question. Increasing the time between the question and the intervention by a few seconds has several positive quantitative and qualitative effects on students' answers [Rowe 1974].
- A group of learners is discussing a concept introduced in a presentation. The most eloquent and extrovert students dominate the discussion. Ideas and arguments of others remain unheard. Providing a set of rules which enable everybody to participate, and structuring the discussion as a cooperative process can guide the interaction in discussions and improve the learning process [Hall & Mancini 1997].

These examples indicate that learning can be improved by defining certain constraints and by structuring the learning process. Our work deals with the question: How can such constraints, rules, or process structuring methods be realized in a computer-supported cooperative learning environment? We call this kind of integrated learning support „learning protocols".

We see several developments which lead to the need for learning protocols. During the last decades learning is regarded more and more important due to the increasing amount of knowledge available world-wide, the increasing complexity of knowledge, and the increasing speed of these changes. This raises demands to establish a new learning culture: (1) Learning has to be a life-long process, we have to better *support adult learners* whose learning processes differ in many ways from those in schools or universities. (2) Individual learning methods are not sufficient for mastering the complexity of knowledge, we have to provide methods and *support for groups of learners* to cooperatively acquire knowledge and transfer it to daily practise. (3) In order to address changes in work organization as well as in society in general, learning cannot be limited to scheduled activities in a common classroom. Learning has to be *flexible over various dimensions* such as time and space. Therefore we need learning environments which support different learning scenarios, e.g. asynchronous learning or learning by geographically distributed learning teams. Our focus is on distributed cooperative settings, in which learning teams of adults want to learn in a flexible way.

Focussing on *co-located and synchronous* settings, a number of field studies have indicated that students can learn effectively in pairs and in small groups, if they are supported by appropriate learning methods [Slavin 1995]. Cooperative learning can improve several cognitive and social aspects of the learning process [Mancini et al. 1998]. In a *distributed* cooperative setting, learning teams need means to communicate and to coordinate their learning activities. Given an infrastructure with networked computers, communication and cooperation environments which address these needs, e.g. by providing various communication channels and shared data repositories, are available (e.g., Microsoft NetMeeting). Can cooperative learning also be used in a distributed cooperative setting in order to achieve similiar positive results as in a traditional setting? Can we transfer the cooperative learning methods?

These topics are tackled by a field of research called computer-supported cooperative learning (CSCL) [Koschmann 1996]. Some positive experiences have been made using computers to support cooperative learning in traditional settings. For example, in the CSILE system a certain cooperative learning method is modelled, and learners are guided through the process by specific rules [Scardamalia & Bereiter 1996]. In [Hron et al. 1997] a system was successfully tested that controlled the dialog in cooperative dyads with a specific communication interface.

There are some additional constraints in a distributed cooperative setting: The quantity and quality of transmitted information is different because many non-verbal signals are not transmitted. E.g., chat and e-mail deal with written communication and provide only limited support for non-verbal communication by using emoticons or attaching sound or image files to a message. Audio/video conferences provide audio-visual information in a lower quantity and quality than face-to-face settings. A major problem is that some cues are missing which structure cooperative learning in the co-located, synchronous setting. As a result, e.g. simple turn taking mechanisms in discussions fail in such settings.

We see two ways to address this issue:

- Integrate nonverbal signals in a CSCL environment by integrating additional communication channels, e.g. sensors detecting whether the learner is currently present in front of the computer or cameras analyzing facial expressions.
- A second way is to develop cooperative learning methods or adapt existing ones to the distributed cooperative setting, and thereby taking into account the constraints of this setting such as changed number and quality of communication channels or less ambient information flow.

The first solution leads to systems which track and check user activities with various kinds of sensors. That can be in the way of virtual reality as immersive 3-dimensional virtual worlds or by enhancing the intelligence of rooms and furniture in the real world. The advantage of these approaches is to represent reality and thereby providing a familiar environment with well-known or easy-to-learn means of communication and cooperation. But this advantage holds only as long as the system more or less clings to reproducing reality; additional support provided by the system has to be learned by the users. Our approach, however, is related to the second solution. We call cooperative learning methods in a distributed setting *learning protocols.*

The remainder of this paper is organized as follows: In the next section the concept of learning protocols is described in more detail. Section three elaborates on the various ways in which learning protocols can help teams of learners to improve their learning process and results. The integration of learning protocols in a CSCL environment is presented in the fourth section. We close with a description of our next steps.

2. Learning Protocols as Implemented Scripts

In cooperative learning we distinguish two kinds of supporting methods [Hron et al. 1997, Mancini et al. 1998]:

- Global methods which structure the cooperation on a general level, e.g. by providing support for group organization, monitoring constraints such as a maximum floor holding time.
- Structured or scripted cooperative learning methods which provide protocols for cooperative learning by structuring the dialog and actions of the learners.

Learning protocols perceived as scripted cooperative learning methods are theoretically based on psychological script theory. In cognitive and social psychology, generalised knowledge about a routine sequence of related events and activities is commonly called a script [Schank 1982], [Schank & Abelson 1977]. A script is a knowledge structure that, once activated, yields information on what events to expect and how to act in a specific type of situation. For example, the well known restaurant script describes the sequence of actions when having a meal in a restaurant (e.g., ordering, eating, paying), and it specifies what to expect from others, e.g., from the waiter, depending on one's own actions. A script can be seen as a type of schema, which, in addition to a prototypical chain of actions, contains slots to specify the temporary circumstances, and default values to guide expectations and inferences if no further information is available. Hence, scripts not only control many stereotyped encounters of daily life, they also reduce cognitive effort by providing guidelines that decrease the need to think about one's actions in well known situations.

Scripts can be triggered by aspects of the situation (situation-controlled script; e.g. initiating a vote in a controversial discussion) or by a specific role (role-controlled script; e.g. a trainer is expected to answer a question and to determine the learning process). To act according to a script one has to know the script itself and one's part in that script. The activation of a script is considered to be mostly automatic.

Cooperative learning methods can be perceived as externalized scripts attached to learning situations or roles in a learning team. In natural face-to-face situations, the actions of persons applying the same script are aligned by a lot of explicit and implicit cues (e.g., non-verbal cues such as pauses or changes in posture indicate turn-taking in a discussion script). In computer-mediated learning environments, however, these cues are largely missing, and the coordinated enactment of a script can be seriously endangered. Especially, cooperating learners may not use the same script at all, or may be uncertain about which script the others apply, or may define their roles in the script differently, or may loose orientation where the group currently is in the script. These difficulties in CSCL environments suggest that one should not rely on an automatic script enactment, but that one should provide scripts as implemented procedures that can be executed on demand. Learning protocols, as defined here, are just a set of useful scripts for learning, externalized as executable methods, with roles, events, and actions made explicit.

3. How Learning Protocols Can Structure Cooperative Learning

3.1 Explaining: An Example of a Learning Protocol

Imagine that in a pairwise learning situation person A needs an explanation about some problem. Hence, he asks for explanation from person B, who tries to provide the explanation. In natural face-to-face situations, all interactions during the explanation process are usually carried out without much friction, since many verbal and non-verbal cues guide the dialog. However, in a distributed computer mediated situation, person A might want to activate an "explanation protocol", which then controls the communication process. The explanation protocol is very simple, basically controlling the right to speak and indicating which type of communication is currently being performed (if, e.g., a question is asked, or if an explanation is delivered). The protocol will, for example, strictly switch between explainer and explainee. The explainee will respond to an explanation either by asking for more information, or by deciding that he is satisfied with the explanation, which will terminate the protocol. The explainer will either deliver a further explanation, or he will declare himself unable to provide the explanation, which will also terminate the protocol. Learning protocols can be represented as a kind of state-transition-diagram; Figure 1 gives an example. The following sections show that this very simple learning protocol can be enhanced by integrating control over other ressources such as learning artifacts and shared workspaces.

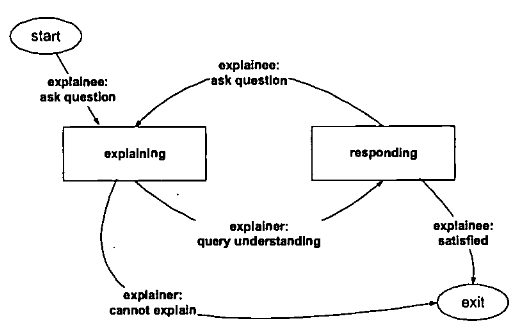


Figure 1: State-transition-diagram of an explanation protocol

3.2 Levels of Learning Protocols

Learning protocols are useful on different levels of the cooperative learning process:

- On the most basic level, they guide elementary communication processes among learners, e.g., discussions (be it by audio or chat), presentations, or dyadic dialog.
- On the next level, protocols support group activities which need some coordination control, e.g., common navigation through hypermedia documents or preparation of agendas and time schedules.
- The third level refers to protocols which are designed to support cooperation, e.g. jointly editing, domain specific role plays or simulations.

On each level protocols range from more generic collaboration protocols, such as a discussion protocol, to very learning specific protocols, such as giving an explanation in a certain domain. In principle, the list of potential candidates of cooperative learning processes that could be translated into learning protocols is almost infinite. Special techniques such as "Jigsaw II" [Slavin 1995], or different cooperation modes such as symmetrical (e.g., a discussion among students) and asymmetrical (e.g. a presentation) modes, depending on role and group structure, could be devised.

We think of learning protocols as a set of potential support tools from which learners and trainers may select what they consider to be useful. At any time, participants may choose from a menu a specific protocol, which is then activated. When finished, the group is free to select any other protocol, or to proceed without systematic support. Hence, the overall learning process is not itself controlled by a protocol, but can be augmented at any time when support seems appropriate.

3.3 Components of a Learning Protocol

Irrespective of the level of a protocol, a protocol consists of a set of components, which can be derived from script theory. First, a protocol has a name; the name signifies the situation type to which the protocol can be applied. For example, a (cooperative) explanation protocol applies to situations in which an explanation is needed by some person and can be delivered by some other person. Unlike in natural situations, learning protocols are selected solely by name, i.e., a person subsumes the situation under the category referred to by the protocol's name, and intentionally activates the protocol.

Secondly, a protocol consists of a set of states and transitions. In each state the users can perform actions such as communicate or manipulate artifacts. A transition to another state is triggered by an action or a specific condition, e.g., the time-out of the preceeding state. Of course, various iterations and conditional branchings may occur. The interface of the learning protocol has to take care that different types of actions are appropriately perceived and classified.

Thirdly, a protocol includes different roles pertaining to the persons involved in the enactment of the protocol. A learning process commonly consists of one or more students, and one or more trainers or teachers. Other roles specific to learning are tutors, experts, and moderators. Each participant of a running learning protocol needs to obtain a definite and unique role, and needs to know which roles other participants have. The role one has is either arbitrarily defined by oneself, or is derived from the overall group structure. Roles should also be indicated on the computer screen, i.e., everybody should be informed about his and the others' roles by some sort of visual indicator, in order to prevent role confusion.

Finally, a protocol may contain various types of artifacts, i.e., text documents, graphical objects, test forms, etc. In many simple communication protocols, however, the definition of special artifacts is unnecessary, or only optional. For example, in the course of an explanation, the explainer and the explainee may use a shared whiteboard to outline some ideas, but this is not essential for the explanation process.

3.4 The Construction of Shared Knowledge

A special problem in cooperative learning is to gain a common understanding of the shared knowledge of the group. Efficient communication requires that each participant knows, at least approximately, what the other participants know. Without this common background, it would require a lot of time and effort to achieve effective cooperation. In cooperative learning, due to the continuous acquisition of new knowledge of each participant, the shared knowledge is ever changing. This makes it even more important to provide systematic support to construct and represent the common knowledge of the learning group in some way.

We propose that learners externalize their knowledge in the form of a diagram with nodes and links: nodes denote specific concepts (from the domain to be learned), and links denote specific relations among concepts, such as "is-example-of", or "is-subtopic-of". Without going into detail (see [Pfister et al. 1999]), it seems clear that this diagram of shared knowledge needs to be modified or updated regularly and systematically. A special type of learning protocol is needed to support the maintenance of the shared knowledge, providing protocols for expanding, for reducing, for restructuring the knowledge corpus, and for establishing consensus among learners on when and how to introduce changes to the knowledge.

4. Implementation

In the CLear (computer-supported cooperative learning) project at GMD-IPSI, we develop computer-supported cooperative learning environments and cooperative learning methods for such systems.

In a first step we designed the VITAL (=virtual teaching and learning) prototype using the COAST [Schuckmann et al. 1996] framework for building groupware. As described in section 2, we distinguish two kinds of supporting methods for cooperative learning: global methods and scripted cooperative learning methods. In VITAL we focussed mainly on supporting global methods. The prototype offers global group organization methods and a limited cooperation support, e.g. by providing a structured communication board and different cooperation modes. Evaluations of VITAL in university settings showed that the system is well accepted but offers only limited support for structuring the cooperative learning process [Beck-Wilson in press]. Therefore we extended the approach and integrated learning protocols [Pfister et al. 1998].

Our approach can be briefly characterized by (1) providing a virtual learning world consisting of different types of virtual rooms, in which learners can communicate and cooperate synchronously and asynchronously, (2) supplying each virtual learning room with a shared hypermedia workspace, (3) using hypermedia to represent the learning material, and (4) using hypermedia to define learning protocols and visualize their execution.

For implementing learning protocols in a CSCL environment we use several techniques:

- Some global methods can rely on access rights, rules and conditions, or mechanisms for conflict resolution. Therefore, we need functionality for defining and checking these methods.
- Scripted cooperative learning methods are modelled using collaboration protocols similar to state transition diagrams (see Figure 1). Each state is defined by specific functionalities and rights of the involved participants, i.e., a set of behavior rules, which define which role is allowed to perform which operation on which resource. The learning protocols are implemented using the modelling method of SCOPE, a system which allows the definition, execution, modification and monitoring of general collaboration protocols [Miao & Haake 1998].

The implementation provides guided interactions between the system and the users. Depending on the kind of learning protocol and his/her role a user may initiate a protocol, e.g., by simply pushing a button. If all preconditions are met, the roles in the protocol are matched with the actual team members. During the execution of the protocol, the user interface provides information, such as the current state and possible actions in this state of the protocol. Special templates, e.g. for requests, explanations, and responses can be provided, and control is passed depending upon team members' actions.

An advanced prototype, called CROCODILE (=creative open cooperative distributed learning environment), is currently being implemented based on the experiences made with VITAL and SCOPE.

5. Next Steps

We want to investigate whether learning protocols really inherit the advantages of their predecessors: cooperative learning methods and scripts. In addition to structuring the cooperative learning process we also expect them to serve as a means for meta-learning, i.e. learning to learn cooperatively. Field studies will show whether users can create (internal!) scripts by multiple usage of learning protocols and thereby transfer their behaviour to other collaborative situations.

We still have a lot of open issues which require further research, two important ones being the usability of learning protocols in medium/large groups and in asynchronous settings.

- Group size

Most research on scripted cooperative learning (with and without using computers) deals with dyads [Mancini et al. 1998], [Hron et al. 1997] or relatively low structured scripts, which structures the learning process in coarse steps [Hall & Mancini 1997]. Only limited knowledge is available on which methods are suited for which group size. This has to be evaluated by performing extensive testing with user groups of various size.

- Asynchronous learning

A problem for learning teams at the workplace is the need to learn asynchronously, e.g. at times dictated by business requirements. Asynchronous cooperation is also very important or in many cases the only possible solution for dispersed learning teams spread over different time zones. Many of the traditional cooperative learning methods assume synchronous settings and have to be adapted for asynchronous usage.

Further information about the CLear project and the learning environments VITAL and CROCODILE is available at our website http://www.darmstadt.gmd.de/concert .

Abstract: A range of pedagogic, administrative, socio-economic, structural and resource issues surround the establishment of a global campus. This paper identifies and discusses such issues, and suggests that pedagogic aspects are paramount. The limitations of conventional subject-based approaches are considered, and local experience in curriculum design and module integration is discussed in the context of flexible learning, wider access and participation. The need for a range of learner support mechanisms is indicated, and our implementation (together with others) is described. The concept of a global campus is underpinned by appropriate technological developments. Internet- and Web-based experience is discussed, as is the need for more radical approaches such as Virtual Reality techniques.

Introduction

The nature of higher education (H.E.) is changing globally: the convergence of wider access demands, greater emphasis on vocational preparation, new teaching and learning delivery mechanisms, and the emergence of globalised economies is propelling forward-looking H.E. institutions into careful self-analysis. At the same time, many countries (for example, U.K., Australia, U.S.) are witnessing a withdrawal from state-funding for both H.E. institutions and for student maintenance costs. With other but equally significant structural and resource difficulties, developing nations also share these problems (Koul, 1995)

As well as financial challenges, certain global trends are beginning to emerge. Valcke and Vuist (1995) describe experiences in the Netherlands that matches our local experience in the UK. Demographic changes mean that the profile of the traditional student is becoming older, often working or balancing the requirements of other family/career commitments: this implies a growing demand for increased part-time and more flexible learning provision. An increasing number of UK institutions have adopted a modular approach to course design and delivery – see, for example, George, Murfin, and White (1992). At the same time, there are many pressures for more effective teaching and learning delivery mechanisms. Active learning, student-centred and case-led methods are now accepted parts of the educator's canon (Rogers [1991]), and such changes have been growing in influence since the late 1980s. What is now emerging as a radically different and (potentially) revolutionary change is the use of Internet- and Web-based delivery channels.

Open Learning and emancipation

Before discussing such issues, it is worth recalling that one of the strengths of an open learning approach is what Reid (1995) refers to as an 'emancipatory tradition' - the barrier-dissolving aspects of such learning. Such emancipatory aspects are principally associated with learners previously denied access to education and assume a much wider relevance within the context of a global campus. Reid (1995) directs our attention to 'structural constraints' relating to institutional, social, cultural, and political/economic factors. While the cost of commissioning and building new higher education institutions may stretch the financial resources of the developing countries, the ability to 'tap' in to such programmes of study offered via the Web may be of great emancipatory, as well as economic, potential.

This implies fundamental challenges for the future of higher education. Dolence (1995) suggests that these challenges stem from the use of an educational model developed from and for an industrial model of society. Is this appropriate in what Dolence calls an 'information model' of society? Is the cost model of such a paradigm still valid given the nature of such an "Information age"? Can the higher education sector ignore the potential of technologies such as Web-based 'push' technology, 'click-thru' mechanisms, video-conferencing, and virtual reality models?
In a wide-ranging survey of current thinking about pedagogical issues facing H.E. Diana Laurillard articulates the necessity of 'situation-learning' (Laurillard, 1993). Such learning implies that "the acquisition of inert concepts (e.g. algorithms, routines, decontextualised definitions - i.e. the stuff of many university courses) is of no use if the student cannot apply them...[We] have to use our knowledge in *authentic activity*, i.e. genuine application of the knowledge; this allows us to build an increasingly rich understanding of the tool itself and how it operates" (page 17). Here, the application of Virtual Reality models and techniques offers potential for implementation of 'authentic activity' and 'situated learning'.

Globalised education

The idea of a globalised higher education sector - a 'global campus' - implies administrative, pedagogic, operational, and technical issues, and the Virtual Online University (`www.tcet.unt.edu`) offers an interesting metaphor for the learning 'cyberspace'. It is structured around a virtual campus, designated as a 'MOO' (an Object-Oriented Multi-User Dimension), around which students can wander as they would around a physical campus. At the same time, the range of courses offered remains very traditionally 'subject-based'. Is this appropriate to such a new learning environment?

Such an environment may well present a lack of unified focus for learners. Laurillard (1993) draws attention to the decentralising effect of new technology. She argues that this can push forward a very fragmented view of knowledge. This is opposed to, what she typifies as, 'academic knowledge', which has an integrative function different from simply 'knowledge'. It is this reflective aspect which is likely to prove difficult to deliver in the information model described by Dolence (1995). Learners in a virtual campus may well require a much stronger structural identity. It is, therefore, important that there is a strong conceptual platform that integrates and preserves a sense of intellectual and discipline consistency.

Local implementation

At a local level, we have attempted to incorporate such issues and challenges within a conceptual and pedagogic framework for the education of information engineers. A set of modules has been implemented within a conceptual framework entitled Systems, Techniques, Implementation, and Integration (STIMI). An outline of this is shown in figure 1 (The STIMI Progression). In stage 1, the concept of systems and systems thinking is introduced to students. This theme is elaborated in separate semesters in stage 2. The first emphasises the usual systems analysis techniques of process, data, and event modelling. Implementation within the context of Computer-Aided Production Management (CAPM) is combined in the second semester. By stage 3, management and management-information related issues are addressed by examination of strategic and operational planning aspects. The integration of 'islands of automation' within the context of manufacturing businesses is the prime concern of the postgraduate programme. This module is designed to enhance the learning experience of those continuing students who wish to pursue their studies at this level, together with providing a firm base for external students entering the programme from a wide range of industrial and educational backgrounds.

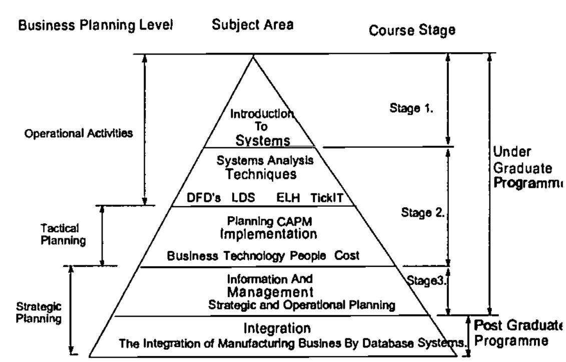

Figure 1: The STIMI Progression

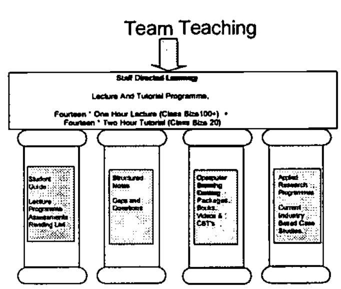

Figure 2: Support for module teaching

The basis of delivery for the modules is illustrated in figure 2 (Support for Module Teaching programmes). A body of structured teaching material (linked and sustained by four pillars that rest on the STIMI conceptual foundation) has been developed to minimise duplication of content and to provide a common platform for delivery. Following Race (1989), this incorporates a range of techniques developed from Open and Distance Learning models, such as self-assessment questions and other developmental questions and activities consolidated within the text.

The particular problems of part-time students, those students beginning their studies at differing entry points, and students who require extra support are recognised, and are of especial relevance within the context of this paper. Such students have significant demands placed upon them by work and family pressures so such students can also access this material via the University web site. Open and distance learning material may appeal to university management because of its apparent cheapness, but such students are likely to require significant support mechanisms. They may be unfamiliar with the nature of independent learning implied by a higher education programme of study. How are such mechanisms to be implemented and managed given an electronic local campus, let alone a 'global campus'? Learner support in the global campus will rest upon two pre-requisites: learner support and technological delivery mechanisms. We will address the latter aspect later in this paper. For now, we wish to describe briefly some of the issues involved in supporting widely-dispersed learners. Such learners may well be dispersed temporally as well as geographically. The use of packaged material (CD-Rom, text-based and other resources) is the conventional means of handling knowledge content. But how can learners benefit from a shared learning experience? Romiszowski (1995) describes how a co-operative programme can be established, and can be extended by various Internet and Web-based technologies - bulletin-board conference facilities, email, links to resource materials (virtual museums, virtual libraries). All of these offer significant potential as an integrated collaborative platform.

Distributed learning

Such initiatives still, however, rest upon a traditional view of teaching and learning. The support of Distributed Learning paradigms should now be considered. Distributed learning is founded on the belief that the personal needs of the student are paramount. Academic institutions can evolve courses based upon modules (STIMI), that can expand choices for students whilst maintaining educational quality across location and time-bound constraints, as well as providing the student with a more self-paced, self directed, career-biased learning experience. A distributed learning environment can essentially be stand-alone with a single subject/operator or can be linked via with a common database and/or other systems into a distributed system/servers. The common database may either be held centrally (and modified if required by each system/server) or local copies can be used with changes highlighted to the other components of the system/network. For example, for a design engineer a distributed learning environment is desirable, but design engineers can be trained individually. For other learning contexts, it is mandatory, especially where teams of operators interact in command and control of resources. An example where a distributed environment would be mandatory is in Air Traffic Control where visualisation of air space needs to be accessed and controlled by many operatives.

