With a course of such a large population size, we have inevitably encountered some problems. Initially we chose to make the size of the project groups between 8 and 10 students. However we were concerned that students should fully commit to a project because failure to fully partake could compromise the ability of other individuals in a small group to earn their grades. This concern about participation was prompted by claims from many students that they did not perceive the need to work with others, despite the OU's unique situation of having a student body whose mean age is 37 and so whose life experience could be expected to motivate this part of the course. Furthermore, we implement a substitution mechanism for the assignments whereby the least scoring assignment is substituted with the average mark from all other assignments. Therefore, due to the distribution of project work amongst the assignments, students can pass the course (albeit poorly) without participating in group working. So, to encourage participation and to maintain the viability of the individual groups, for the 1998 presentation, students could only take part in a group working project by registering for the project by a registration cut-off date. Students used FirstClass to send a proforma, pre-addressed project registration email to the M206 Group Working server. This server (which we developed in-house) collated and acknowledged (via FirstClass) the receipt of all registrations and, when registration had closed, randomly assigned students to project groups and hence to conferences. This involved the creation of about 800 separate conferences. The server then emailed each student the address of their project conference. However, despite email reminders and notices on both our Web site and the conferencing system, some students still failed to register for projects by the registration cut-off dates. This was generally due to two reasons: either they were unable to access the registration mechanism during the registration period (one student was under the polar ice cap in a submarine!) or students assumed that enrollment to the course equated to registration to all projects. Therefore for 1999, we decided to make project groups significantly larger (typically 25 rather than 10) and to automatically register all students for all projects. Due to the larger group size, student drop out from project participation should not significantly effect the viability of a group. At the time of writing the 1999 students cohort have not yet reached this stage of the course.

All the projects have multiple stages, with each stage being associated with a hard deadline. This can be seen in Fig. 1 which shows part of our web-based group working calendar. As various stage deadlines approach, the server sends out automatic reminders of the forthcoming deadline.

Project Schedule

Study Week	Project I Dates	TMA	Due Date
9	Stage 1 starts 10-Apr		
10	**Stage 1**		
11	Stage 1 ends 27-Apr Stage 2 starts 28-Apr		
12	**Stage 2**		
13	Stage 2 ends 11-May		
14		TMA03	18-May

Figure 1: Calendar for Group Working Projects

Typically, in the first stage of a project a student must study some new problem or variation on a familiar one and carry our some task such as writing a critique of a user interface, coding a subclass in Smalltalk or addressing issues to do with the analysis and design of some problem area. Subsequent stages usually involve commenting on, or testing other students submissions and/or going deeper into the problem.

Collaboration on a project is only deemed to take place if it has happened in the computer conference generated for that purpose. This is crucial for allowing graders to check that project work submitted in an assignment actually took place in a collaborative manner. However, this strategy has thrown up challenges. In particular we had to prevent the situation in which a talented student gives a complete answer so preventing others from making an effective contribution. To combat this, for Projects I and II, the project conference is not made visible on the student's FirstClass desktop until after the Stage 1 deadline. This means that whilst students can use the supplied conference address to post their Stage 1 contributions, they cannot see fellow students postings until after that deadline, thus solving the preemptive contribution problem mentioned above. After the Stage 1 deadline for Projects I and II has passed, for each student, the server makes their project conference visible on their FirstClass desktop.

A final issue encountered in 1998 was that of coordination of project participation which was related to the time period allotted for each project (about 4 weeks – see Fig. 1). Because of the varied lifestyles and domestic demands of the several thousand students in the "class", they inevitably tended to want to work at their own pace within the given time frames for the various stages. Some students would start work as early as possible, posting their ideas as to how to approach the posed problem only to be frustrated by having to wait up to two weeks for any feedback, as other members of the group were delaying their work until the latter half of the available time frame. We expect that our decision to enlarge the group conferences described above will also overcome this problem.

Sample Content

In the 1998 presentation of the course, Project I involved critiquing a user interface and consisted of two stages. Before they started this project, students had an opportunity to examine a sample project on the same topic and see how another group of students had tackled it. This sample project consisted of a software application and examples of conference postings that the group had made for each of the two stages. As in the sample project, stage 1 of Project I, involved students in having to analyze and write a critique of a supplied application's user interface, paying particular attention to the principles of visibility, affordance and feedback (principles to which they were introduced early in the course). This critique was then sent to the Project I conference by the deadline for Stage 1. As described above, these Stage 1 postings were not visible until after the stage's deadline had passed. When these postings became visible, Stage 2 involved students making some constructive comments about another group member's critique of the same user interface. This form of group working is of course highly constrained and somewhat artificial. However we deemed this to be necessary, in the first instance, to introduce our students to the notion of group working in a managed fashion. By comparison, the final two projects are much more realistic: students work together to solve a common problem. The group conferences are visible from the start and the interaction is much more fluid and discursive, with students making multiple postings for each stage.

Conclusion

Educational institutions often treat students as individuals who will produce independent pieces of work, and during their education are not often encouraged to share ideas, work together or evaluate each others work so that it can be improved. In the work place the opposite is expected. This is especially true in the software industry. Software developers are expected to work together, be team players, share ideas, and work towards common goals. Increasingly employers want evidence of such skills and aptitudes, which often require some degree of work experience before they can be mastered. Furthermore group working helps the budding software developer to think in terms of complex systems rather than just their part of that system or of traditional simple programs. To meet these industry requirements we have developed a suitable pedagogy and the mechanisms by which students can work collaboratively on projects over extended periods of time.

Introduction

At the start of 1998 Europe's premier distance learning institution, the Open University (OU), deployed a new introductory computing course, M206 "Computing: An Object-oriented Approach" (see Woodman et al. 1998). The course counts for one sixth of a degree (440 hours of study) and represents a radical change to the computing curriculum and a radical change to how supported distance learning courses are presented. Reception of the course was unprecedented, with over 5,000 students registering and its innovations being recognized by a prestigious IT Award from the British Computer Society. Now in its second year, some 600 additional students at the Singapore Institute of Management are taking the course, and with the OU now incorporated in the USA, it should be available in North America by late 1999. The course has a full mix of media: paper, broadcast television, interactive CD-ROM, a Web-oriented programming and learning environment, a Web site and computer-based conferencing. From the start of work on M206, we committed to a Web-centric strategy: "home is where the Web is" became the course team chair's slogan! In other words we wanted to organize all learning resources around the Web (see Sumner & Taylor 1998). Ideally we would like to have all such resources accessible via a common front end – a Web browser. However, pragmatics intervened, as described below, and we have not yet achieved our ideal. In subsequent sections we explain our technology architecture and the problems we experienced, together with consequent changes we had to implement for the 1999 presentation.

The Web Site as a Repository

We believe that the Web should be the seamless mechanism for all electronic communication: email, conferencing, Web pages, downloads, and whatever. For pragmatic operational reasons we had to compromise this ideal in order to provide students with a robust conferencing system that was fully supported by the OU. Hence, electronic communication became split between the M206 Web site and the FirstClass™ conferencing system[1]. Faced with this split we needed a clear principle for deciding what would be available via FirstClass and what would be available via the Web. Such a principle was not immediately obvious, since FirstClass could adequately support more than just conferencing – for example, a read-only notice board could disseminate new information and offer downloads and, with its use of an off-line reader, was arguably less expensive for our students to use in terms of connection time. The principle we arrived at is enshrined in the slogan, "FirstClass announces; the Web pronounces." That is, the Web became the repository for all non-transient learning material (errata and addenda to learning materials, assignments and mock exams, software downloads, etc.). Whenever any new learning material was added to the Web, the fact of the addition was announced on the student FirstClass Notice Board, directing the students to the appropriate Web page by means of a logical reference, for example, "Details of the revised Practical 9 are now available on the Chapter 15 Web page").

The 1998 M206 site was designed very much as a compromise between what was possible and what was acceptable. The main constraints on our site were those relating to the computers and communications used by our

[1] FirstClass is a proprietary conferencing system from SoftArc Inc. See http://www.softarc.com

students. The minimum computer specification precluded the use of graphically intense designs and greatly limited the amount of "bells and whistles" that could be included. In addition there would be a limited amount of staff time available to develop and maintain the site. The 1998 site was therefore designed in HTML 3 using a conventional frame-based solution. Navigation was handled by means of a frame on the left-hand side of the screen, with the contents of pages appearing in the right-hand frame (see Fig. 1). The design of buttons was chosen to reflect those used in other interactive course materials.

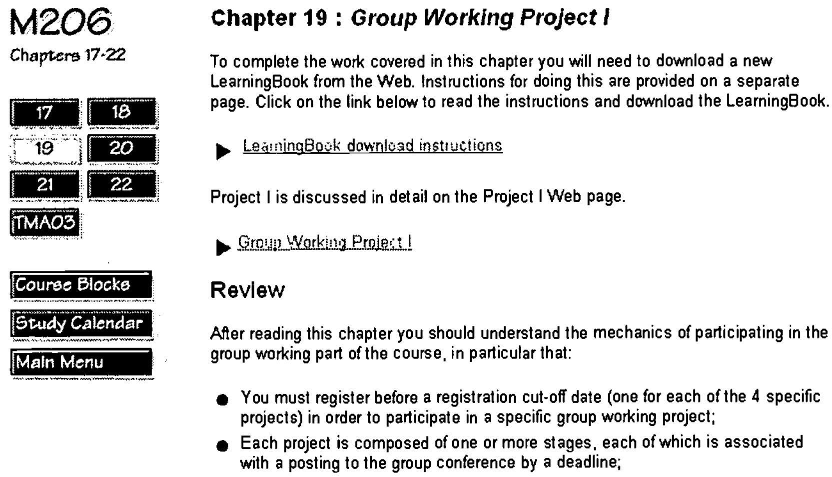

Figure 1: M206 Web site

The site was sub-divided into a number of areas relating to different aspects of the course, including information about using the site, calendars, etc. The main resources sections were:

Course Blocks – the course is broken into seven "blocks" each one covering a number of "chapters" (any multimedia unit) with an associated assignment. Chapter Web pages comprised of a recap of the important points and a section detailing any misprints or omissions. These pages also provided additional learning material, such as background reading, or transcripts of television programs.

Assessment – this section contained pages for the seven assignments and a specimen exam paper. On each page there were links to downloadable copies of the documents.

Software – students could use this section to update, download or test their software. Links were provided to software vendors and full installation guides given for the software.

Contacts – students must deal with a number of different parts of a large organization like the OU whilst studying. The contacts page listed the types of problem students might encounter (such as the failure of a password or missing course materials) alongside the appropriate postal or email address or contact phone number. As well as making the contact procedure less problematic for the student, it reduced the amount of mis-addressed email and post for the university.

News – originally all course news was distributed by means of the FirstClass system (see below), however, it was later decided that the Web offered a more robust solution to all of our users and the two systems were used in parallel. Items relating to the course (such as the posting of new pages, corrections to materials or notices about computer downtime) were posted on this page; old items were archived on linked pages for reference.

Conferencing as a Community

Of course, electronic conferencing was used for much more than notice board style announcements. Conferencing underpinned the support for group working that is an important part of M206 as well as providing an electronic forum for students to discuss all matters of interest to them in relation to the course. In our first year (1998), we created a detailed national conference/sub-conference structure based around the structure of the course (fifty two chapters organized into seven blocks, essentially). This conference structure was available to all 5,000 students.

We used FirstClass in several ways: first as the primary means of communication between the central academic team and both the student body and the part-time tutors supporting them. For example the M206 Notice Board conference was used for our "pronouncements". FirstClass was also the most direct way students had to communicate with us via an email id called M206 Course Office – a front for administrators and academics. We also used it for informal discussion of the course materials and, crucially, collaborative group working (see Griffiths et al. 1999).

Ease of asynchronous electronic communication immediately created a very real sense of a community of learners and teachers, interacting with the material and with each other's ideas and views. As teachers, we felt we had to be part of that community, reacting to requests, clarifying issues and (occasionally) defending ourselves against suggestions about the elegance, clarity and relevance of some of our teaching. Such involvement made huge demands on the academic's time, with the course manager and an academic often devoting 50% of their time to queries. The locus of control of the course was no longer firmly teacher-centered and the nature of the relationship teacher and taught was irrevocably changed.
There was a strong tendency for this community to be one that was sharing "bad news" or telling "war stories" – from inability to read some file, to ambiguity in an assignment question, and on to downright errors in learning material. This could actively construct a perception of a troubled course when the reality was quite different. Fortunately, there were various episodes where hundreds (if not thousands) of students actively emailed their general (and often enthusiastic) appreciation of the course. This did much for the frayed morale of teaching staff!

Problems Leading to Reorganization

Whilst the first year of presentation was successful, it was not without its problems. Students began to voice frustration at having to go to FirstClass to find a news announcement and then having to go to the Web for the detailed pronouncement. Furthermore we broke our own principle of "FirstClass announces; the Web pronounces." when it came to dealing with clarifications and tips and hints on assessment material – for both urgency and ease of student use, we made these pronouncements available via FirstClass on the M206 Notice Board. To avoid this confusion, for the 1999 presentation we have moved the M206 Notice Board to our Web site. The Web is now the sole site for both news announcements and pronouncements whereas FirstClass is solely used for conferencing.

Another problem that manifested itself with the 1998 presentation was that our use of national conferences placed an unacceptable burden on the central academic team and there was evidence that whilst it provided a vehicle for articulate and competent students it did not always support students in difficulty. Our use of national conferences also ignored an important resource – the 250 tutors who are employed part-time to assess student assignments and offer face-to-face tutorials and other support to groups of (typically) twenty to thirty allocated students. We have therefore adopted a somewhat different conferencing approach for the 1999 presentation. Instead of large national conferences each tutor now manages a tutor-group conference for their allocated students. The tutor-group conference is a vehicle for (a smaller, more focused and supportive) discussion of the course and associated issues throughout the year, as well as being the basis for sub-conferences to support group working. This will undoubtedly construct a different learning experience for both us and our students. Gone will be the wild roller-coaster ride of an electronic community of 5,000 students and teachers discussing every aspect of the course. In its place we aspire to a more localized and supportive structure of small groups, centered around a tutor and her/his students.

Conclusion

A pragmatic organizational requirement to use a proprietary conferencing system as opposed to a Web-based system led to a split in our computer-based resources we would rather have avoided. Consequently we had to establish a clear principle for dividing material between two "places" students would see as distinct, something that would be reinforced by the very different user interfaces. We initially determined that the FirstClass conferencing system would "announce", whereas the Web site would "pronounce". This supported the metaphor that FirstClass was a place to meet for talk, both informally and (in group working) formally and that the Web was a repository of useful, indeed vital information. However this split proved unacceptable, as it forced students to access two resources in order to find important course information. Hence for the 1999 presentation FirstClass is being used strictly for conferencing and the Web for both student notices and static, more considered information.

Hypermedia and Telecommunications
Are Only Good If You Can Use Them

Lois Hendrickson
Wang Global, Wang Government Services, U.S.A.
E-mail lhendri2@gmu.edu

Abstract: In education, our desired arena of presentation has moved from the immediate environment to the world, but we have not been able to make the necessary paradigm shift in the way we think about design and accessibility to allow the world to join in. Projects are typically dictated by the *content*, the *audience*, and *available space*. Using the Internet and Intranet has altered some of these limitations but the main concern is still the content. It requires that we look more carefully at how to organize and present the content. Concerns of how to display a project have moved from a concern of space availability to concerns of usability and accessibility.

Your web pages cannot be all things to all people. They can be accessible to and usable by the largest audience possible. This paper looks at some easy-to-implement ways to do this.

They Are Only Good If They Can Be Used

Multimedia/hypermedia and telecommunications activities are only good if they can be used. That, obviously, is common sense. Why even bother stating it?

Why? Because in many instances we design these activities to keep potential learners at a distance. Not deliberately, of course, but we still do it, especially in web-based instruction. In education, our desired arena of presentation has moved from the immediate environment to the world, but we have not been able to make the necessary paradigm shift in the way we think about design and accessibility to allow the world to join in. Projects are typically dictated by the *content* (that which is to be taught) the *audience* (those who are to be taught), and *available space* (the size of model or poster board that can be carried to school or the amount of shelf or wall space available in the classroom). Using the Internet and Intranet has altered some of these dictates but the main concern is still the content.

Use of the Internet or Intranet requires that we look more carefully at how to organize the content into meaningful chunks that can be presented in a clear, concise manner on web pages that are robust enough to stand alone, yet are small enough to be downloaded easily. The target audience is no longer simply the class, the school, and the parents. It is now anyone, anywhere with an interest in the school, the students, or the content of the web page. Concerns of how to display a project have moved from a concern of space availability to concerns of usability, accessibility, and intuitiveness.

Your web pages cannot be all things to all people. They can be accessible to and usable by the largest audience possible. This paper looks at some easy-to-implement ways to do this.

The Audience

Knowing that your audience can be anyone—of any age —with any interest is not helpful in the analysis process. You have to decide who your main audience will be and work from there. If you're involved with a school, you can assume the school's administrators, teachers and students will be part of your audience. Students in other schools, relatives, friends, former students, and anyone with an interest in the use of technology in educational settings will also be interested in your pages.

Your audience, and here we are talking only about the people who actively seek you out, will include those with the fastest modems and latest computers to those with old systems, slow modems, and monochrome monitors. It will also include the deaf, the hard of hearing, those who are blind or have limited vision, individuals with physical disabilities, and users who feel challenged by technology. They are individuals who may have problems discerning colors in graphics and text or those who have turned off the graphics function on their computer or those who use a screen reader. Unless an alternative method of delivery is available, content presented only via audio may be lost to individuals with hearing impairments or those without soundcards in their machines. Pages with closely spaced hyperlinks can create navigational problems for individuals with certain physical disabilities. Context that is not easy to understand, distracting graphics, or noisy backgrounds make pages less accessible or less usable for most users.

Web pages that do not meet the needs of the user will suffer the fate of either the "Back" or the "Stop" button. Without that audience, there is no reason for your web pages to exist. The information could be presented just as effectively face-to-face in a classroom.

What Is There And How We Get To It

Focus On Content

We build web pages to convey content. If there is no content, there is nothing to convey. Pages that are simply lists of links to other sites are useless if those sites are down. The links you put on a page should be additional resources to give more value to what is presented on your page, not the primary reason for the page's existence.

Unlike printed pages, pages on the web must be designed to stand alone. A user can enter at any page using any browser. Just as you would want a guest in your home to feel as comfortable as possible, a guest at your web site should also feel comfortable. Upon entering any page, the users should know where they are, what else is available to them, and how to navigate from one page to another.

Provide Relevant, Reliable Links

- Check your links frequently. A page filled with "dead" links is frustrating.
- Provide a visible link at the top of each page to allow users to move back and forth between the graphical and alternate versions of the page.
- Have the text only version of the page link to other text only versions. Otherwise, for every page the user is linked backed to a graphic version, only to have to link back to the text version.
- Place non-link printable characters (surrounded by spaces) between links that occur consecutively, e.g., the use of "|" between the links at the top and bottom of this page.
- Screen reader users often read the page, then tab through the page moving from one link to another. Since they are tabbing past the surrounding text, landing only on the links, a link may be meaningless. Create meaningful link phrases. The phrase "full text of document" is more meaningful than "click here".
- One way to make the links stand out clearly for the screen reader user is to make the links separate from the body of the text, e.g., in a list or a menu following the text.

Provide Alternatives

Providing alternatives makes your site accessible to the largest number of people possible. This means, among other things, providing alternative versions that convey the same message as the graphics or audio.

A page does not have to be dull and boring to be equitable. It just needs to present alternatives.

- Give users the ability to use the browser of their choice and not to be forced to use the one for which your page was designed.

- Use the "alt" attribute to provide alternated text for images, e.g., <IMG SRC="dod.gif" alt="Department of Defense Logo"> . In using the "alt" attribute, keep the text short. It might be easier to describe the function of the graphic rather than the graphic itself.
- A D-link is a link to a long text only description for graphics, such as tables, charts, or diagrams, which have important information. Example: <IMG SRC="enrollment.gif" alt="Chart of school enrollment 1998><A HREF="enrollment98.html">D</A> The "D" would appear next to the graphic of the enrollment chart. When the user clicks on the "D," a text only description of the chart will open.
- If possible DO NOT use frames. If you do use frames, provide an alternative text version.
- Provide a text transcript for all information presented in auditory form.
- Provide an auditory alternative for all information presented in video form.
- Provide a text transcript for all information presented in video form.
- Provide text summaries of tables for non-visual users.
- Provide both graphic and text versions of web pages.
- Users should be able to determine the colors for backgrounds and text as well as the size of font used. They should be able to work in an environment that is comfortable for them.
- Include a note about accessibility. Encourage users to notify you with concerns about accessibility or usability.