Technological aspects

One of the potential problems with distributed learning is data transmission rates over networks. Optical Fibre technology has developed such that within the near future transmission rates of 10 Gigabits sec^{-1} will be possible over broad band optical networks (Chan, 1995). A current or near term technology is the so-called "DVD" CD-ROM (Bell, 1996) where data is written to a multiple layer CD. This technology gives the CD-ROM the capacity to store up to 17 Gigabytes on a single disc with a data rate capacity of 11 Mbits sec^{-1}.

Such technologies (given development) are of direct relevance to Distributed Learning and its application, by affording a platform for the development of such teaching aids as Virtual Reality (VR). Given the inherent ability of VR to display three or multi-dimensional properties of objects to a operator its uses in teaching and training are virtually endless. It must, however, be remembered that VR is essentially only a display tool and therefore cannot fully substitute for other forms of learning. It is also important, given the growing importance and development of VR technology, that VR itself should be taught as a module at core level (STIMI). Being a multi-disciplinary subject it can only be taught at a relatively high level. It should however become a mandatory subject in all information technology courses even if minimum time is devoted to it (Elson, Simms [1997]).

Table 1 below lists some potential applications for VR in teaching. This list is not meant to be complete and many other applications may occur to the reader.

Table 1: Some Uses of VR in education

Subject	Use
Physics	Motion, Orbital Mechanics, Gas Physics, Multi-dimensional analysis
Chemistry	Structure of compounds, molecules
Biology	Structure of organisms, behaviour of organisms
Earth Sciences	Earth observation, landscape
Geography	3-D structure
Geology	Structure of fossils
Engineering	CAD/CAM
General	Display and analysis of multi-dimensional data

For basic tutorial type work the basic technology already exists with PC's and CD-ROM's. For more extensive use lightweight cheap helmet-type displays need to be available along with the appropriate computer technology (fast networks delivering M-Bytes sec^{-1})

In conclusion then, the Global Campus is a rapidly developing field with many potential applications. It has direct application to teaching and training at many levels. Educators should be made aware of the capabilities and limitations of the technology. Distributed systems are required for its effective use. The concept of a Global Campus offers a useful metaphor for the delivery of a new mode of education, supported by fast and flexible delivery mechanisms.

Agent-Based Instructional Design Model for Cognitive Mapping

Piet Kommers, Lora Aroyo and Svetoslav Stoyanov
Faculty of Educational Science and Technology, University of Twente, The Netherlands
{kommers, aroyo, stoyanov}@edte.utwente.nl

Abstract: This article is purposed to present an intelligent agent-based instructional design model on the subject of cognitive mapping strategy. It is a further conceptualisation of the rational behind the existing SMILE-Maker tool. SMILE-Maker is a prototype of computer programme aimed at supporting the user to build some knowledge and skills in cognitive mapping technique when problem solving occurs. A new instructional design scenario based upon this model has been added to the programme.

Introduction

The ambition behind the agent-based instructional design model is to construct, in more effective and efficient way, the interaction between the learner as a user and the facilitator as a system instructional designer. Cognitive mapping is the content this interaction deals with. Instructional events are supposed to play an intermediate role. The interaction is formalised in the concept mapping format as the gaps in overlapping the behaviour patterns of the user and the system designer are identified and then some advises are provided. It is hypothesised that this computer-based instructional design should solve some of the fundamental all-the-time issues of learning and instruction. What seemed impossible for the domain of instructional design is very likely to happen now because of the new hardware and software development and the more appropriate formalism for data retrieval and knowledge representation. The model tries to balance constructivism and objectivism as instructional design paradigms, content-treatment and aptitude-treatment interaction as didactic approaches, system- and user locus of control in human-computer interaction, and preferential versus remediation matches to individual differences. The article starts with a short description of the SMILE-Maker tool, providing the context that calls for a new instructional model and than an agent-based instructional design model (4 AID) is presented.

SMILE-Maker Tool

SMILE stands for Solution Mapping Intelligent Learning Environment. The SMILE-Maker tool consists of the components such as 'ideas', 'profile', 'map', 'method', 'template', 'partner' and 'draw'. 'Ideas' means creative problem solving techniques. 'Profile' is associated with individual differences. 'Method' proposes a cognitive mapping strategy based upon synergy of problem solving techniques and mapping approach. 'Map' includes types of maps such as concept map, mind map, process map, and flowscape. 'Template' provides with some examples produced in a wide range of particular subject domains. 'Draw' leads to a graphical editor. 'Partner' proposes a strategy and a convention for group problem solving using cognitive mapping method.

Three different scenarios can be recognised in SMILE-Maker tool - instruction scenario, adaptation scenario and laissez-faire scenario. With instruction scenario a user follows a general predefined path. Each information unit (map information collection, map idea generation, map idea selection and map idea implementation) is studied in a fixed order of instructional events - explanation, example, procedure, practice. Adaptation scenario create opportunities for user to identify her- or himself, for example, as a type of learning style, and than to go to the particular direction determined by user preferences. It is expected that different users have tendency to one of the instructional events - explanation, example, procedure, and practice. Laissez-faire scenario implicitly enables a user to construct own learning environment selecting different components and available instructional events in unique order. It is supposed that user will create own cognitive mapping method combining in an idiosyncratic manner the different SMILE-Maker components. The three scenarios might be distinguished according to a disjunctive theoretical framework consisting of two dimensions:

- Objectivism versus Constructivism educational paradigms
- Content-Treatment Interaction versus Aptitude-Treatment Interaction didactic approaches.

Within objectivism/constructivism paradigm an additional dimension of system control versus user control in human computer interaction can be recognised and preferential match versus remediation match to individual differences makes a part of content-treatment/aptitude treatment interaction.

The three scenarios have their either advantages or disadvantages. They dispose themselves on the continuum at the one extreme of which is laissez-faire scenario and at the another pole is instruction scenario. Adaptation scenario takes a middle position. Laissez-faire scenario is with predominantly constructivistic and aptitude-treatment interaction orientation with user locus of control, while instruction scenario has more objectivistic and content-treatment interaction direction, with system locus of control. Adaptation scenario is more objectivistic than constructivistic and it is more close to aptitude-treatment interaction than to content-treatment interaction. The control is located mostly on the system.

A need for designing a new versatile scenario within SMILE-Maker has appeared. The versatile scenario is based upon the *4-AID* instructional design model as an intelligent agent is assigned to take the very important role of facilitator when trying to accomplish a balance between objectivism and constructivism, content-treatment interaction and aptitude-treatment interaction, system control and user control, preferential match and remediation match.

4-AID Model

Generic Agent-based instructional design model consists of four sub-models: user (U), facilitator (F), content (C), and instructional events (IE) (Fig.1).

Learner sub-model is defined by *four* learning style components: activist (A), reflector (R), theorist (T) and pragmatist (P).[1] Learning style is a construct to refer the people preferences to the way of approaching to a learning task and how they behave in a learning environment. Honey and Mumford (Honey, Mumford 92) defined the learning styles of activist, reflector, theorist, and pragmatist in relation to the four stages of learning cycle - experiencing, reviewing, concluding and planning. Learner sub-model is a set of learning style components (LS = {A, R, T, P}) reflecting the behaviour of the user.

Instructional events are presented as explanation (E_{xp}), example (E_x), procedure (P_{ro}), and practice (P_{ra}). The explanation provides information what is the cognitive mapping approach and the rational behind it in the terms of facts, concepts, principles etc. Examples require some templates of different cognitive maps to be available. Procedure explains in the step-by-step format how to construct a sequence of maps - information collection map, idea generation map, idea selection map and idea implementation map. Practice is associated with opportunities to build up some skills in cognitive mapping technique. The large-scale complexity of the instructional approaches might be reduced to those *four* events: $IE=\{E_{xp}, E_x, P_{ro}, P_{ra}\}=\{IE_i \mid i \in N, i \in [1,4]\}$. They represent all variety of the treatments. Different combinations of events, according to the stylistic preferences, enhance the probability to design an effective and efficient instruction.

Content $C=\{M_{InP}, M_{IdG}, M_{IdS}, M_{IdI}\}$ is a set of *four* information units concerning a cognitive mapping strategy: map information collection (M_{InP}), map idea generation (M_{IdG}), map idea selection (M_{IdS}), and map idea implementation (M_{IdI}). Map information collection is purposed to assemble all available information in problem space. Map idea generation is aimed at generating as many problem solutions as possible . Map idea selection finds the best candidate among the alternatives. Map idea implementation operationalises a selected solution in the terms of sequence of events and activities.

[1] There is not enough room to go in details with discussion what is the relationship between learning styles, cognitive styles, cognitive controls, abilities, personal traits and why learning styles have been chosen as representative of individual differences of learner. Learning style is a psychological construct including itself abilities, cognitive controls, cognitive styles, personal traits and prior knowledge.

These sub-models are closely related to each other by the behaviour of the user who influences the behaviour of the system facilitator. Every user's action concerns the sequence of instructional events and content units depending on the user learning style. When the user takes an action $U_{actions} \in IE=\{IE_i \mid i \in N, i \in [1,4]\} \Rightarrow F_{action} \in$ {identifies LS_{ij}, $i,j \in N$ and $i,j \in [1,4]$} U {IE/IEi} it is in respect to the selecting of an instructional event that stimulated facilitator F to come in action and identify user's learning style and make suggestions to him/her for further IE sequence. User's action could be also in respect to content units, $U_{actions} \in C=(IU_i \mid i \in N, I \in [1,4]\} \Rightarrow$ $F_{action} \in$ {identifies LS_{ij}, $i,j \in N$ and $i,j \in [1,4]$} U {IU/IUi} that also stimulates facilitator F to come in action in a corresponding way.

Each learning style manifests the subject's preferences to one of the instructional events. The theorist is very likely to attached him- or herself to the explanation. Reflector should feel comfortable with example. Pragmatic should choose procedure, and activist should go directly to the practice. The four preferences could be reformulated as explanation type, example type, procedure type and practice type. This might provide more room for flexibility in the attempt to deal with the great diversity and complexity of the situations. Learning style is a valid psychological construct, but it is not fixed to a person, a situation or a task. One can be theorist in one situation, or reflector in another.

It is also assumed that the user will demonstrate some preferences to the different content units. The theorist likes information collection map, activist has strong bias to idea generation map, reflector is in his or her own with idea selection map, and pragmatist has a talent to idea implementation map. We could reformulate those tendencies as information collection, idea generation, idea selection and idea implementation preferences that opens the door for more flexibility as well as. The instructional events and the content are stable factors that can accumulate the learning styles. Or put it in another way, individual differences are defined in the terms of instructional events and the content.

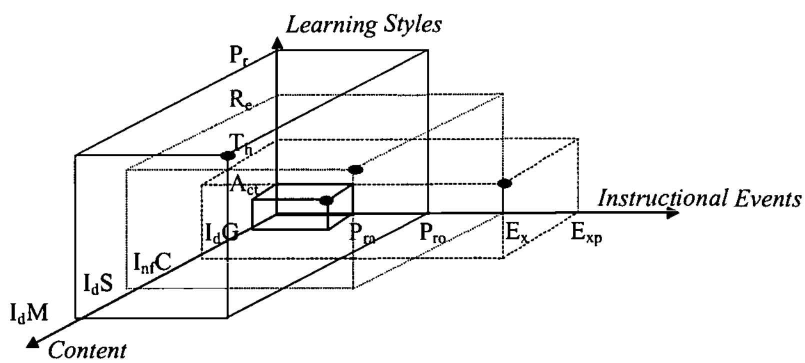

Figure 1: Agent-based Instructional Design Model (4-AID Model)

The behaviour of the facilitator, from the methodological point of view, is premised upon the assumption that everybody has a potential to be complex and flexible in style manifestations, and if it is so, the issue is just to provoke ("wake up") the personal capabilities potential. Facilitator adds flexibility as creating a new versatile style. It is done as it capitalises on the strong points and eliminating the pathologies of any particular style instead to adapt the instruction to the user's stylistic preferences (Stoyanov 97). The agent-based facilitator (F) is patterned by a Master Performer Concept Map (MPCM) which combines knowledge of content, instruction events and user's model. Facilitator monitors user recognising behaviour patterns before reacting on them. This is not only pattern retrieval, but also a pattern assembly. The facilitator identifies the gaps between Master Performer Concept Map ('what should be') and particular user's model ('what is') presented also in concept mapping format. What happens is that user behaviour is a stimulus for facilitator to trigger pattern retrieval on the master concept mapping. If the user demonstrates learning style preferences to explanation type, than the facilitator completes the processes spreading activation to example, procedure and practice. Or if the user demonstrates a pragmatic learning style and starts with procedure keep staying on that strategy, than the facilitator provides opportunities for practice, example and explanation. Thus, the user is free to select the first instructional event (constructivism, aptitude-treatment interaction, learner locus of control, preferential match). At the same time he or she is recommended to take benefits from the whole format containing the other instructional events as the order is not a substantial factor (objectivism, content-treatment interaction, system locus of control, remediation match).

The facilitator imposes the control on the meta-level as well. If the user is mostly affected by instruction scenario, than the facilitator will provide with some suggestions how to become more open to the opportunities for constructing own learning environment and own cognitive mapping method. If the user is determined only to play freely with the SMILE-Maker components, than the facilitator will pop up advises for more structured approach. The facilitator also might identify the user's preferences to the learning after an inventory or a questionnaire has been filled. It prescribes a particular learning path accompanied with some suggestions how to compensate the style's weaknesses.

The working cycle behind *4-AID* model involves user action in respect to the presented content and instructional events. Facilitator recognises and analyses user's behaviour and reacts to it with a specific proposal. This cycle could be repeated on every step in the user-system interaction (Fig.2).

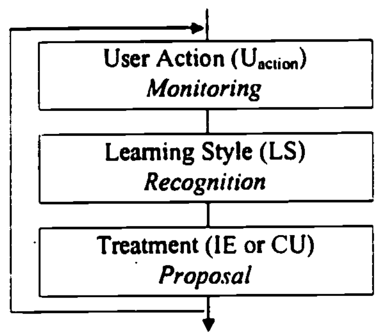

Figure 2: Concept map based diagnostic-treatment cycle of the agent-based facilitator

Facilitator possesses characteristics of a Monitor agent and Helper agent. As a monitor it is operating autonomously watching for a specific event to happen (gaps between Master Performer Concept Map and particular user model). As a helper it performs autonomously instructional or content actions in correspondence with the occurred events. After proposing the 'treatment' for the detected problem it performs automatically analysis of the situation and monitors for other evens. In other words, agent F is monitoring the behaviour of a particular user U_i and based on the concept map knowledge tries to identity user's U_i learning style $Ls_i = \{IE_{ij} \mid i,j \in N[1,4]\}$. The activation of facilitator F is calculated by: $F_{action} = D_{min} \{U_i , IE_{ij}\}$, where D_{min} is the minimum distance between the Master Performer Concept Map ('what should be' stage) and particular user model ('what

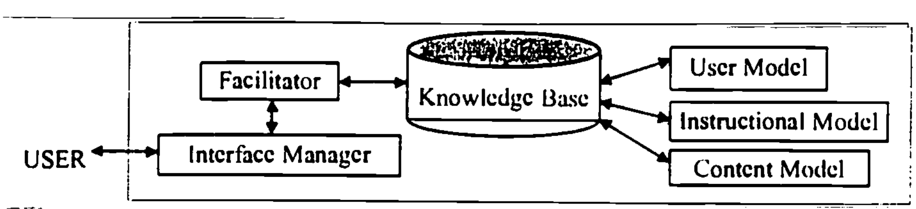

Figure 3: System Architecture

We refer to intelligent agents technology as a proper one to fulfil the tasks of the facilitator in this system. Agent technology enables instruction, user and content concepts to be directly represented in software. Proposed agent-based facilitator meets the dynamic and sophisticated requirement in respect to user modelling in the process of providing instructional material. With intelligent agents, instructional processes and user behaviour are modelled, so that if the processes change this can easily be reflected in the software by changing the interactions, or at most the combination of objects. The actual objects remain unchanged (Aroyo, De Diana, Dicheva 98). Agent technology is our best candidate because of the properties of agents that make them different from the other type of software entities. We present some of the relevant for the facilitator case internal agent properties (from the 'internal being' of agent) that determine their actions (Brenner, Zarnekow, Wittig 98). Although we describe a single agent system in the moment, we would like to leave the space open for employing new agents if necessary. In this respect, we are focusing on some of the external properties of agents that affect the interaction with other agents and human-agent interaction. *Autonomy* is one of the basic agents properties and presents the ability of the agent to follow its goals autonomously without interactions or commands from the environment. The *intelligence* of the agent is formed from three main components: internal knowledge base, reasoning capabilities based on the content of the KB (semantic networks, neural networks) and ability to *learn/adapt* to changes to the environment. Agent is software capable of *reacting* appropriately to influences or information from its environment. It reacts either by having internal sensor or by possessing internal model of the environment. Agent is also *proactive*, that means that it not only reacts to the environment, but also takes the initiative under specific circumstances. The fact that agent can be proactive and take the initiative requires a well defined set of sub-goals within the limits of the main *goal*. In respect to multi-agent systems agents also can *co-ordinate*, *co-operate* and *communicate* among each other and with other entities of the system. In this case we are interested in providing agent means for a single agent system and we are not concerned with their social abilities. Based on all this agent properties we believe that agent technology is the most appropriate one for implementing facilitator behaviour.

From an implementation point of view the semantic net has been considered as the most direct and natural representation of knowledge in SMILE-Maker. A semantic net is a knowledge representation scheme consisting of a directed graph in which concepts are represented as nodes, and relations between concepts are represented as links (Lehmann 92). The analogy of a semantic net to concept map is straightforward and has long been recognised. Semantic net can be used as a unifying representation for a single user model, content units and instructional events or for a group of users. In order to maintain the consistency of the semantic net, rules governing its description are needed. Two classes of rules can be defined: (1) graph-based rules for enforcing structural constrains, and (2) semantics-based rules for enforcing semantic constrains.

The operators on the semantic nets can be generally classified into two categories: semantic net manipulation operators and semantic net presentation operators. Semantic net manipulation operators include creation, copying, modification and deletion of nodes, contents, links and documents. Semantic net representation operators include the generation and display of hierarchical views and semantic net views, and filtered views (Wang, Ghaoui, Rada 97).

At that stage of the SMILE-Maker development, the 'intelligence' of the facilitator is restricted to the master performer model (expert model). The ambition to add 'more intelligence' in facilitator behaviour should be done soon when the 'Partner' component is going to be designed. The idea behind 'Partner' is to build a learning environment for creating and exchanging cognitive maps in group problem solving. The facilitator will take a responsibility on the behalf of the user for initiating a group session, for searching the best team composition, controlling group dynamic process in respect to rules of brainmapping methods (brainmapping pool, pin maps, mapping gallery etc.), brainmapping data- base storage and retrieval. It is expected as well as that the facilitator will 'learn' during this process and will adapt its behaviour according to that.

Abstract: The aim of the ECIC (European Continuous Improvement Circles) project is the development and promotion of methods of group learning in innovative organisations. In the course of the project, project members realized that the paper versions of the manual did not convey one of the basic principles of the ECIC methods, that is, a high degree of participation and user activity, in an adequate way. Therefore, an electronic version of the manual was developed which is more interactive than the paper version and which describes the situated character of the ECIC methodologies in a better way.

1. Introduction: The ECIC project

The aim of the ECIC project is to offer public and private organisations and structures a set of flexible organisational instruments, which contribute to enable them, not only to react upon approaching changes, but also to use the new options in a work for continuous improvements. The ECIC project has thus created a "toolkit" of methodologies, designed to support SMEs (small and medium enterprises) and SMOs (local and regional authorities, communities and other organisations) in their internal capacity to deal actively with development and innovation within a continuously changing context. A particular attention is given to the organisation's capacity to profit from developments in science and technology and specially the challenges and chances of IT as part of innovative solutions.

The central element in the ECIC toolkit is the CI-Circle (CIC) - a model for groupbased participatory learning, problem solving and change-management. It builds upon the rich experiences from study and research circles (Eriksson & Holmer 1991, Karlsson et al 1991), in combination with best practices from continuous improvements (CI) work in both the private and the public sectors. The CI circle relies on the dynamics of the group. The group motivates the members to put forward and examine developmental issues important for themselves as well as for the organisation. The search for relevant and valid information and the structuring of this information and the forming of a new understanding of the issues mentioned above are core activities. Traditional ways of acquiring information and for documentation do not always support these activities.

The circle methodology has so far with few exceptions mainly been established in the Scandinavian context, where it forms part of the general societal culture (Gustavsen 1980). The ECIC project tries to disseminate this imminently participatory methodology also in other European countries and contexts where other organisational traditions dominate.

A general dilemma when introducing participatory formats into more vertical organisational cultures, is how to do this in a non-vertical way. One of the consequences of using linear text can be that authors "dictate" the participation through very detailed instructions. This might lead to more activity but hardly more genuine participation. Added to the more general new and increased opportunities that ICT offers the CI-circles in their daily work, the use of inherently activating hypertexts in manuals etc. with a built-in participatory approach, might be an adequate answer to the above mentioned dilemma.

2. The interactive approach of the ECIC methodology and the electronic manual

The electronic version of the ECIC manual tries to inform about the basic ideas of the project in a way which is inspired by the ideas of participation and openness. The electronic manual is interactive and highly structured to support active forms of information processing with the users. These properties do not only reflect the general orientation of the ECIC project, they also reflect the results of recent research in the area of computer supported learning (Kafai & Resnick 1996, Jonassen 1996). There is evidence, that active involvement of users and intensive processing of the material is superior to the more traditional approach of merely presenting the material to the users. People who are interested in the ECIC methods can browse the system freely at their own speed and according to their own needs. They can explore the examples given in the program and try to find out the relationship of these example to the more abstract and theoretical discussions.

In this context, it is also important to make the structure and the interrelatedness of the material transparent (see Fig.1). Users should be able to look at the contents of the subject matter from different points of view. In the electronic ECIC manual there is another page compareable to Fig. 1 which shows the relationship between the study circle concept and the other methodologies from the point of view of the other methodologies - how they use the ideas of the study circle method in their concrete context.

Another important aspect of modern computer supported systems of instruction is the practical relevance and the situatedness of the systems. Real insights can only be gained by discussing theoretical results in the context of real and relevant situations. This is in accordance with the ECIC approach which assumes that the ECIC methodologies can easily be learned by using them in concrete situations. To support this, many practical examples were added to the electronic ECIC manual. In most cases, the methods from the ECIC toolkit are open for creative forms of application. The ultimate goal of the ECIC methodology is to enable the users to find their own solutions for the problems rather than strictly follow any guidelines. The ECIC electronic manual can give a first introduction into this kind of attitude because electronic documents convey a sense of flexibility and malleability much more than printed text which is always authoritative and fixed for eternity.

3. Description of the ECIC electronic manual

In the ECIC electronic manual we tried to implement the desirable properties of computer based educational systems described in the last section: showing the interrelatedness of the material, supporting the active involvement of the users, use of practical examples. In the following, we want to describe the details of this process. It is important to mention in this context, that the project members are active participants in the development of this system.

3.1. Interrelatedness of the material

The structure of the ECIC information system is a rather complex one because of the many interrelationships between the methodologies. In this sense, the topic of the ECIC project is probably an ill-structured domain (Nix & Spiro, 1990). Ill-structured domains consist at least partly of complex concepts with complex relationships between them. These concepts and their relationships cannot be defined easily because of their dynamic character. In this case, it sometimes helps to use diagrams to make difficult ideas more transparent and easier to understand. In the course of the project, the diagram which is shown by Fig. 1 was developed cooperatively, and it is still not "finished". Project members still work on it and change it. Because of its electronic form, this is easily possible. This diagram is a form of a "concept map". Concept mapping is a method to support learning processes. The presentation of concept maps is a more efficient way to communicate ideas in instructional situations (Kajstura et al 1998, Novak & Gowin 1984, Reader & Hammond 1994).