Make the page clear, concise, intuitive, and consistent

In your classroom doors look like doors and the doorknob is where you would normally expect it to be, not on the ceiling. Elements on your web page should also look and act the way you would expect them to do. Selecting the blue, underlined text Contents should take you the Contents page, not start a movie about the migration of ants.

-
- Be consistent. Page elements that perform the same function on different pages should be located in a constant location on every page. Pages that are consistent in layout are easier to navigate and easier to maintain.
- Users should be able to determine the colors for background and text was well as the size of font used. They should be able to work in an environment that is comfortable for them.
- Use an internationally understood date format: January 9, 2002, not 01/09/02.
- Make sure there is clear contrast between the text and the background.
- The background should be just that – a background. Don't let it be more interesting and attention-getting than the content.
- Test your page by running it in monochrome mode.
- Provide a visible link at the top of each page to allow a user to move back and forth between the graphical and alternate versions of the page.
- Test your pages with a variety of web browsers.
- Keep it simple.

HTML is not a desktop publisher

HTML not a desktop publishing environment. It is a content markup language. Web authors prepare and present content. They use HTML to structure paragraphs, headings, lists, and tables. It is the users who can configure their browsers to choose font size and color. When building web pages, start with the content and then add the necessary, relevant the links and images. Don't use HTML to create a page that cannot be reconfigured by the users to meet their needs. Use it to create pages that are proportionally structured so users are able to change font size and color.

- Use style sheets to control layout, alignment and positioning.
- Use standard HTML. Do not use functions that will work only on specific browsers, e.g., <Blink> is not supported by all browsers.
- Marquee text is often read one word at a time as it appears on the screen. It may be read backward one word at a time if that is how it appears.

- Use logical rather than physical markups: for italics use the logical <EM> instead of the physical <I>. For bold text use the logical <STRONG> instead of the physical <B>.
- Provide a single downloadable file for documents that appear on separate pages.

The Display

Keep the pages small, no longer than a screen-and-a-half in length. The total page size, including graphics, should be about 30K, 40K is pushing it. It should take no more than 10 seconds to download a page. Keeping it small means it is usable even on old systems with slow monitors.

- Do not use frames.
- Keep page layout simple and straightforward.
- Use text that is clear, concise, and easy to understand.
- Keep the backgrounds simple. Users, especially those with low vision, colorblindness, or a monochrome monitor may have trouble reading text on busy backgrounds.
- Leave ample space around items to be selected.
- Avoid large graphics taking a long time to download. Usually a smaller version will do. Provide a link to the larger version.

Tables

Tables may be difficult for screen readers to read. If tables must be used, provide a text only version of the table.

Try this to see how a table might be read by a screen reader:

1. Open a web page that has a table.
2. Hold a piece of paper up to the screen so it can read only one line at a time.
3. Read the line aloud. Does it make sense?

For example:

Distance Learning	Traditional Classroom
allows asynchronous	allows teachers to grasp
interaction — not the	teachable moment.
dependent on time	
or place.	

With a screen reader, this might be read as:

Distance Learning Traditional Classroom allows asynchronous allows teachers to grasp interaction — not the teachable moment. dependent on time or place.

Lists

Lists can also be confusing for non-visual users. A list that is several layers deep may be easy to follow visually; however, if it lacks discernable clues to indicate the layers the non-visual user will be unable to read it easily. Additionally, if text wraps to the next line it may appear as two separate entries.

The list:

- School Supplies
  - Paper
    - Lined
    - Graph
    - Sticky pad
  - Pencils
    - Black #2 lead
    - Red for marking
  - Pens
    - For writing

Black ink
Blue ink
For marking
Yellow highlighter
Blue highlighter

Might be read like this by a screen reader:
School Supplies
Paper
Lined
Graph
Sticky pad
Pencils
Black #2 lead
Red for marking
Pens
For writing
Black ink
Blue ink
For marking
Yellow highlighter
Blue highlighter

Use formatting options, such as numbering conventions, such as compound numbering to understand.

School Supplies
1. Paper
   1.1. Lined
   1.2. Graph
2. Pencils
   2.1. Black #2 lead
   2.2. Red for marking
3. Pens
   3.1. For writing
      3.1.1 Black ink
      3.1.3 Blue ink
   3.2. For marking
      3.2.1. Yellow highlighter

Eight easy tips

1. Provide text summaries of tables for non-visual users.
2. Avoid using tables if possible.
3. Avoid using tables as a way to control layout, such as putting text in columns.
4. If you are using a table to layout text and numbers the screen reader may append all of the numbers from the different columns in the same row into one number. Provide a text only version if you want to use the table.
5. Using numbered (ordered) lists makes it easier for those using screen readers to keep track of where they are in the list.
6. State the number of elements in the list.
7. Provide text summaries of tables for non-visual users.
8. Test your table.

Being aware of the need to make web pages more accessible and usable is the first step. The next step is to incorporate accessibility and usability design features into your web based instruction. Using the design suggestions mentioned in this paper will not make your web-based materials accessible to everyone. Their usage will, however, help you get started. Designing accessible and usable web pages may require a learning curve but, like all good things, it is well worth the effort. To help you, there are many excellent resources on the Internet to help you in designing accessible and usable web pages. The World Wide Web Consortium (W3C) at http://www.w3.org, one of leaders in this area, even provides an HTML validation service to test your pages.

Remember, your multimedia/hypermedia and telecommunications activities are only good if they can be used.

Concept Tagging and Dynamic HTML Generation for Adaptive Teachware

THOMAS T. FUHRMANN

Praktische Informatik IV
University of Mannheim
Germany
fuhrmann@informatik.uni-mannheim.de

Abstract: Static HTML links are not appropriate for quickly evolving teachware to which several authors independently contribute material on overlapping topics. Furthermore static links are not capable of providing students with an individualized linearization of the hypertext suited to their individual level of previous knowledge and competence. We hence propose a linking mechanism based on concept maps and a respective tagging of the source material for the course. These tags are used to dynamically generate HTML pages that reflect the learning level of the individual students.

1. Introduction

The ability to use mathematical language is one of the most important ingredients for a successful study of natural sciences and engineering. It is also one of the subjects feared most by students since training in its abstract way of thinking is not thoroughly practiced at school. Hence a dislike of mathematics or the self-perceived failure to understand its concepts is one of the most frequent reasons for not choosing technical subjects.

The Faculty of Physics at the University of Heidelberg is thus trying to smoothen the entry into the abstract world of physics by offering a two-week tutorial course in mathematics for first year undergraduates. During this intensive course the students can revise and practice their skills in central areas of mathematics like calculus, complex numbers, vectors, and matrices that are required in physics almost from the first day on. Especially students who are not fresh out of school but who have completed their military service or an apprenticeship prior to their studies show a great need for intensive recapitulation of mathematics.

Since the mathematical knowledge of first year undergraduates differs vastly from student to student a personal tutor for each would be highly desirable though of course not affordable. Therefore, two years ago we began experimenting with various electronically enhanced means for undergraduate mathematics education that can do more than the usual multimedia-enhanced teachware.

Two specific challenges characterize our project. Firstly, many authors with different objectives contribute on a continuous basis to our courseware even though it is already being employed. Secondly, the students using the courseware are rather disparate with regard to their previous knowledge, motivation and intended careers. The notion of links as incorporated in the HTML specifications suffers from some major drawbacks with respect to either challenge:

A link can only be established if its destination is known upon coding the source for the page containing that link. If for example an author decides later on to provide additional information on a specific topic all pages that are to link to that new page will have to be re-edited.

Links to a given page will be broken if that page is removed. If for example an author splits a page in order to better accommodate the topics contained in the original page, all links pointing to that page then have to be updated to the respective locations of the newly created pages. This requires not only a complete check of all pages that could possibly be linked to the page in question but also a certain understanding of both the source and the destination topic.

Human knowledge and human thinking differ profoundly in structure. While the structure of the former is interwoven the latter is in principle strictly linear. This linearity can only be broken by again picking up points of thought abandoned earlier. This pseudo-linearity is commonly realized as a hierarchical tree-like structure.
However, HTML courseware based on this principle tends to resemble what can be done in books. An unstructured linkage on the other hand is hard to use and therefore often rejected by students.
A novel mechanism able to circumvent these drawbacks should hence be able to link the different parts of the courseware using invariant features of the content itself. It must not depend on a specific representation of that content. The mechanism should also reflect possible linearizations that are meaningful to the reader.
We propose a three-step solution to that problem: Firstly, we describe the invariant structure of the course content by means of a simplified type of concept map. We then tag these concepts to the HTML material. In the third step we use the mapping and tagging in steps one and two to dynamically generate HTML pages that have now been individualized for each user.
Concept-based structures are a common tool for providing HTML metadata. Concept maps or graphs are described by several authors as a graphical tool for structuring ideas [1], [2]. Novak presents many examples of how concept maps improve the results of teaching efforts [3], [4]. Based on these and other experiences concept maps have meanwhile been directly employed in several hypertext applications [5]-[9].
This paper is structured as follows. In section 1 we have given an overview of our motivation and the problems encountered during the preparation of our courseware. In section 2 we present our concept map approach and the corresponding tagging mechanism that we developed to handle these problems. Section 3 explains the dynamic HTML generation and gives a practical example. Section 4 reports on the early experience with our tools. In section 5 we summarize our project and draw conclusions.

2. Concept maps and HTML tagging

Thinking is often equaled to speaking. Particularly if we also consider non-verbal symbols to be words in an abstract language. In this sense, words or phrasal combinations of them are the building blocks of our thinking. They reflect our concepts of a certain subject. Naming concepts is a major activity during the cultivation of new areas of knowledge. And being able to appropriately name and relate concepts during a dispute is taken as a sign of understanding.
Relying on this fact we made concepts the features on which we base our linking. Concepts, however, should not be confused with the words which describe them. The former are essential and unique, the latter somewhat arbitrary. The scientific context often establishes a rather strict terminology, mostly with one, sometimes with two but rarely more equivalent names for a concept. We will consider this equivalence problem later, for the time being taking uniqueness for granted.
As the building blocks of our thoughts and knowledge concepts are glued together by their mutual relations. These in turn can differ greatly in depth and complexity, ranging from easy 'has a'-type relations to more intricate relations such as 'changes color if in contact with' when for example describing an indicator - acid relation. A graphical arrangement of concepts and their relations is called a *concept map* and can serve as a tool for structuring one's knowledge. Some authors explore more complex mappings where relations can also be equipped with attributes, e.g. further concepts.
For our purpose that multitude of relations disturbs the automated handling of concept maps. Relations in our initial prototype were restricted to the following three types: 'requires an understanding of', 'explains' and 'is an example of'. While this simplified the coding and usage of the concept map it also spoiled the clear definition of concepts. Information had to be incorporated into the concept that originally should have been contained in the relation. An example presented in the course is no concept in the original sense but content related to another concept already defined in the concept map.

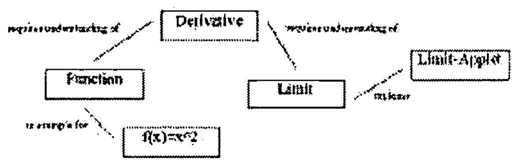

Figure 1: Simplified example of a relation structure used by our initial prototype. Concepts are linked to other concepts by three kinds of relations: 'requires an understanding of', 'explains' and 'is an example of'. The distinction into different types of relations depending on the didactic use of a piece of content spoils the clear definition of concepts.

Although our initial prototype that incorporated this scheme was rather successful we improved the scheme of concept maps. This new, improved scheme more clearly separates the two types of concepts which had been mixed in the initial prototype. Concepts describing the content itself and the associated didactic aspects are now handled by two different concept maps. The first contained concepts like "Function" and "Derivative", the second, concepts like "Introduction", "Example" and "Exercise". Didactic concept maps are much less complex and hence treated differently in our system. The content concept maps on the other hand have now degenerated into a prerequisite map, i.e. all relations have the meaning "is prerequisite to". For later reference we call concepts that are prerequisite to a given concept "ancestors" of that concept.

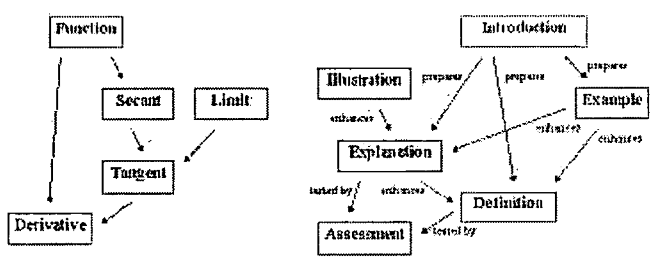

Figure 2: Simplified example of content concept maps (left) and didactic concept maps (right) used in our improved prototype. Content concept maps describe the relation "is prerequisite to". Pieces of content in our courseware are tagged using both content and didactic concepts. This allows for individualized linerarization of the material.

The HTML courseware is now tagged with pairs consisting of one concept from each category. Each piece of content is provided with a concept name and a tag indicating its didactic function.

```
<CONCEPT NAME= "Derivative" TYPE= "Definition"> The function mapping x to the
slope of the tangent to the function f in x is called the derivative of f. It will
be denoted by f'. <\CONCEPT>
```

This tagging can be done in parallel to the authoring of the text itself. Different authors have only to agree on the didactic concepts, i.e. they must have a common idea of basic didactic tools like introductory texts, examples and exercises. However, no further structural definition is required. Concepts can be identified by the author of the respective part of the course. Overlapping material is then combined automatically by means of the content concept map and the tagging in the HTML source.

3. Dynamic HTML generation

The content and the respective concept maps can be used in two ways. The first integrates the capability to deal with concept maps into the browser. The second possibility employs a modified HTTP server which itself processes the pages before they are shipped to the students.

Since our initial prototype pursued not only the integration of these concept-based navigation facilities but also more elaborate multimedia integration of mathematical texts and Java applets, we implemented a special browser in Java. Here Java animations could be seamlessly mixed with the bitmaps created from LaTeX sources, providing full rendering of all mathematical formulae without the usual hurdle of having to mix HTML and GIFs..

The improved prototype is currently implemented as a Java application running on the course's web server. The applets communicate the assessment results to that server process and receive in return the URL for the next course segment.

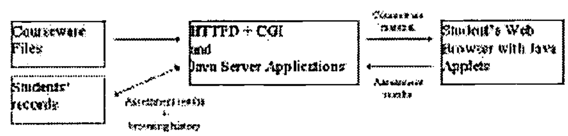

Figure 3: Brief outline of the data flow in our courseware. The sources containing the concept tags are stored on the web server together with the students' records. A mixture of CGI-scripts and Java applications ship the HTML pages to the browsers and maintain the records with the assessment results provided by the Java applets on the client side.

With the help of the concept map and the concept tags we now generate HTML pages that are transferred to the student's browser. The browsing history of each student is logged on the server together with the students' results obtained in the assessments. If a student's result is better than the defined threshold of 0.5 the prerequisite relation is assumed to have been satisfied for that student. A concept is said to be established if all its ancestors have been established and all its prerequisite relations have been satisfied. This mechanism provides at each point in time a set of concepts with fully established ancestors. From this set and according to the didactic concept map the server chooses a piece of content that is next shown to the student. Presentation of a new concept will typically begin with an introductory part. Where no introduction has been provided the server will choose an example to enhance an explanation or definition. Finally the student will do some exercises and take some tests as an assessment. Sufficient performance on these tests then establishes the concept.

In the common case that there are several concepts with fully established ancestors, the student is presented with several possible tracks. This provides the greatest possible freedom to the students while guaranteeing a sound trail of study.

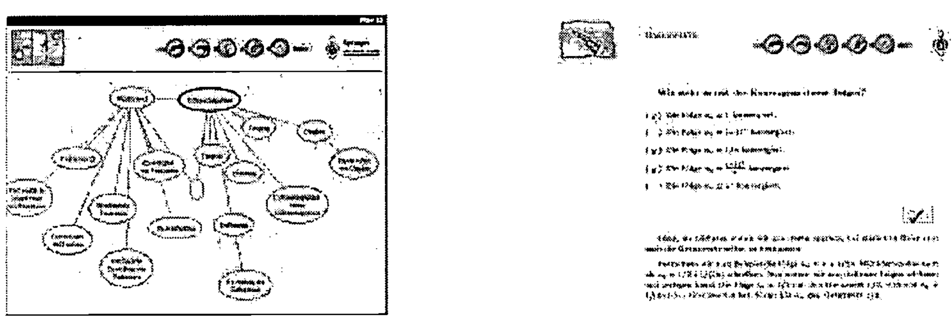

Figure 4: Screenshots from our intial prototype. The left hand side shows a content concept map for the current concept and its nearest descendants. On the right hand side a typical page from the course itself is shown. Besides multiple choice questions tests can require entering of numerical values and simple formulae.

BEST COPY AVAILABLE

In our implementation we paid less attention to the students' browsing history, relying more on their assessment results. This allows the students to quickly pass through topics that are already clear to them. Accordingly the courseware provides introductory pages that sketch the problem and directly lead to relatively tough questions and tests. Students are free to try these questions to quickly establish the concept or take the long way through the explanatory pages of the course.

4. Early experience

Two main reasons inspired us to investigate the techniques described above. Firstly, our students have a vastly disparate previous knowledge of the mathematics taught in our course. Secondly, the hypertext material and the accompanying Java applets are in constant evolution. Especially this issue could not have been handled conventionally. During the two years of this project the text for the entire course was rewritten three to four times, not counting the dozens of minor changes like splitting and combining chapters, or the insertion of new examples and deletion of old ones. Finally the exercises and tests were modified almost daily. During this time the course was taught by five professors and two more lecturers provided additional material.

Despite this ongoing evolution we were always able to provide the students with a working prototype of the course. That prototype could be handled by a single person, who administered the web and video streaming servers and supervised the students programming Java applets for the course. Our approach greatly reduces the amount of work required to maintain our teachware.

Students were also very impressed with the possibilities. Although the staff members did offer tutoring in persona the students used the electronic courseware. After the two-week introductory course more than 90% expressed the opinion that this courseware could provide them with significant tutoring if no traditional tutoring by staff members was available.

However, the results are somewhat unsatisfactory since the capabilities of our system were not really tested independently of the traditional course. A profound analysis can only be done if students work solely with the electronic courseware. Since our program is scheduled to be published by a large scientific publisher in 1999, we are confident we will soon obtain real data on usage and performance of our courseware.

5. Conclusions

Transforming tutorials that have been traditionally held by staff members into interactive courseware is a challenge for two reasons: Several authors, each with their own ideas and objectives about the course, contribute simultaneously to the teachware. The resultant constant evolution hinders any centralized planning. Secondly, the students differ greatly in their previous knowledge and are interested in different aspects of the course. It was hence necessary to design a mechanism that is able both to combine different contributions without the need to define a fixed structure or hierarchy of the content and to allow for individualized linearizations of the material.

We chose concept maps as the base for linking the different parts of the course. Content concept maps reflect the structure of the topics taught while didactic concept maps describe the different functions of the individual pieces of the course. Both concept types are used to tag the source of the courseware. Server applications then dynamically generate HTML pages that are shipped to the students' browsers.

The system has proven very successful. Despite the constant changes in the course a consistent view of the material could be given at any time. The necessary maintenance work was minimal. On the other hand, students could quickly navigate the material since the system was able to present them the material best suited to their individual level of competency. We are confident to soon be able to provide a thorough analysis of the capabilities of our system since the courseware is scheduled to be published for general use in 1999.

Abstract: Increasingly universities have supported several innovative flexible learning projects over the past few years, and there exists a small but enthusiastic group of staff who have demonstrated that something is possible. Our task is to suggest additional strategies that can realise some of the strategic goals set for Flexible Learning over the next few years. This paper is based upon the assumption that a strategic direction has already been chosen and suggests some strategies to ensure practical and realistic outcomes.

Introduction

The notion of flexible learning is that of providing students with choices about when, where and how to study. Through flexible learning programs we can begin to cater for individual needs in a higher education system that is expanding to accommodate an increasingly diverse student body. Flexibility can be introduced in a number of different forms that include:

Flexibility in time: Tuition is not restricted to a set schedule of events. Rather, students can choose a time that is of most convenience to them and their lifestyle.

Flexibility in place: Students are not restricted to coming to the University campus to attend teaching sessions. Learning materials can be accessed from both on and off-campus.

Flexibility in the curriculum: Students are provided with choices in the teaching resources and methods to best suit their particular learning needs.

Flexibility in pace: Students can progress through a course at their own pace in accordance with their academic background, and personal circumstances.

Traditionally distance education programs have provided some flexibility in that they provide choices in the time and place of study. Teaching programs were usually delivered using a number of different resources most commonly print, audio and videotape. However, there has been a strong distinction between the course offerings and learning experiences of students studying on and off-campus. The more recent notion of flexibility is one that aims to bridge the gap between on and off-campus contexts by providing all students with substantially the same teaching materials and learning experiences. Thus students are truly provided with a choice.

> Flexible learning is concerned with access, free of the constraints of time and place, and organizational structures, and in the presence of dialogue and other student support systems. (Kirkpatrick, 1997, p.166).

Fleming (1993) suggests that flexible learning is taken to mean:

> …the organization and resourcing of learning in ways that shift the emphasis off the traditional format of lecture and seminar, with its tendency to reinforce a one-way conception of teaching and learning as the dissemination of wisdom from teacher to learner. Flexible learning offers the learner a more actively constructive role by providing a framework in which learning goals can be more independently pursued (Fleming, 1993, p.322).

When reviewing the implementation papers at her university, Kirkpatrick (1997) identified four different discourses of flexible learning:

- *Flexible learning as efficiency*. A concern of academics in that they feel that more pressure is being placed on them to teach more students with the same or declining resources.
- *Flexible learning as the competitive edge*. This is incorporated into the university's strategic plans to initiate flexible learning approaches.
- *Flexible learning as equity and access*. A frequent statement in the flexible learning strategy.

- *Flexible learning as information technologies.* This is part of every dialogue, while saying information technology does not equate with flexible learning, there are often plans for some use of the Web.

And in several institutions, there is also a fifth discourse:

- *Flexible learning as a strategy to increase the quality of learning experiences.* This discourse is in line with newer approaches to learning theory and the advent of constructivism as an increasingly dominant philosophical approach to learning (Jonassen, Mayes, & McAleese, 1997).

The Role of Technology in Facilitating Flexibility

With the convergence of computer and communications technology through the World Wide Web, we now have the capacity to offer enhanced forms of flexibility. The capacity of the Web to hyperlink and layer information, provide interactivity and support multimedia formats makes it a valuable and exciting tool which can used to develop, deliver and manage flexible learning programs. At its simplest the Web can be used to coordinate and manage learning and act as a point of communication for staff and students. At its most sophisticated it can be a virtual learning environment that facilitates the entire educational process.

However, while the technologies can be used to increase the quality of the learning experience, by rigidly re-packaging the curriculum rather than re-conceptualising the learning required for a particular knowledge domain, it is possible to lock students into the need to use technology when they are loath to do so. Without thought the exercise may simply be converting the learning experience from a group listening experience to an isolated and singular one.

Several studies have pointed out that the way in which information technologies are integrated becomes critical to their effective use. In many institutions IT is "bolted on" to each of the traditional operations and practices, they in effect become adjuncts to traditional classroom practices. More importantly, they need to be reconceptualised so that they are joined in new integrated combinations of classroom teaching and new configurations of older media and technologies as appropriate. It is logical to expect that in time, the second approach will help to redefine the relationship between teaching, and research for each academic. In particular, new on-line technologies can potentially redefine the relationship between student and teacher, enabling non-sequential, concurrent and collaborative relationships. Moving toward the extremes might mean that databases of resources (including multimedia and other new forms of data display) can be individually structured for each course and accessed as required by students. These resources can be grown by staff and student and eventually hold contributions by multiple stakeholders.

The growth of the Web and the movement away from individual technological implementations such as one CD-ROM or a computer assisted learning package (CAL) has produced an environment which integrates a range of teaching and learning functions. For example, the web enables not only the presentation of ideas including using multimedia forms but also computer mediated communications (CMC) in discussion spaces and chat rooms, together with computer managed learning (CML) using password testing and result collating software like Topclass. In effect this enables the mass production of a series of useful products for teaching and learning. For instance, it is possible to collect a set of readings, case studies and other resources and the select from them for different groups of students or different units.

Elements of a Flexible Learning Program

Several design, developmental, implementation and management issues need to be considered when introducing flexibility into educational programs. All teaching and learning resources must be firmly grounded in the aims and outcomes of the unit. The introduction of flexible resources will also require new approaches to teaching and learning. Both students and staff may need assistance in accommodating these new approaches.

In moving a subject into a flexible framework, decisions need to be made about how flexible is it going to be. Remembering that the greater the flexibility, the more effort is required to keep the records and ensure the students have a chance to experience the required issues in the most effective way. For instance, the 14 week session might be required as the basis for group and joint project work. It is very difficult to create groups to work on joint problems if they are all at different stages in a subject. The skill in offering alternative study patterns is in the understanding of student learning and how instructional strategies need to be redefined for mediated approaches to learning. Strategies such as problem-based learning might be considered as alternatives to traditional approaches (Boud & Feletti, 1997).

In any flexible learning program there are several options for configuration. Options existing for the way students access the content of the subject, options also exist for the way they are assessed, and the forms of collaboration that are possible. Traditional essays and examinations are of course possible within any flexible framework. However, as the nexus between attendance and geography is broken, the assessment patterns and forms can provide some challenges: both for marking and in new forms of assessment. Marking assignments is not easily undertaken electronically. Reading and correcting documents on screen is a learned skill. However, many students will submit assessments through e-mail and use a variety of word processing software awareness of the options will be necessary and be reviewed regularly. However, there are also tools that enable a quality turnaround, consider the use of the revision tools in Microsoft Word which will enable a marker to annotate the submission in a different colour font.

One technique that might be applicable in several knowledge domains is the exercise of getting the students as part of their assessment to complete some form of Web document that can form a basis for other students learning. Instead of writing traditional essays, the document could form a guide to a new area of study. It might also be a series of discussion summaries which would be undertaken verbally in a face-to-face class but the on-line class might rotate the task of summarising the computer mediated chat sessions. In many subject areas such as information systems and communications, producing a product that embodies all the attributes being discussed in the class is the most obvious method to test for application and transfer of the principles learned.

The challenge is not necessarily one of adding to the knowledge presentation, rather it is the unlearning of traditional ways and re-conceptualising other ways of achieving similar outcomes with less demand on staff and less demand on redundant systems. Realistically, universities are increasingly in a competitive environment and the options for some might be solved by electronic access to prestigious institutions such as: Harvard and Stanford on-line. From the work described in this paper, provided that the cost differentials are appropriate, face-to-face access to a local academic will be more appealing to many students.

An Example of Implementing "Flexible Delivery"

The availability of the Internet is facilitating a change in teaching and learning strategies as Universities take up the challenge of investigating flexible modes of delivery in contrast to the traditional fixed time and place lecture style format. This account describes the first two implementation cycles of one particular postgraduate subject and illustrates the change that has occurred in terms of the learning process and the nature of assessment by virtue of the technology used.

Implementation Cycle One: A Postgraduate Virtual Class

In 1996 the postgraduate subject: *Implementation and Evaluation of Technology-Based Learning* was chosen as a pilot study to trial World Wide Web and videoconferencing technologies. This subject had previously been offered as two separate classes on two separate evenings; one held on campus, the other held in Sydney (80kms north). The use of the Web and videoconferencing would allow both classes to be held on the same evening with one instructor/lecturer.

The two geographically separate classes met each week on the same evening for three hours during a fourteen week semester. There were eight students and a participant observer in the on-campus class and six students in the Sydney class. The instructor physically met with each group on alternate weeks. Interaction between the two sites was facilitated by a class web site and videoconferencing except for the last week when all the students, the instructor and the participant observer met face-to-face.

For assessment purposes, students were required to complete three pieces of work:

1. A seminar presentation of an agreed topic to facilitate learning and discussion (30% of final grade). This task was to be conducted as a collaborative exercise between two students, one from each site. Students were to lead a discussion for the entire evening and provide online activities to engage the virtual class. A web page was to accompany the presentation and each student was required to submit a piece of writing, in the form of a publishable paper for assessment. The paper was due three weeks after the seminar presentation or at the end of semester, whichever was earlier.
2. A portfolio of resources relating to implementation and evaluation of technology-based learning (40% of final grade). Students were to compile useful articles, evaluation instruments, web sites, etc. that would help them further their understanding of the issues raised in the subject. Each item collected was to be accompanied by a short reflective piece that explained its selection as a useful resource. The portfolio was due at the end of semester.
3. An evaluation of an educational software package *or* a review of the implementation of this subject as a technology-based learning project (30% of final grade). Th evaluation report was due at the end of semester.

Content delivery was structured so that a new topic was addressed each week. The first five weeks consisted of instructor-led discussions and workshops and the remaining nine weeks were designed as student-led seminars. Figure 1 depicts the model that emerged from this subject.

The themes that surfaced from this implementation are summarised as follows:

- **Nature of interaction**

On-line interaction was predominantly synchronous in nature. "Synchronicity" was encouraged by the nature of the course design that was structured to present new content each week. Due to much social interaction taking place within each physical class, the role of the web site became a storage mechanism for student seminar web pages and a pointer to the online discussion tools.

A problem-based approach was used to facilitate online interaction. All the online discussions were structured around a problem or a series of questions that students needed to answer. On-line interaction occurred mostly during "class time" and was not linked to an assessable task. The quality of discussion was influenced by time constraints and it is contended that the incentive and motivation for students to engage in meaningful discussion was affected by the non-assessable nature of the tasks.

- **Nature of student activity**

Students attended class each week and worked either individually or in small groups when contributing to the online class discussions. Apart from a small group exercise that was organised in the early weeks of semester and pair work that occurred for some of the seminars (not all students presented in pairs), there was little need for group collaboration.

- **Nature of assessment**

Grading was based on individual work submitted. The majority of assessable work was due at the end of semester. (Seminar papers were submitted from Week 9 to Week 14).

- **Nature of content**

Content material drove the learning process. Each week students attended class expectant to address a new area of content. Upon reflection, the strategies implemented to present content and encourage student interaction (both in the physical groups and online) were couched within a traditional university lecture framework of fixed weekly meetings (see Agostinho, Lefoe & Hedberg, 1997 for specific examples). The technology was used to facilitate a weekly "virtual class" and little asynchronous discussion transpired.

For the subsequent implementation we felt that the features of asynchronous communication could be better utilised and tasks given to students could provide a more flexible and effective learning environment. The reliance of fixed-weekly meetings could be reduced. In an asynchronous mode students would be able to spend more time discussing an issue and contributions to the discussion could occur outside the set "class time". Face-to-face meetings or workshops could then be better utilised to discuss student concerns, resolve problems or provide technical "skilling" workshops. However, to implement this concept requires a change in the learning process. In this case the content and weekly meetings drove the learning process. In the following implementation we wanted to use the assessment tasks as the facilitator of the learning process.

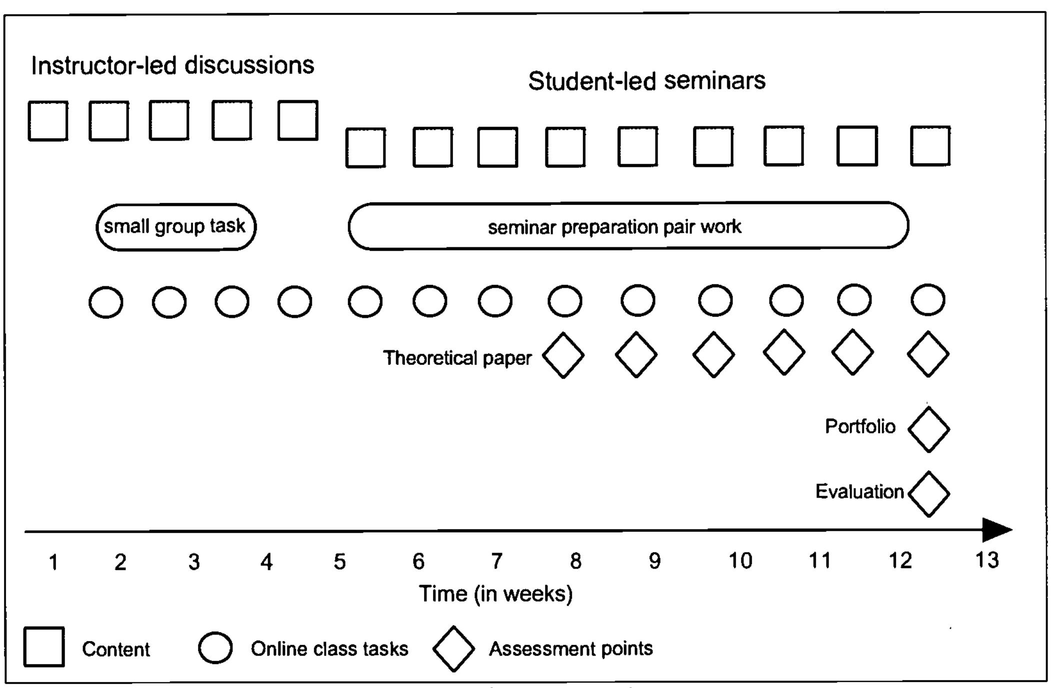

Figure 1: Virtual Class with a "Content" Focus

Implementation Cycle Two: A Postgraduate Virtual Community

In 1997 the subject was restructured to encourage a more flexible asynchronous approach. During the fourteen week semester, students attended eight class meetings (Weeks 1, 2, 4, 6, 8, 10, 11 and 14) and were to participate in asynchronous and synchronous online discussions during the non-meeting weeks. The two geographically separated groups (eleven students and a participant observer in the on-campus class and six students in the Sydney class) met for three hours on different evenings and the instructor was physically present in each group. A class web site facilitated interaction between the two groups and amongst all the students outside class time.

Assessment tasks were restructured as follows:

1. A written paper based on class and online discussion about evaluation theory and its relevance to technology-based learning was to be completed by Week 4 (Worth 30% of final grade).
2. A Web Study Guide on an agreed topic to facilitate learning and discussion was to be completed by Week 8 (Worth 30% of final grade).
3. An evaluation of all the Web Study Guides was to be completed by Week 11 (Worth 10% of final grade).
4. An evaluation proposal for a technology-based learning project was to be completed and presented as a group project in Week 14. (Worth 30% of final grade).

Tasks were completed at various intervals during the course rather than submission at the end of semester. In doing so, the assessable tasks became resources that students accessed to assist them with the final group project. Thus, the first three tasks act as "stepping stones" to the final group project.

The delivery of content was structured with a task focus. Content material was provided to help with the completion of an assessment task. The concept of a Web Study Guide replaced the need for content to be presented in class time in a sequential sequence as the content is in an electronic form that can be reviewed by students at a time and place convenient to them.

The instructor incorporated several online tasks during the semester. The first online task involved students working in small groups to asynchronously discuss the content required for the first assignment. Each group worked on different content and posted a summary of their discussions on the class web site. The intention was that students could then view the summaries from the different groups to help them write the first assignment. Other online tasks included synchronous and asynchronous discussions about particular readings. The model that emerged from this implementation is illustrated in Figure 2.

The themes that surface are summarised as follows:

- **Content, on-line tasks and assessment are integrated**

Delivery of separate chunks of content was replaced with an "assessment chunk". In this model, content material and online tasks support the production of an assessable piece of work. The technology is used in a much more integrated way as web page summaries and Web Study Guides are then available as resources.

- **Nature of student activity**

In the early weeks of semester, students engaged in group work and produced a group summary to assist in the completion of the first assignment. Asynchronous discussions were encouraged to discuss readings whilst production of the student's individual Web Study Guide took place. Then a period of individual self-paced work occurred when each student reviewed other students' Web Study Guides. Group work then occurred for production of the final group project. Therefore, although students did not meet each week there was a sense of community as they were involved in either physical group work, online class discussions or reviewing other student's work.

It became apparent that for many students the non-meeting weeks were viewed as a "week off". In summary, the feedback obtained through a questionnaire suggests that students are still working to come to grips with this way of learning. They exemplify the concern by asking for more incentive, more time, more structure and more guidance.

- **Nature of on-line interaction**

There were varying patterns of online interaction during the semester. For example, as students were busy with Web Study Guide production the online environment became very quiet. Students expected facilitation in the online discussions mainly from the instructor. There was little spontaneous online discussion, although some students did attempt to initiate online contact.

- **Nature of content delivery**

More than half of the class thought that reviewing the Web Study Guides was an effective learning strategy in comparison to sitting in class listening to the traditional student seminar presentation. As Web authoring tools become easier to use, it is possible for students to use such tools to construct their own interpretation of the course content. In effect, they can use the Web environment as a cognitive tool (Reeves & Reeves, 1997). The learner is the designer (Jonassen & Reeves, 1996). The student becomes the author.

- **The evolving nature of the on-line environment**

By producing a Web Study Guide and then using the Web Study Guides as background for the final project, students are creating resources. This becomes a resource-based learning environment (Hannafin, 1997). This evolving dynamic nature of Web-based resources means that subsequent groups of students can access previous student products and on-line discussions which enables the concept of "learning on the shoulders of others" to result. (Hedberg, Brown, Larkin & Agostinho, in press) Unlike delivering a traditional face-to-face course where the same content is presented over and over again and the same assessment tasks assigned, this dynamic learning environment enables students to learn from their predecessors taking "learning" to a new plateau.

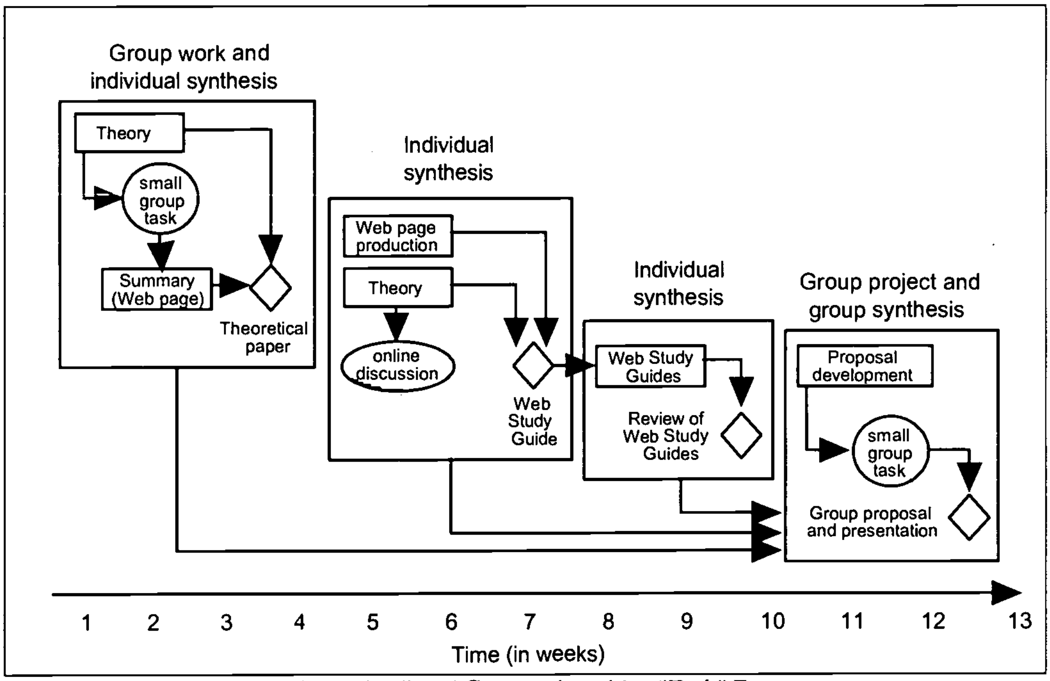

Figure 2: Virtual Community with a "Task" Focus

Conclusion

The focus of this paper was to discuss the rhetoric and the required infrastructure for the flexible delivery of courses in different ways within a traditional campus and to illustrate an example of how one subject has changed to a more flexible delivery approach. As the nature of academic discourse changes, it will be expected that the infrastructure and the courses offered flexibly will become more commonplace. Often postgraduate students seek out potential places to study based on course and common interests; this paper has described how technology can be used to promote a virtual community to provide a flexible yet effective learning environment.