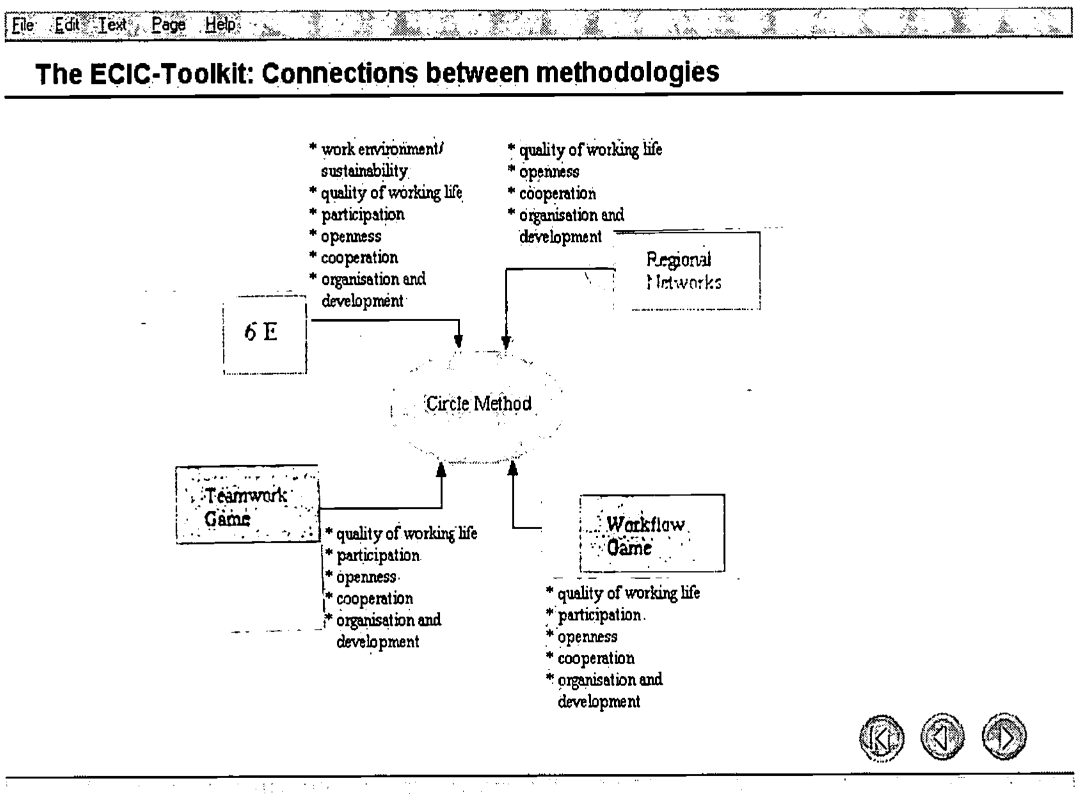

Fig. 1. One of the views of the structure and interrelations of the ECIC methodologies

3.2. Active involvement of the users

The teamwork game (Fig. 2), one of the methods of the ECIC toolkit, shows, that working and playing at the same time can develop a very interesting symbiosis for reaching a company's aim in a teamoriented way. The philosophy of the Teamwork Game is that ideally, working as a team everyone can profit from each other's knowledge and skills. Working in a team is a step towards becoming a learning organization and achieving a continuous stage of development. There are some basics for teamwork, e.g. "getting to know each other", "developing co-operation, interaction and communication skills", "becoming aquainted with group phenomena", "practicing anticipation, identifying and solving problems".

In the game different questions are put forward which concern the above mentioned teamwork disciplines. The players can choose, if they want to score points and someone wins with the highest score or if groupdynamical processes are prefered. The multimedia documentation of ECIC shows, by presenting some examples, how easy playing this game is. Moreover it should motivate people who are a part of an organization to play it. In order to play the full version you have to contact the authors responsible for the Teamwork Game at the Helsinki University of Technology. During the phase of implementation the question arose, if it is possible to learn teamwork-skills by using a computer program, sitting alone in front of the screen of a machine. But in our opinion teamwork-skills are not developed by the program itself.

The object of the computer program is predominatly to encourage people to reflect on their own situation in an organization. This accomplishes the goal of acquiring these skills because the game enables them to feel responsible for solving the problems or at least wish to participate and thus knowing that they are solvable. Using this multimedia documentation should shift the players focus on real situations and problems in an organization, which have to be dealt with in real life rather than by a computer game.

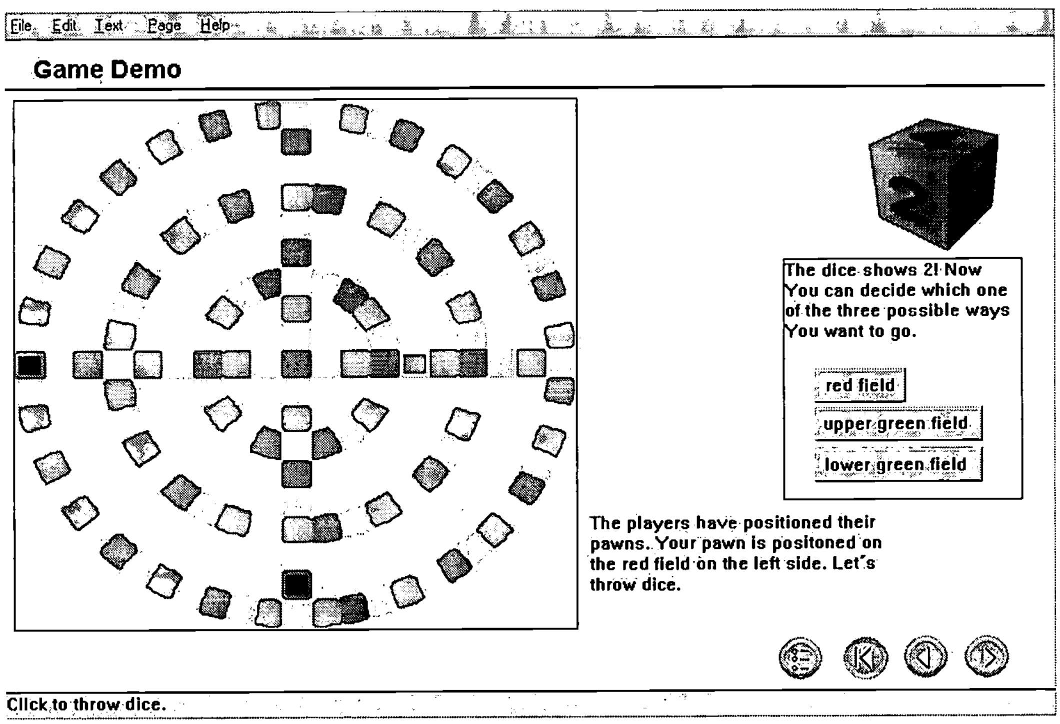

Fig. 2. The gameboard of the Teamwork Game

3.3. Use of practical examples

The study circle method is described at great detail in the electronic ECIC manual because it forms the basis for all the other methods in the ECIC toolkit. The basic idea of study circles is very simple. A group of people meets regularly to learn cooperatively. Nevertheless, it is very difficult to apply this method because much experience is necessary to make study circles work smoothly. Reality is often richer and more varied than any manual can anticipate. Therefore, it is often useful to show the application of theoretical principles in the context of a concrete example (Kommers et al 1996).

Early on in the project, a group of Spanish female entrepreneurs, who formed a study circle, complained that the manuals contained no practical examples showing ways how to implement this method successfully. Therefore, we included two concrete examples of study circles in the electronic ECIC manual. It is possible to look at the more theoretical guidelines for running study circles and at the concrete examples in parallel. There is a complex web of links between the guidelines and the examples. In this way, it is possible to jump from a specific guideline to a description of the concrete realization of this guideline and back again. This very rigorous use of the concrete examples in the electronic ECIC manual also showed deficiencies in the paper version of the manuals and led to a reformulation of these manuals.

4. Conclusion

The ECIC electronic manual differs fundamentally from the paper version. It can therefore provide specific support for people who are interested in the methods of the ECIC toolkit (e.g. study circles, teamwork game). It allows users to browse the material at their own convenience and motivates people to develop their own views about the ECIC methodologies. It supports a more active and critical approach of the users towards these methodologies. Furthermore, the interrelated character of the methods can be represented more detailed and from different points of view because interactivity is a main focus of the ECIC electronic manual. The electronic manual includes several practical examples which show the situated character of the various methods. In this way, the electronic version of the ECIC manual can motivate users to a more active, critical and participative behavior than the paper version. This is especially important because it corresponds to the main goals of the ECIC methodologies.

Abstract

The Virtual Reality Model Access Project (VR-MAP) plans to design and develop a prototype for the application of virtual reality technology to the enhancement of the social self-sufficiency of individuals with physical disabilities. VR-MAP will utilize Quick Time Virtual Reality software to create virtual experiences that can be computer accessed through a web page on the Internet or through provision of free CD-ROMs. The prototype created for this project will consist of' 2Osites placed into virtual environments. Using the computer mouse or an adaptive device, individuals will be able to "navigate" through the various environments or access "hot spots" indicating each photographic scene. Annotations about access issues will be provided for each site. Head-mounted displays (HMD), hardware similar to goggles with small computer screens, will be available to provide individuals with an immersive experience. A "head tracking" feature on the HMD allows the user to look at a scene by simply moving the head, and when realistic audio is added, the user can be provided with an experience that simulates reality. In order to use this prototype to assist individuals with physical disabilities integrate into society, certified therapeutic recreation specialists will be trained to access the technology. As hospital lengths of stay become shorter, helping clients ease back into society "virtually" might be a viable addition to traditional therapeutic approaches which seek to maximize self-sufficiency. By enhancing social self-sufficiency of individuals with physical disabilities, it is anticipated that carry-over into employment, independent living, family support, and economic independence will occur.

The promise of virtual reality (VR) technologies to provide powerful and unique educational and informational experiences is well known (Heim, 1998). Unfortunately, the public has often turned away from these technologies when expectations went unfulfilled due to hyperbole on the part of the media. Despite setbacks, however, use of VR is growing and will soon become commonplace, according to some researchers (Von Schweber, 1998). Currently, researchers at Metropolitan State College of Denver are using VR to assist individuals with physical disabilities become more self-sufficient. Specifically, VR software is being used to model various public buildings and other sites that individuals with disabilities may want to visit. Therapeutic recreation specialists then use the software with patients to allow them to virtually preview sites that they may later want to tour in person. This approach may build confidence in the clients and may lead to greater independence once they reenter society. By enhancing this social self-sufficiency, it is anticipated that carry-over will occur into employment, independent living, family support, and economic independence.

Need and Target Population

One in seven Americans, or 35 million individuals, have a disability severe enough to interfere with life's day-to-day activities (Scherer, 1996, p. 4). Of those individuals, 305,000 reside in the City of Denver, Colorado (United States Census Report, 1990). Providing avenues for these individuals to maximize their full inclusion and integration into varied aspects of community life is essential.

Statistics support the need for inclusive, transitional services. Figures indicate that over 1,500 youth with disabilities are preparing for transition into the community from the public schools (Denver Public Schools, 1994). Furthermore, clinical agencies (e.g., rehabilitation hospitals) in the Denver Metropolitan area have over 1,600 new patients each year (Denver Parks and Recreation Special Needs, 1996), with over 200 referred to community-based services annually (Denver Parks and Recreation Transition to Recreational Activities in the Community, 1994, 1995).

A number of factors have influenced the growing need for integration of individuals into society. With advanced medical care available, individuals with multiple and severe injuries are surviving traumatic accidents. Additionally, due to medical advances, individuals with chronic illness are living longer and demanding the services and resources to enhance their quality of life.

The national trend of hospital-based services toward managed care has also impacted the need for inclusive services. In rehabilitation, this managed care includes regulation and monitoring of patient lengths of stay and generally, shorter lengths of stay. As people transition back to the community in shorter amounts of time, providing the resources for their full inclusion and integration into society becomes paramount.

To assist individuals with disabilities transition back to their home environment from hospital settings, healthcare professionals (e.g., physician, physical therapist, recreation therapist, occupational therapist, speech pathologist, social worker, and case manager) work cooperatively to plan patient treatment. However, due to shorter lengths of hospital stays and the need to manage fiscal resources, patients are discharged quickly after achieving medical goals. While the individual with the disability has been medically stabilized, moving that person to successful independence in the community might not have been realized. This is especially true for individuals with severe disabilities that utilize adaptive equipment (e.g., manual and electric wheelchairs, and walkers). Not providing the opportunity to experience use of this equipment outside of the hospital facility prior to discharge is unfortunate for the consumer. In fact, people with disabilities have expressed their fear of injury in new environments (Scherer, 1996, p. 77), and research has suggested that 36% of the women with physical disabilities that were surveyed indicated unfamiliar surroundings as a barrier to social involvement (Boyd, Coyle & Shank, 1998).

To mitigate these negative influences requires new approaches. It is proposed that virtual reality environments be created to help transition individuals back into the community. Virtual reality integrates computer graphics, body tracking devices, visual displays, and other sensory input devices to immerse a participant in a computer-generated environment.

Thus, the Virtual Reality Model Accee Project (VR-MAP) will attempt to answer the following question: Can virtual reality technology be used effectively to assist persons with physical disabilities transition from clinical therapy into the community?

Review of Literature

Definitions

The concept of virtual reality as we know it today was developed during the late 1960s by researcher Myron Krueger (Heim, 1996). Since that time, VR has been so widely used that that it is nearly impossible to reach a consensus as to what the term really means. Here are a few examples:

"(VR) can be defined as a class of computer-controlled, multisensory communication technologies"--(Biocca, 1992, p. 5).

"Virtual reality is an alternate world filled with computer-generated images that respond to human movements. These simulated environments are usually visited with the aid of an expensive data suit which features stereoscopic video goggles and fiber optic data gloves" (Greenbaum, 1992, p. 58)

"Virtual reality is an event of entity that is real in effect but not in fact" (Heim, 1996, p. 16). This definition is expanded to list seven concepts that currently are guiding VR research. (1) Simulation--use of computer graphics and digital acoustic space sound to realistically represent an object, site, or other "reality"; (2) Interaction--ability for the user to interact with objects and other representations within the artificial world; (3) Artificiality--Extension of the term VR to include everything artificial; (4) Immersion--

ability to achieve the illusion of being submerged in the artificial reality. (5) Telepresence--ability to achieve robotic presence at another location; (6) Full-body immersion--use of data suits, gloves, goggles, and other items produce a wide range of sensory representations, including visual, aural, and tactile; and (7) Networked communication--ability to achieve all or some of the above concepts over a computer network.

Little of what today is called "virtual reality" includes use of all seven of these concepts. However, the technology is being used successfully today in numerous applications with various combinations of the seven elements.

Major applications of VR

In addition to specific health care applications, which this paper deals with in depth, VR is being used in a wide variety of other disciplines and industries. Although most use centers around information and education, the telepresence function is being used in areas where hazardous environments and remote locations prohibit use of humans to perform the tasks. Examples of widely disparate uses of VR today include:

--Use by NASA to train astronauts in International Space Station operations (Covault, 1998).

--Use by companies such as Motorola to train assembly line workers months before the lines are actually completed and operating (Minehan, 1996).

--Use by NASA to realistically portray the surface of Mars as a result of exploration by the Pathfinder mission (Jet Propulsion Laboratory, 1997).

--Use in theatrical productions to produce more complex, elaborate, and realistic sets (Reaney, 1996)

--Use in the courtroom as forms of evidence (Dunn, 1997)

Use of VR in Health Care

Virtual reality literature also discusses many benefits for patients. Rothbaum, Hodges and Kooper (1997) reduced the fear of heights in patients after virtual reality exposure therapy. Wilson, Foremen and Stanton (1997) demonstrated that spatial information acquired by physically disabled children from exploration of a virtual environment will transfer to a real-world equivalent environment; Ring (1998) has suggested that patients with disabilities can be trained with virtual reality to judge architectural barriers and tackle environmental obstacles. The researcher advocates the use of virtual reality as a significant assistive technology in the future (Ring, 1998). This clear support of technology deserves the opportunity for development, not just to provide individuals with simulated experiences but to use the technology for the integration of people with disabilities into society.

Methods

The Virtual Reality Model Access Project (VR-MAP) is designing and implementing a prototype for the application of virtual reality technology to enhance the social self-sufficiency of individuals with physical disabilities. As hospital lengths of stay become shorter for patients with physical disabilities, helping them ease back into society "virtually" may be a viable addition to traditional therapeutic approaches. It is hoped that this enhanced social self-sufficiency will carry-over into employment, independent living, family support, and economic independence.

The prototype created for this project will consist of VR models of 20 public sites in the Denver, Colorado area that individuals with disabilities may want to visit. Examples include libraries, airports, recreation centers, sports stadiums and arenas. In addition, other facilities frequently used, such as public transportation, will be represented virtually as well.

Most Effective and Appropriate Technology

Two technologies, Virtual Reality Modeling Language and Quick Time Virtual Reality, were considered to accomplish project objectives. Virtual Reality Modeling Language, or VRML, allows three dimensional structures to be produced from blueprints or from "scratch" by a graphic artist. Complex buildings, objects, and other elements will be produced using this technology.

The second technology considered was Quick Time Virtual Reality (QTVR), a product of Apple Computing. Instead of producing models from blueprints or photographs, this technology uses actual digitized photographs of existing structures. Multiple photographs are "stitched" together to produce a larger panorama. This panorama can then be traversed by the user in much the same way as VRML. QTVR also allows for stereoscopic head-mounted display, head tracking, and sound.

Both of these technologies were pilot tested by Dr. Clark Germann and Dr. Jane Kaufman Broida, and it was decided that QTVR was the desired and most effective technology to use in developing the VR-MAP prototype. QTVR can be viewed by users with Internet access on the World Wide Web or on a stand-alone computer using a CD-ROM. Use of the Web allows for broader and more convenient distribution of the prototype.

Two means are available for the user to "navigate" through the various scenes of buildings and other objects. First, various scenes are linked together so that the user can tour a building by using a series of mouse clicks. Second, a map of the area is available with "hot spots" indicating each photographic scene. By clicking on a particular spot on the map, the user is quickly transported to that location. Additional information concerning each scene is "annotated" into the margins. These annotations provide additional information useful to persons with disabilities, including location of handicapped parking, availability of electronic doors, and location of elevators, and accessible drinking fountains.

With additional hardware, users can become more "immersed" in the scene. The hardware consists of a head-mounted display (HMD) that is similar to goggles with small computer screens for each eye. The HMD allows for stereoscopic viewing of the scenes that add to the realistic effect. In addition, the HMD contains a "head tracker" that allows the user to look around a scene by simply moving the head. A third element that adds to the immersive experience is that of sound. Realistic audio, such as that of a door opening or a wheelchair lift rising, completes the effect.

This technology is the most effective and appropriate currently available considering the likely computer equipment and Internet connections available to the user with a disability. QTVR is also "cross-platform", meaning it can be used on PCs, Macintoshes and other types of computers. Virtual reality technologies change and improve rapidly and these would be closely monitored during the course of the project. If better technologies emerge, the the project would consider taking advantage of them.

Developed on Sound Conceptual Model & State-of–the-Art Technology

An extensive literature review was conducted into both the available virtual reality technologies (i.e., VRML and QTVR) and use of virtual reality for individuals with disabilities. This research resulted in the formation and implementation of a pilot project, funded through the Provost's Incentive Grants at Metropolitan State College of Denver (MSCD). The pilot project tested application of VRML and QTVR and began to use the technology for the integration of individuals with disabilities into the community. From the pilot project, it was determined that QTVR was the preferred technology and that using virtual reality did, indeed, positively impact the transition of individuals with disabilities into the community (Germann & Broida, 1998).

QTVR sites were researched and located on the Internet. No specific applications were found that were being used for previewing access to sites and locations for people with disabilities. However, many sites were found that provided a preview to physical environments for other purposes. For example, the Dallas Cowboys professional football team (http://www.cowboys.com) uses QTVR to allow prospective season ticket holders to view the playing field from a variety of locations with the stadium prior to making a decision. A number of home builders use QTVR to allow potential customers to walk through new houses before they are constructed. Volkswagen uses the technology to allow prospective buyers to inspect new models on the Internet prior to going to a dealership, and Purdue University provides a virtual tour of their campus (http://www.tech.purdue.edu/resources/map). It is interesting to note that providing three-dimensional experiences are becoming more common place in society. This is best evidenced by the provision of 3-D glasses in the August issue of National Geographic.

Development and Testing in Appropriate Environment

The virtual environment will attempt to simulate electronically the actual environment to the greatest degree possible. Technology today allows for the use of photo-realistic images within which the user can navigate to some degree. By using the mouse, the user can move left and right, up and down, and zoom in and out. In addition, these images may then be linked to other images located nearby. Development will also include a map of the facility or object and annotations containing information useful to persons with disabilities.

The technologies and techniques for allowing the individual with the disability to preview public buildings, recreation centers, and other locations prior to an actual visit will be developed and tested in therapeutic environments including rehabilitation centers and community-based settings. Agencies that have provided assurances of participation include Craig Hospital, University Hospital, M.S. Adult Day Enrichment Program, and the City of Denver Parks and Recreation Department: Special Needs Program. Dr. Dennis J. Matthews, medical director of the Rehabilitation Center of The Children's Hospital, has provided a letter of support for the project.

Herrick and Associates will be contracted to test the prototype with the target markets. They will conduct the alpha and beta testing with each user group, varying the applications. Further qualitative data will be gathered from a Consumer Advisory Council and the therapeutic recreation specialists using the prototype with their clients.

Assessment

The research question for this project is as follows: Can virtual reality technology be used effectively to assist persons with physical disabilities transition from clinical therapy into the community? To assist in answering this question, patients who have used VR-MAP will complete questionnaires and respond to interview questions. The questionnaire consists of 78 items in the following categories: background information and VR technology preference; importance of VR features; assessment of leisure participation.

Interview questions will be individual and site specific and will follow-up on questionnaire items.

Results

Since this is a work in progress, questionnaires and interview summaries had been neither completed or analyzed at the time of this writing. However, anecdotal evidence gathered in testing phases of the project has been positive.

1. The VR software was initially tested with one of the project coordinators Will Spence. Spence is a 21-year-old, student at Metropolitan State College of Denver who uses a wheel chair and is afflicted with multiple sclerosis. He indicated that the ability to virtually tour a public facility before going there in person could help reduce his anxiety of making such a trip.
2. The program was also shown to a group of 30 persons at the Rocky Mountain Multiple Sclerosis Center Adult Day Enrichment Program. Users responded very positively to the ability of VR-MAP to assist them in visiting sites throughout the Denver area. Specifically, users mentioned the usefulness of preparing them to navigate older sports stadiums that were not constructed with access features.
3. The program was demonstrated to 70 professional recreation therapists at the American Therapeutic Recreation Association 1998 Annual Conference. Reaction to the project was overwhelmingly enthusiastic and positive.

Discussion

The idea that patients can be assisted through the use of artificially created worlds is indeed seductive. Literature reviewed as a part of this project indicates that the technology and processes are advanced enough to meet the goals set forth. However, several factors need to be considered:

1. No literature could be found indicating that VR has been used before for the specific application of assisting individuals with disabilities successfully transition back into society. Thus, no predictions of success can be made at this point in the project.
2. Although it has been around in some form for many years, VR technology as defined by Heim is still in its infancy. As with much advanced technology, hardware, software, and techniques change rapidly. The technology chosen for this project--QTVR and VRML--could quickly become obsolete.
3. Thus, it is obvious that significantly more research is required before projects such as VR-MAP can become truly useful and helpful.

Abstract: The "lessons learned" project uses empirical methods to support quality improvement for several technology integration projects at the University of Calgary. Meeting this goal led to several challenges and discoveries that may be of interest to similar projects. The project began with the expectation that some of these challenges may be met with case-based performance support tools. Two case-based tools formed the technical backbone of the project. An instructional design evaluation agent (IDEA) guides users to select evaluation strategies. The IDEA tool is embedded in a case repository of evaluations and designs for instructional technologies (CREDIT). These two performance tools have supported around twenty development projects over an eighteen month period. Two major design hypotheses drove assessment of the tools. The first conjecture has implications for improved efficiency in organizational learning systems. Developing case studies for case-based learning systems represents an overhead in the development process and can be very time consuming. The CREDIT case-library is constructed from documents created during the normal development schedule. Our first conjecture was that storing these artifacts would present less time outlay for projects than building post-hoc case narratives. The second conjecture was that the information contained would be more representative of events and decisions than post-hoc case stories. Experimental use investigated the accessibility of "lessons learned" from repository artifacts. We expected that retrieving "lessons learned" from these artifacts would be difficult, but believed experimental use would clarify any special requirements for retrieval mechanisms and perhaps particular information designs that would improve users access to useful case elements.

Evaluation practice and the case model

Case-based repositories for learning and performance support represent a promising approach to some of the difficulties of organizational and workplace learning (Guzdial et al., 1997; Leake, 1996; McCalla et al., 1997). Case-based learning deals with some perceived limitations of conservative instructional design by, increasing engagement through collaborative group work, increasing authenticity through focusing on real experiences, supporting knowledge construction through reflective practices, and improving transfer through encouraging comparison between problems and cases (Leake, 1996). Case repositories have been successfully used in problem-based learning and some studies even show learners improve their argumentation skills particularly when the repository is linked to specific support for reflection (Kolodner et al., 1997). The case-based approach may be superior to less structured resource-based approaches. Learning in a problem-based situation from disordered materials, for example from the internet, requires considerable support (e.g., Dobson & McCracken, 1997). Structuring cases so that learners can predict length and outline headings, may supports learners' use of resource based information. Providing cases in a similar template is the simplest use of case-based learner support.

Workplace and organizational learning tasks are often relatively formalized and supported by pre-constructed forms and quality assurance manuals. In these situations, case-based approaches can benefit from more sophisticated fine-grained case-based reasoning techniques that automate some of the case-related processing (e.g., McCalla et al., 1997). These systems provide a kind of just-in-time support for learners who reach an impasse in their work. Accurate case comparison allows presentation of appropriately similar cases to help the learner overcome their immediate problems.

Learners using case-based systems without these support features have sometimes been limited by their problem solving skills. Even when cases are well designed and relevant to the target problem, learners may still need support to help them manually compare, match and synthesize cases (Guzdial et al., 1997). Although forms and quality manuals mirror a significant proportion of organizational effort, a lot of work in organizations cannot be easily systematized in this way. Computer-based courseware development and evaluation is one such areas. Although several projects have aimed for reliable computer based courseware production models (Dobson, Rada, Chen, Michailidis, & Ulloa, 1993; Kaye, 1993), the scope for improvement and variation seems not to have diminished. The processes of courseware design, implementation and evaluation can only partly be systematized. The current development practices in computer-based learning systems at the University of Calgary, suggested the need for attention to evaluation processes. Enhancing the implementation and understanding of evaluation practices for technology based learning systems is a high priority of the "lessons learned" project. Empirical methods of evaluation, particularly those intended to inform design, evidently form an important part of an organizational learning strategy.

Evaluation of technology-based learning is a good example of a domain undergoing constant improvement. This alone makes provision of case-based support difficult and makes fine-grained case-based reasoning support (e.g., McCalla et al., 1997) extremely difficult. Universities may provide the additional challenge that researchers from different disciplines have a variety of conceptions about evaluation. Conceptions of evaluation vary on the questions it can address, the stage of development when it is best implemented, the data to collect, and which methods of analysis are useful. Established research methods in each discipline loosely reflect assumptions about evaluation methods. Assumptions are also sometimes a reflection of dominant methods of assessment in non-technology based learning. In fact, several schools of research have developed methods that can be used, sometimes with modification, to support improvement of computer-based learning systems. Market researchers pioneered the focus group, economists created the cost-benefit and impact analyses, learning sciences created the phenomenographic study, program evaluators make extensive use of surveys, experimental psychologists have championed the controlled condition study, and computer scientists have developed several methods for assessing usability. The IDEA system is designed to support users in their selections from alternative evaluation approaches.

The IDEA and CREDIT systems are one part of the "lessons learned" project. Overall, the project has roles in communication, professional development and training. An important element of all parts of the project includes the improvement of learning system design through the use of empirical methods.

The instructional design evaluation agent (IDEA)

Evaluating technology integration systems can be thought of as a set of communication and documentation processes. Activities in group organizations often require a sequence or collection of documents to be written by individuals in special roles. The individuals who have those roles must also have required skills to adequately complete their tasks. This approach to modeling many collaborative work processes has been developed in several object oriented languages including AMIGO (Advanced Messaging in Group Organizations) and AME (Activity Modeling Environment). A review of these and other object-oriented group modeling languages can be found in (Hennessy & Benford, 1989). The AME and AMIGO languages were used to model several aspects of collaborative authoring of courseware in order to design a distributed support system for designers of computer-based learning (Dobson et al., 1993). The IDEA system uses a variation of these object oriented models as a simple visual language to demonstrate evaluation approaches supported by the agent. The diagrams are also used as an interface to descriptive materials, document templates and fully implemented cases stored in a repository.

The agent currently includes descriptions of twelve evaluation protocols. Each is a condensation of research from several sources that emphasizes the practical steps and skills needed to implement a study with the protocol. The methods come from many different disciplines of research and evaluation. Some, for example, are motivated by conversation theory (Pask, 1984), including a conversational breakdown protocol (Laurillard, 1987) that has been successfully used in evaluating distance learning environments (Dobson & McCracken, 1996). Other protocols are distinctly qualitative, including a "connoisseur method" that draws on "Arts-based" approaches to evaluation (Eisner, 1991) and a version of the "phenomenographic" approach that draws on

Marton's work (e.g., Lybeck, Marton, Strömdahl, & Tullberg, 1988). Methods developed for marketing, such as the "focus group" protocol (Flores & Alonso, 1995; Krueger, 1994) can be useful for establishing and elaborating the views of people involved in technology integration. The focus group protocol is included in the IDEA tool.

The IDEA tool provides users with templates for many of the documents typically used in each of the protocols. All empirical projects that use human subjects, for example, have certain ethical obligations to the university . These obligations are dealt with in a proposal to an ethics committee. Projects must describe the proposed experiment and provide a copy of any instruments used. Provisions for getting the informed consent of all subjects and for describing the nature of the study are included in a template proposal to the ethics committee. Since most of the study approaches use human subjects, the template forms an important component of the IDEA tool. As completed documents, such as the ethics proposals are generated, they are intended to be stored in the case-repository.

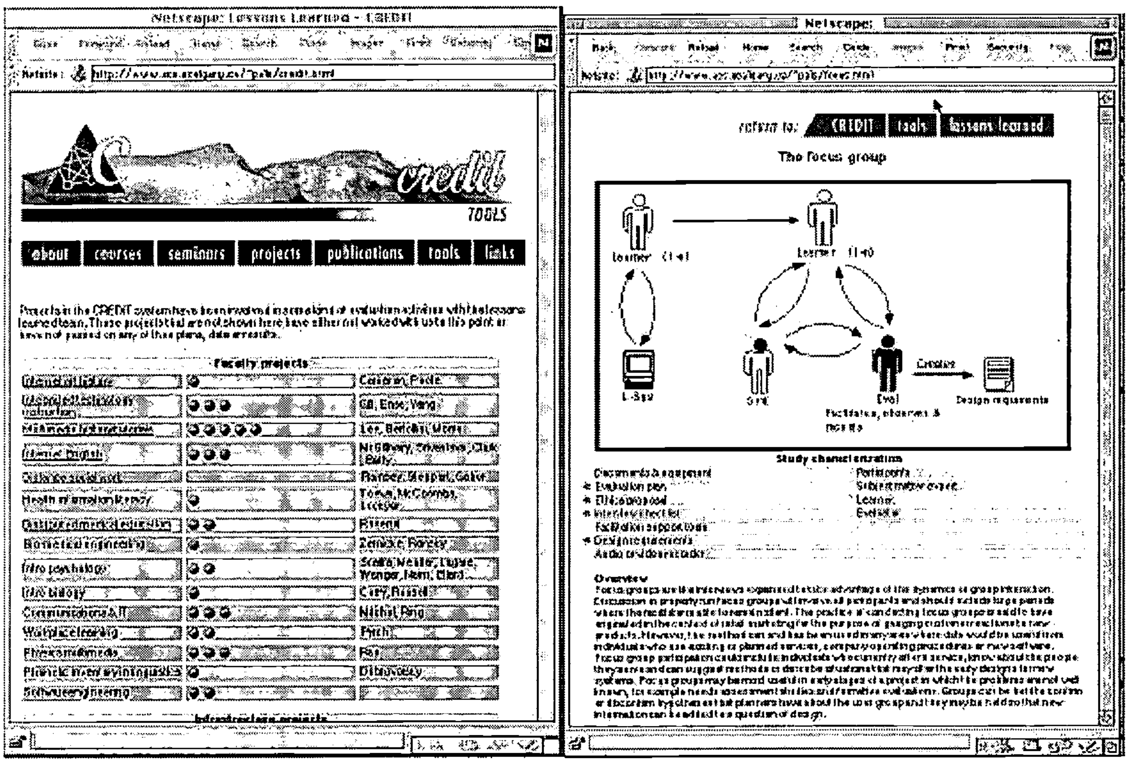

Figure 1: Left, the CREDIT tool, showing tabular view of project progress, and right, a page from IDEA showing description of objects, roles & documents in the focus group evaluation protocol.

The initial design for IDEA included a plan to elaborate several heuristic-conditional rules that when implemented, would guide project directors to select evaluation strategies best suited to their project needs. Several guiding principles were considered. For example, many of the qualitative approaches, including the "phenomenographic interview" can only produce useful data once the development has reached a suitable stage. Other evaluation strategies such as the "connoisseur" approach can determine that the courseware is ready for these other protocols. Before these qualitative studies are really useful, the evaluators need to know that users will have no special navigation or other interface related problems. These qualitative studies can capture learners' subtle misconceptions about a topic, but not if subjects are consumed by difficulties operating the software.

Access to the development team may also affect selection of appropriate methods. Many integration projects choose to buy ready-developed courseware, rather than develop their own. Evaluation methods designed to provide information for improving product design, may be less valuable in these cases than approaches designed to compare competitive products. These and several other heuristic rules have been tracked during face-to-face interactions with the development projects in the university program.

A case-based repository for evaluation & design of instructional technologies (CREDIT).

Most users of the CREDIT and IDEA systems are engaged in a technology development project and are beginning to plan an evaluation study. Users can benefit from reading about similar projects that have gained by failure-driven or success-driven learning. Users benefit, more directly, from seeing worked examples of documents that they are responsible for writing. Projects that have implemented the same kind of study, but perhaps in a different topic discipline, are likely to contain useful information that can be quite easily transferred to the user's particular needs.

At least two factors make it difficult to implement all desirable case-based functionality. There are no pre-designed forms for evaluation of technology-based learning, and the practice of evaluation in this field is constantly under revision. Lack of a consistent methods of technology evaluation leads to difficulties in indexing cases. Only loosely structured cases would normally be possible for similar domains, and this limits the sophistication of possible case-based reasoning approaches.

The CREDIT tool uses a practical and potentially valuable indexing system that depends almost solely on normal project activities. Project development requires several stages of effort that are often represented directly by a document. Examples include the project proposal, a description of course objectives, the ethics committee evaluation proposal, meeting minutes, instruments used in evaluation, interim and year-end reports, external audits and self assessments. The CREDIT architecture makes names of these documents stand for the case outline in the case repository. When a case is retrieved in the simplest of retrieval strategies, all the documents relating to a project are presented.

A case-library populated with this historical record of decisions, hypotheses, discoveries, timing, researching and iterative outcomes holds many, if not most, of the "lessons learned" during a project's life time. It is possible that these results will be more difficult to retrieve from such a repository than from a case library built from hand crafted cases. One of our design conjectures, however, is that this approach may support two major advantages over other case-based approaches, (1) the cost and consequent likelihood of cases being created, and (2) the accuracy of the record.

The combined CREDIT and IDEA tools are designed to be used by two major groups of users. The more obvious group are project developers actively working on evaluations of their computer-based learning. These users can browse any of the pages without guidance, retrieving the materials as simple resource-based support. Beyond browsing, the evaluation agent provides direction to appropriate evaluation models, templates and cases. The IDEA tool is designed to prioritize information for the user based on knowledge about the relevance of the case. Active project workers may also see which documents have been submitted by other projects in the same group, although they are not able to read those documents unless the owners have made the pages public.

An evaluation support team are less obvious users of CREDIT and IDEA, however the advantages for management and organization for this group are quite considerable. A tabular view of project progress is based on our process-oriented approach to evaluation (Dobson, McCracken, Hunter, Gaines, & Wenger, 1996). Projects generally pass through several stages of development before completion. The exact sequence of milestones may differ between projects and may or may not be accompanied by a formal document. A tabular view of documents that have been completed gives quick progress information on each project. Projects faced with immediate document needs can be quickly referred to the author of a similar document in another project.

Conclusions

During eighteen months of preliminary research, development and implementation the project has produced several valuable insights that might be of interest to others considering similar projects. These insights will partly guide the next stages of our work in supporting technology-based learning initiatives in the University of Calgary.

Tracking the value of heuristic-conditional rules during our interaction with projects revealed an overarching factor important in methodology selection that had not been previously considered. Different departments and faculties often have experience with their own preferred research methods. Unless the particular discipline's research methods are difficult to apply to technology based learning (say Historians), this factor influenced preference for study types more than any other. Early indications suggest that researchers without applicable research methods tend to think first of survey methods like those found in "sociological" and "program evaluation" disciplines.

The current program of around twenty technology development projects resulted from competitive bids to a central funding agency. The period and scale of funding, was in the majority of cases, inadequate to take a project from design to completion. This dependency on future funding appears to have exaggerated certain roles for our "lessons learned" project. More than half of the twenty projects requested support and cooperation at the proposal development stage. Many of the projects have been slow to make their evaluation plans available in the semi-public CREDIT environment, although a handful of projects have regularly met to discuss their project and have kept and submitted meeting notes each week. Instruments and decisions have been carefully noted and the documents produced by this small group of projects will be used to determine the difficulty of retrieving "lessons" from these files.

The IDEA tool has been used as a resource centre for evaluation planning. Again, more than half of the twenty projects have made extended use of the evaluation planning guides and templates. General reflections on the value of these materials suggest that they are not yet in a form suitable for projects to use without additional face-to-face support. Early indications suggest these evaluation guidelines represent a profound shift of thinking from what instructors and developers understand about evaluation methods. Producing the on-line support helped condense the descriptions of protocols, but if the tools are to be used as independent support, they will need further development.

The "lessons learned" project will continue to work with the twenty or so projects in the program and will continue to develop the IDEA and CREDIT tools. After the experience of the initial eighteen months, we will likely spend more time in face-to-face interaction that we had originally planned.

Continuous Improvement of Workflow Models Using an Explorative Learning Environment

Heimo H. Adelsberger, Frank X. Körner, Jan M. Pawlowski
Information Systems for Production and Operations Management
University of Essen, Germany.
{h.adelsberger|koerner|jan.pawlowski}@wi-inf.uni-essen.de

Abstract: Facing rapidly changing market conditions new requirements for information and communication technologies have arisen in the last years. This paper presents a new approach to integrate computer supported learning environments and workflow management systems to optimize workflows. The first step is the integration of learning processes into workflow models. This enables an easy development of explorative learning environments, particularly simulation games which are used to train users on basic and advanced levels. Solutions developed by the users are evaluated and transformed into process models which might improve current processes. The presented integration approach offers important synergy effects: a substantial improvement of the individual educational level, a new concept of employee participation, and an essential increase of continuous process improvement.

1 Introduction

The increasing relevance of flexibility and adaptability to rapidly changing market conditions leads to distinctive requirements for information and communication technology as well as for organizational concepts. In this paper we focus on the integration of Computer Supported Learning Environments (CSLE) and Workflow Management Systems (WfMS). Both are influenced by the requirements of continuous changes.

On the one hand, WfMS are affected because these systems manage and control the processes of value creation. Obviously, these processes have to be immediately adjusted according to required changes. On the other hand, it is essential to work with well-educated employees who are able to carry out both the current and modified processes. For this reason CSLE are so important. In previous work we have demonstrated the need of an integration of WfMS and CSLE (Adelsberger, Körner, Pawlowski, 98a, Adelsberger, Körner, Pawlowski, 98b). In this paper we introduce the idea of an integrative approach using simulation games for the optimization of adaptive workflows. We demonstrate the particular suitability of an explorative learning environment.

During the normal use of WfMS improvements are detected and realized during explicit (internal or external) projects. This procedure corresponds to adaptable processes or workflows in contrast to a continuous improvement. Integrating an explorative CSLE into the WfMS enables to continuously realize hidden optimization potentials exposed during the learning process using the real information system and real data. Thus, the integration approach offers two important advantages: an substantial improvement of the individual educational level and an essential increase of continuous process improvement.

After introducing the basics of WfMS and CSLE we present our approach of an integrated design of business and learning processes. Finally we describe the construction of an explorative CSLE within a WfMS and the potentials concerning the continuous optimization of workflow models.

2 Workflow Management Systems

The use of Workflow Management Systems (WfMS) improves the effectiveness of internal and external process management by realizing the process orientation, supported by modern information and communication technologies. The *Workflow Management Coalition (WfMC)* (Workflow Management Coalition, 96) defines a *WfMS* as "a system that defines, creates and manages the execution of workflows through the use of software, running on one or more workflow engines, which is able to interpret the process definition, interact with workflow participants and, where required, invoke the use of IT tools and applications."

The presentation of tasks, the respective data, and applications to the users avoids competence conflicts and wrong document routing, and reduces the time to get into the new task. It is one of the important advantages of a WfMS that its Run-time behavior exactly matches the defined (and 'optimized') process models. Furthermore existing applications and information systems might be integrated into a WfMS. Among other things, this results in a standardized user interface and the avoidance of redundancies (Becker, Vogler, Österle, 98).

According to the Basic Model (Workflow Management Coalition, 96) the use of WfMS covers two main phases – the Build-time and the Run-time. Within the Build-time, i.e. the creation of the respective workflow models, different workflow types are created, checked, and administrated. During the Run-time control functions execute the workflows by interpreting these Build-time definitions and models. Accordingly, the models cover the following fundamental perspectives (Bussler, Jablonski, 96, Jablonski, 95):

Workflow execution means to carry out specific tasks according to the modeled manner. In this sense *Workflow Definitions* answer the question "What has to be done?" by defining (Build-time) re-usable workflow types. For the execution (Run-time) workflow instances are created. The definition of these types is hierarchical; elementary workflows (the lowest level) refer to Workflow Applications (see below).

To provide the right data at the right time, *Data and Data Flow Definitions* represent the data exchange between the workflows on all hierarchic levels. Control data and workflow relevant production data influence the workflow control and the selection of roles. In contrast, production data do not have any influence, as these are not managed by the WfMS.

Control Flow Definitions determine the order of workflows in a range between absolutely fixed to undetermined or unknown. (Khoshafian, Buckiewicz, 95) describe a corresponding workflow classification. Traditional programming constructs are used and combined to specify the control flows.

The *Workflow Application Definitions* specify interfaces and parameters to handle automated and manual applications. The functions and tasks themselves are not implemented in the WfMS but invoked by the WfMS.

Workflow instances are assigned to actors (human beings, machines, or information systems). Actors are described by resources with certain skills and competencies, influencing their participation in a role. The *Organization Definition* refers to the question "Who executes the workflow?" by evaluating the members of the required role.

All terminated, interrupted, and active workflow instances are recorded in the *Audit Trail*. Those data might be used to identify the actor of a specific operation, for recovery, and for the revision, analysis, and re-engineering.

To meet the increasing need for flexibility (Allweyer, Scheer, 95) formulated specific requirements for the creation of adaptive business processes to enable continuous process improvements without realizing a long-term and expensive Business Process Re-engineering project. They formulated requirements for adaptive business processes – requirements which are fundamentally fulfilled by WfMS.

The Build-time definitions (see above) and the recorded Run-time data (Audit Trail) offer a large potential to continuously adapt the workflows to changing needs. Nevertheless these potentials are seldom used for a continuous improvement. On the one hand, this might result from missing manpower or missing skills, because workflow models normally are created by external consultants. On the other hand, the users, apart from the traditional suggestion scheme, are not included in the improvement process.

By integrating explorative learning environments into WfMS we obtain a better participation of the users. Thus it is possible to expose and use hidden optimization potentials for a continuous workflow improvement.

3 Learning Environments

Due to the enormous amount of publications from a variety of research fields and perspectives the basic terminology of Computer Supported Learning Environments (CSLE) differs considerably.

Computer Assisted Learning (CAL) denotes the conceptual framework and methodologies as a base for learning, assisted by computers. Although the exact meaning might be interpreted slightly different several terms are used synonymously, e.g., Computer Supported Learning, Computer Assisted Instruction, Computer Based Education. Therefore, this term is the generalization of any concept and method of learning using information technologies.

A *Computer Supported Learning Environment (CSLE)* denotes the realization of CAL and its concepts and methods through information systems. The term CSLE therefore is a generalization for a wide range of instances and classes of instances of educational information systems (Adelsberger, Körner, Pawlowski, 98b).

According to (Kalkbrenner, 96) Computer Supported Learning Environments might be classified into five classes:

Drill & Practice Systems are based on the behavioristic learning approach. Learning contents are gradually presented, followed by repeated training assignments. Still being used on a regular base in practice this approach mainly serves for repeating or enhancing familiar learning contents.

Intelligent Tutoring Systems denote systems transferring knowledge specifically adapted to the level of an individual user. The human teacher is substituted by a computerized tutorial function guiding the learning process, answering questions, or evaluating the user.

Hypermedia Systems are used for the presentation of learning contents. Historically developed as a means for structuring text based documents by links and relations, recent developments integrate complex media formats, e.g., audio, video, and graphical elements.

Cognitive tools are "both mental and cognitive devices that support guide, and extend the thinking processes of learners." (Derry, 90) Therefore those systems support the learner's cognitive processes.

Simulation games provide a specific task or problem to the learner and a *micro world* for independently exploring and solving this task. The goal of the learning process is to acquire complex and interconnected learning contents. The teacher and/or the systems supports the user by coaching the learning process.

This paper deals with complex learning contents: business processes. Owing to its suitability for acquiring complex learning contents and complex thinking we concentrate on simulation games (Graf, 92, Schulmeister, 97). Furthermore our approach using the integrative development of WfMS and CSLE is particularly suitable for a cost effective and straightforward development of simulation games.

4 Integration of Business and Learning Processes

The following section is divided into two parts. First of all we describe the utilization of WfMS for the development of CSLE. Especially for the development of a simulation game the access to existing process models is essential. Therefore it is a prerequisite for the integration to add learning processes as an equivalent of business processes to the workflow models.

The second part deals with the generation of a simulation game as an example of an explorative learning environment. As a result of using the simulation game new and/or alternative solutions to the given task might be determined. These solutions contribute to the optimization of existing processes. The results are transformed into a workflow model which serves as a proposition for an improved process model. After that the proposition is evaluated and, in case of a positive evaluation, the process model will be updated.

4.1 Integration of Learning Processes into Workflow Models

Traditional WfMS concentrate on the co-ordination of workflows directly referring to the production of goods or services. They are mainly limited to the core business of the enterprise. Although learning processes, i.e. the acquisition of a specific skill, are a prerequisite for the successful execution and realization of workflows, process models rarely cover this important aspect. As a consequence the planning of basic as well as advanced training is mostly independent of the current demand of adequately skilled employees. Our integrated approach will eliminate this weakness, connecting learning and business processes in a common model.