Analysis of Trends in Delivery Systems for Training

Steve Schlough
University of Wisconsin-Stout
144 Communications Technologies Building
Menomonie, WI 54751 USA
schloughs@uwstout.edu

Abstract: This paper discusses the emerging trends in the use of delivery systems in the field of training and development, the process used to explore those trends, lists identified trends and makes recommendations on how to implemented those changes in the curriculum of a Masters of Science program in Training and Development.

Introduction

There is a well-documented need expressed by business, industry, military, government, and education to more effectively deliver training. This need is bound to increase as the demand for training increases and organizations want to enhance the quality of training while containing cost. To meet this need media systems are becoming increasingly important in the effective and efficient delivery of training and are changing at rapid rate.

The Situation

The University of Wisconsin-Stout (UW-Stout) offers a graduate level program in Training and Development. The "hands on-minds on" portion of the program emphasizes integrating theory with practice to design, develop, and delivery training programs. Previous studies and reviews of the current literature, indicated there is a need to monitor and continually enhance the delivery of training through the use of mediated delivery systems. Feedback from the Training and Development program advisory committee, employers and graduates reinforced this need.

In a 1995 study (Furst-Bowe) recommended that programs in training and development need to review their instructional technology courses and competencies. The study also found that there is a need to examine the professional development needs of trainers in the area of instructional technology. A 1996 (Schlough) study found that it was important for all UW-Stout graduates to be able to create multimedia presentations and participate in videoconferences. The study also stated because of rapid changes in the competencies needed in the workplace that educational institutions continually monitor those changes.

Literature Review

The following chart from longitudinal studies conducted by the American Society for Training and Development (http://www.astd.org/virtual_community/research/bench/96stats/graph13.gif) shows the changes in the use delivery systems over a three-year period and gives an overview of current delivery systems.

Percent of Companies Using Selected Delivery Systems (1994-1996)

	1994	1995	1996
Classroom	97%	100%	100%
Advanced Technology Classroom	53%	56%	47%
Televised Distance Learning	47%	64%	69%
CBT	72%	90%	84%
Interactive/Multimedia CBT	47%	85%	81%
Internet/Network-Based Electronic Distance Learning	12%	33%	53%
EPSS	34%	45%	37%
Other Self-Paced Delivery	66%	77%	75%
Other Delivery	12%	10%	10%

Note: Definitions available.

ASTD Benchmarking Forum

Table 1: ASTD study of the use of delivery systems in training. Definitions of the delivery systems follow.

Classroom (Instructor-led lecture)
Definition: Classroom training that is lecture- or discussion- based. Also referred to as instructor-led. Does not include advanced technology, interactive classrooms, or electronic distance learning.

Advanced technology/interactive classroom
Definition: An advanced technology/interactive classroom is an instructor-led classroom with some degree of automated facilities, including student response units.

Televised electronic distance learning
Definition: Televised electronic distance learning refers to teleclasses broadcast via satellite, microwave, telephone lines, or other means. May or may not be interactive.

Internet/Network-based electronic distance learning
Definition: Internet/network-based electronic distance learning refers to CBT classes made available via Internet or other electronic networks. May or may not be interactive.

Computer Based Training (CBT)
Definition: CBT uses a computer as an integral part of an instructional system, with the learner engaging in real-time interaction with the computer.

Interactive/Multimedia CBT
Definition: Interactive/multimedia CBT uses any two instructional media together; interactive multimedia platforms, typically employ a computerized learning programs that are learner-controlled. Learning response will initiate one of several program sequences, and can be presented in video form as still shots, regular, slow, and fast speed motion. May include sound and other features.

Electronic performance support systems (EPSS)
Definition: EPSS is an integrated computer program that provides any combination of expert system, hypertext, embedded animation, CBT, and hypermedia to an employee on demand. Electronic performance support systems allow employees to perform with a minimum of support and intervention by others (e.g., help systems, electronic job aids, expert advisors).

Other self-paced instruction
Definition: Other self-paced instruction represents any other method of instruction not identified above where the learner controls the rate of instruction. Typically does not require advanced technology or unusual equipment. Includes such methods as paper-based instruction using training manuals and videotapes

Among the future trends appears to be the movement toward more Internet delivery of video and more video simulation. John Chambers (1997) CEO of Cisco felt that training video distributed over networks will be the application that drives the growth of PC networks. McLean (1997) discusses that the use of digitized images and video to create simulations for training has the potential to become a $4 billion market.

Based on these findings, the following actions were taken to assure that the course, *Delivery Systems for Training,* stayed current and continued to meet the needs of students in Training and Development program at UW-Stout.

Methodology

To discover new trends related to delivery systems, it was originally proposed to do an in-depth phone needs assessment and a series of site visits. It was felt the from the literature review and other information obtained that it would be prudent for the Communications, Training, and Education Department to obtain a digital video to allow students to easily integrate digital video into their projects. A grant proposal was submitted to the Stout University Foundation to cover these items. Funding was provided to purchase the digital video camera, but was not adequate to carry out the in-depth research project. A Hitachi MP-EG1A camera was purchased and produces acceptable results.

As it was not possible to do the research as planned, an alternative was implemented. Taking in to consideration that the students in the course Delivery Systems for Training were graduate students and the trends continually change, the trend analysis was turned into the following student project, which was assigned during the Spring semester of 1998. There were 9 students enrolled in the course.

Trends in Delivery Systems for Training

You will need to explore future trends related to delivery systems to be proactive in this rapidly changing and critical area for training and education. To discover new trends related to delivery systems you will conduct a trend analysis. This analysis, quantitative in nature, will focus on obtaining data from individuals who develop leading edge training programs. As a class you will develop the trend analysis instrument and procedure. Each student will contact one respondent, either by phone or in person to answer of "What do you feel will be the biggest change in delivering training over the next ____ years." or similar question(s). Each student will write up a write up a one to two page paper on his or her findings. You will exchange papers and develop a presentation based on the findings. The presentation will be presented during the final class period. Before you conduct your interview make sure the class has came to a consensus on the instrument, the procedures, format for the paper, and format for the presentation. Make sure **NO ONE** contacts the same site and you have my approval before you begin.

Evaluation Criteria

Paper

Format	0 1 2 3 4 5
Technical Execution	0 1 2 3 4 5
Content	0 2 4 6 8 10

Total ____

Team Presentation

Delivery	0 1 2 3 4 5
Visual Appeal/Technical Execution	0 1 2 3 4 5
Content	0 2 4 6 8 5

Total ____

Your evaluation by your peers is worth up to 15 points

You are to evaluate the other members of the class on their role as a team member in the trend analysis project. You should rate each member on a 15-point scale. I will average the scores your classmates gave you and that will be the number of points you earn. The following questions should help you evaluate your team members.

Was the individual cooperative?

Did the individual take initiative?

Was the person open-minded and accepting of other's ideas and opinions?

Did the individual contribute a fair share to the success of the group?

Did you feel the person acted in a professional manner?

Did the person keep the goals and objectives of the group in mind?

Did the individual complete their designated tasks in a timely fashion?

Did the individual submit materials that were accurate and composed well?

Was the individual in attendance and punctual for group meetings?

How would you rate this person's overall ability to function as an effective team member?

The students meet as a team and developed procedures and the following research questions:

What training delivery systems has your organization used in the past 5 years?

What delivery systems do you currently use?

What delivery systems to you expect to be using in the next 5 years?

What constraints does your organization face with the development and use of training delivery systems?

The students contacted a luxury hotel, a national computer manufacturer, an international computer component manufacturer, a national brewing company, a regional high-tech manufacturer, a public utility company, a leading manufacturer of innovative products, a university, and a national aeronautics company. The results of their study are presented in the next section.

Results

The following is a composite the challenges and constraints that were identified:

- Money & Budget

- Time
- Justification
- Development
- Selection
- Time to Train
- Geographic
- Information Systems Support
- Staffing
- WWW Access
- Language Barriers
- Management Support
- Training Quality
- Soft Skills
- Shifts
- Process Changes
- Apathy Toward Training
- Union (Trust Issue)
- Keeping Up With Technology

The following table identifies the use of delivery systems in organizations:

SYSTEM	*PAST*	*PRESENT*	*FUTURE*
Instructor Led/Classroom	9	9	9
Self-Directed Study	4	5	4
CBT/WBT	5	7	9
OJT	3	5	4
Video / Audio:	6	7	4
Satellite Downlink:	1	1	3
Video Conferencing:	2	4	2
Intranet:	0	0	3
CD-ROM	0	3	3

Table 2: Use of identified delivery systems.

Summary

This method of research proved to be a viable alternative to the originally planned research. Although, the results of the research were based on a small population they appear to give a good snapshot of what is happening in training delivery systems. The same project was repeated in the Summer of 1998 with thirteen students contacting thirteen different organizations and producing similar results. The advantages of this methodology is that the students individually talk to a training manager, collaborate at the beginning and end of the project, spend time to together discussing their results, get current results, and have a sense of ownership in the results. It is planned to continue to use the project and refine as time goes on.

From Research to Teacher Professional Development to Technology and Back Again: The development of *A Video Exploration of Classroom Assessment*

Karen Cole and Christina Syer
Institute for Research on Learning

Abstract: This paper describes a research-based process for the development of teacher professional development materials. *A Video Exploration of Classroom Assessment* is a CD-ROM-based set of assessment workshops designed to be used by small groups of teachers at their school settings. Unstaged classroom video of assessments is a key feature. At the Institute for Research on Learning, we incorporated ongoing teacher professional development and assessment research into every aspect of the development of our assessment CD-ROM. Everything from the target audience and setting to the interface design incorporated research findings. This has resulted in an extremely functional and usable product, which itself can help us organize future research.

Introduction

If you're a teacher, the opportunity to watch the goings on in another classroom is a rare and exciting thing. The opportunity to talk about your observations with a group of teachers, and plan experimental teaching based on your discussion, is still more rare. Even more unusual is the opportunity to obtain perspectives and advice from teachers who have tried similar experiments.

This paper tells the story of the development of a CD-ROM called *A Video Exploration of Classroom Assessment*. This assessment CD-ROM gives teachers all these opportunities as they work to develop their repertoire of classroom assessment strategies. Teachers can view classroom video of assessments in a real classroom, and get perspectives of teachers and students who have tried the various assessment strategies. The CD-ROM includes complete workshops for teachers who want to develop assessment strategies together.

The story of the assessment CD-ROM is important because it illustrates the crucial symbiosis and synergy between educational research and educational product development. The assessment CD-ROM was developed at the Institute for Research on Learning (IRL). IRL is committed to a research strategy that is deeply embedded in real-world practices. The assessment CD-ROM is the culmination of many years of IRL's research in classrooms and in a teacher professional development (TPD) community.

In the next three sections we will describe the research projects that inspired and contributed to the design of the assessment CD-ROM, explain how research findings were incorporated into the design of the CD-ROM, and suggest directions for further research uncovered by our development process.

Historical Overview

An emerging community in MMAP

The assessment CD-ROM grew as the next logical step to a series of research and development projects at IRL. We had formed a community of about 30 teachers who were co-developers of our Middle-school Mathematics through Applications Project (MMAP) curriculum (funded by the National Science Foundation). These teachers worked with us over five years and came to IRL for monthly work days and three-week summer institutes. Work days included MMAP curriculum development activities, math and technology workshops, guest speakers, and collaboration on our research on math teaching and learning. Although nominally about curriculum development, the MMAP teacher community became a rich professional development experience for participants and a research opportunity for us (Lichtenstein, Weissglass et al. 1998; Greeno, McDermott et al. in press).

A year of assessment research

It became clear as the work days progressed that assessment was a primary interest and concern of our teacher community. Because MMAP is a project-based math curriculum, old assessment methods were not always appropriate, and using authentic assessments required learning, time, and effort for many teachers. We decided to conduct research on ways of building classroom assessment systems. We spent a year of intensive work with one teacher, Mona Muniz, developing assessment strategies, testing them in her classroom, and revising our strategies (Cole 1996). We video taped extensively in Mona's classroom and analyzed the tapes at teacher work days. We also solicited comments from our teachers on the assessments we developed. This project continued a trajectory of several years of this type of assessment research at IRL (Moschkovich 1994; Hall, Knudsen et al. 1995/1996).

The Assessment Club

These activities inspired the creation of the Assessment Club, which met monthly at IRL to discuss and design assessment strategies. Teachers, as a result of their participation in Assessment Club activities, began to experiment in their own classrooms, and reported their experiences and difficulties in Assessment Club meetings. Several teachers became experts and resources for the group in particular assessment techniques. Every teacher in the club used new assessment techniques that year, and most began to use a greater variety of assessments (Goldman and Cole 1997). We had a growing collection of very knowledgeable teachers on our hands.

A Video Casebook

Many of the liveliest discussions in MMAP and Assessment Club were inspired by classroom video from members' classrooms. Teachers found reasons to watch the tapes again and again, as they tried to interpret the effects assessments had on student learning. Video supported in-depth discussion and examination of teaching practices in a way that oral or written cases did not. We began to compile video cases that teachers outside MMAP could use to seed discussion about using standards-based math curriculum. The result was a video tape of real classroom vignettes called *Seeing powerful mathematics.* We tested this tape on groups of teachers outside of MMAP and found that their reaction to real classroom video was as positive as that of our MMAP teachers (Goldman 1996).

As MMAP neared completion, we felt the need to develop a product by and for teachers that would capture the diverse and extensive knowledge MMAP teachers had about assessment. Although much of this expertise had been fed back into the development of the MMAP curriculum and support materials, we wanted to reach teachers outside MMAP. We also wanted to inspire teachers to form supportive and dynamic learning groups like the one that had developed in MMAP, and give such groups materials to work with once they had formed. The next section details how all this research work informed the design of the assessment CD-ROM.

Creating a tool for collaborative teacher learning

Valuable communities around assessment had been created, and we needed to find a way to keep this kind of community formation and discussion alive. Looking back at all of our research, what had been the key factors in stimulating discussion and growth around assessment? We needed to answer this question before we started making a tool that had the main focus of producing this type of interaction.

From Research Findings to Technology Choices

We synthesized the findings from our research into five key elements we wanted to preserve as we moved to a technology-based tool:

- *Unstaged classroom video:* In Assessment Club meetings and other MMAP teacher workday activities, discussion and learning had always resulted when the teachers were confronted with unstaged classroom video of assessment in action. This fact alone mandated that we needed to present real classroom examples that would spark discussion around assessment practices. This meant that out tool needed to have a space for video.
- *Access to classroom artifacts:* We saw the tremendous benefit of teachers sharing student work and assessment tools they had created. This meant that along side the classroom video, we also needed to have a space where pictures of paper documents could appear.
- *Multiple Perspectives:* Our teachers had learned from hearing the opinions of the teachers around them. Having multiple teachers' perspectives available in our tool was a must.
- *Workshop structure:* We also realized that we needed to imbed a structure inside the tool that would help teachers find what they wanted and support discussion and experimentation. We decided to organize the content into workshops similar in structure to Assessment Club meetings.
- *Clear and inviting interface:* Lastly, we knew that the tool would have to be inviting and accessible to teachers. For example, in our testing of the *Seeing Powerful Mathematics* video, we found that teachers needed a transcript to hear video conversations clearly, and that they used these transcripts to go back to parts of the video for discussion. Easy transcript management thus became one of many interface requirements for making the whole tool useful to teachers.

Keeping all of these factors in mind, the one piece of existing technology that met all of our needs was the CD-ROM. A CD-ROM would allow us to present classroom and interview video and all the supporting material we needed.

Figure 1 shows how the workshop screen of the CD-ROM is organized. The upper left corner contains the workshop, including prompts for discussion, video watching, student work analysis, and experimentation. Beneath the workshop frame is a frame for showing student work or other artifacts from the video being shown at the upper right. Perspectives from other teachers and students also show in this window. Finally, the lower right frame contains continuously updated transcript of the video currently being played. Teachers can click on any point in the transcript, and the video will begin playing at that point.

Figure 1: Workshop, classroom video, artifacts, and transcripts

The choice of the CD-ROM media thus gave us two powerful ways to meet our goals. First, video, transcripts, and artifacts can all be synchronized within a workshop structure. Second, teachers can quickly and easily access any part of the video and play it as many times as they want to.

Restructuring the video presentation

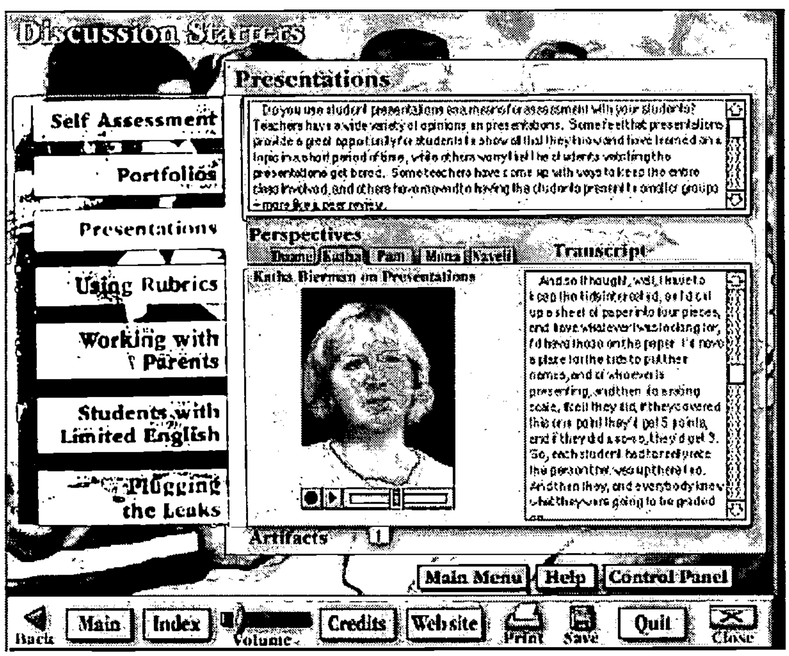
Our first step in creating the assessment CD-ROM, *A Video Exploration of Classroom Assessment*, was to capture the classroom video that would be the core of our disk's content. We turned to a teacher, Mona Muniz, who was a primary collaborator in our assessment research. Our first inclination was to follow her through an entire year of her classroom assessment. This approach matched our research techniques, where we often taped weeks of class in chronological order.

When we brought our research team together to look at the tape we were gathering from Mona's class, we grew dissatisfied with the chronological organization. We remembered that when teachers went to a piece of classroom video, it was always in the context of a question they had or an issue they wanted to explore. Teachers who would use our tool needed to be able to access video according to their interests and questions. Our unstaged tape needed a new organization.

In considering what a teacher would be looking for when working with a CD-ROM focused on assessment, a natural organization came to the surface. Mona was primarily working with four assessment techniques: peer review, notebooks, walk-arounds, and testing. We decided to group the classroom video on these specific techniques, so that teachers working with the disk could focus in on one technique at a time. We also had the video from interviews with multiple teachers and two students. They had commented on specific assessment techniques and issues, and their comments could be paired with our classroom examples. This change from presenting the content in chronological order, as we had been used to doing during our research analysis was a large shift in thinking, and it was critical to the development of a useful teacher tool. Figure 2 shows how teachers can select the six workshops that resulted from the new organization.

Figure 2: Content organized by topic

Figure 3: Discussion starters, teacher interviews, and teacher tools



Realizing that there are many other important assessment techniques and issues outside of those covered in Mona's classroom, we interviewed teachers to explore their experiences with self assessment, portfolios, presentations, rubrics, working with parents, and students with limited English. Figure 3 shows these "Discussion Starters," where teachers who are using the disk can read an outline of an issue, hear from teachers on the disk, and then discuss the topic on their own.

Interface, look and feel, and ongoing development

During the five years of working with teachers on the development of a middle-school math curriculum that included units that involve technology, we saw that teachers' comfort with technology varies considerably. In designing the disk's look and feel, we wanted it to be inviting and intuitive to use. Through every step of the design process, we kept our end goal in mind: creating a disk that would feel inviting, warm, and professional. We combined familiar images of the classroom with a binder-like interface design.

Another challenge we faced during this CD-ROM's production was that we knew that once the disk was finished, duplicated, packaged, and shipped, there was no way to further develop the content presented on the disk. This kind of finality was never felt during the research process. With our research, if another intriguing theme emerged from our data, wc could always start writing a new paper and continue our analysis. We addressed this concern by creating a web site (www.irl.org/assess/assess.html) that can be reached by pressing the "web site" button inside the disk. Inside the workshops, we encourage teachers to go to this web site to report on their use of these assessment techniques. They can also read what others teachers have had to say. This is our attempt to keep the dialogue going and growing outside of the disk.