Furthermore teaching and learning processes have to be integrated into existing models as a prerequisite for generating a learning environment to utilize existing applications, models, and data. A simplified example of those processes is shown in (Fig. 1) and (Fig. 2). Those models clarify the general steps of learning/teaching processes and the interfaces between components of CLSE and WfMS.

As a result of this integration the learner as well as the developer are enabled to work in their usual working environment (WfMS, applications). They can easily access the existing applications, models, and components.

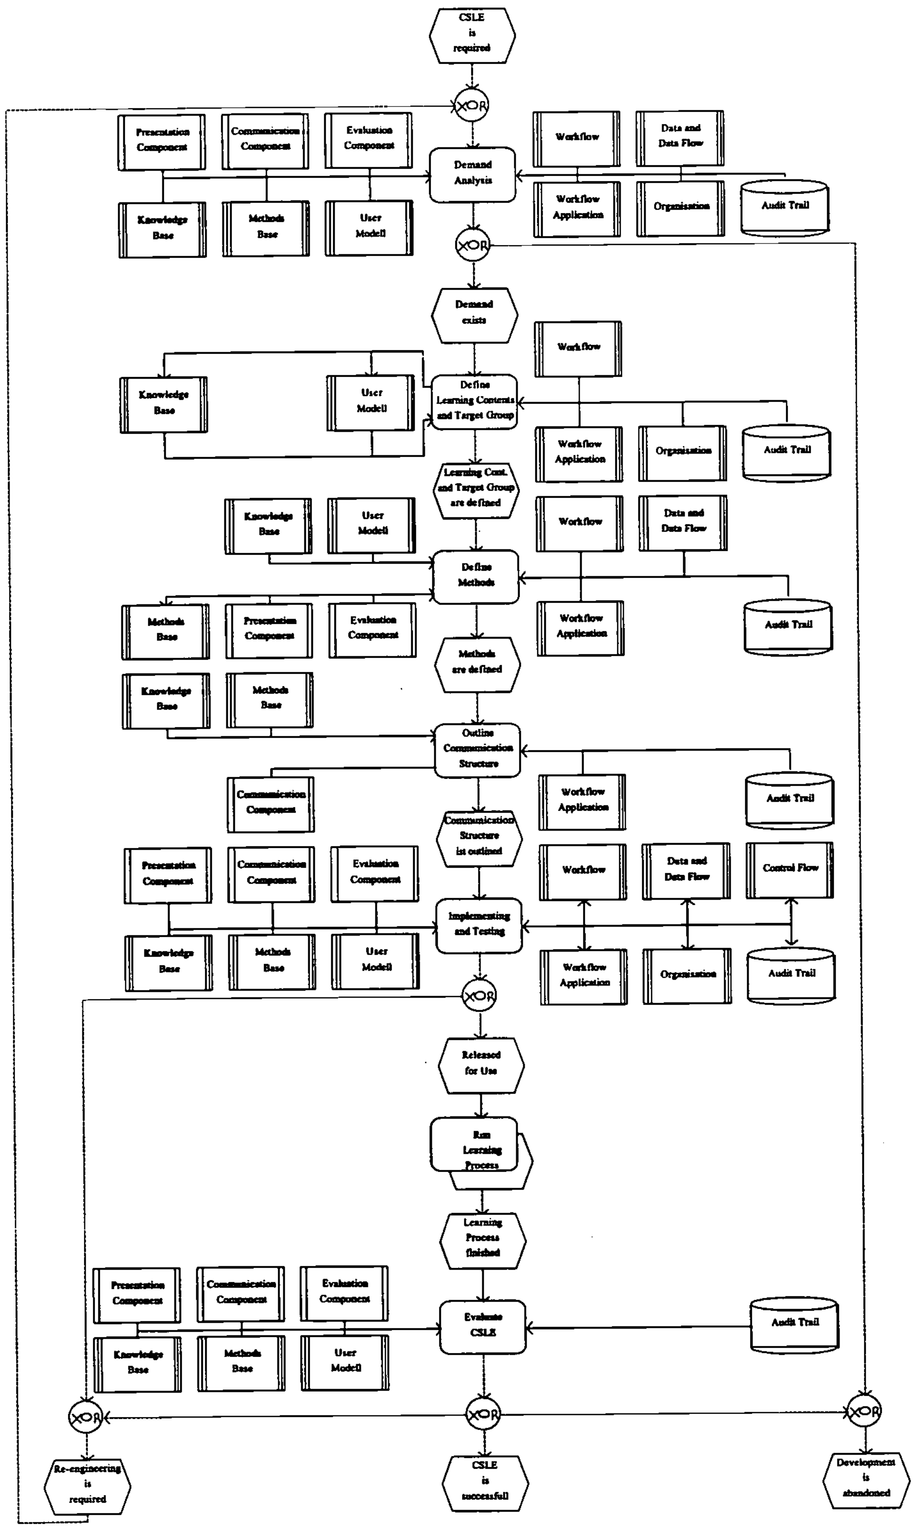

Fig. 1: Teaching Process

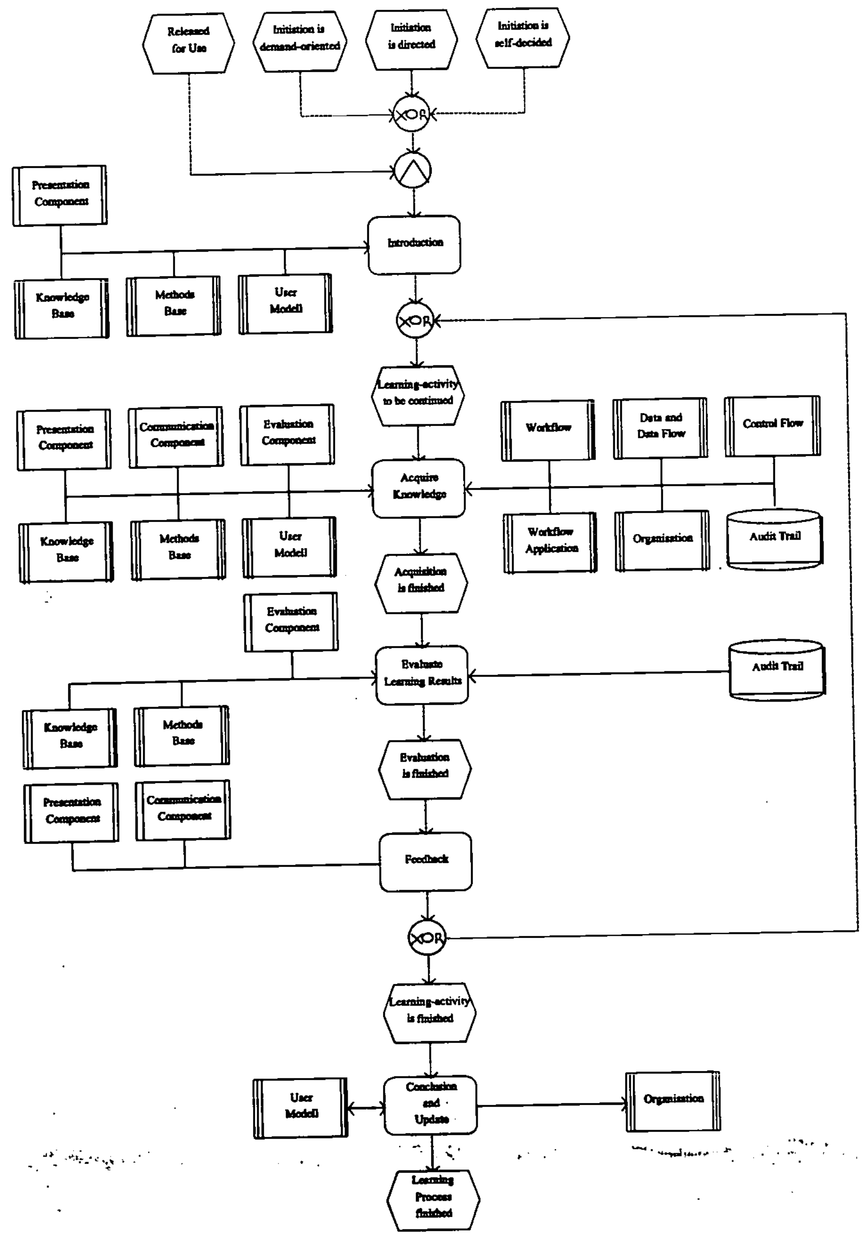

Fig. 2: Learning Process

4.2 **Optimization of Workflow Models using an Explorative Learning Environment**

This section deals with the generating of an explorative learning environment based on WfMS components. Furthermore we present ways how learning processes may contribute to the optimization of workflow models.

The *learning content* is the mastering of a specified task, available in the form of process models. Corporate processes are rather complex because of the multitude of participants, the problem structures, and the adequate use of several applications. Thus, a simulation game as an explorative learning method, is appropriate.

On the basis of the integrated design the development of simulation games – based on the WfMS – is possible without large expenditure. The learning environment consists of all applications, components, and the functionality of the real system. Obviously the learning environment cannot use sensitive data to ensure that the daily business is not influenced. The real history data recorded the Audit Trail are used as real but insensitive data for the learning environment.

The learner learns within a well-defined micro world. It consists of one or more sub-processes extracted from the process model. The interfaces to the related processes outside the micro world have to be defined. The corresponding data are exchanged with the related processes, either extracted from history data, or automatically calculated. Alternatively, an administrator or coach has to make available the interface data during Run-time.

Furthermore, several constraints have to be cancelled to enlarge the learner's scope. These constraints are defined/modeled in the real process model as control flows, data flows, or workflow applications. If the learner violates unavoidable rules, e.g., legal regulations, the learning environment must point to the consequences of this acting. The cancellation of constraints enlarges the scope of the learner, because his actions are not restricted by existing process definitions and the prescribed applications. The learner himself decides about the tools, applications, and manner to solve the problem.

During the learning process the learner produces results, i.e. data. These have to be evaluated making use of historic data to determine the learning success. Certain deviations in the results should be allowed within certain total tolerances. The learner can access the WfMS as specified in the model of the learning process. Thus, the actions and the use of available applications within the micro world are approximately unrestricted. The business processes and the learning process are both recorded in the audit trail.

The learning results have to be evaluated regarding several aspects: At first it has to be discovered whether the right data types have been modified. Furthermore the modified and generated data values must be within the total tolerances. If the realized results vary from the historic data because of significant process modifications the evaluation has to be checked by a human teacher. In addition individual evaluation criteria, e.g., the duration of the learning process compared to the real duration of the task have to be taken into account.

Besides, apart from the learner's evaluation, the recorded actions from the beginning to the problem solving are analyzed. This analysis serves as a basis for the transformation of the existing model to a modified one. During the transformation filtering (Fig. 4) redundant and non-productive learning steps are eliminated. The remaining steps are used to create the modified process model. The realized steps are modeled as workflows, the order of the steps influence the new control flows, and the actors involved are included in the organization definition. Afterwards the modified model is evaluated by use of process controlling ratios. In case the modified process should be better than the existing process an optimized model is suggested. The suggestion will be checked and, if positive, serves as a basis for the optimization process to update the actual process model.

In the following figures (Fig. 3) and (Fig. 4) the traditional isolated life-cycles of WfMS and CSLE are compared to the life-cycle of the integrated approach.

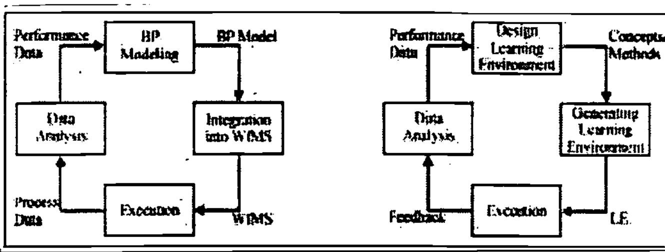

Fig. 3: **Isolated life-cycles of WfMS and CSLE**

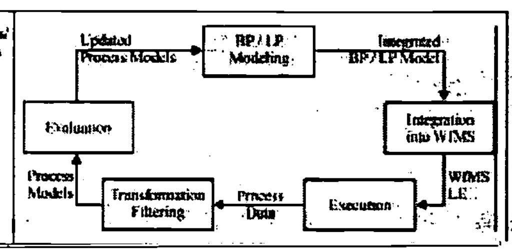

Fig. 4: **Integrated life-cycle of WfMS and CSLE**

The integrated approach offers substantial advantages compared to the isolated approach: The conception and implementation especially of explorative learning environments is not very complex. In addition the planning of the basic and advanced training is considerably simplified. Furthermore, the integrated approach may increase the motivation of the learners, because those learning processes that have been successfully completed may cause respective modifications and improvements in the daily business processes. Thus, there is the possibility that the employees actively and creatively take part in the design of their working environment and business processes.

Compared with the traditional suggestion scheme the integrated approach does not demand any additional work on behalf of the employees, because the creation of suggestions is integrated in the learning process. Besides the procedures of unprejudiced and neutral employees might be more creative than the procedures of employees having performed the processes for a long time.

5 Summary

In this contribution we described the integration of CSLE and WfMS using a simulation game for the optimization of workflow models. As a first step we presented an integrated modeling of business and learning processes. This integrated approach significantly decreases the effort to develop learning environments. As an additional benefit the planning of basic and advanced training is .

We presented the application of this approach, using a simulation game which can be easily developed basing on existing processes, applications, and training data of a WfMS. On the one hand, this method is particularly suitable for learning complex problems, e.g., the acquisition of knowledge concerning business processes. On the other hand, we achieved synergy effects for the optimization of business process and for motivational aspects. Even in the learning phase employees are involved in planning and improving business processes as well as their working environment. Compared to the traditional suggestion scheme this method of active participation will improve both the employee motivation and effectiveness.

The presented approach is implemented at the University of Essen as a prototype. During the next phase of our research activities we will evaluate the results by an empirical study. Furthermore we will investigate this approach from different perspectives, using varying learning methods and learning contents. This investigation will provide in-depths results concerning the suitability of the integrative development for specific requirements and fields of applications.

Web Integration in Courses: Which Factors Significantly Motivate Faculty?

Tawni Hunt Ferrarini, Economics, Northern Michigan University, USA (tferrari@nmu.edu)

Sandra Poindexter, Business-CIS, Northern Michigan University, USA (spoindex@nmu.edu)

Abstract: University and college administrators intensely push for increased Web integration into lecture-based and other types of academic courses. As students' competencies with Internet usage increase they, too, demand educators to revise their educational methods. Some faculty members do move forward pedagogically in the age of high technology. However, some do not. Hence pedagogical and technological gaps between traditional and multi-media teaching methods appear. The general lauding of the Internet's educational benefits comes quickly, perhaps too quickly for the comfort of some in academe.

What motivates some faculty to use the Web to deliver and to display course materials as well as to provide lectures? Or conversely, what inhibits other faculty from doing so? By obtaining analyzed quantitative and qualitative data from faculty members from all disciplines this paper starts a cross-disciplinary study intended to answer these questions.

Introduction

Educators first utilized the Internet to communicate with fellow scholars and to gain access to remote research centers. Recently interest in the Internet and the World Wide Web (Web) becomes intensely more popular as use increases among individuals living in households and operating businesses. Riding on the coat tails of a non-academic wave of the Internet, educational applications can capitalize on the tools afforded by the Internet.

The Internet facilitates learning while increasing the number of educational opportunities for students. Introduced to the Internet in grades K-12, collegiate learners naturally utilize the Web and other Internet tools. This interest and proficiency coupled with the increase in computer ownership and access by students, means that the Internet can become a powerful educational tool in higher education. While the Internet *is* a significant tool that combines delivery medium with instructional content and course management, *effective use* requires careful consideration (McManus 1996). Universities should hesitate giving a Web mandate without this consideration.

Literature Review: Diffusion Patterns for Instructional Technology

Various diffusion models explain the pattern of user acceptance of a new technology over time in hopes of increasing the adoption rate (Brancheau & Wetherbe 1989) (Rogers 1995). A simplified "S" curve of Web integration (Fig. 1) based upon Roger's (1995) diffusion model illustrates that initially a small number of enthusiastic users pave the way for the next, but larger, generation of faculty adopters.

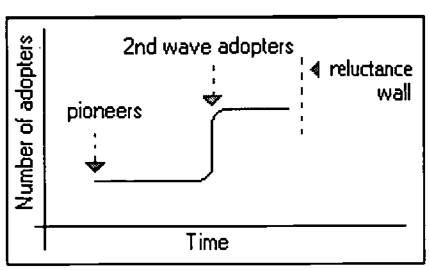

Figure 1. Diffusion Curve

Proficiency for the entry-level Internet integration occurs quickly within one semester instructors can include basic Internet options and establish student e-mail communication lines. Typically, the next step involves the creation of a Web site as a means of pulling the techniques together and managing them at a central location. The early pioneers had both the HTML skills and desire to experiment independently with Web integration, usually without administration incentives.

Some of the past primary drawbacks to extensive use of the Web in the curricula have been the time, effort, and HTML skills required of instructors (LeCroy 1997). Today, many universities employ instructional technology specialists who provide training and purchase Web course development software to speed the process of Web site development. These types of management actions overcome major hurdles and enable the large second wave of adoption—the vertical portion of the "S" curve. Shortly after this point in the diffusion process, the "reluctance wall" appears and the number of users remains fairly static, suggesting further management intervention is needed if additional adoption is to occur. References to these issues and software reviews are appearing in non-technical academic journals such as the Chronicle (McCollum 1997).

Current Study

At a selected regional liberal arts university of the researchers, this current study surveys faculty to identify: (1) this chosen university's pioneers and second wave Web adopters, the significant motivational factors that influence their Web use, and the hurdles they face(d) in using the Web; (2) the reasons other faculty do not use the Web (reluctance will not be treated derogatorily) and possible motivators for nonuse; (3) patterns in faculty demographics leading to adoption or non-adoption;

Findings

Of 179 faculty responses, three groups of self-reported Internet usage and one group of non-Net users emerged. The user groups are: (1) Current—use the Internet within existing courses; (2) Expected—plan to use the Internet in courses within the next academic; (3) year; (4) Non-User—do not plan to use the Internet within courses within the next academic year.

The demographics of the reported Net users indicate that 69 percent of the current users are tenured, and 25 percent are not. However when one compares what the "non-tenured" individuals are doing with the Net and Web to what the other faculty expect to do and what they do not expect to do, the percentage of non-tenured faculty actively using the Net and Web is slightly higher than the percentages of other two groups. This may dispel the belief that non-tenured faculty are not motivated to work on innovative teaching methods.

99 percent of the faculty responding to the surveyed maintain that they use the Net and Web for professional reasons daily. This may suggest that the all the survey participants are competent users. They are just not necessarily innovators and developers. 43 percent of the survey responders maintain that they do not use the Net and Web simply because they do not add anything to their currently effective styles of teaching. 39 percent of those interested feel that Internet specialists need to be hired to assist interested faculty. 36 percent are not educated on how the Net and Web can be used effectively in their classroom environments. Finally, 35 percent of the faculty maintain that they faced more formal incentives for spending time bettering their classes in traditional ways than for integrating the Net and Web into their classes.

A regression analysis was tested against these percentages to ensure they were not due to random chance. With the exception of "lack of university incentive", the t-statistics of all else is significant at a 90% confidence level. Holding all else constant, this suggests that NMU faculty decrease the number of Internet features used by roughly 1 if they do not find Internet and Web assessment tools useful [don't like e-assess] or do not know how to use these cybertools in their educational environments [applications]. They will decrease the number of Internet features used by roughly 2 if they find that their teaching styles are already effective [not teach style] or that they spend too much time in front of the computer [computer overuse]. NMU faculty would increase the number of Internet features used by roughly 2 if specialists were hired to assist or do the work for them [need specialist]. Lack of university incentive [no university incentive], though shown as 31-50% in the graph, proved not to be a valid statistical factor in determining Internet use within a course.

As might be predicted, current users have overcome many of the hurdles. The experienced group identifies three problem areas and appears more concerned about addressing these problems than the less experienced groups. These problem areas are: Experienced users now feel they spend too much time in front of a computer, that an Internet specialist is needed, and that there is a lack of technical support. Non-users need more information on Internet integration before they are apt to adopt this technology.

Motivating factors, shown in Fig. 2 for responding faculty currently using the Net and Web appear more proactive than reactive. The current users appear to be motivated by intrinsic pressures ranging from professionally driven motivation to desires to improve the quality of their courses, enhance communication with students, and disseminate course information and materials efficiently. Newer users appear reactive to pressures from administration, peers, and technological advancements. External motivators are all pressure points: from students, from marketplace, from peers, from technology, from administration. NOTE: it is possible the results would be different if the survey instrument had listed motivational factors rather than requested a written comment.

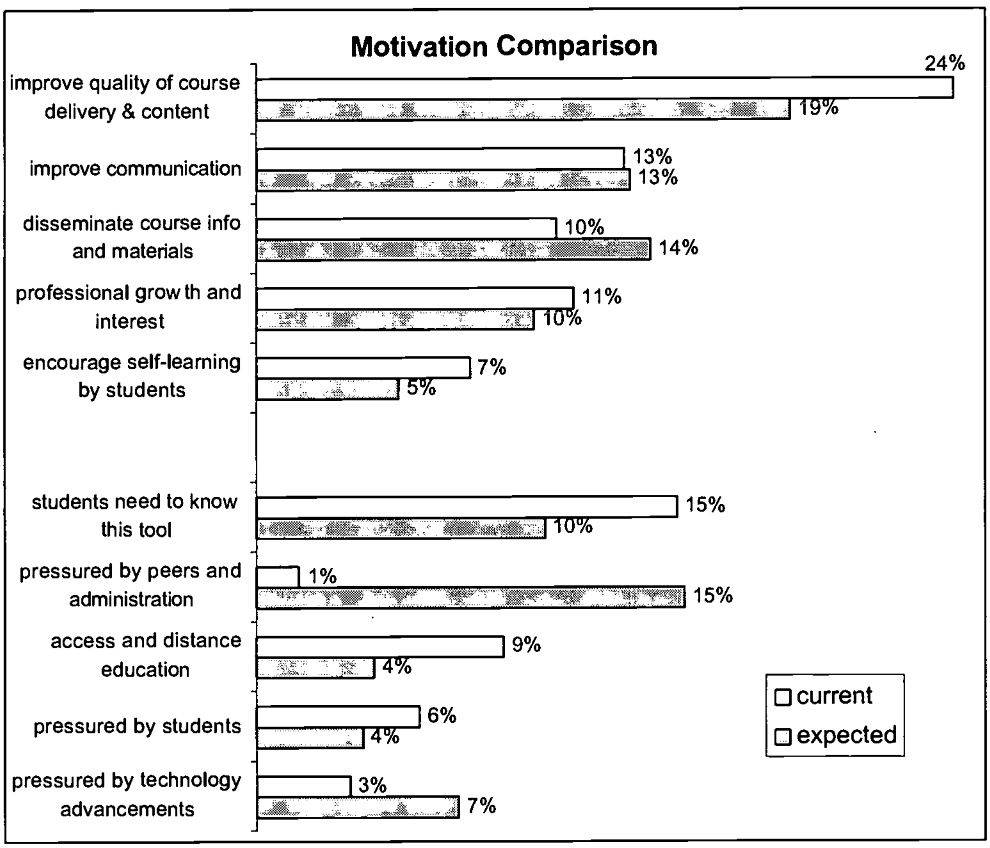

Figure 2. Faculty Motivators

Adoption Patterns

Based upon studies of how of innovations spread in their use, categories of adopters have been identified. The adoption, or diffusion, of an innovation typically takes the form of an S-shaped curve (Rogers 1995) (Cottrell 1997). The sample university's distribution of adoption follows this pattern; thus sample faculty can be considered "normal" in their approach to new ideas. The position and numbers of current adopters, and the expected 77 adopters within the next year indicate that a critical mass has been reached. A critical mass is the point at which a new idea has taken hold and, barring unforeseen circumstances, will eventually spread to almost all members of a group.