Preliminary testing and feedback

When we selected the preliminary video segments, we tried them out with teachers to get their reactions. Were we on the right track? We found that the cases that we picked did indeed spark discussion, and teachers found it very easy to talk about the positive aspects of the assessment as well as the ways that they might try to make it better. These discussions highlighted another positive aspect about the disk. It gave teachers a classroom to talk about that was not their own or their peer teacher's. They felt free to comment openly about what they saw, and their reactions were not guarded. The disk gives teachers a credibility for trying new techniques. Having the teachers' on-going feedback about the content inside *A Video Exploration of Classroom Assessment* as well as its design and functionality was invaluable.

When teachers had a chance to work with the disk, here were some of their reactions:

- "I really like seeing the classroom; it feels so real. The teacher perspectives help with knowing how to realistically apply these techniques in my classroom. Very nicely done."
- "I love the assessment CD-ROM; it is wonderful to be inside Mona's classroom. Four other teachers and I get together and watch sections together."
- "It is thought provoking. It gives some concrete suggestions. It stimulates conversation between my colleagues."
- "I am a MSDP Evaluator (Middle School Demonstration Program) for John F. Kennedy Middle School in Redwood City, CA. This school is doing some intensive work in math assessment. In my report to them, I recommended the use of the CD-ROM, *A Video Exploration of Classroom Assessment*, as an invaluable resource for their summer school training of math teachers and training throughout the school year. This report also goes to the State Department of Education."
- "The Assessment CD-ROM is excellent. Our school is planning on using it in our staff development program in August after returning from summer break."
- "Should you develop further materials that explore student learning/teaching in a similar way, I should be most interested to learn about them."

Back again: Directions for research

Now that the CD-ROM is finished, we have shifted our thinking back to research mode. Our field testing has left us with at least three big questions to explore. First, what is necessary to support the many possible uses for the CD-ROM? It is our hope that *A Video Exploration of Classroom Assessment* will be used in multiple settings. The disk is useful to both current teachers who are going through continual professional development as well as to future teachers who are in teacher training programs. Teachers use the disk alone and in groups with other teachers. We can improve our understanding of teacher professional development by exploring how tools are used differently in different settings.

Our second question is, how can we keep the content of the workshops current and continue to spark discussion as teachers' needs change? Web delivery is one obvious future alternative, and others are emerging. Whatever technology we use, our research will continue to drive our innovations.

Our third question is, how does using our tool change what teachers do with their students? We know our disk is successful in that teachers like and use the disk, but we do not know much about what happens in classrooms as a result of this kind of professional development experience.

We believe the tight integration of ongoing, multifaceted research with product development was the biggest factor in the ultimate high quality of our CD-ROM. This connection works the opposite way too: by keeping research in mind through the product development cycle, we have a whole new set of questions to explore.

A Pre-authoring Environment for the Development of Hypermedia Courses

Clovis Torres Fernandes, Miguel R. Flores Santibañez, Delfa M. Huatuco Zuasnábar
Computer Science Department
Aeronautical Institute of Technology - ITA
Brazil
{clovis, raymundo, delfa}@comp.ita.cta.br

Abstract: Based on the design of a hypermedia application for educational purposes, a hypermedia course developed through some hypermedia model or methodology, it is possible to produce the authoring or effective implementation of the course. To support the effort of designing hypermedia courses, here called pre-authoring activity, one must use appropriate models and tools. This paper presents a pre-authoring environment supporting the development of hypermedia courses, called APACHE. This environment offers supporting tools to simplify the author's task of designing hypermedia knowledge domains, based on a model that incorporates both concept maps and information mapping techniques. It propitiates, still, the automated design of guided-tours for hypermedia courses, according to pedagogic criteria imposed by the author, the target population and the learning objectives. Based on the designs of hypermedia contents and related course guided-tours developed under APACHE, it is possible to implement the hypermedia course easily using any hypermedia-authoring tool.

Introduction

For designing general hypermedia applications several models found in the literature can be used, such as HDM (Garzotto et al. 1993), RMD (Balasubramanian 1994), OOHDM (Schwabe & Rossi 1995), etc. However these models are not suitable for modeling hypermedia courses, since they do not incorporate didactic and pedagogic aspects in its processes of modeling the hypermedia content and related course guided-tours (or trails). To support the effort of designing hypermedia courses, here called pre-authoring activity, one must use appropriate models and tools. The problem is in defining how to design both the hiperbase and related course guided-tours before doing the, strictly speaking, authoring task.

This paper presents such a pre-authoring environment supporting the development of hypermedia courses, called APACHE. The paper organization is the following: firstly the architecture of the APACHE environment and the research context is presented; next the APACHE pre-authoring tools, called SICH and SPR, are showed.

APACHE Environment and the Research Context

For the purpose of this paper, we understand a hypermedia course as including the following:

- A specific hyperbase for the subject
- One or more navigational guided-tours or trails defined on the nodes of the related hyperbase.

where a hyperbase is a base of subject nodes related through concrete links and a guided-tour is a sequence of nodes of the hyperbase.

A guided-tour is a course when it presents a certain subject in a didactic and pedagogic sequence of nodes. In this case, some additional nodes added to the sequence do not refer to related nodes belong to the hyperbase. A guided-tour is a hypermedia course when one or more hyperlinks in a number of nodes belonging to the sequence is active, except forward-backward links that must be always active. The course author must predefine whether a hyperlink in the guided-tour is to be active or not.

Usually three activities are considered in the development of hypermedia courses: pre-authoring, authoring and reader or learning activities. In a pre-authoring activity, all the hypermedia context of an intended course is designed beforehand. This includes the design of the hyperbase and related guided-tours. In this case, the design of the contents of a hypermedia course can be developed by using hypermedia models or methodologies. In an authoring activity, the hypermedia content of an intended course is effectively developed, considering or not previous designs of hyperbases and related guided-tours. In the reader activity, an apprentice can navigate through the guided-tours of the course trying to satisfy the objectives imposed by the course author. Both the authoring and the reader activity can be supported by academic or commercial hypermedia systems.

Some tools supporting the pre-authoring activity are reported in the literature (Gaines & Shaw 1997, Moroni & Señas 1997). Such a tool is presented in this paper. In order to help the author to design the hypermedia content of a course prior to the authoring activity, the APACHE environment offers support to the pre-authoring activities. APACHE is an acronym for Pre-Authoring Environment for Extended Hypermedia Courses. (Fig. 1) shows the whole research context, emphasizing the architecture of the APACHE environment.

Through the SICH tool one can develop a base of hyperbase designs. Through the SPR tool one can develop the base of guided-tours designs based on the hyperbase designs developed with SICH and considering didactic, pedagogic and motivational aspects. In the authoring activity, by using commercial tools such as Quest and ToolBook or specific tools for Internet, the real hyperbase and the real guided-tours of the hypermedia course will be created. The learner, using a hypermedia system as an interface, will be able to navigate freely through the hyperbase nodes or follow the trails of hyperbase nodes indicated by the guided-tours. In the latter case, the learner can be coached by the system in a non-intrusive way.

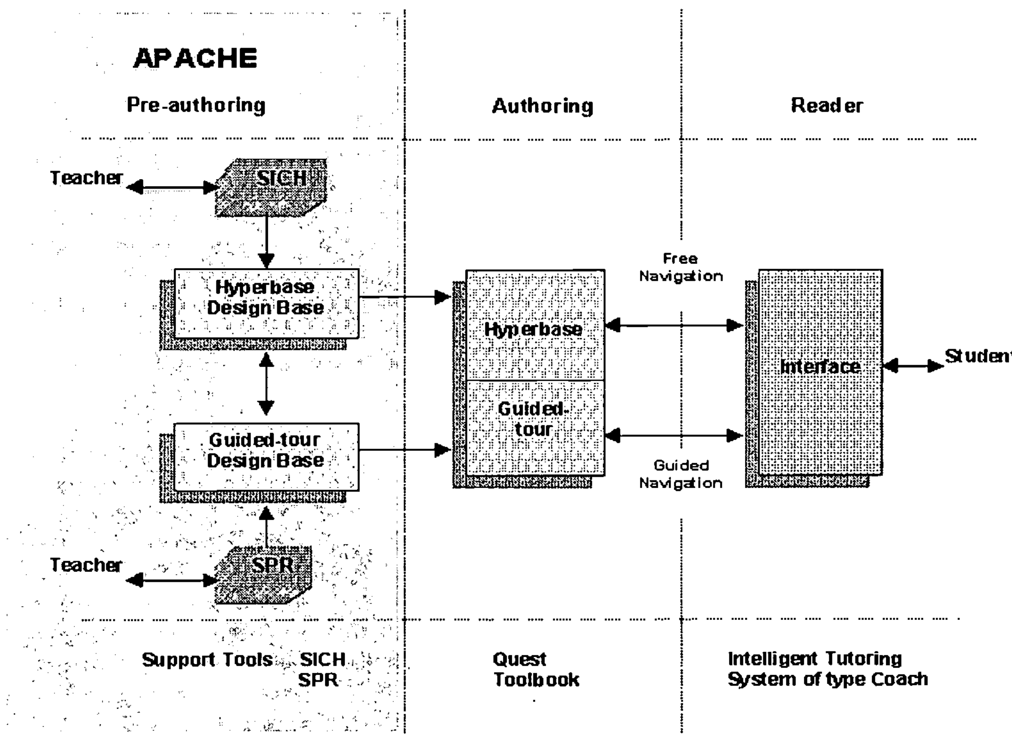

Figure 1: Research context and the APACHE environment.

Pre-authoring Tools

The pre-authoring tools help design and model the hiperbase and related guided-tours. In the design of a hyperbase, the hypermedia knowledge domain is modeled. In the design of guided-tours, a sequence of concepts taken from the hyperbase is modeled in a didactically effective way by the teacher. Next the two pre-authoring tools offered by the APACHE environment, namely SICH and SPR, will be presented.

BEST COPY AVAILABLE

SICH Tool

SICH (acronym for Hypermedia Course Construction Tool) offers support to the author in the design of hypermedia knowledge domains or hyperbases. The underlying model, called Daphne (Kawasaki 1996), incorporates both concept maps and information mapping techniques in a harmonic way. The goal is to supply the teacher with effective means to design the hypermedia content of the course, according to the objectives and the methods borrowed from pedagogic techniques used for designing courses for traditional classes.

SICH is composed of a manager for hypermedia courses and four auxiliary editors, as prescribed in the Daphne Methodology: editor for description of the course, concept map editor, information map editor and editor for direct access structures. The manager for hypermedia courses allows doing the following tasks: creating, opening, deleting and renaming a course. Each course will be the root of a specific file directory. From the manager of hypermedia courses one can have access to the editors description of the course, concept map, information map and direct access structures.

Through the editor for description of the course, one can identify in a concise form the whole course, defining the area of interest of the course and its extent. Next, one can define the general objective, writing in a simple sentence what is intended that the apprentice must know after completing the course. The specific objectives and sub-objectives in the cognitive, affective and corporal levels must be also defined.

The concept map is an educational tool of great versatility (Jonassen & Marra 1995, McAleese 1990, Novak & Gowin 1984). The use of the concept map technique allows structuring the knowledge domain of a hypermedia course in a graphic form. This technique has been successfully used as a simple and explicit modeling of educational software (Kawasaki 1996, Moroni & Señas 1997). In the process of construction of concept maps, one can define the group of information that should compose the course, considering that learners may bring a degree of previous knowledge on the subject.

The concept map editor helps the teacher build a specific concept map for a given target subject. (Fig. 2) illustrates the four types of nodes used in a concept map. The creation of a node is accomplished through the corresponding buttons Initial, Middle, Final and Context. An initial node corresponds to the name of the current concept map. A middle node corresponds to intermediary concepts. Final nodes correspond to nodes without any relation to child nodes. Finally, context nodes will indicate other concept maps, facilitating the nested or hierarchical construction of concept maps. The initial, middle and final nodes will directly indicate information maps. In (Fig. 3), a graphical interface shows an example of a concept map elaborated by the concept map editor.

Figure 2: Four types of nodes in a concept map.

The information map editor helps the teacher to structure the nodes of a concept map through the information mapping technique. Information maps provide a high degree of modularization for the instructional material. They help organize, store and present information. This process consists of dividing the target information into more detailed pieces of information called blocks and, in more general way, to obtain an overall understanding of the subject, called maps. Blocks of information represent the smallest portion of information that can be individually accessed. When these blocks are organized in larger and related structures, they form information maps.

According to Horn, all basic information can be classified in seven types of information maps (Horn 1989): Concept, Structure, Procedure, Fact, Process, Classification and Principle. Each one of these types consists of a group of two or more blocks of information referring to a certain topic. The following are examples of types of blocks: definition, introduction, formula, example, remark, etc. In the interface for building information maps, the inner circle represents a topic, whose content corresponds to an initial, middle or final node taken from a concept map. In (Fig. 4), the graphical interface shows an example of a concept map topic, namely the initial node of the concept map illustrated in (Fig. 3), with four information maps, each one with its respective blocks.

Finally, the interface of the direct access structure editor provides functions for defining glossaries and bibliographies. In this case, the teacher can register specific words and their respective meanings related to the target domain or subject. He can also register the authors and respective data of publications. The lists of words or bibliographic references are alphabetically ordered, facilitating the search during the edition task. The information defined through this editor will provide a course with additional resources for the learner. For instance, when navigating through a hypermedia course, the learner will be able to access the meaning of a word belonging to the course glossary directly.

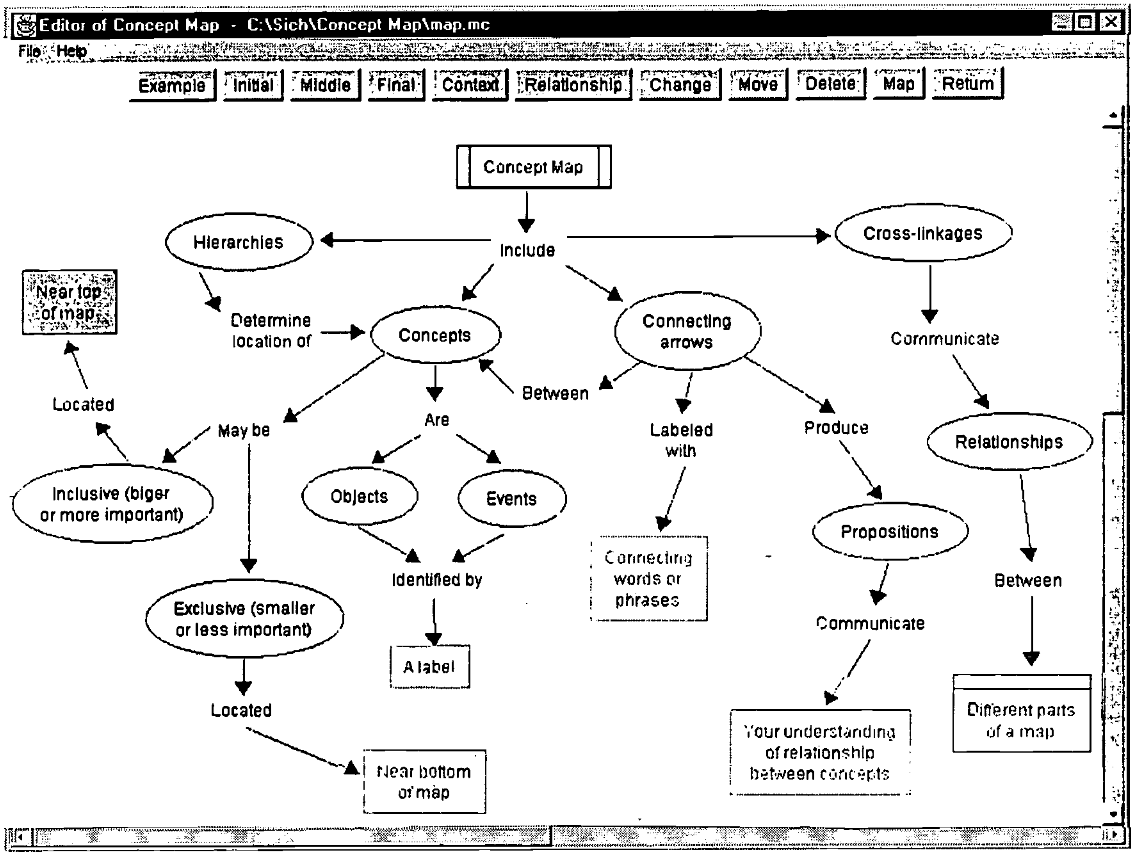

Figure 3: Graphical interface illustrating the construction of a concept map.

SICH is implemented in the programming language Java, an object-oriented language that executes independently of the platform and browser. In the design of the interfaces the essential activities aiming at minimizing cognitive overload, and the correspondent adaptation effort of the author to the interface were taken into account. The operations of saving and opening files are automatic in all the four editors. The tool also facilitates the reuse of the content of a hypermedia course material in other courses.

Related Works

For building concept maps in hierarchical levels, there are two main tools in the literature: JMap (Gaines & Shaw 1997) and MCH (Moroni & Señas 1997). SICH is also a tool for building hierarchical concept maps. JMap presents a diagrammatic notation with only three kinds of nodes, a not so friendly user interface, and does not allow reusing concept maps in other similar applications. SICH presents a better diagrammatic notation, offering four kinds of nodes. It has a friendlier and highly interactive user interface, offering a strategy of automatically opening and saving files related to a specific course, minimizing both the cognitive overloading and adaptation effort of the author to the interface. SICH also presents a specific editor for developing information maps, not present in JMap, which allows better concept structuring and concept maps reuse.

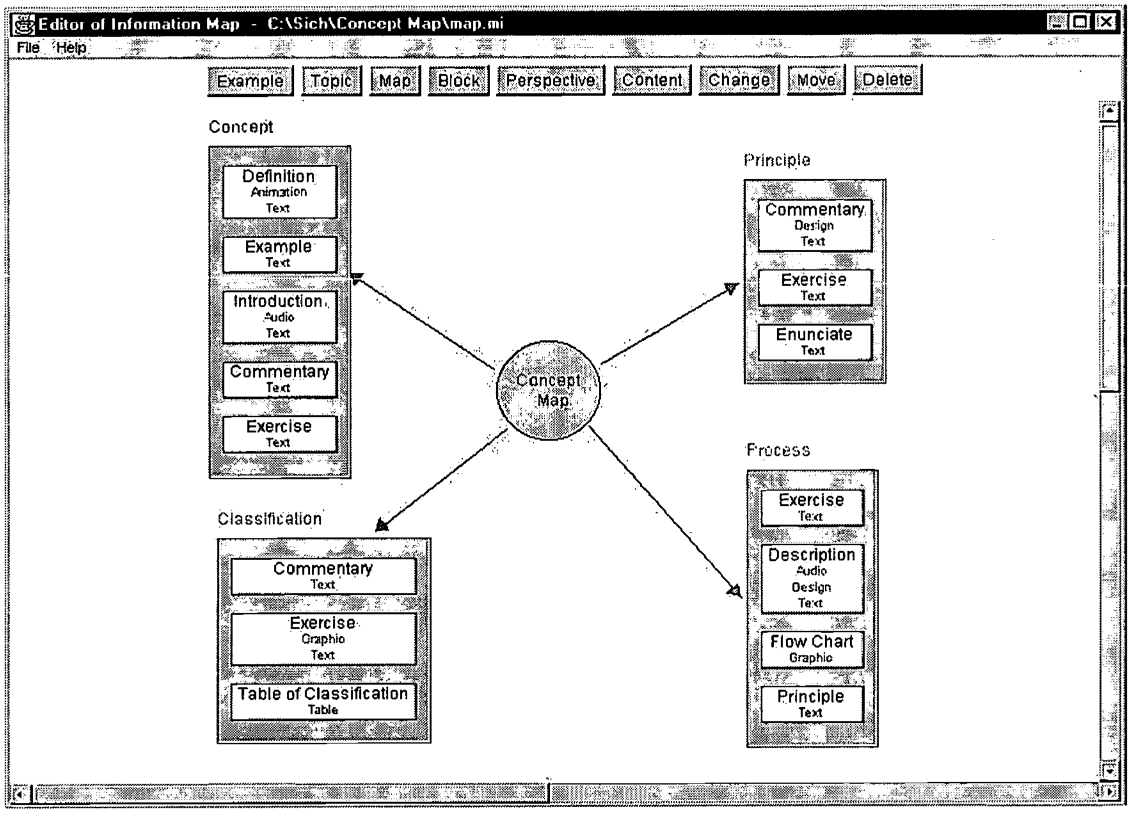

Figure 4: Graphical interface illustrating the construction of a information map.