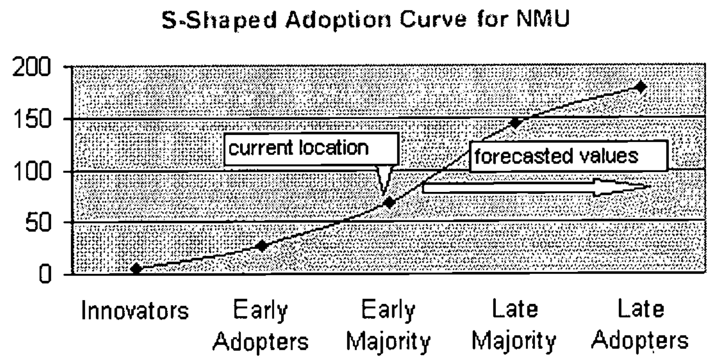

Figure 3: Adoption pattern at studied institution

Future Research

This study will be expanded to include numerous other universities. Internet and Web policy recommendations will be offered to university participants. Significant national trends may be identified as the national database expands and survey results are analyzed. Institutions interested in participating should contact the authors.

saltmarc@inow.com

Abstract: This session will demonstrate the results of two years of summer workshops designed to teach K-12, community college, and CalState instructors how to use, and how to motivate students to use, multimedia and the WWW in their classrooms. The presenters will describe the training paradigm that was used with both groups of faculty: K-12 instructors and university professors. In both 1997 and 1998 there were disparities between participant and instructor expectations. The biggest problems lay in the initial lack of student understanding of the complex nature of multimedia design and execution, the amount of time needed to devote to the construction of even simple multimedia projects and the steepness of the learning curve for some multimedia tools. These training workshops were organized by the Mathematics And Science Teacher Education Program (MASTEP), a five year NSF sponsered consortium to improve mathematics and science in the greater San Francisco Bay Area.

Theoretical Framework

According to Fryatt (1995), the challenges of training teachers to use multimedia and to integrate multimedia and the WWW in their classrooms are not easy ones. In her review of the literature, she found that traditional in-service instruction in the use of technology is not effective because there is little active involvement, inadequate practice, and little or no follow up and support. Ferrier (1997), based upon his review of the current literature on effective adult learning strategies, believes that changes in teaching practice will happen only if professional development workshops: emphasize a commitment to try out new ideas in the classroom the next day, provide a supportive environment to discuss problems and solutions and report successes and failures, encourage participation in a wide variety of teaching and learning approaches, and reflect the needs of the school communities. Szabo and Schwarz (1997), in a study of three randomly drawn samples of 1000 full-time teachers in Alberta Canada, identified opinions of teachers that might influence them to make greater use of computers in their classes. When the teachers were asked who should use computers with students, 71 percent of the teachers responded " only those teachers interested in doing so." In addition, 99 percent of the teachers said that the ideal number of minutes per week of computer use by students should fall between 30 minutes and eight hours.

Models of Education

The focus of these summer MASTEP workshops was on training teachers to incorporate technology into their classrooms. Our focus (and mantra) was to encourage authentic uses of technology rather than traditional uses of technology. According to an Office of Educational Research and Improvement case study, reported by Barbara Means and Kerry Olson (1994), traditional uses of technology include: technology as a teachers presentation tool, technology for remedial instruction, and teaching students about technology. In contrast, authentic learning focuses on the student practicing advanced computer skills; in addition, these types of technology uses in education are generally collaborative with teachers as coaches and feature extended time for completing assignments. According to Singh and Means (1998), authentic uses of technology can have a significant impact as a catalyst for changing schools in ways that better support the acquisition of higher order skills. According to Brown, Collins, Duguid (1989), authentic or contextual learning increases the likelihood that students can apply what they learn in school to similar contexts.

The learning approaches emphasized by the summer MASTEP workshops were resource-based learning, collaborative learning, and project-related learning. As another study (Bos 1997) found, having K - 12 students create their own projects can serve several purposes within a science curriculum. Through WWW projects, student work can be enhanced and the authenticity of the work increased. According to Harrington and Oliver (1995, 1997), there are nine critical characteristics related to situated learning environments. The learning environment needs to: "provide an authentic context that reflects the way the knowledge will be used in real-life; provide authentic activities; provide access to expert performances and the modeling of processes; provide multiple roles and perspectives; support collaborative construction of knowledge; provide coaching and scaffolding at critical times; promote reflection to enable abstractions to be formed; promote articulation to enable tacit knowledge to be made explicit; and provide for integrated assessment of learning." (Harrington & Oliver 1995, 1997)

Results

Placement of the workshops in the institutional environment

The most successful attempts to equip faculty with the skills and knowledge, as well as equipment to create multimedia based learning materials, have occurred where there is a institution-wide effort; as demonstrated at Pennsylvania State University with Project Empower (Noel & Brannon 1997) and outlined in the TESSI Project adopted by the Ministry of Education in British Columbia (Woodrow et al. 1997). Unfortunately, not all higher education institutions or educational agencies have arrived at this juncture.

The MASTEP summer workshops permitted the initiation of the type of efforts carried out by Project Empower within a limited framework. Since these summer workshops could not provide the total framework of institutional support, as provided in Project Empower for faculty trying new technology, the challenges for both the workshop participants and instructors were greater. The difficulties for both participants and instructors as well as some of the compromises which had to made, can be instructive and helpful to other educators in educational institutions where a total institutional commitment to new technologies is not likely to made in the near future.

Summary of First year workshop

A summary of feedback from the initial workshops which included two one-week "basic" workshops and two three-week "advanced" workshops indicated that the participants felt that they received valuable information and that they were able to produce multimedia products during the workshop period. The participants who entered the workshop with a clear project idea were most able to take advantage of the instructional materials presented during the workshops and were also closest in their performance and outcome expectations to those of the workshop instructors.

The workshop instructors identified several areas of concern in their assessment of the workshop. These included a lack of appreciation by a significant number of the participants in the advanced workshops for the complex nature of multimedia software and hardware. In effect, these participants came into the advanced workshops with the expectation that they could create "plug and play" products with little effort on their part. These same participants were overwhelmed by the expectation during the workshop that they would actually have to create a multimedia product. They had trouble making the transition from passive learning ("chalk and talk") to active learning (participation and creation). Many faculty came into the workshop with the assumption that it would be a traditional "chalk and talk" even though they were informed before hand that they would be expected to design projects. For many students, the preconceived notion of a "chalk and talk" experience negatively impacted upon their ability to complete a project during the period of the workshop. In this finding, our results agree with previous research done by Oliver and Lake (1997) who found that students in an authentic learning environments found it took longer to learn by doing then to learn by lecture mode.

Many participants in the basic workshops did not have an awareness of the state of multimedia technology prior to the workshops. They would have benefited by having more time to be "brought into the technology" using an approach similar to that developed at Pennsylvania State University through the Project Empower program (Noel & Brannon 1997). In our course, as in the one by Oliver and Lake (1997), using technology seemed to hinder learning when technical problems arose.

Many of the participants in the advanced workshops also had trouble devoting enough time and energy to the workshops since they were not compensated in monetary terms nor were they assigned college or continuing education credit for attending the workshops except for the K-12 teachers. The higher education instructors from the state and community colleges were taking time from personal projects and other work projects in order to attend the workshops at cost to themselves. Because of these factors, attendance and attrition during the advanced workshops was a problem during the latter part of the workshop where participants did not receive formal instruction but were expected to work on individual projects. Some higher education instructors looked forward to release time during the next academic year to continue the multimedia projects developed during the summer workshops and these participants were more motivated to complete their projects.

Summary of second year workshop

June Higher Education Workshop

In all, fourteen faculty participated in the June 1998 workshop. The workshop was divided into four one week sessions. The first week focused on a pedagogical and philosophical introduction to the use of computers and education. Topics in the first week included an overview of various areas related to the use of multimedia and education. The specific content for this first week included the philosophy of using multimedia, teaching styles and their impact upon educational technology used in the classroom, using the WWW in your classroom, an overview of basic instructional models, story boarding ideas for multimedia, and copyright guidelines and issues. The first week ended with demonstrations and self paced tutorials of three authoring programs: PowerPoint, Hyperstudio, and Authorware.

The second week focused on the use of multimedia in the classroom and the third week on the use of the WWW in the classroom. These two topics were covered in separate weeks in order to provide more time to develop educational modules that maximized these different types of multimedia. The last week in the June session was spent on special projects.

Since these workshops were sponsored by MASTEP, the participants were surveyed by external evaluator. According to the evaluation summary, the participants indicated that the best aspects of this workshop were the emphasis and time for hands-on experience, the tutorials, the excellence of resources, and the staff technical knowledge. Additionally, most participants wrote that they could use what they learn in all courses they teach for creating presentations for classroom use.

The attendees of this workshop differed in many respects from the workshops of the previous year. Most of the faculty entered this session with highly defined, preconceived ideas of what they wanted to do. Sometimes, this led to a conflict between teacher and student expectations; incidentally, *this situation was not not reflected in the teaching evaluations that were excellent*. In many ways, students were resistant to any suggestion or teaching that did not fit into their paradigm regardless of the need of their design. For example, to engineering faculty members attended the June workshop with the goal of designing course Web pages. These faculty members refused to participate in any tutorials or class discussions, or learn any software , that was not directly related to their task at hand. Although this goal seems acceptable, this resistance precipitated the re-teaching of many concepts and software throughout the four weeks.

July K-12 Workshop

The July workshop session was structured differently than the June workshop in some respects. This session was again divided into four weeks. However, the fourth week had a different focus (the first three weeks of this workshop paralleled the content of the same weeks in the June workshop). The attendees of this workshop were all K - 12 teachers who had been selected to receive equipment and software through a proposal competition run by MASTEP. The teachers, by their own admission, expected that the workshops would follow a "chalk and talk" format. At first, the teachers were dismayed that they had to actively learn and produce tangible products. However, compliance to teacher expectations and motivation was high. Also, the students in this section were graded on the quality and appropriateness of their outcomes.

Comparison of 1997 and 1998

Length and focus of workshop

In 1997, the one-week "basic" workshops were well attended with little attrition during the week. These workshops were highly instructor-directed with a mixture of lectures and structured hands-on activities. There were simple step-by-step tutorials designed to give a brief introduction to various software packages. The "advanced" workshops in 1997 also initially had good attendance while the instructors were directing all activities during the first week in a similar format to that used for the "basic" workshop. However the number of individuals who enrolled for the "advanced" workshop was lower than for the "basic" workshop due to the three-week time commitment. During the second and third weeks of the "advanced" workshops, attendance was sporadic for many participants who were not fully committed to working the full workshop time on open-ended projects in spite of the available equipment and instructor expertise.

Based on the 1997 issues about attendance for the "advanced" workshops, it was decided in 1998 to shorten the workshops to one week modules. Two distinct groups of instructors were also identified and presented with separate workshop schedules and activities designed to address particular group needs. The two groups of instructors were 1) higher education instructors from community and state colleges and 2) K-12 teachers who had committed to being club advisors to science student clubs at their respective school sites.

For the higher education instructors, the workshops were divided into four consecutive one week sessions (discussed previously). The focus for each week was very specific with extensive resources and step by step tutorials provided to the participants and a project expected to be completed by the end of the four week period. All participants were expected to complete the first week but could choose which other weeks they wished to attend. These participants were not compensated monetarily but some community college instructors received college credit hours for the workshops.

For the K-12 club advisors, the focus of the workshops were also specific but the participants were expected to attend all four weeks of the workshops. These participants received college credit, monetary compensation and the promise of a multimedia station at their school sites upon successful completion of the workshops. The focus of these workshops addressed basic multimedia concepts and philosophy, use of multimedia and web tools and the design of multimedia student directed activities for the school sites. A key difference was that these K-12 teachers had to produce specific multimedia project outcomes in Weeks 2 and 3 and group-designed activities in week 4.

Compensation issues

It is not surprising to find that faculty, that are more vested in learning multimedia, produce more tangible outcomes. A continuing problem in providing multimedia workshops for faculty is the subsequent ability of the faculty to pursue multimedia on their own after the workshop ends. Since the K - 12 faculty in the 1998 section were given equipment as well as financial remuneration for their attendance and participation, there was more motivation for the K - 12 faculty to produce outcomes in the workshop. These unsurprising results was also found by Barnes (1997). In this study, project FIRST, activities and projects were developed by district teams consisting of a regular educator, a special education preservice teacher paired with a regular teacher for a year, and a university faculty member in special education. In addition, each team was loaned technology, both hardware and software, for classroom use for one year. Barnes found that, after six months, participants continued to integrate technology in their classrooms. The need for external reward also has been documented by Reiss (1998), in his analysis of project **T.E.A.C.H.** in the Camden school district, New Jersey.

In project **T.E.A.C.H.**, 48 of the original 50 teachers finished the training program and received a horizontal step raise. In subsequent years, the external motivation was that every teacher would receive a Macintosh computer for the classroom about halfway through the program. These computers would remain with the teachers, even if the teachers moved to other rooms or other schools in the district. Overall, as a result of this training, the Camden school district now has more than 250 **T.E.A.C.H.** graduates out of about 1750 teachers. More importantly, for most **T.E.A.C.H.** graduates, computers are used in the classroom on a daily basis.

Instructional pedagogy/philosophy

In the first year, the philosophy was integrated into the workshops in concert with the instruction about the multimedia tools. Although the first week was advertised as a beginning multimedia workshop, the instructors discovered that few faculty considered themselves to be beginners in technology. Therefore, about half of the faculty attending the "advanced" workshop did not attend the preceding "basic" workshop. This made it difficult to build upon skills taught in the first week. It also necessitated re-teaching of various techniques, philosophy, and multimedia tools in the second to third weeks of each session.

In both 1997 and 1998 there were disparities between participant and instructor expectations. The biggest problems lay in the initial lack of student understanding of the complex nature of multimedia design and execution, the amount of time needed to devote to the construction of even simple multimedia projects and the steepness of the learning curve for some multimedia tools. Many participants came in thinking that all they needed to do was to assemble ready-made pieces into a whole. There was resistance to the realization that each piece of a multimedia project has to be created.

Another expectation among the higher education instructors was that since they were not being compensated that they could pick and choose what they wanted to learn and to do regardless of instructor opinion and expectations. As discussed above, two participants in 1998 only wanted to create web pages and only worked on web pages with virtually no attention to the other multimedia possibilities or design considerations. The K-12 instructors were committed to (and extremely motivated by the level of renumeration) attending the four week workshop but did not initially understand the expectation that they would be expected to produce multimedia projects and that they would be graded on the results.

Use of multimedia tools

In the 1997 workshops, the participants were given brief tutorials covering various authoring software products as well as tutorials on how to incorporate audio, images and video segments. There was a great deal of latitude and one-on-one instruction with respect to other various software applications used to manipulate images, sound, animation, and video clips. Participants varied considerably in their relative technological sophistication and experienced some frustration with this approach.

For the 1998 workshops, the participants were provided with step-by-step tutorials for all software applications used in the workshops. There were specific applications (donated to the MASTEP project by Adobe Systems, Inc) used for image manipulation and creation, video capture, and editing. Three authoring application choices were offered for general multimedia projects and two web based authoring tools were offered for creating web pages. The participants, who had little familiarity with computers or multimedia applications, were satisfied when offered very specific instructions with limited choices in software applications.

Project outcomes

The seven multimedia projects produced for the 1997 "advanced" workshops were most complete and complex for the participants who took the workshops for college credit or who had well defined projects in mind before attending the workshops. In 1998, the higher education instructors completed two multimedia and two web projects during the workshop time but these projects varied considerably in the degree to which they incorporated multimedia design principles and features based on participant attitude and expectations.

For the K-12 instructors, the projects were consistent in level of use of multimedia design and use of features based on highly defined instructor instructions and expectations. These projects were generally more complex and complete than those created by the higher education instructors who were not compensated for their workshop participation. In week two, each K-12 instructor was required to design a interactive, non-tutorial, multimedia mini-lesson in math or science using Authorware or PowerPoint. In week three, the basic requirements for the mini-lesson were the same but the multimedia projects were designed using web tools (Adobe Pagemill was the only web authoring tool used in this session because this software was included in the equipment package they were to receive). In the fourth week, the participants were divided into collaborative pairs to devise eight student-centered learning activities for use in the math & science clubs.

Conclusions

Based on the experiences from these workshops conducted during the last two years there are both positive and negative implications for training instructors to use multimedia in their classrooms. From a positive standpoint, the level of motivation among faculty in general for improvement of their teaching was very high based upon workshop attendance by individuals who received no compensation. This fact is heartening based on the often expressed observation that faculty are rigid and disinterested in any improvement in their instructional methods. Another positive outcome of the workshop experience was the ability of technologically naïve (and fearful) individuals to produce fairly complex multimedia teaching mini-lessons in short period of time. From a negative standpoint, it is difficult to assure consistent instructor use of new technologies in the learning environment when there is not complete institutional support. These workshops were funded by NSF grant monies which are not an assured source of funding on an ongoing basis for regular instructional support within the institution.

Abstract: The following report illustrates how educational researchers and software developers can work in conjunction with teachers to optimize learning and provide an empirical basis for software revision. Using the Design Experiment Technique, teachers and researchers together determined, through successive classroom implementations, how to optimize the use of new software. Objective assessments made along the way indicated whether the curricular adjustments led to improved learning. The current research involved four implementations of software that teaches science content and inquiry skills. After each implementation, the data were analyzed, and classroom activities were revised. Revisions included the addition of time tables, the jigsaw method for doing background research, daily questions, and activity summaries. These revisions will also be incorporated into future versions of the software.

Introduction

User feedback is a central component of a successful software development project, whether the project is targeted for entertainment, self-help, or other commercial purpose. A primary consideration is ease of use, and developers customarily solicit impressions from users or observe users as they attempt to run the software. Developers of educational software, on the other hand, are interested not only in ease of use, but also in the impact the software will have on learning. Unfortunately, the difficulty of obtaining accurate user feedback on learning is complicated by the diversity of implementations teachers may use to integrate the software into their curricula. The research reported here illustrates how educational researchers and software developers can work in conjunction with teachers to optimize learning and provide an empirical basis for software revision.

The Design Experiment Technique is a recent advancement in educational research (McGee & Howard, 1998). Using this technique, teachers and researchers together determine how to optimize the use of new software through successive classroom implementations. For each implementation, there are objective measures that assess whether the curriculum adjustments have led to improved learning outcomes relative to the previous implementation. This technique was used by researchers at the NASA Classroom of the Future to evaluate the *Astronomy Village®: Investigating the Universe™* multimedia package. This paper will describe the design experiment process for four classroom implementations and how that process led to refinements.

Astronomy Village: Investigating the Universe

The NASA Classroom of the Future™ Program (COTF) is a NASA-funded research and development center that specializes in the development and testing of educational multimedia for math, science, and technology education. In March 1996, the COTF produced a CD-ROM called *Astronomy Village: Investigating the Universe* for use as a curriculum supplement in high school science classrooms. It was distributed to over 11,000 teachers, educators, and resource centers, and it won *Technology and Learning* magazine's Science Software of the Year Award for 1996. *Astronomy Village* uses the metaphor of living and working at a mountain-top observatory (the village) as the primary interface from which students investigate contemporary problems in astronomy (see Pompea and Blurton, 1995). Academic activities are designed to promote learning of astronomical concepts and processes related to scientific inquiry. Students join a research team and choose one of ten investigations to complete. In the Stellar Nursery investigation, for example, students investigate how stars are born. For each investigation, students progress through five phases: background research, data collection, data analysis, data interpretation, and presentation of results. For any given phase, there are from three to seven content-related activities to be completed before proceeding to another phase. The primary means of tracking progress through an investigation is the *Research Path Diagram*—a chart that displays icons representing activities within each phase. Each time a student clicks on one of the icons in the Research Path Diagram, a virtual mentor appears and describes activities relevant to that particular investigation. A second means of tracking progress is the electronic LogBook, in which students record their scientific notes and observations.

Method and Data Sources

The design experiment consisted of four one-semester studies. In each study students from one of two area schools visited the COTF facilities to use the *Astronomy Village* software.

Design Experiment Populations

The participating schools were from a rural community with a population of approximately 35,000. The demographics for each study varied (see Table 1). In the first study thirteen students from the ninth-grade class of a girls' academy (college preparatory) participated. In the second study nine students from the eighth-grade class of the same academy participated. In the third study twelve students from the tenth and eleventh grade of a large public high school participated. In the fourth study nine students from the eigth-grade class of the same girls' academy participated. Students from the third study were from an at-risk population. In each case students attended class daily for approximately four weeks at the COTF facility in lieu of their science class. Sessions using *Astronomy Village* were co-taught by the students' classroom teacher and the first author.

It should be noted that the students in Studies 2 and 4 were younger than students in Studies 1 and 3, and in Study 3 the population consisted of at-risk youth in a public school setting. Research predicts that the ninth-grade students from the college preparatory academy should have outperformed the other groups of students (those in lower grades and at-risk) (Blank and Gruebel, 1995).

Data Sources

There were three sources of data for this investigation. The first source was a compilation of documents in the students' electronic notebooks. In the first two studies students used the electronic notebook embedded within *Astronomy Village*. This notebook was called the LogBook. In the third and fourth studies, students used an electronic notebook called the Collaboratory Notebook as their LogBook. The Collaboratory Notebook was

	Study 1	**Study 2**	**Study 3**	**Study 4**

Table 1: Demographics of Design Experiment Populations

developed as part of the Learning Through Collaborative Visualization Project (CoVis) Project at Northwestern University (Edelson and O'Neill, 1994). For each activity in *Astronomy Village*, students were expected to produce activity summaries in their LogBooks. These summaries consisted of a brief description of the activity, a statement of the importance of the activity in the context of the main research question, and any new questions that arose from the activity. The second source of data was videotapes of student interactions while using the software. The third source of data was field notes and classroom observations by the teachers and first author.

Dependent Measures

There were two aspects of the activity summaries that were considered for each design experiment. First, how many of the activities in *Astronomy Village* did students complete? Within each study the primary dependent measure for this question was an indicator of activity completion called the *activity completion rate*. This was an objective measure of the extent to which students were able to complete the assigned activities. Activity completion rate was defined as the number of activity summaries students completed, divided by the number of activities the mentor suggested. Second, were students able to relate the individual activities to the basic question for each investigation? In each study the primary dependent measure for this question was a measure of how closely the statement of importance within the activity summaries was linked to the overall investigation.

Design Experiment Results

In brief, the design experiment began by using the instructional procedures prescribed in the *Astronomy Village* package, and examining the effects as the program was implemented. Each succeeding study refined the procedures in order to achieve more effective outcomes. The next section describes each study and the impact of changes to the activity on the activity completion rate. Along with a description of each successive study, there is a discussion of how the instructional procedures were modified for the next implementation.

Activity Completion Rate

Study 1

In the first study the overall goal for the students was to complete all of the activities as suggested by the *Astronomy Village* virtual mentor. Our purpose was to implement the program as closely as possible to the intentions of the software designers. Students completed activities related to background research, data collection, data analysis, data interpretation, and presentation of results. As intended by the developers, students began by watching a videotape introduction to the software. Next, they worked within their project teams to complete a tutorial on using the software. After completing the tutorial, students proceeded to the virtual Conference Center in *Astronomy Village*, where the virtual mentors described the different investigations. The students selected different mentors and listened to a description of the research that each mentor was conducting. The students chose an investigation that interested them and joined an investigation team. Next, they accessed the Research Path Diagram, which introduced them to the resources on the *Astronomy Village* CD-ROM that related specifically to their investigation. By following the Research Path Diagram, students should have been able to complete the steps necessary to learn the appropriate concepts and conduct the level of problem solving needed for their investigation.