Both SICH and MCH allow the reuse of concept maps. However, MCH presents a diagrammatic notation with only two kinds of nodes and only a one-to-one relationship between nodes. Besides, the content of each node is inserted directly on the same screen where the nodes are created, making it a confusing operation. The diagrammatic notation of SICH offers two kind of relationship: one-to-one and one-to-many. For inserting the content of a concept node, SICH offers another editor, allowing the developing of information maps.

There are other tools for developing concept maps in the literature (Fisher et al. 1990, Jonassen 1995), all similar to Jmap and MCH, but differing significantly from SICH.

SPR Tool

SPR (acronym for Guided-tours Designing Tool) provides special features for the automated design of guided-tours for hypermedia courses, according to pedagogic criteria imposed by the author, target population and learning objectives.

A hypermedia course is composed of one or more entities, where each entity is a complete set of information about a certain subject. The inner structure of a hypermedia course can be determined through a concept map. In the context of the course, an entity or topic can be classified as belonging to one of the following categories: Body, Complementary Note and Prerequisite. Body is the set of new information that the author intends the learner to acquire. Prerequisite is all knowledge that the learner has to know before doing the course. Complementary Note is all information used for illustration, comparison or reinforcement of the new concepts introduced in the Body part.

The design of a guided-tour takes into account the correspondent hyperbase design. A hypermedia course can have one or more navigational guided-tours. The goal of a guided-tour is to facilitate the learning of the subject. A course guided-tour has a didactic way for presenting de subject, following some pedagogic and motivational scheme.

SPR is an undergoing tool, written in Java, offering a friendly and interactive interface supporting the author of the course in the following tasks:

- Selecting the subjects for each part of the course design and classifying the selected entities as belonging to the Body, Complementary Note or Prerequisite.
- Designing a sequence of pre-defined learning units based on the correspondent hyperbase.
- Designing of limited and programmed access to the hypermedia content related to the topic under the learner's attention.

Conclusions

The process of modeling hypermedia courses should include the pre-authoring task for the design of hiperbases and related guided-tours. The APACHE environment, composed of SICH and SPR tools, will help the planning and development of a hypermedia course. The SICH tool allows a teacher to design educational applications on different knowledge domains, through a friendly and interactive interface. This aspect contributes effectively to the creation of educational hypermedia material. The SPR tool allows the teacher to define guided-tour designs for hypermedia courses based on the correspondent hyperbase. Finally, once APACHE is implemented in Java, it can be used for designing hypermedia courses through the WWW.

World Wide Web Based Simulations for Teaching Biology.

Jeffrey Bell, Department of Biology, California State University, Chico, United States, jbell@csuchico.edu

Abstract: The Biology Labs On-Line Project is an attempt to create simulations of important biology experiments that students normally can not perform in typical undergraduate laboratories. All of the simulations are designed so that the student has the flexibility to design and interpret their own experiments. The programs generate large amounts of data and are fast enough for students to do multiple experiments. The simulations are all written in Java and are accessed over the World Wide Web. Ten of the simulations, covering the topics of evolution, Mendelian genetics, protein translation, human population demography, protein structure-function, human genetics, mitochondrial electron transport, enzyme kinetics, cardiovascular physiology and photosynthesis will be ready by the summer of 1999, with five more planned for the summer of 2000.

Introduction

The Biology Labs On-Line Project is a component of the California State University System (CSU) Integrated Technology Strategy (ITS), which calls for anywhere, anytime access to information. The project initially brought together biologists from throughout the CSU system and the CSU Center for Distributed Learning (CDL) to explore ways to use technology to improve learning in introductory biology laboratories. Later, multimedia developers from Addison Wesley Longman were added to the development team. A major goal of the collaboration was to allow students to learn as biologists do, *i.e.*, by actively designing experiments and interpreting their results. Another goal was to extend student learning opportunities by creating simulations of experiments that they might not normally do because of expensive and/or inaccessible lab equipment, lack of field opportunities, time constraints, complexity, danger, or ethical problems. Eliminating the time constraints of the traditional experiment and two or three hour laboratory period gives students the opportunity to design and interpret experiments, learn from their mistakes, and to revise and redo their experiments just like real scientists. The simulations are not designed to replace the traditional "wet labs" found in the normal biology course, but rather are designed to extend the laboratory experience to subjects and experiments that can not normally be done, or not done enough, in a traditional laboratory. The simulations are also *not* multi-media presentations, stand-alone tutorials or on-line courses.

The project has produced seven different educational simulations covering the subjects of evolution, Mendelian genetics, protein translation, human population demography, protein structure-function, human genetics, and mitochondrial electron transport. Current projects in progress and due to be finished by the summer of 1999 will simulate enzyme kinetics, cardiovascular physiology and photosynthesis. While each of the simulations is unique, all of them share many common interface elements and functions. All of the simulations have been designed so that the student can carry out many different experiments, allowing the student to design and interpret their own experiments. The flexibility of the programs make well designed exercises an important part of each laboratory. However, while sample exercises will be included with each lab, instructors can easily design their own exercises to meet the needs of their students.

The simulations have all been created in the Java programming language, so that they can be easily accessed over the web using any standard browser. This solves the problem of widely disseminating the applications, a common problem with most educational software. The Java application provides the user interface where students set the starting parameters for their experiment and get graphical feedback on their current settings. In some of the simulations the Java program also calculates the results, while in others the input parameters are passed back to the server, where the real calculations take place. When the server is done it sends the results back to the Java application, which presents the results to the student.

The downside of using Java is that only individuals and schools with fairly new computers and software (Netscape 3 or better, etc.) and an internet connection can use the software. Another disadvantage of using Java is the inability of Java programs to save to disk or print. This limitation has been overcome through the use of a notebook that can be exported to a web page. All of the data tables, such as numbers of different types of progeny, or results of statistical calculations, can be imported directly into the notebook. After typing in their comments the student can export the notebook to a web page for printing, or to email to themselves or an instructor. The web page is temporarily stored on the server. Graphical images such as graphs and charts produced by some of the programs are also exportable to the notebook, where they can then be printed.

All of the programs share some common user interface elements, including a title bar with links to an introduction to the lab, help, sample assignments, the notebook, etc. While there is much diversity in how the different labs operate, most of them start in an input mode where the student designs their experiment by adjusting different parameters. After designing the experiment the student runs the simulation. The program calculates the results of the experiment, usually in a minute or less, and then presents the results in the output mode. In this mode there is a tabbed interface where the student chooses which type of output they wish to view, a table of the data, a graph, the input values, etc. After analyzing their results they can import them into the notebook and then go back to the input mode to design another experiment. This ability to quickly go back and forth between the design of an experiment and the results is one of the powerful advantages of a simulation approach to teaching science.

Seven of the programs are currently available for beta testing and all ten should be finished by the summer of 1999. Descriptions of each of the labs can be found below. Current plans call for a $19.95 fee for access to all ten of the simulations and a lab manual with printed instructions and sample assignments. The fee is necessary to support the servers and for maintenance of the various programs as operating systems and computers change. . The option of selling access to individual labs is also being considered. Below is a fairly complete description of EvolveIT along with brief descriptions of the other simulations However, the best way to learn about these simulations is to go to the CDL site, http://www.cdl.edu/html/biology.html, and try out some of the five simulations currently available there.

EvolutionLab

Although evolution is the unifying theme of the biological sciences, it is perhaps one of the most misunderstood and difficult concepts to convey in a laboratory setting. The study of evolution is especially suited to computer simulations because evolution normally occurs over very long time intervals, large data sets are usually needed to understand it, and there are usually a number of important parameters that are difficult to control in real experiments. EvolveIT (http://www.cdl.edu/EvolveIT), is a web based, interactive computer simulation designed to teach the basic concepts of natural selection and to convey the importance of time in the evolutionary process.

Students using EvolveIT observe evolutionary changes in bird beak morphology in hypothetical populations of birds isolated on two islands. In the simulation students can set the annual rainfall on island(s) containing finch populations, and then observe the effect of this environment on the evolution of the finch's beaks. Students may also change several other properties of the bird populations, such as initial mean beak size, beak size variability, beak size heritability and mean clutch size, to determine their effect on beak evolution.

To help students clearly see the effects of changes in the different variables, the simulation uses two islands with independent and isolated populations. A student can either directly compare two different sets of conditions, or do a duplicate run where both populations have identical starting conditions. As many students will also be unfamiliar with some of the variables, the program gives extensive feedback on what is being changed with each alteration of one of the initial variables. For instance, when the slider for mean beak size is moved to the right a picture of a finch head shows the finch beak growing larger, or when variability is increased a graph of the current distribution of beak sizes spreads out.

The program creates several hundred different virtual "birds" using the initial parameters entered by the student. These birds then go through a round of natural selection where each bird's probability of survival is a function of the seed distribution (determined by the setting for rainfall) and that bird's beak size. After the selection step the surviving birds are randomly mated to one another. They then produce offspring based on the values for heritability and variability entered by the student. This new population of birds becomes the starting population for the next year. This repeats for each year of the simulation. Because of the random selection and mating each simulation run is unique and will produce a different result than any other run, even one that starts with exactly the same starting parameters. The program produces several different outputs: a scrolling table with the mean beak size, the variability and the population size for every year of the simulation, for both populations; a series of histograms showing what proportion of birds of different beak sizes survived, for each year of the simulation; a plot of the mean beak size versus time for both populations; and a plot of the population size versus time for both populations. The final output is a table with the initial values for the simulation.

The student can rerun the simulation with the same initial values, revise the experiment, or start over with the default values and design a new experiment. Students can study the effects of different amounts of rainfall on the evolution of beak size to get a feel for how natural selection works. They should be able to determine that large beaks are favored in low rainfall, the optimum beak size for different amounts of rainfall, the effect of varying the severity of the selection, and the importance of the environment in determining the direction of selection. Similar experiments can be done in which only population variability or beak size heritability is manipulated to study how these parameters affect beak evolution. Changes in island size affect the carrying capacity of the island and allow the student to investigate the stochastic effects that can result from small population size. Variations in clutch size permit the student to investigate the consequences of different fecundities on the capacity of different species to evolve. Some aspects of population dynamics can also be investigated using this parameter (rate of exponential growth, boom bust population cycles, etc.)

While the simulation is based on Darwin's finches, changes in the species variables such as mean beak size, variability, heritability and clutch size create virtual species that can have properties similar to many other wild species. Students can investigate the parameters that are more likely to lead to the extinction of endangered species, see why some species might evolve faster than others, and examine many other facets of evolution. The program generates large data sets, one run can produce 600 data points, so students can learn how to analyze and interpret large amounts of data, unlike the situation in a typical lab. The great flexibility of the program should allow individual instructors to tailor student assignments to their particular preferences and provide students with a real opportunity to design their own experiments. Actively engaging students in exploring and studying evolution through this simulation will provide another avenue for students to learn about evolution in addition to the traditional text and lecture explanations.

Virtual Fly Lab

Two genetics labs are currently planned. One is a simulation of classical fruit fly genetics while the other one lets the student study human genetics by analyzing pedigrees. The Virtual Fly Lab (http://www.cdl.edu/Flylab) simulation is an update to the Virtual Fly Lab originally created by Bob Desharnais. In the Virtual Fly Lab students design their own fruit flies by choosing from many different possible phenotypes for characteristics such as eye color, wing shape, body color, etc. They then mate their flies and analyze the progeny to determine the rules of inheritance for different traits. Each experiment is unique and students can have up to 10,000 progeny produced from one mating. Offspring can also be mated so a wide range of different experiments are possible. There are 29 different traits that can be studied in isolation or in various combinations so the number of possible experiments is in the millions. The traits are all represented graphically so the student can observe the phenotypes directly. For instance, if the student selects the white eye mutation for the female parent their picture of the female parent will change to have white eyes. After the mating they will get a picture of the different progeny, along with numbers beside each picture to indicate the number of progeny of that type (number of females with white eyes, females with red eyes, etc.) The program includes a Chi Square calculator for doing statistical tests of the students hypotheses, and a notebook for recording results, observations, hypotheses and conclusions. Students can import the numerical results from their crosses and statistical tests directly into the notebook.

Using this program students can discover or study most of the important principles of Mendelian genetics, including dominant and recessive alleles, sex-linkage, lethal alleles, independent assortment, epistasis, linkage, gene order, linkage groups, and linkage maps. More importantly, students can discover these principles by doing the same sort of experiments as the original researchers, only much faster. The program is appropriate for a wide range of biology courses as the assignment determines the level of difficulty. Students can do statistical tests, but this is not required. Students can do complicated crosses with multiple traits, or simple crosses with only one trait at a time. If a student is confused by a complicated cross, they can always do some additional simpler crosses to try to figure out what is going on. They can also do additional crosses with the progeny from their crosses, and their progeny, etc. This ability to devise their own experiments and try many different permutations is a major strength of the FlyLab.

PedigreeLab

PedigreeLab (http://caldera.calstatela.edu/PedigreeLab) generates a hundred pedigrees for several different genetic diseases. The student can examine the pedigrees to determine the inheritance pattern of the particular disease. In addition, the student can examine various molecular markers and determine whether they are linked to the genetic disease. Students can use the molecular markers to map the disease gene to a particular chromosome or to a region of the chromosome. This is a key process in the current search for human genetic disease genes and is normally very difficult to explain to students. The program keeps track of the results from each pedigree they use and can determine the statistical significance of their results. Having them actually go through the process of mapping a human gene should significantly improve their learning of these difficult concepts.

TranslationLab

So far, the Biolabs project has produced two molecular biology simulations. The first, TranslateIT, http://www.cdl.edu/TranslateIT, simulates some of the original experiments used to crack the genetic code, one of the key discoveries in molecular biology. These experiments rely on radioactive materials and difficult to produce RNA templates so they can't be done in the normal biology lab. Students design and create simple RNA molecules in the simulation that they then translate in a virtual *in vitro* translation mix. The program shows a simple animation of the techniques that would be used to analyze the products of the translation and then gives them the amino acid sequence of any proteins produced in their experiment. The student must logically analyze the results of multiple experiments to deduce the properties of the genetic code, just as the original researchers did, only with the advantage of being able to do experiments in minutes that normally take months to carry out. Various properties of the code that can be determined using this simulation are the triplet nature of the code, that the code is non-overlapping, codon assignments for particular amino acids, and the existence and identity of stop codons.

HemoglobinLab

In the second molecular biology simulation, the HemoglobinLab, http://www.cdl.edu/HemoglobinLab, students investigate various aspects of the molecular biology of hemoglobin, using case studies. The goal is for the student to learn how changes in the nucleotide sequence of a gene *may* effect the protein sequence, which *may* effect the structure of the protein, which *may* effect the function of the protein, which *may* effect the properties of the cell, which *may* in turn effect the physiology of the individual. Students choose a case by selecting a patient from a pull down menu with a list of over a dozen patients. For each case the students can examine the doctors notes about the symptoms and medical history of the patient, examine the color of a vial of the patients blood, examine the blood under a microscope to see if there are changes in the red blood cells, run a sample of the blood on an electrophoresis gel to determine if there are physical changes in the globin protein, and, finally, the student can determine the amino acid sequence of the patients globin protein. Having determined the sequence of the protein the student can go to the DNA sequence editor and try to alter the

DNA sequence of the normal gene to see what type of DNA mutation would cause the changes found in the patient they are examining. The patients have a variety of mutations in the globin gene ranging from simple point mutations that change one amino acid, such as in sickle cell anemia, to deletions and insertions causing frameshifts, such as some of the thallasemias. The mutations cause many different patient phenotypes, such as anemia, brown blood, polycythemia (too many red blood cells), and purple skin color.

DemographyLab

The Demography Lab, http://caldera.calstatela.edu/DemoLab, models human population growth in several different countries around the world. Students can use this lab to investigate how differences in population size, age-structure, and age-specific fertility and mortality rates affect human population growth. Default values for seven countries have been incorporated into the program to allow comparisons between nations with very different demographics, such as Japan and Nigeria. In addition, students can change any of the parameters to create their own experiments. The proportion of males and females in each five year age group, the total population size, the mortality rate for males and females in each five year age group and the birth rate per female in each five year age group can all be set by the student using a simple graphical interface. After running the simulation for 100, 200 or 300 years, students get summary statistics for the population at the end of the time interval, such as life expectancy, birth rate, population growth rate, etc. They can view a line graph of population numbers over the course of their experiment, see a graphical representation of the population structure for every five years of the experiment, or examine the number of males and females in each age group for each five year period. Using the program a variety of demographic phenomena can be demonstrated, such as exponential growth and decline, stable age structure, zero population growth, demographic momentum, dependency ratios, sex ratios and marriage squeezes.

MitochondriaLab

Three biochemistry and cell biology labs currently in development are MitochondriaLab, EnzymeLab, and LeafLab. MitochondriaLab, http://www.cdl.edu/MitochondriaLab, simulates electron transport, proton gradients and oxidative phosphorylation in mitochondria. Students recreate the classic experiments that established the chemiosmotic theory as the mechanism for energy production in the cell. They add various substrates and inhibitors to their virtual mitochondrial extracts and then measure the consumption of oxygen over time. From their results they can work out some of the steps in the pathway and the mechanism by which the chemical energy is converted into ATP molecules.

EnzymeLab

In EnzymeLab students will study the enzyme kinetics by varying quantities of substrates, cofactors and inhibitors and then measuring reaction rates. They will also be able to vary temperature and pH to determine their effects on a typical enzyme catalyzed reaction.

LeafLab

The LeafLab will simulate the photosynthetic reactions in leaves. Students will vary wavelength and intensity of light, CO_2 and oxygen concentrations, temperature, and type of leaf and then measure the consumption of CO_2 in their simulated leaves.

CardioLab

The tenth lab currently under development is CardioLab. This lab will simulate the cardiovascular function. Students will be able to inject various hormones, remove or add blood or plasma, alter diet and exercise, and stress their virtual subjects and then can track various physiological responses such as heart rate, pressure, and blood flow over time. Students will also be able to do experiments on virtual patients with various health problems such as obesity, heart disease, atherosclerosis, etc. Student experiments should lead to a greater understanding of hormone action, positive and negative feedback loops, homeostasis, and physiological pathways. Understanding this physiological cycle is obviously of great importance to the students and will also teach them many important physiological concepts.

Assessment

The precursor to all of these labs is the original virtual Fly Lab. This simulation of fruit fly genetics is now used in biology classes all over the world, and has created so much demand on the server hosting the program that there are now five different mirror servers. The Virtual Fly Lab, EvolveIT and TranslateIT have been field tested in an upper division genetics course with encouraging results. 98% of the students in this course considered their Virtual Fly assignments useful in learning genetics, 83% found EvolveIt to be useful and 93% found TranslateIt useful. Some sample comments from the students are:

"Excellent 3 part demonstration of Mendelian genetics - each lesson built on the previous one - excellent practice for the tests. Also includes repetition of important concepts (X linkage, etc.)"

"Liked best - actually enjoyed! (what a concept) Virtual Fly I, II, and III. These were great fun to puzzle out - someone's going to hate me for saying this"

"TranslateIt was enjoyable because it requires the student to investigate and solve the problem."

"Virtual Fly and TranslateIt were the assignments I got the most out of. I liked the way it made you systematically think to solve the problems."

"I liked the Virtual fly and EvolveIt activities because they allowed you to do some investigation on your own and they made you think about what was really happening, which made you understand the material better."

There were only a few negative comments, usually having to do with the difficulty of getting on-line and using the programs. Students who are uncomfortable with computers are at a disadvantage when using these simulations and special care must be taken to make sure they get the most out of the simulations. The only other negative comment was, "I liked TranslateIt the least because it made my head hurt." While this is unfortunate, if the BioLabs project can produce more simulations that cause some students heads to hurt, then the project will be producing simulations that change, for the better, the way biology is taught.

Acknowledgements:

The following individuals contributed to the development of these simulations, their contributions are gratefully acknowledged: Bob Desharnais, David Caprette, Mike Palladino, Steve Wolf, Zed Mason, Ron Quinn, Terry Frey, David Hanes, Judith Kandel, Nancy Smith, Sally Veregge, Abbe Barker, Michelle LaMar, Mark Crowley, Chuck Schneebeck, Rachel Smith, Lou Zweier, Scott Anderson, Peilin Nee and Anne Scanlan-Rohrer. Partial support was provided by U.S. National Science Foundation grant DUE 9455428 to Bob Desharnais.

Facilitating Virtual Learning Teams in Online Learning Environments

The Challenge of Virtual Learning Teams

Exceedingly, today's educators are expected to adapt teaching and facilitation techniques to new and emerging delivery systems. The number of educational courses and training programs migrating to the World-Wide-Web, the Internet, and corporate intranets is astounding (see Bassi, Benson, and Cheney 1996). For most educators, the migration to computer-mediated distance education does not come easily. Although at first glance, it seems that traditional teaching methods such as presentation, discussion, and team-based learning can be easily adapted to on-line delivery systems, in reality research is showing that teaching and learning in on-line environments is very different from face-to-face instruction (Luetkehans 1998; Sherry 1996). Of particular interest to educators is the effective facilitation of collaborative team learning in on-line environments.

From a student perspective, participating in a virtual learning team (VLT) is a new, and perhaps frightening, experience. Mary Lou Crouch and Virginia Montecino (1997) note a phenomenon experienced by on-line learners called "cyberstress." The asynchronous nature of many on-line courses and communication tools, and the perceived distance between learners and other team members contributes to fears of contributions and assignments left unnoticed and "lost in cyberspace." Students have not developed sufficient experiences for dealing with delayed communications, the generative nature of on-line learning, nor the ability to express themselves effectively to team members through written communication.

The purpose of this paper is to present tips for educators who would like to successfully integrate and facilitate virtual learning teams within their on-line courses. The techniques are grounded in current research and the theoretical foundations of systems theory and group dynamics. Tips emphasize facilitation of virtual learning teams assembled for the purpose of formal education who are supported by computer-mediated communication tools.

Critical Elements of Virtual Team Learning

Task or Problem

A team is defined as "a number of persons associated in some joint action" (Webster's Unabridged Dictionary 1992). However, all virtual teams are not created equal. The VLT process is affected by the type of task or problem it is given (Straus and McGrath 1994). As with other instructional strategies, virtual learning team activities can be classified by learning domain (Bannan and Milheim 1997). Specifically, team activities can be classified as those designed for a.) motivation or attitude development, b.) problem-solving, c.) skill building, and d.) knowledge construction. The instructional goal and the type of team activity has a direct impact on how the team members explore and define team objectives, plan a course of action, and their perceptions of success. A clearly communicated instructional goal and desired performance outcomes of the team are essential no matter the delivery system.

Team Dynamics and Interaction

As with face-to-face teams, VLTs are governed, in part, by the dynamics of group communication. Group dynamics is concerned with both the productive (task) communication of members as well as the development of roles and relationships among team members (maintenance). All teams, whether on-line or face-to-face, will develop and enforce group norms (e.g., acceptable and unacceptable communicative behaviors) and methods for leading, stimulating, rewarding and punishing team member contributions. Often, on-line educators overlook these elements of VLT interaction because they are focused solely on content (task) learning and interaction. Taking a more systems view of team interactions may help avoid so-called "internet pitfalls" (Boettcher 1997) of on-line communication.

Team Member Roles

The greatest value of team learning may also be its greatest challenge. That is, a group is made up people with a diversity of talents, strengths and experiences. This brings with it the foundation for stimulating discussion, creativity, and effective problem solving. However, it also means that each member of the team comes into it with established habits, learning styles, and preferred team roles. Most of the current literature agrees that effective teams are able to represent a balance between task roles (goal accomplishment) and maintenance roles (process satisfaction and efficiency). Task roles and maintenance roles take on new character in on-line environments. Task roles dominate and are performed both on-line and off-line. Maintenance roles, although critical to team connectivity, may not be performed until conflict arises or inefficiency is felt. The maintenance role of leading consensus is more difficult to achieve on-line (Harasim 1993).

Mediated Communication

Two factors differentiate a VLT from a face-to-face team: 1.) team members who are "out of sight" and unless a face-to-face introduction has occurred, who are based on an impression established by text and description, and 2.) a reliance on connections between team members made through electronic or computer-mediated technology. Both facilitators and team members must rely on virtual (as opposed to tangible, touchable) connections in order to achieve goals. The result may be a perceived loss of control and security for both the facilitator and the team member. Members fear a loss of productivity if that connection is not reliable or effective.

Facilitation

To facilitate is "to free from difficulties or obstacles; to make easier; to aid; to assist" (Bailey 1996). VLTs are generally facilitated both from the outside (by the educator) and within (by team members). The role of the outside facilitator (the educator) in on-line environments is changed from that of face-to-face instruction. The role of the outside facilitator, because of the nature of VLTs, entails 1.) ensuring that no barriers (technical, informational or motivational) exist to team learning, 2.) ensuring essential elements for learning are accessible (such as interaction, task information, and feedback), and 3.) aiding team members in times of conflict or confusion.

Ten Techniques for Virtual Learning Team Facilitators

Tips for Facilitating Motivation and Efficacy

Tip #1 - Help team members manage "cyberstress"

Help learners overcome initial stress by sending a detailed advance e-mail at the onset of the team activity. Include a welcome, a description of the team goals and desired outcomes, and tips on being a successful team member in an on-line course. Ask members to contribute personal information about themselves as a first communication to the VLT. Ask them to include their background, familiarity with the task/problem, and talents/contributions they will be bringing to the team. As the course continues, manage the stress resulting from delayed communications by sending "receipt" messages. A receipt message is a short feedback message indicating that, although you cannot immediately respond to the learner's message or review the assignment, you received it. Encourage team members to do the same. Help teams establish ground rules for frequency of checking computer-mediated communications.

Tip #2 - Plan frequent e-mail prompts to help team members overcome procrastination

It is important to help team members sustain participation. "The major reason for disappearance has to do with a student's feelings of not being connected" (Crouch and Montecino 1997). E-mail reminders are useful in helping to keep the team activity in the forefront of learner's thoughts. E-mails should not be nagging, but serve as friendly reminders to log-on to the site, ask if assistance is required or for reports on team progress.

Tips for Facilitating Problem-Solving

VLT activities for problem solving typically require methods that encourage both creativity and decision-making. Activities which integrate knowledge and skill sets with real problems and contexts may include case scenarios, simulations, team research and reporting, negotiation, and decision making. The facilitator of problem solving must be skilled at supporting the phases of problem solving and in helping teams achieve consensus.

Tip #3 – Provide a variety of tools to support the different phases of problem solving

Provide each team an exclusive area on the course website for posting team resources and strawman solutions. Because problem solving requires both exploration and consensus, VLTs should have the ability to access and post hypertext resources for information searching and sharing, as well as tools to develop and debate solutions. Provide a combination of tools for different stages of problem solving. If the problem or case study will take several sessions to solve, teams will benefit from access to an asynchronous tool that can be used to keep the history of the team's discussions and negotiations. If the problem can be resolved in a single sitting, a synchronous tool for discussing and defending individual perspectives or even voting can be useful. Asynchronous problem solving is best supplemented with a synchronous tool during stages of negotiation and decision making.

Tip #4 – Assist team members when they struggle with achieving consensus

Teams often appreciate the intervention of a neutral facilitator when it comes time to make critical decisions or select among alternatives. Explore methods for polling team members, and for conducting on-line voting. The summary is an effective tool for leading to consensus. Often team members are too busy looking forward to see where they have been. Review team progress, and summarize it as you see it. For example, "I see you are developing two pretty distinct alternatives. The first appears to focus on the navigation needs of the learner. The second focuses on the simplicity of design. Which do you feel are priority given the goal of immediate access?"

Tips for Facilitating Skill Building

Activities that allow for the development of skills may include small group projects and expert modeling. The facilitator of skill development must be expert at designing authentic projects, offering timely and meaningful feedback, modeling, and leading effective reflection and debriefs of skill activities.

Tip #5 - Assemble teams strategically based on task and talent

In online environments, larger groups are less productive and have more difficulty arriving at consensus, so consider 3-4 members per team as a target (Dennis & Gallupe 1993). If possible, teams can be balanced on talent and experience (e.g., with HTML) so that an "expert" in the team is able to provide modeling of the skills and scaffolding for other team members. Assess the skills targeted for development. Design tasks around the targeted skills, and communicate them through clearly stated objectives. Focus tasks on the development of a single competency area, or a small number of skills.

Tip #6 - Provide timely and meaningful feedback

Skill building depends on frequent practice and feedback. The facilitator can use semi-private and private communications for feedback. Semi-private communications can be established by providing "exclusive" threaded discussions, chat rooms or Listservs accessible only by team members. Individual feedback should be conducted via e-mail. The facilitator should plan and use process checks as part of project activities. A process check is a planned "check point" for communication, reporting, and questioning on a project's progress. Synchronous tools are effective for conducting process checks. When the activity is complete, conduct an asynchronous debrief discussion. The facilitator should use questioning techniques that stimulate reflection and processing. Modeling difficult tasks and behaviors is another form of feedback, allowing students to compare their outcomes to a benchmark or standard. Use hyperlinks to show learners examples of completed projects, forms, or reports on the course website or in threaded discussion.

Tips for Facilitating Knowledge Construction

Activities that develop new concepts, contexts, and meaning may include reading, information searching and sharing, discussion, inquiry, and reflection. The facilitator of knowledge construction must be skilled at scaffolding discussion, and encouraging exploration and elaboration.

Tip # 7 - Scaffold topical discussions using a threaded discussion (asynchronous) tool

An effective scaffolded discussion involves a.) providing an initial structure and b.) facilitating concept construction through questioning. The structure can be minimal. If the discussion topic is new to learners, post a topic name along with 1-2 open-ended questions to initiate thinking. This allows students to construct the concepts and detail. Facilitators should avoid dominating discussions by using relay questioning techniques and only participating when necessary. To encourage continued contributions, reward participants' thoughtful responses with short affirmations. Finally, when discussion objectives have been met, the facilitator can quickly "point to" the learning with a brief summary. Summaries provide both rewards and reinforcement.

Tip #8 - Encourage elaboration through questioning and hypertext linking

As in face-to-face facilitation, effective questioning techniques are useful to encourage elaboration. Use open-ended questions to stimulate a response that builds on prior concepts. For example, "Jack, you indicated 'a survey as one ways to gather information for a needs assessment.' What other techniques could you employ?" Hyperlinks to additional information or expertise can also be used for stimulating elaboration. Many Internet communication tools accept HTML links within the message body. The facilitator should model the use of hypertext in her responses. In addition, e-mail links can be included as a way to access outside experts willing to participate in discussions or private e-mail exchanges.

Tips for Resolving Conflict

Teams will rely on the facilitator to intervene in times of dysfunction. It is the facilitator's primary function to remove these obstacles to learning.

Tip #9 – Discourage judgment, criticism and personal attacks

Carefully phrase retributions to comments that are clearly not constructive. For example, "While I realize that we will not always agree with all point of view expressed on this forum, this is a reminder to reflect and build on IDEAS, not judge the PERSON." This typc of conflict can be avoided if teams adopt ground rules that encourage members to suspend judgment and accept diverse views. Post the rules at the beginning of a team activity or on the course website. Monitor the interaction and remind members when a contribution is outside of the accepted rules.

Tip #10 – Intervene to highlight areas of common ground among conflicting team members

Team members will expect the facilitator to intervene when conflicts get personal or unproductive. Start by helping team members see areas within their conflict that they agree upon. For example, "Sara and Tom, you seem to be at a stand still. In reviewing your discussion, it appears that you are both concerned that the end product be visually appealing. Is that correct?" Encourage the use of synchronous tools to resolve heated conflict in a timely fashion. Phone conferences may be more effective than computer-mediated communication to resolve personal conflict.

Drawing on a theoretical framework emergent from constructivism, systems theory and group dynamics, this paper presented ten tips for facilitators of virtual learning teams (VLTs). An on-line facilitator's required skills range from selecting and designing appropriate on-line tasks to assembling teams and removing obstacles to team task and maintenance roles. Of greatest importance is to intervene on any matter that deters a team's technical, informational, or motivational needs. As more courses migrate to computer-mediated environments, on-line facilitation skills will become increasingly critical to educators.

Abstract: In this paper we present the prototype version of MGCoop, a set of CSCW tools developed for Management Game, a simulation-based learning environment developed by the University of Carnegie Mellon. This paper presents the design of CSCW tools that allow the students to plan and establish virtual meetings through the internet, maintaining them aware of their capacities, commitments, availability and activities, in a learning environment. The students can work in a cooperative way, being coordinated using a WYSIWIS workflow environment, and presenting and discussing their points of view in an asynchronous or asynchronous way. We included the results obtained during the analysis from the interaction problems presented by the members of the learning group during their cooperation meetings. Some examples of these tools are presented, which were implemented in JAVA, permitting platform independence.
Keywords: CSCL (Computer Supported Collaborative Learning), Groupware, CSCW (Computer Supported Cooperative Work), JAVA, Workflow, Simulation Based Learning.

Introduction

Currently, learning environments based on the cooperation and the collaboration of students present new alternatives to the teaching-learning process (O'Malley 1995) in educational institutions as well as in organizations. Learning environments, based on technologies of CSCW (Computer Supported Cooperative Work) (Khoshafian & Buckiewicz 1995), allow the training and the collaborative work in companies, increasing their competitiveness. Since1995 research and development projects in educational software have been proposing the adjustment of the concepts of CSCW within a theoretical learning collaborative framework, appearing the area of CSCL (Computer Supported Collaborative Learning) (Ayala & Yano 1998) (Ayala & Yano 1994).

Together with researchers of the University of Carnegie Mellon, and continuing the same research guidelines (Cadiz et al. 1998), in the UDLA-P we have developed a set of CSCW tools for a simulation based learning environment (Medélez 1998). These tools have been designed based on the interaction study of members of learning groups, who need to cooperate and be aware of the activities each one must accomplish and the students that are working in a given moment, supporting in this way their coordination. The activity that the group must accomplish together is the creation of a report that must be presented periodically to a committee. This activity is the one which the students require more coordination and cooperation in Management Game, which is the reference framework of our research project.

Management Game

Management Game was developed in the 50's, with the participation of teachers of the Graduate School of Industrial Administration (GSIA) of the University of Carnegie Mellon. The purpose of this game is to learn by applying knowledge of business administration in a competitive and dynamical simulation environment. A learning environment based on simulation provides a great number of advantages in comparison with the simple analysis of cases of studies or the readings of textbooks. The simulation promotes the competition between several companies, each one of they formed by a group of students (Lerch et al. 1997). This game, already a tradition in the University of Carnegie Mellon, became an international game in 90's, when students of Sweden, Japan and Mexico were included (Lerch et al. 1997). The UDLA-P participated in the game with a group formed by students of the master course in Business Administration and Industrial Engineering. Using this game, the students put in practice their knowledge, competing with students of different parts of the world, living an experience of international training.

In Management Game, the students can play two or more roles in their company (president, counting, investigating of market, responsible for marketing and sales, of production, of operations, of finances, of competitive analysis, strategic planning and of communications). It is very important to assign the roles to the most suitable person, as well as to keep the students aware of (1) the roles that each student plays, (2) her/his commitments, (3) the assigned tasks and (4) their schedule and deadlines. After some experiences with the learning groups, it was determined that the learning environment required a set of CSCW tools for the coordination and the efficiency of the work in the learning group.

Interaction Requeriments

After some meetings with the students participating in Management Game, we found the following interaction problems in the learning groups, which were affecting their performance and therefore their learning:

a) Meeting Difficulties. Some of the group members already had established commitments in other enviroenments, like companies or other institutions. In occasions, they have to make trips outside the city, which made difficult to plan face to face meetings.

b) Lack of cohesion and awareness of the group. The students presented problems based on the ignorance of who was available and what activity was performing in a given moment, when they required cooperation.

c) Lack of control and follow-up of the workflow. The students presented coordination problems, not knowing exactly to who they have to deliver the results of their task This causes a delay in the accmplishement of the report to be submitted by the group.

d) Lack of awareness about the capacities and commitments. Some groups presented problems in the assignment of roles, since the student playing the role of president was not aware that some peer had a greater capacity or experience in some specific activity within the simulation. There were also awareness problems concerning the assigned tasks and commitments by each student.

e) Heterogeneity and conflict in the decision making. The groups include students of industrial engineering as well as business administration. As a result, the interaction between students presented conflicts due to different points of view.

It was considered that without a cooperative working environment designed for Management Game these problems could not be solved, specially if in a near future it is planned to have more heterogeneous groups from different institutions and, later from different countries.

CSCW Tools for Management Game

In order to propose a solution to the problems mentioned in the previous section, we have designed and developed an environment in JAVA where the students learn by collaborating with their peers through internet while working in Mahnagement Game. These CSCW tools allow the student to:

1) Be aware of the participants who are working in a given moment.

2) Be aware of the activities of each member of the learning group, via an electronic agenda supported by a calendar.

3) Be aware of the tasks already concluded by the members of the learning group, the relationship between these in the context of the common work, as well as of the deadlines of the tasks, via an workflow environment.

4) Clear assignment of the tasks to perform by the members, an agreement of the role assigned to the members play, according to their capacities, via a users manager tool. There is a document manager that includes the concurrence managing, including the access and modification privileges of shared files.

5) A synchronous communication tool between peers (chat), as well as a asynchronous communication tool (e-mail) developed *ad hoc* the needs of the environment.

MGCoop

In order to support awareness, the cooperative work and learning of the students that play with Management Game, we developed MGCoop. MGCoop has been implemented in JAVA. We used the WIMPs (Windows, Icons, Menus, Pointers) interfece concepts (Van Dam 1997) and the classes *AWT* (Abstract Window Toolkit) (Sun Microsystems 1998) and *Swing* (Fowler 1998).
We have organized theMGCoop tools in three groups:

a) Users Manager
b) MGCoop Workflow Environment
c) Communication Tools

Users Manager

The work assignment in a responsible way is a very important aspect that we consider when we designed the environment MGCoop. In this way we could improve the group performance. The users manager module includes tools that keep awareness, communication and coordination, so the students can work in a cooperative way. These tools are referred to the following functions:

a) Assignment of the student's role. Used by the coordinator of the groups in an institution. S/he assigns the role to perform by each student in the virtual company.

b) Consulting and modifying student information. Any student of the group have on line access to the name, role and electronic mail address of her/his peers. The coordinator can modify the assigned role previously to any student when it will be necessary (Fig. 1).

c)Users Directory. Keep aware any student of the group about who is working in the environment in a given moment, as well as the role that it is performing (Fig. 1).

d) Synchronous Communication. A chat tool was specially designed for Management Game. Any student is able to communicate and collaborate with one or more of their peers in real time (Fig. 2)

e) Asynchronous Communication. An email tool was specially designed for Management Game. Any student is able to communicate and collaborate with one or more of their peers at any time.

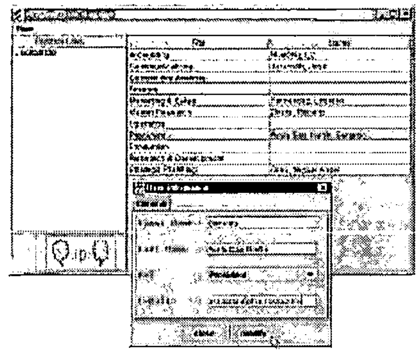

Figure 1: General Information of a user

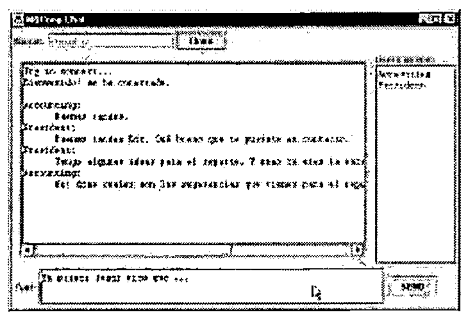

Figure 2: Synchronous conversation between two members

MGCoop Workflow Environment

Within the technology of Groupware, automated workflow systems are environments that permit the control of activities, task assignment and the coordination and cooperation (Khoshafian & Buckiewicz 1995). For MGCoop we have developed a workflow environment based as a WYSIWIS (What You See Is What I See) interface. This tool allows any student to observe in real time the changes and the advance of the report constructed by the group, represented as a sequence of related tasks. It was necessary to study the interactions between the members in order to design the workflow environment.