Completion Rate. Summary worksheets made activity completion easier, although completion rates were still below teacher expectations. The average activity completion rate for this study was 42%. This value indicated that over the four-week period, students completed less than half of the activities the mentor suggested. Further analysis of the activity completion rate within each phase of research (background research - 55%, data collection - 75%, data analysis - 35%, data interpretation - 20%, and presentation - 27%) revealed that the activity completion rate was much lower during later phases of research. This analysis of the activity completion indicated that the Research Path Diagram and virtual mentors were not sufficient to guide students through the complex problem solving required by the activities in the investigation. If students were not able to complete the activities in the investigation, it was believed they would not achieve the desired learning outcomes.

Study 2

In considering the disappointing performance of the students in Study 1, the teachers for Study 2 modified the implementation slightly from that intended by the designers of the *Astronomy Village.* The modification took three forms: *target dates* for phase completion, *more time* for activity completion, and *more contextualized training.*

Modifications. First, students were given target dates for each of the phases of research so they would have sufficient time to complete later phases of research. Second, teachers eliminated activities that did not seem to benefit the students. That is, the tutorial was eliminated, and students selected a investigation from a list of abstracts instead. These two changes resulted in approximately 17% more time for completion of activities (3.5 instructional days out of 20). Third, training was now given on an as-needed basis.

Completion Rate. The average activity completion rate for this study was 85%. This value indicated that over the four-week period, students completed twice as many activities as the students in the first study, even though these students were a year younger. The activity completion rate within each phase of research was as follows: background research - 78%, data collection - 100%, data analysis - 83%, data interpretation - 62%, and presentation - 100%. The students in this study had more opportunity to achieve the desired learning outcomes than students in the previous study. Thus, the use of an objective measure such as the activity completion rate made it possible to see what factors were preventing students from completing the activities.

Study 3 & 4

Although the modifications in Study 2 improved the completion rate, the teachers noticed that students were having difficulty seeing the connection between the individual activities and the investigation as whole. In Study 3, the researchers and teachers initiated several major modifications to help students see the connection. These modifications took three forms: all students working on the same investigation, the addition of a motivating question phase, and a shortened investigation structure.

Modifications. To help students complete their investigations more quickly, the research phases were revised and truncated. The new phases were the motivating-question phase, the background research phase, the background review phase, the data analysis phase, and the reflection phase. In the motivating-question phase the teacher posed the main investigation question, and the students individually typed responses in their LogBooks. Next, the teacher showed the students the data they would be analyzing and asked them to record observations. These two activities were meant to activate students' prior knowledge and connect it to the activities of the investigation. This approach was similar to Minstrell's benchmark lessons (Bruer, 1993). In the background research phase the teacher selected the three most relevant articles from the investigation, and each student read one of the three and developed an activity summary. In the background review phase students used their activity summaries to answer questions as a team, prompting themselves to integrate across the individual readings. Since each student was an expert on only one of the articles, students would be forced to discuss the readings with one another in order to answer the questions. In the data analysis phase students completed analysis worksheets as a team. And finally, in the reflection phase students responded to integrative, teacher-posed questions in their LogBooks. Using these redesigned research phases, it was possible to fit three investigations, rather than one, into the four-week period.

Completion Rate. The average activity completion rate for Study 3 was 74%. This rate was comparable to the activity completion rate from Study 2, even though the third group consisted of students who were at risk. The activity completion rate for each phase was as follows: motivating question - 82%, background research - 85%, background review - 62%, reflection - 73%. The activities for this study involved more explicit prompts for students to reflect on their background knowledge and relate that knowledge to the activities in the research investigation. These more explicit prompts increased the likelihood that students would assimilate the new information from *Astronomy Village* into existing knowledge structures.

Study 4 used the same structure as in Study 3, with one primary exception. The students only completed one investigation during an eight-day period. Also, researchers once again worked with eighth-grade students.

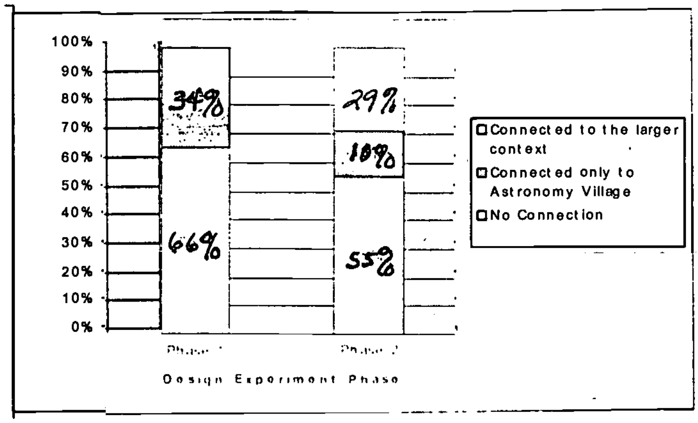

Figure 1. Percent of Activity Summaries that Relate to the Larger Context of the Basic Science Question

LogBook Quality

In addition to activity completion rates, researchers wanted to know how well students were connecting their activities over the four-week period to the larger context of the basic science question. (A basic science question addressed a fundamental issue in astronomy such as, Is there other life in the universe? In contrast, a research investigation question addressed a specific issue in astronomy such as, How do you determine what areas of the universe to examine for evidence of planets orbiting a distant star?) To evaluate these connections, the researchers examined students' LogBook responses to a particular question in the activity summary worksheets that queried the importance of the activity. A rating scale was developed to judge the responses. Responses that related the activity to a basic science question were rated more highly than those that merely related the activity to the research investigation question, while those that discussed only the activity itself (zero connection) were rated lowest. Statements of importance were extracted from the LogBook activity summaries for each article that students read. Raters were blind as to which study the statement of importance came from. Raters made judgments by comparing the statements of importance to the article content, the investigation research question, and the basic science question.

Researchers investigated the impact that the various implementations had on the quality of the LogBook entries. In order to simplify the analysis, the studies were clustered into 2 phases, based on the similarities of the implementations. Phase 1 encompassed Studies 1 & 2, in which students worked on one investigation *at their own pace* over four weeks. Phase 2 encompassed Studies 3 & 4, in which students worked on several investigations-- as directed by the teacher-- and used a truncated set of activities for each investigation. In addition, Phase 2 studies were more explicit in providing students with assistance in making connections between activities.

Results indicated that students from Phase 2 studies were able to connect almost one-third of the activity summaries to the basic science question for each investigation (see Figure 1). In contrast, students from Phase 1 studies were able to connect roughly one-third of their activity summaries *only* to the research investigation question. The two phases were comparable in the percent of activities that contained no connection between the articles and the research investigation or basic science question. A Chi-square analysis indicated that the higher percentage of students in Phase 2 who were capable of connecting the activity summaries to the larger science context was statistically significant ($\chi^2 = 12.19, p < .01$).

These results indicated that the addition of a motivating-question phase and a reflection phase helped the students to draw connections between the various activities within the extended project. By making explicit references to the basic science question and prompting students to develop hypotheses about the basic science question, the teachers in Phase 2 helped students connect individual activities to the larger scientific context.

Conclusions

The specific modifications in this design experiment were unique to the *Astronomy Village* software and to the particular classroom setting used at COTF. However, the general issues that were revealed are germane to many software programs and classroom contexts. If teachers understand the issues they will face while implementing technology and are given guidance on how to address these issues, there will be a greater chance that educational reform will be sustained beyond the initial pilot projects (McGee & Howard, 1998).

The results of the design experiment helped the developers at the COTF understand the kinds of supports that would be needed to optimize learning. These supports are now being incorporated into a new version of *Astronomy Village* that will focus on the solar system. In this new version the investigations will be shortened to one week to help students better manage their time. With more time, students will have four opportunities to conduct investigations in a four-week period. To help students connect individual activities to the investigation question, an exploration phase will also be added, to take place prior to the background research phase. The exploration phase will serve the purpose of the motivating question phase in Study 3. In addition, the LogBook will provide structured prompts (similar to the activity summaries) to help students reflect on the learning process.

Reform will only take place when teachers are able to explore the implications of a new curriculum within the context of their own classrooms. That an educational multimedia program was used successfully in a one school district does not necessarily mean that it will be effective in another. Design experiments can be especially powerful when results lead to teacher-generated design principles. Creating partnerships between teachers and researchers will enhance reform by giving teachers tools for evaluating their own implementations and providing researchers a means of comparing implementations across different contexts.

User Interface Issues for Telepresentations *

Wolfgang Hürst
Institut für Informatik, Universität Freiburg, Germany
Email: huerst@informatik.uni-freiburg.de

Abstract: Common paradigms for human-computer interaction used in the design of general computer interfaces are often not suited for the telepresentation scenario. This is true for hardware input devices, generally keyboard and mouse, as well as for software user interfaces. The use of alternative input devices and the adaption of the according software is necessary to gain full profit of the augmented possibilities computer supported presentations can offer. In this paper we will present different hardware devices and discuss their usability for telepresentations. Various experiments carried out in miscellaneous lectures at our university indicated numerous problems and requirements for the hardware and software. We will present our experiences, discuss the occurring problems as well as possible solutions, and address current and future research areas.

Introduction

Telepresentations, i.e. presentations given with the use of computers, offer great advantages and augmented possibilities compared to regular talks. The additional functionalities can be useful to improve the presentation and to support the person giving a talk. Multimedia supplements facilitate the understanding of complex facts and offer new insights into difficult problems. Online transmission and recording for offline use can be done with a high quality at low costs. Time and space independence can be achieved through these recording and transmission facilities. However, the tools and devices which are generally utilized for such a telepresentation require additional training and customization before they can be used in a gainful way. Common computer interfaces are not designed to give presentations but to operate regular computer programs, such as wordprocessing systems, databases, web browsers, and so on. In the telepresentation scenario these interfaces normally lack required functionalities and force the lecturer to adapt to an interface which is not suitable for the respective needs. In this paper we will address the user interface issues for the teleteaching scenario. We will have a closer look on what the needs are, we discuss alternative input devices, how they can be applied in telelectures, and the consequences for the design of user interface software.

Telepresentations and Ubiquitous Computing

In the presentation and teleteaching scenario a computer in combination with a data projector is generally used as a replacement for traditional presentation facilities, i.e. chalk and blackboards or slides and overhead projections. The screen of the computer running a so-called *electronic whiteboard* program is projected on the wall with a data projector and transmitted over the network to the stations receiving the talk. The presentation is given at the computer interface with the use of common input devices, i.e. keyboard and mouse. Many whiteboards contain connectability to the internet and transmission facilities. Some of them, such as the *AOFwb* [4] developed in our group, also have integrated recording features.

One problem with this approach is that the whole presentation has to be given on a computer interface. This is not the common environment for giving a talk and is especially a problem if the lecturer is not used to work with computers. Common electronic whiteboards have interfaces which can be handled easily by people who work with computers in their everyday life but are not suited if the lecturer has limited experience with common user interface paradigms. The lecturer also has to sit in front of a computer. This might result in a lack of social contact with the local participants of the presentation. Ideally the user interface in the teleteaching scenario should be intuitive and

*This research is supported by the German Research Foundation (Deutsche Forschungsgemeinschaft DFG), project *Generation of Multimedia Documents on the Fly*, No. Ot 64/13-1, part of the research initiative V3D2.

no special training should be required for new users. The presenter should be able to concentrate completely on the content of the talk and not on the operation of the teleteaching interfaces. No restrictions should apply to a lecturer about which presentation techniques to use. The new tools and interfaces should be able to be operated in the same manner as the traditional ones which would be used if the presentation had been given without computers.
An interesting aspect in this context is the concept of *ubiquitous computing* introduced by M. Weiser [9]. Ubiquitous computing is "the method of enhancing computer use by making many computers available throughout the physical environment, but making them effectively invisible to the user" [10]. Computers are integrated into our everyday environment in a way that we can interact with them without realizing them. Therefore we are able to gain from the augmented possibilities offered by the computers without even having to think about their existance. In this way the computer becomes invisible to the user. To apply the ideas of ubiquitous computing to the teleteaching scenario we need tools similar to a blackboard or an overhead projector that are also able to perform additional tasks, such as easy transmission and recording or the use of multimedia supplements. Electronic whiteboards could be used for this purpose but require adaption of the hardware interface used for human-computer interaction on one hand and of the software interface on the other hand. In the next section we will discuss the resulting hardware issues.

Hardware User Interface Issues

Experiments with Different Hardware Input Devices

As discussed in the previous section, there is a need for hardware devices which replace blackboards and overhead projectors in regular classrooms. Therefore we require a wall mounted interactive board and a touch sensitive device on a high desk in combination with a data projector. They should be similar to handle by a user like the respective facilities they are replacing. Additionally they should offer full access to the software interfaces providing the supplementary features which make telepresentations such a useful and exciting area.
A relevant overview on user interface hardware currently available on the market can be found at the Web page provided by B. Buxton at [2]. Several of these hardware devices can be used as an interactive board to replace a wall mounted *blackboard*. In our tests we used two large digitizing boards (see Fig. 1, left and middle). They are touch sensitive and send the coordinates of every position that a person contacts, either by hand or by the use of another tool, e.g., a pen, to a connected computer. If the content of the computer screen is projected on the board, then the mouse pointer can be moved and mouse clicks can be executed just by touching the board. This facility can therefore be used to operate an electronic whiteboard. The behavior of the board is similar to a touchscreen mounted on a regular desktop computer. In the board shown at the left side of Fig. 1 the computer content is projected on the board from a data projector standing in front of the board. The one shown in the middle of Fig. 1 has a rear projection system where the data projector is placed behind a transparent input area. This circumvents the problem of covering parts of the board with your own shadow while standing in front of it. It turned out that in combination with an electronic whiteboard, e.g., the *AOFwb* [4], such a board is very suitable as a blackboard replacement. Both the lecturer and the students attending the talks locally found it a pleasant and convenient tool. However, several problems occurred which will be discussed in the next paragraph. One problem was the limited size of the board. The boards used in our experiments had a diagonal screen size of 58 1/4" (148 cm) and of 72" (182.9 cm). In large rooms this might be to small to provide reasonable input and output facilities for a regular talk or presentation. Even the largest board available on the market today seems to be to small for our purpose. One possibility to circumvent this problem is to take two or three of these boards and put them next to each other to get a wide interactive blackboard, such as it is done by the Integrated Publication and Information Systems Institute, IPSI, at the German National Research Center for Information Technology, GMD. They connect three boards, each having a diagonal screen size of 72" (182.9 cm), to form one large interactive wall, called the *DynaWall* [8]. The connection of more boards next to each other poses new requirements on the interface design and the implementation of the underlying programs which we will address later.
There are also some input devices on the market useful (in combination with a data projector) as a replacement for *overhead projection systems*. We tested a regular computer screen equipped with a touchsensitive display. An electronic whiteboard runs on the connected computer and can be operated by the user with the fingertip or a pen like facility. The display should be mounted horizontally to resemble writing on a piece of paper or a slide lying on an overhead projector. The content of the interactive computer screen is projected on the wall with a data projector. We tested regular touchscreens and found out that they are not reasonable for our purpose because they

Figure 1: Hardware used in our experiments: interactive boards (left and middle) and graphic tablet (right).

usually react to every kind of input performed on the display. Therefore it is, for example, not possible to rest your wrist on the surface when writing with a pen. Freehand-writing on a horizontally mounted display equipped with such a touchscreen is only possible by radically changing your regular writing style. This is not acceptable in our scenario. However, there are a few hardware devices commercially available which use special techniques only recognizing input from a particular tool, such as a special pen, but not from other facilities, such as the users hand. However, most of them lack a size appropriate for our purpose. This is the reason why we used a regular graphic tablet for our experiments, such as the one shown in Fig. 1 (right). Here the input is done on the writing surface of the graphic tablet with the use of a special pen recognizable by the tablets hardware. Every other kind of input, e.g., touching the tablet with the hand, is rejected from the hardware. The output is indicated only on the computer screen, but not on the graphic tablet. With this technique our electronic whiteboard can be operated remotely using a pen instead of a mouse. The principle of this kind of operation is the same as using a regular computer mouse but allows easier writing and freehand drawing for the lecturer. Due to the separation of input and output area, this kind of interface requires some time to get used to it. Our experiments indicated that some people found it a very useful tool for telepresentations while others did not feel comfortable with this kind of "remote writing". Therefore, with some training and in combination with a data projector, such a graphic tablet can be used as an alternative input device and a replacement for classical overhead projection systems. However, it is not a perfect solution. Another problem resulting from this setup is that the lecturer is still sitting or standing in front of a large computer screen which might block the view to the local attendants. The students felt this loss of eye contact as a disturbing factor during our experiments.

Problems, Consequences, and Requirements

The used input devices for our teleteaching scenario should act as reasonable replacements for traditional representation tools, such as blackboards and overhead projectors. The various experiments and real-world tests that we did during miscellaneous lectures and classes with the devices introduced in the previous section pointed out several consequences and requirements the new hardware interfaces should fulfill:

- An input device similar to a pen or a chalk should be supported. Additional input facilities, such as a keyboard, might be desirable in special situations.
- The input area should be identical to the output area. Remote input and control of the electronic whiteboard is not appropriate because it requires special training and an adaption to the interface. In our scenario this is not an intuitive way to interact with the application program(s).
- "Input by accident" should be avoided. For example, resting your hand on the input area while writing with a pen should not be misinterpreted as any kind of input.
- The input and the output area should provide an appropriate size, i.e., they have to have about the size of a regular blackboard or overhead projection. The presentations have to be large enough to be readable by the local attendants and large enough that an appropriate input by the lecturer can be guaranteed.
- The resolution and the sensitivity of the screens replacing the blackboard or the projector have to be adequate.

- The surface has to provide good reading and writing. For example, no reflections should disturb the audience or the lecturer and no concavity should complicate the input.
- There should be no need to darken the room, because dark rooms are not acceptable for the local attendants.
- The use of special hardware should not block the attendant's view of the lecturer or to the board. Eye contact between the person giving the talk and the audience is important.

These basic requirements resulted from the experiments we did with special hardware facilities. However, the list given here generally applies to every kind of input interface. Further problems and requirements we identified are due to the design of the software interface and will be discussed in the next section.

Software User Interface Issues

Experiments with Standard Graphical User Interfaces

The software design of an appropriate user interface has to meet the requirements resulting from the different input devices and the ubiquitous computing scenario. In stressful situations, such as giving a talk, people tend to have wrong input behavior or to get confused by the interface more often. They are concentrated on their presentation and not on the interaction with the computer hardware. Therefore the interface should be easy and intuitive to handle.

For the experiments with the alternative input devices discussed in the last section we used our electronic whiteboard, the *AOFwb* [4]. The interface of this whiteboard is comparable to regular computer interfaces found in programs with similar tasks. No special adaption of the software to the new hardware facilities has been done. A screenshot of the *AOFwb* interface can be found in Fig. 2.

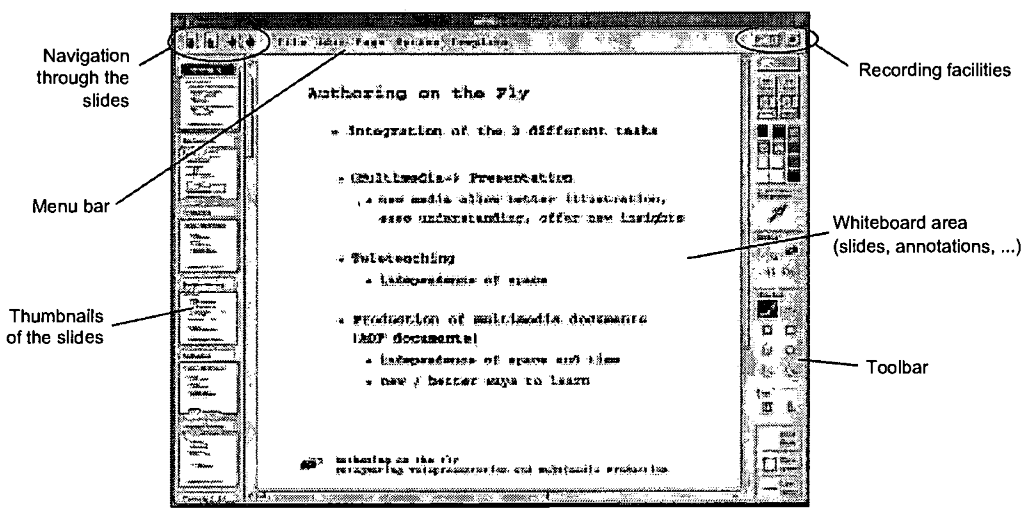

Figure 2: The interface of the electronic whiteboard *AOFwb*.

This is a typical Graphical User Interface (GUI) found in many similar computer programs. These interfaces, sometimes also called WIMP (*W*indows, *I*cons, *M*enus, *P*ointing) interfaces, follow the desktop paradigm. They have been designed for the use with desktop computers for tasks such as word processing, database management, and so on, but not to interact with large interactive walls. Our experiments showed that even users experienced with such common human-computer interfaces have problems in operating them during a telepresentation. We discuss these issues in the next paragraph.

Problems, Consequences, and Requirements

Typical Graphical User Interfaces, such as the one used in the *AOFwb*, have been designed to be used on desktop computers. They are not suited for the operation of large interactive walls. Various modifications have to be applied. For example, with the remote operation using a regular computer mouse, navigation through nested menus seems to be a reasonable way to interact with a desktop computer and to execute commands. When standing in front of an interactive board using a pen as input device, pressing just a single button seems to be more appropriate. The desktop paradigm has to be replaced by a "blackboard paradigm". The different size of the interaction devices also has to be considered in the interface design. Regular computer programs usually place things like a toolbar on one side of the interface. This is an appropriate solution for the screen of a desktop computer, but causes problems on a large scaled interactive board because the user always has to walk to the specific position where the toolbar is placed. Ideally the toolbar should be accessible from anywhere the lecturer is standing. "Popup toolbars" might be a solution for this problem. Another approach can be found in [7]. Here an additional palm top computer is used to hold the toolbar. It can be carried by the lecturer in his/her none-dominant hand and is connected to an interactive board via a wireless connection.

Another problem is that it is hard to remember which tool is activated at a particular time. Similar to the use of a computer mouse, the finger or pen of a user has a different functionality depending on which tool is selected. Regular whiteboards or graphic programs usually indicate the currently selected tool by highlighting the according icon on the toolbar and by displaying the mouse pointer as a symbol indicating the functionality of the selected tool. These software solutions do not work well with interactive boards. Due to the direct interaction with the board, no remotely controlled pointer is required. Indication of an icon representing the current tool is usually only possible at the last position of the board that was touched by a user because the hardware normally only recognizes if a board is touched, not if the pen is moved without touching it. The indication of the selected tool at a particular place on the board still requires that one looks at this position before whiteboard actions are performed. The question rises whether it is reasonable to assign more than one functionality to the same input device if the operation is done directly instead of remotely. Some boards offer hardware based solutions to this problem. For example, the board that we used comes with an integrated pen tray holding several pens in different colors and a sponge. Sensors capture the tool which was picked up at last. Each contact with the board is now interpreted as the board is touched with this tool. This method can also cause problems, for example, if the user picks up more than one tool at a time or forgets to put a tool back to its place. In our experiments we discovered that such mistakes happen especially often if the board is used under stressful situations such as giving a talk. Furthermore, such a hardware oriented solution is not particularly flexible and thus not open to further modifications and extensions as a software based one. An interesting approach in this context is work done by the Integrated Publication and Information Systems Institute, IPSI, at the German National Research Center for Information Technology, GMD, and a group at the Xerox Palo Alto Research Center. Contrary to the traditional approach of first selecting a tool and then using it, they recognize gestures that represent different functions. Therefore operations such as moving of objects or the reorganization of tables can be done without the need to activate a special tool. Additional information on their work can be found in [3] and [5, 6].

The question of what functions should be offered to a user must also be addressed. The toolbar on our whiteboard has a variety of different functions, while the *ZenPad* [1] used in the classroom 2000 project at Georgia Tech offers only a few ones. Their reason for offering only some essential tools to the user is that they determined that most of the lecturers which utilized their whiteboard only used few of them. We experienced the same results when external lecturers used our whiteboard. An increasing number of options also reduces the manageability. However, we also discovered that people who are familiar with our whiteboard tend to utilize more of the additional tools we offer. Based on this fact, we believe that there is a demand for these functionalities. So on one hand high functionality discourages and confuses potential users. On the other hand reducing the functionality experienced users might want or need does not seem to be an appropriate solution. One good compromise we are working on right now is to make the toolbar customizable by the user. A "low level" user interface should only offer the basic functionality needed to give a presentation. Based on his/her own needs and experience, the lecturer can decide what features are necessary and still can be handled during a special presentation and add them to the configurable toolbar.

In our experiments we used either the interactive board or the graphic tablet, not both in common. In an ideal scenario one would like to have a wall mounted blackboard as well as an interactive high desk functioning simultaneously. The lecturer could then walk around and switch between the two input devices during the presentation depending on his/her personal aims. However, due to the use of more than one interface at a time the software has to handle the communications between both. No inconsistency should result from the use of different input devices. Even if both hardware devices, the interactive board and the high desk, are controlled by the same computer several problems have to be solved. Most of the common operation systems permit connections with more than one screen to a computer. However, it might be irregular for one program to run on both screens. Copying of an object from one screen to another is generally also not possible. This task is especially necessary if you put more boards next to each other to form a large interactive wall. Therefore appropriate network connections and protocols have to be established that allow such operations without the loss of consistency. Work in this area has been done by [8] and [7].

Finally the question has to be answered of how the content presented on these interfaces during a talk should be indicated on a receiver station during transmission or at a local desktop computer during offline viewing. The relationship between the hight and the width of the input devices we used were about the same as with regular computer displays. As we already mentioned, a larger size, especially concerning the width of the interactive blackboard, is desirable. Therefore intelligent representation techniques must be introduced that handle the conflicts resulting from the different size of the input devices used by the lecturer and the output devices used by the remote attendants or the viewers of recorded talks. As well, the integration of back channels for feedback from the audience placed at the remote channels has to be done in an appropriate way.

Summary

In the preceding sections we discussed some hardware and software issues on new user interfaces within the scope of telepresentations and teleteaching. We introduced discoveries which we gained with two alternative input devices: interactive wall mounted blackboards and a graphic tablet as replacements for regular computer input via mouse or keyboard. Our experiments and analysis showed that input devices currently available on the market can be used very well for teleteaching but somehow still are a compromise and lack especially in the provided size. We also illustrated that the use of these input devices raises new problems and offers additional challenges in the software design of the user interface. Our current work is to implement a new user interface that addresses the problems we discussed and to test and evaluate it with other hardware devices we are about to install in the teleteaching environment at our university.

DoCTA: Design and Use of Collaborative Telelearning Artefacts

Barbara Wasson & Anders Mørch
Department of Information Science, University of Bergen, N-5020 Bergen, NORWAY
Email: Barbara.Wasson@ifi.uib.no Anders.Morch@ifi.uib.no

Abstract: Project DoCTA focuses on the design and use of artefacts in a set of collaborative telelearning scenarios. From a research perspective, the exploratory studies being carried out within DoCTA will provide us with insight into the processes of collaboration enabling us to identify collaboration patterns and further our understanding of how instructors, students and other learning facilitators organise their learning and work. This paper describes the theoretical foundations, the four collaborative telelearning scenarios and the evaluation approach of project DoCTA.

1 Introduction

DoCTA (Design and use of Collaborative Telelearning Artefacts) is a Norwegian research project with partners at four different institutions and funded by the Norwegian Ministry of Education, Research and Church Affairs under their program on information technology in education (ITU). The project partners include is the University of Bergen (leader), Nord-Trøndelag College (HiNT), Stord/Haugesund College (Stord) and Telenor Research and Development, Kjeller (Telenor FOU). The 16 researchers and graduate students involved have various backgrounds including computer science, psychology, sociology and education.

Within project DoCTA (http://www.ifi.uib.no/docta) we focus on the design and use of artefacts in collaborative telelearning scenarios aimed at teacher training. Various scenarios utilising the Internet will be used to engage the students in collaborative learning activities. Through participation, teachers gain experience with not only collaborative learning, but with collaborative telelearning, and the design of textual or visual artefacts. Each collaborative learning activity has been designed to place a strong emphasis on active engagement through both "hands-on" practical experience and explicit reflection on the collaboration process. Experiences can be transferred back to their own schools, and ideas about collaboration can be integrated into their everyday teaching.

Four different collaborative telelearning are studied. The first scenario, PedInfo, is a pilot study for analysing the use of TeamWave Workplace for collaborative activities in a graduate university course at the University of Bergen (UiB). The next two scenarios, IDEELS and Demeter, involve European inter-cultural simulations where the goal is to design a textual artefact (such as a treaty or policy statement). A fourth scenario, VisArt, that has been designed and developed explicitly for use between the three educational partners (UiB, HiNT and Stord), has the goal of designing a visual artefact to be used in teaching a subject of choice.

From a research perspective, the exploratory study being carried out within DOCTA will provide us with insight into the processes of collaboration enabling us to identify collaboration patterns and further our understanding of how instructors, students and other learning facilitators organise their learning and work. The community of study includes teachers, learners and facilitators participating in the various collaborative telelearning scenarios. The main research question has been formulated to ask how these students, teachers and facilitators organise their work given the different scenarios. The four collaborative telelearning scenarios vary with respect to:

- actor characteristics (e.g., within a common community vs. disparate and divergent cultural backgrounds; similar knowledge and preparation vs. different knowledge and preparation; etc.),
- aspects of the learning activity (e.g., text based vs. visually based; well-defined learning tasks and goals vs. ill-structured tasks and goals; etc.),
- the kinds of artefacts they have access to (e.g., the artefacts provided in the various internet environments), and
- the kinds of artefacts they are to design (e.g., textual or visual)

This paper provides an overview of the theoretical foundations that influence our research and describes each of the four collaborative telelearning scenarios. The paper concludes with a brief description of the evaluation activities being carried out.

2 Theoretical Foundations

The theoretical perspectives that provide inspiration and guidance for this research come from: computer supported collaborative learning (CSCL), in particular Salomon's (1992) work on genuine interdependence; coordination science (Malone & Crowston, 1994); sociocultural perspectives (Wertsch, del Río & Alvarez, 1995) on learning and thinking; and, the emerging notion of distributed learning communities.

Computer supported collaborative learning (CSCL) is an emerging paradigm (Koschmann, 1996) for research in educational technology that focuses on the use of information and communications technology (ICT) as a mediational tool within collaborative methods (e.g., peer learning and tutoring, reciprocal teaching, project- or problem-based learning, simulations, games) of learning. It is an approach to ICT in education that emphasises an understanding of language, culture and other aspects of the social setting (Scott, Cole & Engel, 1992). Its intellectual heritage can be found in social constructivism (Doise, 1990), the Soviet cultural-historical psychology (e.g., Vygotsky (1978), Leontiev (1978), Davydov (1988)) and situated cognition (Suchman, 1987; Lave, 1988).

CSCL research involves naturalistic observations being used in an exploratory fashion to permit a more complete understanding of this instructional mode. The emphasis is on the process and not so much focused on outcome. Evaluations often result in descriptive studies which focus on artefacts that support or are produced by teams of learners and usually contain participant accounts of their own work. The influence of CSCL research on DoCTA is evident in the type of research questions we ask and in the choice of conceptual framework for organising our evaluations.

Guribye & Wasson (1999) describe the underlying conceptual framework adopted in DoCTA as an integration of three different, although closely interrelated approaches: activity theory (Leontev, 1978, Engeström 1987), distributed cognition (Hutchins, 1995), and situated action (Suchman, 1987, Lave, 1988, Mantovani, 1996). All three approaches underscore the need to look at *real activities* in *real situations* (Nardi, 1996, our italics), and always, in some way, include the context in studies of human activity. One of the goals of this research is to argue that, together, these approaches make up a rich framework for describing, evaluating and analysing collaborative telelearning scenarios.

Salomon (1992) is concerned with effective collaboration and he argues that collaboration will only be effective if there is genuine interdependence between the collaborating students. Genuine interdependence is described as 1) the necessity to *share* information, meanings conceptions and conclusion, 2) the necessity for *division of labour* into complementary roles, and 3) the need for *joint thinking* in explicit terms. In project DoCTA, Salomon's ideas influence the design of the collaborative tasks given to the students – effort is placed in designing tasks which create genuine interdependence between the students.

Coordination theory (Malone & Crowston, 1994) provides a means for specifying (inter)dependencies between, and among, actors, goals, activities, and resources by identifying a *dependency type* (e.g., shared resource) and a *coordination process* (e.g., group decision-making) for managing the dependency. In their work, coordination is defined *as managing dependencies between activities,* hence they have focused on dependence between activities. Wasson & Bourdeau (1997) report that viewing collaborative telelearning from a coordination theory perspective offers a means of understanding the inter-relationships between actors and entities and how these relationships can and should be supported. Adopting Salomon's ideas about genuine interdependence and a coordination science approach, they modelled (inter)dependencies between actors in collaborative telelearning scenarios and they have extended the definition of coordination to be *managing dependencies between activities* (Malone & Crowston, 1994) **and** *supporting (inter)dependencies between actors.* Wasson (1997, 1998) proposes a set of actor (inter)dependencies and related coordination processes for collaborative telelearning. The importance of this work for DoCTA lies in making sure the technological environment within which the students carry out their tasks provides mechanisms that make coordination as effortless as possible. Otherwise coordination issues can become a bottleneck that hinders students from carrying out their individual and collaborative work.

The final area providing inspiration is summarised as follows "...a distributed collaborative learning community is a *'place'* that is created by the individual students through their individual and collective actions, ...The designers' role is to *support the students' work of creating that community*, and in such a way that the computer systems become integrated parts of the students' activity (Fjuk, 1998, p. 70)". Furthermore, Fjuk (1995) concludes that collaborative telelearning applications need to have both a mediating role between the individual learner and the peer-students **and** between the individual learner and her learning tasks. Thus, collaborative telelearning can be understood as a medium for inter-human interactions and articulation of individual work. As designers of DoCTA learning tasks and the technological support environments, we must keep in mind that our role is to provide a supporting environment that makes coordination, communication and collaboration as transparent as possible (Bourdeau & Wasson, 1997) enabling students to create their own learning community. The environment must also support both individual and collaborative work.

3 The Scenarios

The design of collaborative telelearning requires the instructional design of collaborative learning tasks and the specification of the technological design comprising the learning environment configuration including the tools and services available (Wasson & Bourdeau, 1998). Four scenarios PedInfo, IDEELS, DEMETER and VisArt have been studied.

3.1 PedInfo

In the PedInfo scenario, 7 of 18 students in a graduate class *on research issues in pedagogical information science* at the University of Bergen, are geographically dispersed over Norway from Alta and Mo i Rana in the far North, to Holmestrand outside Oslo, to Stord and Haugesund on islands south of Bergen. The class meets physically in Bergen one day every third week. The challenge is to support the students in their creation of a distributed collaborative learning community. Collaborative learning tasks and the technological environment have been carefully designed. The technological environment is comprised of their own email system, a word processor of their choice, and groupware TeamWave Workplace (TW, http://www.teamwave.com). In TW (which uses a room metaphor), 14 tools are provided enabling teams to easily plan, set up a database, design, share documents, link to the web, chat with one another etc. In order to become better acquainted with one and another and to become familiar with TW, a collaborative team building activity was designed (see team building room in figure 1).

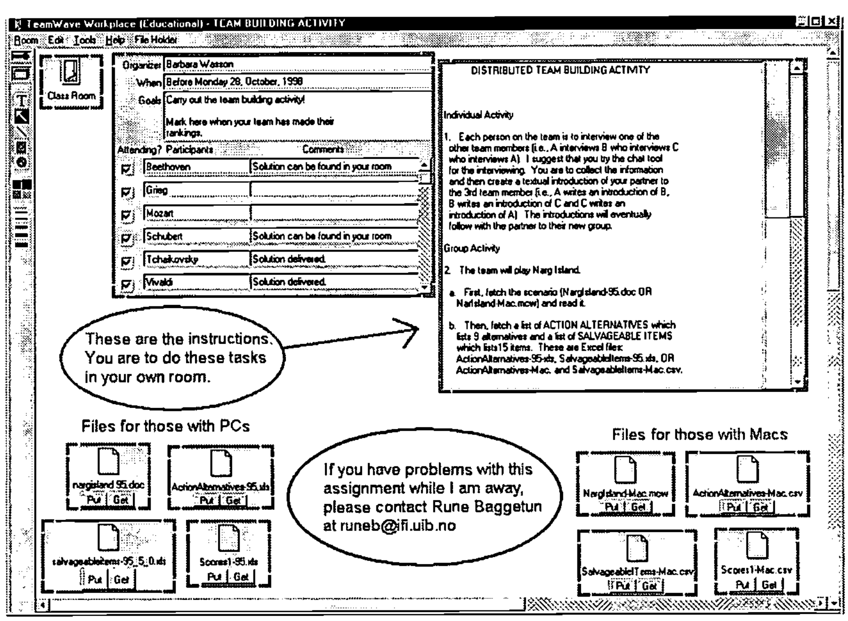

Figure 1 Team building room in TeamWave Workplace

BEST COPY AVAILABLE

The team building activity consists of first interviewing one another (virtually) and making a presentation of the interviewee to the others (these were placed in a Participant Profile room), and a group activity (the class was divided into 6 groups) which was a survival game where they had to negotiate a team strategy.

In the top left hand corner you see a doorway tool allows easy movement between rooms – here you see the link to the Class Room. Beside this there is a voting roster tool which has been used to enable teams to indicate when they have completed the activity. Next to this, a file viewer tool holds the directions for the team building activities. In the bottom left and right corners, file holder tools contain files (actually the files sit on the TW server) for the students to download. To access the files the students just press the Get button and the file is saved onto their local machine (to place a file on the server, one just uses the Put button). On the shared whiteboard (the background) text and graphics can be placed, and synchronous communication can be carried out.

TW was chosen for a number of reasons including that it grew out of several research systems developed in the Grouplab Project at the University of Calgary, it is tailorable by the learning environment designer (it is extensible through a easy to use toolkit), and the instructor and students themselves (by creating rooms and though access to a large number of tools), it support both asynchronous and synchronous collaboration, and not the least it is both easy to learn to use and is reasonable priced. TeamWave Workspace will also be used in the IDEELS and VisArt scenarios.

3.2 IDEELS

Project IDEELS (Intercultural Dynamics in European Education though on-line Simulation) brings together a diverse group of educators and researchers from five tertiary institutions in four European countries who share a common interest in simulation and games. IDEELS is an EU Socrates curriculum development project with partners at the University of Bremen, Germany (co-ordinators), the Polytechnic University of Valencia, Spain, the University of Nice, France, and Nord-Trøndelag College and University of Bergen, Norway. The goals of IDEELS include adding impetus to the curriculum development trend towards content & process-based learning and to enhance European competitiveness by providing students with opportunities to learn essential cross-cultural, linguistic and negotiating skills. A generic simulation game is used to complement existing curricula in a wide range of areas including language learning, negotiation, policy studies, political science, environmental issues, cross-culture communication, law, education, and computer science. In IDEELS simulations, students act as high-level negotiators, consultants, and journalists in a fictional world, working to resolve real problems of importance to the European Community – problems that can only be solved through co-operation at the international level.

Teams from the various partner institutions take on different roles in a simulation conducted on two levels: deliberations within a team and negotiations between or among teams. Thus, it can be said that the simulation scenarios are designed to require (inter)dependence among both team members and between teams. Teams are given a common mission where the goal is to produce and ratify a jointly-written document (e.g., come to a consensus and sign either a policy or treaty, or write a set of recommendations). For example, the scenario that is running in the fall of 1998 (http://www.zait.uni-bremen.de/wwwgast/fzhb/ideels/public_html/) requires that the students draw up and agree on a design plan for the educational system for Eutropolis, the New Eutropian Capital. Using Salomon's (1992) definition of genuine interdependence it can be argued that in order to participate in the game there is a necessity to share information, meanings and concepts about the topic of the simulation, a necessity for division of labour within a team in order to build up the teams position before negotiation with the other teams, and a need for joint thinking to come to a consensus so a policy or treaty can be signed by all partners.

The Norwegian participation in project IDEELS (UiB and HiNT) is organised through project DoCTA. The technological environment that has been designed for the participating Norwegian students includes their own word processor, TeamWave Workplace and OPUSi, a computer-based communications system that is accessible through the world wide web and was developed at the Department of Computer Science, University of Bremen. OPUSi enables the students to send written messages within and between teams as well as providing for real-time, online teleconferences. As in the PedInfo scenario, the Norwegian students participating as teams in IDEELS are geographically spread over Norway. It was decided that OPUSi does not provide enough support for these students to collaborate, so TeamWave Workplace has been added to support the collaboration activities.

3.3 Demeter

Demeter (http://hugin.hsh.no/prosjekt/demeter/index.htm) is a European distance education project run by ITE (Organisation for Internationalization of and Innovation in Teacher Education) involving15 European Educational Institutions in Norway (Stord), Sweden, Ireland, Netherlands, Germany, Greece, England, Scotland, Austria, Lithuania, Portugal. Project DoCTA will be evaluating the Norwegian students' (Stord) participation in Demeter. Like project IDEELS, Demeter involves role-playing and provides for cross-cultural education and communication in Europe and includes inter-cultural networks for democracy education, and education in European citizenship within the framework of teacher education. The education is open to students all over Europe to study, compare and produce materials about issues that are of interest for most parts of Europe. Students contribute solutions to local problems in Europe from perspectives true to both their own cultural background, but also as European citizens.

Demeter is based on a parliament metaphor that supports the vision of how a true cross-cultural exchange of ideas, knowledge, understandings and meanings can be arranged. Participation in the parliament requires debate, research, submitting proposals and propositions and voting on the decisions that flow from them. When a consensus cannot be reached, respect for the ideas of others taking part in the democratic process must be shown. Topics discussed in the Demeter Parliament are authentic problems that occur in the real world are considered. For example Children Rights were discussed in the spring of 1998 and in 1999 the topic to be considered will be the preservation of heritage sites. The collaboration tasks are designed around committee work. Students participate as Members of Parliament and join committees where they are to elect a chairperson and secretary, and solve a number of tasks from a problem-oriented and problem-solving perspective. The committee members are to collaborate to write a report to be delivered in a parliamentary session that is working towards a Children's Bill of Rights. At the end of the Parliament session, members of parliament write a farewell speech which summarises the work they have done, the decisions this has brought about, what has been learned, and how the parliament session has influenced their view on the issue that has been discussed. The farewell speech also describes how the work has been conducted including both a description of socialising and the problems encountered while having to cope with parliamentary working methods. Again, it can be argued that this fulfils Salomon's criteria for genuine interdependence.

The technological environment is the Demeter Parliament accessible through the web. The Parliament is a virtual world that includes a Café, a Library, a Post Office, a Lobby where participants can post messages and join discussion groups, and it provides participants with a number of services including an agenda, access to experts, a means of join committees, an area for voting, a means for chatting, a forum for debate and help.

3.4 VisArt

While IDEELS and Demeter dealt with the design of textual based artefact, VisArt has been designed to explore the collaborative design of a visual artefact. The collaborative task will involve intra team collaboration to design a TW room for use in teaching some subject of their choice. Teams will comprise a student from each of the Norwegian partner educational institutions (UiB, HiNT and Stord). This gives a rich mixture of students with various backgrounds. The UiB students are graduate students studying pedagogical information science and thus have a either a background in both pedagogy and information science or just information science. The HiNT students are teachers taking an introductory evening course on information technology and education thus they have little if no backgound in the use of information and communication technologies. The Stord students are third year undergraduate students taking a pedagogical information science course so they are primarily educated as teachers, but have been taking a number of information science courses as well. We feel that this will make an interesting blend and will create (inter)dependencies between the students. We are curious to see how they divide their work and reach a consensus first on what they will design (we expect the students with more pedagogical background to take a lead here) and second how they will carry out the development of the web artefact (we expect the students with more technical backgrounds to take a lead here). The technological environment being designed for these students includes email, TW, their own word processor and the web. Prior to the design task, students are trained in both use of TW and in collaboration.

4 Evaluations

The evaluation aims at a naturalistic study of how participants in collaborative telelearning organise their work and learning activities. In order to collect data about the activities in which the student are engaged, different methods and techniques are being used. The most important sources of information will be derived from observing the students as they collaborate and interviewing them, and also from electronic logging of artefacts used for collaborating (e.g., email, shared whiteboards, chats, to-do-lists) and artefacts designed (e.g., a TW room) during the collaboration. Our theoretical framework influences the evaluation question we have asked and the analyses we can make. Guribye & Wasson (1999) provides a more in depth rationale to the choice of our evaluation approach. For example, three graduate theses focus on using an Activity Theory perspective to examine collaboration patterns in the IDEELS and VisArt scenarios. We are supplementing this overall focus on collaboration patterns and how the participants organise their work, with several graduate theses that will focus on evaluation of the technological environment. For example, one thesis is focusing on the usability of TW by monitoring how students' opinions about the utility of the tools changes from their initial impression to a final judgement after a semester of use. Another thesis is focused on the analysis of TW data logs to look at how the different artefacts were used for collaboration activities. A third thesis is concerned with coordination.

Multimedia Technologies in Education of Mathematics: An Experiment with Pythagorean Numbers

Sae-Hong Cho & Forouzan Golshani & Youngchoon Park
Department of Computer Science & Engineering
Arizona State University
Tempe, AZ 85287-5406, USA
{shcho, golshani, ycpark}@asu.edu

Abstract: Whereas for most people the only application of multimedia technologies in education is hypertext arrangements of topics plus "page turning," we view multimedia technologies as an effective way of visualizing the abstract concepts that are generally hard to grasp. As such, we attempt to create virtual representations of difficult concepts as teaching/learning aids. The important issue is that the student can then work with the virtual representation by making meaningful changes to the object and seeing the results.

In this paper, we visualize the notion known as the Pythagorean numbers, i.e. the equation $a^2 + b^2 = c^2$, in a way that it can be manipulated by the student. As a part of this, we animate a proof for this equation. In addition, we implement the following variation of the Pythagorean theorem: if the congruent shapes are drawn extended from each side of a right triangle, then the area of the shape which extends from the hypotenuse is equal to the sum of the areas of the shapes which extend from the base and height.

1. Introduction

A number of experiments for improving the quality of education by using the modern technologies are currently underway. Especially, mathematics educators show a great deal of interest in the impact of computers on teaching and learning mathematics. A typical example of new ideas in this area is providing additional visual and/or auditory effects to students. This is commonly achieved by simultaneous use of data in different forms such as text, audio, images, graphics, video, animation, and so on. Generally these representations involve the usage of multimedia tools and techniques. We will explore applications of multimedia technologies used to develop the educational tools for mathematics.

Many students experience difficulties in understanding certain concepts presented by the traditional teaching methods. For such students, a computer can be a useful tool to enhance the students' understanding by providing the visual and/or auditory effects. Most of the currently existing learning and teaching tools are nothing more than mere "page-turning" programs on the computer. That is, these kinds of tools do not make the best use of the strength of the computers as a supplementary method to typical schooling because they are just a copy of the textbook on computer. We will examine these motivations for the project closely.

Another angle of this research is investigation of supporting theories for the development of teaching tools for mathematics. Many existing tools adopted behaviorism as their basic idea. Since this philosophy has been the cause of a number of fundamental problems, we added constructivism and cognitive theory to construct a new background theory as an alternative to behaviorism. The basic concept of the newly synthesized theory is that students can learn the new knowledge by logically connecting it to already existing knowledge. A more detailed discussion of the background theory will be presented in the following sections.

To demonstrate how teaching tools may be developed, we have developed several modules for a variety of concepts in mathematics, physics and chemistry. As an example of selected mathematical concepts, we will present a tool for understanding the Pythagorean theorem which seems very easy at first glance but requires much more work to achieve mastery level. The new educational theory is applied at each step of implementation so that the resulting program will not be a mere explanation of the theorem.

2. Multimedia Technologies and Education

In this section we discuss the steps involved in the development of multimedia tools for educational purposes. While this is not intended to be a complete list, we highlight the major steps.