The students, as members of a virtual company, should present a report to an established executive committee, composed by real executives supporting Management Game. The meetings where the reposrt are prersented are given in three occasions during the development of the game. In the first is made known the strategic plan that the company will follow. In each one of the remaining two a summary of the company operations is presented. Each report consists of a set of related projects. Each one of these projects consists also of a set of tasks to be performed by the members of the learning group.

The characteristics of the MGCoop workflow environment include:

a) Graphic workflow.

The projects and the tasks are represented in an workflow graph (Fig. 3) in which projects or tasks are presented as squares related with others considering their requeriments. Each task or project in the interface are sensitive to the action of the mouse, presenting to the user the relevant information, as name, responsible, requesting, completion date, requeriments and current state. A project indicates the tasks that compose it, and each project has its respective workflow graph representing the tasks implied. Tasks and projects are presented in red color while they have not been ended, and in blue color when they have been accomlished. The environment allows the user to build the workflow graph using the mouse and selecting information related to the tasks or projects

through menus, buttons and text areas.
The president must assign the deadlines of the projects that conform the report, in this way the members of the group will know the completion dates of each one of the projects.

b) Task assignment
The environment automatically provides to the president the suggestion of the most indicated person as responsible for a work, according to the specifications of Management Game.

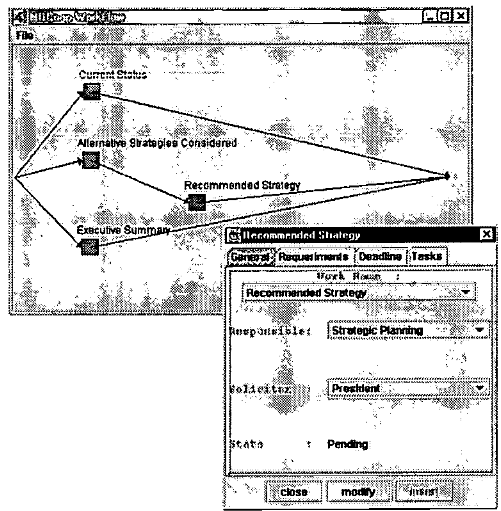

Figure 3: Interface of the Workflow, showing a report composed of 4 projects.

Communication Tools

MGCoop contains tools of chat, electronic mail and agenda electronics designed specifically for Management Game. The possibility of synchronous and asynchronous communication and cooperation permits to solve the problem of the physical meeting difficulty. Through these tools the members of the group will be able to take decisions in group, to solve their different points of view and to plan meetings they will be physical or virtual. The electronics agenda provides necessary information to plan these meetings, the members of the group will be aware of the activities of each one of their peers.

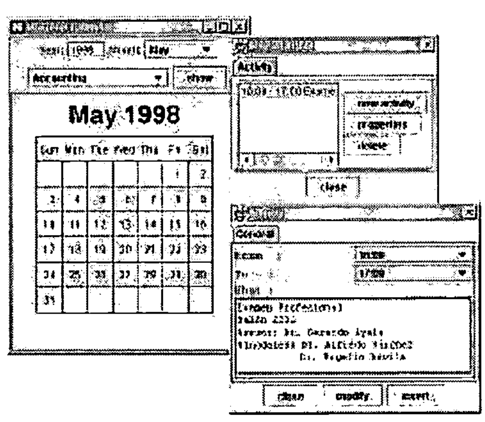

Figure 4: Activities to accomplish by a member of the group

It was necessary to study the way in which the members of the learning group would have to be communicated, in an asynchronous or synchronous way. The asynchronous form that we employ was the electronic mail, and the synchronous way was the "Chat". Both tools were designed in a special way for the users of Management Game due to they were not familiarized with already existing tools. We consider that to use various tools and interfaces for their work can influence negatively their performance.

The chat tool of MGCoop includes the representation of the roles of the users, permitting them to be aware of their commitments. The electronic mail of MGCoop is also very easy use and forms part of the environment. The issued messages can be read from any other email tool, not only by MGCoop.

The environment also provides an electronics agenda that shows the students the calendar of the other peers actvities in a graphic way and sensitive to the action of the mouse. When a day of the specific month is selected, the activities that the selected member has for that day appear (Fig. 4). At any time a student can add a new appointment or activity into her/his personal calendar.

Conclusions

MGCoop is a set of colaborative tools designed for a simulation-based learning environment. These tools were developed as a result of the research in the area of CSCW on the interaction required by the users of Management Game. The developed environment permits the students to plan and establish virtual meetings, and be aware of the capacities, commitments, availability and activities of their peers. Also it allows the cooperative and coordinate work thanks to a workflow environment and the presentation and discussion of their points of view in a synchronous or asynchronous way.

Currently we are working in the development of more classes in JAVA in order to include in MGCoop the interaction through videoconference. MGCoop it is currently in a test period and it will be used in the beginning of the following year when Management Game is going to be played again.

Abstract: The paper presents the design issues of SALLE, a life-long learning environment based on software agents modeled for the social construction and use of Japanese language knowledge. This research proposes the new paradigm of agent based life-long learning environments for Japanese language, based on the idea that the study of a second language, specially the Japanese for western people, is a life-long learning process.

With the development of SALLE (Software Agents for a Life-long Learning Environment in Japanese) we try to determine the real, relevant and truly useful educational material for the study of the Japanese language, also motivating the discovery, use and sharing of knowledge by the learners in a virtual community in the Internet.

Introduction

The concept of life-long learning has become one of the most important topics in computer assisted education. Life-long learning refers to the continuous education that implies the updating of our knowledge in order to be more capable, productive and competitive, adapting ourselves to the dynamic changes in our ever evolving world. Lifelong learning, according to the definition by the European Lifelong Learning Initiative (ELLI) and presented in (Longworth, 96), is:

> "a continuously supportive process which stimulates and empowers individuals to acquire all the knowledge, values, skills and understanding they will require through their lifetimes, and apply them with confidence, creativity and enjoyment in all roles, circumstances and environments."

In a global and internationalized world, lifelong learning has become a necessity for everyone due to the rapid changes in our knowledge based society (Berge, 98a). Lifelong learning environments are needed for the competitive advantage and success of leading-edge companies and universities. In this context, it is clear that the study of a second language is a life-long learning process, since language is dynamic and in constant change.

A learner centered approach (Berge, 98b) has become the actual tendency in educational software for second language learning. From this point of view, the learner has the responsibility of her/his own learning, not the teacher or the tutor. This approach, supported by theories of Constructionism (Resnick, 96), has been promoting the research and development of learning environments, as an alternative to tutoring systems. Nowadays there are two main problems of actual interest in this learner centered approach (Berge, 98b), first we have to determine how to provide access to real, relevant and truly useful educational material; and second, we need to motivate the discovery and use of knowledge by the learner, and make her/him share it with others. We believe that the solution to these problems implies the design and development of a life-long learning environment based on the concept of social construction of knowledge (Barret, 92). For a life-long learning environment the continuous social construction of knowledge should be not a specialized activity, but a way of being in a community, which represents a culture that consists of ideas, beliefs and knowledge shared by its members.

We are considering the World Wide Web as the main source of knowledge and information which contains the real, frequently used, current and popular language patterns, words, expressions and kanji compounds of the written Japanese language, situated in a real context. Since Japanese language changes continuously, specifically in new words adopted from other languages and expressions, the knowledge represented in a life-long learning environment must be updated with the language elements used by the producers of WWW pages in Japanese and by the participating members of the community of Japanese language learners. Our objective is to develop a computer mediated learning environment where the participants can learn using and constructing together a knowledge base representative of the written Japanese language currently and frequently used.

In this paper we introduce SALLE (Software Agents for a Life-long Learning Environment in Japanese). SALLE is a multiagent learning environment where software agents cooperate and assist their learners, providing a learning environment based on the coordinated social construction of a knowledge base as a representation of the current use of the Japanese language.

Software Agents and Japanese Language Learning

A software agent (Nwana, 96) works on the behalf of the user, reducing her/his work and information overload (Maes, 94). Here we refer to the term agent as an entity that functions continuously and autonomously in an environment in which other agents exist (Genesereth, 94). Of particular interest to the life-long learning approach is the work of Norrie and Gaines, introducing the Learning Web as an agent based distributed intelligent learning environment (Norrie, 95).

There have been proposals in the modeling of agents for Japanese language collaborative learning environments (Ayala, 95). With GRACILE (Ayala, 98) we proposed a collaborative learning environment where foreign students learn by constructing a dialog together, applying vocabulary, language patterns and expressions of the Japanese language. The agents in GRACILE are implemented in PROLOG and work on a local area network of Macintosh computers, since GRACILE was designed as a second language collaborative learning for the enculturation of the learner (foreign student) in a geographically defined community (a school of a given university), with its own language characteristics. In SALLE the interaction of learners is indirect, through their contributions to a virtual community knowledge base via the Internet, and there is not a collaborative task to be solved synchronously by a small group of learners, as in GRACILE. The *virtual* community of practice in SALLE is indefinitely wide, and the members participate by cooperating asynchronously at any time from anywhere. The software agents in SALLE have been designed based on an object oriented methodology, which permits its implementation as a set of software components in JAVA (Bigus, 98), allowing the client to be platform independent.

In SALLE we have modeled four software agents; an *information agent* that works on the acquisition of knowledge from html files in the WWW, a *facilitator agent* that assist the learners in the social construction of knowledge, a *knowledge negotiation agent* to allows the learner to agree or disagree in a viewpoint provided from other member and a *knowledge agent* that applies language patterns and vocabulary, providing assistance concerning their reading, meaning and use.

Knowledge Agent

The knowledge agent in SALLE plays three important roles in the learning environment:

a) *Management of the knowledge base.* The knowledge elements (nouns, expressions, adjectives, verbs and the corresponding language patterns for their conjugation, together with their meanings and readings) are organized, accessed and registered in a knowledge base of the community, implemented through a DBMS.

b) *Recognition of knowledge elements and language patterns.* Recognition of conjugated adjectives and verbs, as well as nouns and expressions provided by the information agent, obtained from Japanese material in the Web or by the facilitator agent, from contributions of nouns and expressions by the members of the virtual community.

c) *Assistance.* Pedagogical presentation of the meaning, pronunciation of nouns, expressions, and language patterns analysis of conjugated adjectives and conjugated verbs. The knowledge agent provides the meaning together with the conjugation features of the pattern involved, the reading of kanji (furigana) and the corresponding meaning in English. In this way, it helps the novice and advanced user to understand the Japanese language pages s/he is reading while navigating the Internet. The knowledge assist the learner, applying its vocabulary and the language patterns and expressions. The requests of analysis from the learners may be in hiragana, katakana or kanji.

In our first prototype version, the knowledge agent contains around 2,000 nouns considered of frequent use. Their representation includes hiragana and kanji compounds. Around 400 of them are in katakana. Each noun object includes its meaning in English and, in the case of a kanji compound, its reading (furigana). A request to the knowledge agent from a learner, concerning a noun, can be in English or in Japanese, using hiragana, katakana of kanji. The user can copy a kanji compound from a text (e-mail or WWW site in Japanese, for example) and paste it into the request dialogue. Then the knowledge agent will show the corresponding reading and the meaning.

Utterances which do not obey a language pattern are called expressions (Alfonso, 89). These are referred to greetings, apologies, etc. The knowledge agent contains more than 200 frequently used expressions including their reading meaning in English.

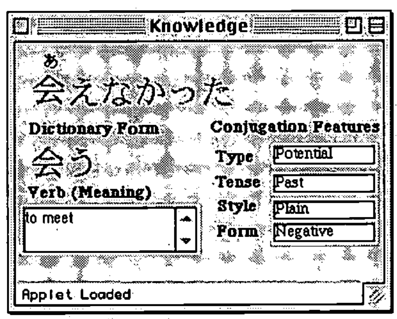

Figure 1. Analysis of the knowledge agent from a given verb.

Language patterns

We consider a language pattern as a template which represents a general structure that includes conjugation forms and grammatical particles (Alfonso, 89). The knowledge agent contains the language patterns for the conjugation of verbs and adjectives, and applies them when constructing a conjugated verb or adjective, under the learner's request, or while analyzing text (tokens) provided by the information agent from html files in the WWW or asked by the learner.

The knowledge agent currently contains more than 100 adjectives, together with all the language patterns corresponding to the adjective conjugation rules according to the Japanese grammar. The knowledge agent is able to recognize a conjugated adjective either in hiragana or kanji. The knowledge agent provides the meaning in English and the information of the language pattern used for the conjugation of the adjective, together with the respective kanji and its reading. It is also able to conjugate a given adjective in English, with the corresponding conjugation features indicated by the learner.

The knowledge agent currently contains more than 900 verbs, together with all the language patterns corresponding to the verb conjugation rules of the Japanese grammar. It is able to recognize conjugated verbs, either in hiragana or in kanji, taken from text obtained from the WWW by the information agent or requested by the user. The knowledge agent manipulates its language patterns and provides the meaning, kanji reading, dictionary form of the verb and the conjugation features corresponding to its language pattern for verb conjugation (see figure 1). When the learner asks for the conjugation of a verb, s/he selects the verb and the conjugation features in English, and the knowledge agent presents the results indicating the conjugation in Japanese and the reading of the respective kanji.

Information Agent

Japanese language learners have special topics and interests. In SALLE people learn more independently using materials that meet their individual needs. The information agent has been designed in order to determine the real, relevant and truly useful knowledge of the Japanese language. It helps in the recovery of Japanese text from html files, navigating through the Internet starting its travel from the favorite urls provided by the user, which represent her/his topics of interest. In this sense, the information agent is a "Web spider" or "indexing robot". The information agent keeps track of the Web sites already analyzed, autonomously checks for new information on them (nouns, adjectives and verbs) and provide it to the knowledge agent, which will register it into the community's knowledge base.

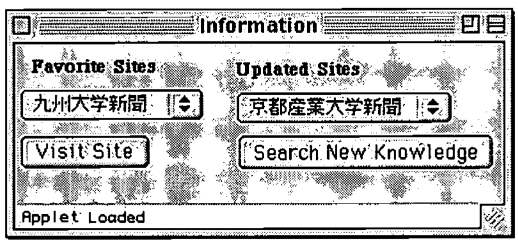

Figure 2. Information Agent Interface

The learner visits one of her/his sites being sure that it still contains material and that the knowledge agent already included nouns, expressions, verbs and adjectives from that site. This is because her/his information agent autonomously checks all the favorite sites and remove from the list those which are not longer available. On the other hand, it provides a list of updated sites which refer to those favorite sites that have been updated since the user's last visit (see figure 2).

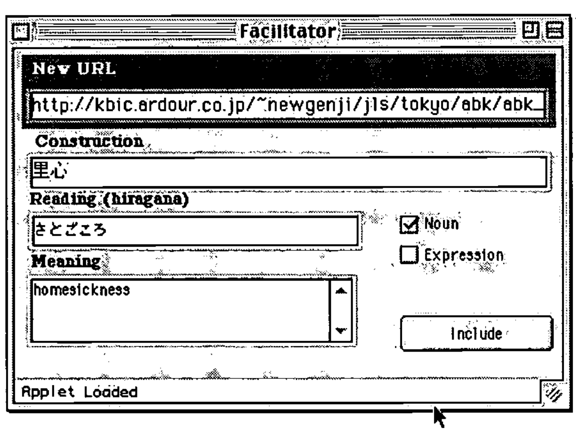

Figure 3. Facilitator Agent Interface

Facilitator Agent

With the facilitator agent we are implementing how distributed knowledge can be turned into shared, collective knowledge of a virtual community. According to the constructivism approach in learning environments (Resnick, 96), knowledge is also constructed by the learner, not just acquired from browsing or attending presentations. Interacting via SALLE learners participate not just passively reading educational material in the Web, but as active agents in the construction of new knowledge, with the help of others (Berger, 98a). According to this learner centered approach in the design of learning environments, the learner develops first a sense of ownership of her/his knowledge and later share it while participating in the virtual community of practice.

In SALLE learners are allowed to write their own understanding of nouns and expressions registered by the knowledge agent (from the tokens given by information agent) and which has not a reading and/or meaning associated. The learner can provide the reading and meaning to expressions and nouns used in her/his personal context. The facilitator agent allows the provision of new nouns and expressions together with their meanings and proper use to the knowledge agent (see figure 3). Later, with the help of a knowledge negotiation agent the community will be aware of the different viewpoints and adopt those believed correct and meaningful contributions. Also, students are invited to locate and define Japanese Web pages according to their interests. New urls for the information agent are provided through it (see figure 3).

Knowledge Negotiation Agent

Knowledge negotiation (Moyse, 92) is an important topic for computer assisted education and life-long learning. Life-long learners need to develop a critical attitude, giving more importance to their own constructions (what their discover or believe is true in practice) than to the theoretically correct knowledge indicated in an authoritative source, as in the case of a book.

In SALLE knowledge is distributed in each member and later shared among the participants via the facilitator agent. Each noun or expression provided by the learner may imply one with a different viewpoint concerning its reading or meaning. Therefore it is necessary to allow the learner to approve or reject the ideas of their peers, justifying her/his position. The role of the knowledge negotiation agent is to decide the delivery of new knowledge from the facilitator agent to the knowledge agent, based on the social acceptance of knowledge, and including the comments (justifications) of the beliefs provided by the community members. The knowledge negotiation agent promotes the agreement of members and at the same time consider their status in the community (novice, advanced or native speaker) in order to help the other learners to consider their contributions (see figure 4).

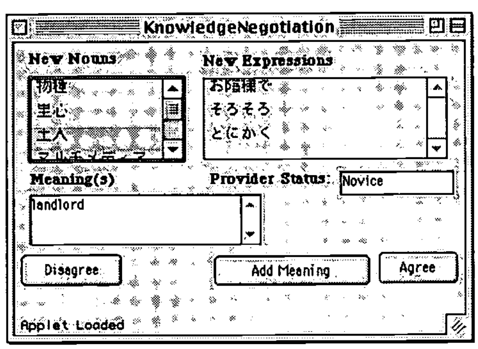

Figure 4. Knowledge Negotiation Agent Interface

Conclusions

SALLE is a prototype for a life-long learning environment based on software agents modeled for the social construction and use of Japanese language knowledge. This is our first step in the proposal of a paradigm of agent based life-long learning environments for Japanese language, as a space for the application and social construction of knowledge. We believe that the development of environments where learning is based on the actual and real content and use of knowledge, taking place at any time and any place, will be the future for all the life-long learners of the Japanese as a second language worldwide.

Revisiting the Web-based Performance Support Systems for Lifelong Learning: Learner-Centered Resource Development Tool

Joanna C. Dunlap, Ph.D.
University of Colorado at Denver
U.S.A.
Joni_Dunlap@ceo.cudenver.edu

Abstract: Influenced by generative and intentional learning environment strategies and tools, a Web-based tool has been developed to empower learners to build their own Web-based Performance Support Systems (WPSS) to support their learning, professional development, and performance within a domain. The original version of the WPSS tool was presented at ED-MEDIA 98. The original version did not address the need to create unique Web-based resources when available WWW resources did not meet the learners' needs. Using document sharing, synchronous chat and whiteboard technologies, a learner-centered resource development tool has been incorporated into the original WPSS structure. In this way, the WPSS not only enables learners to (1) build a learning and performance resource that will provide them with immediate support and guidance and (2) help them develop structure, strategies, and skills for subsequent lifelong learning activities, but also (3) take responsibility for creating original resources that support lifelong learning and performance support.

[**Note:** A full version of this paper is available at http://www.cudenver.edu/~jdunlap]

What do you do if...?

- Your company has just completely a major reorganization in which a number of number of positions — including yours — have been restructured and responsibilities reassigned. Now you are required to work on tasks you've not done before.
- You're a UNIX programmer for a company that has decided to replace its UNIX servers with PCs. Now, all new application development must be done for the PC platform.
- You've been a technical writer in your organization for three years. Now, in a move to reduce costs and build in quality assurance measures, instead of out-sourcing the desktop publishing of the documents and manuals you develop you will be required to "publish" the documents yourself.
- Your company has caught the WWW bug and wants to implement a company-wide Intranet. You've been assigned to convert the print-based Employee Handbook to an HTML document — by next Friday!

In a climate of rapid change, increasing innovation, emerging technologies, and proliferating knowledge, lifelong learning is a necessary professional development objective. In order to keep current, people have to be willing and able to continually "retool" their knowledge and skill base. Simply knowing how to use tools and knowledge in a single domain at a specific point in time is not sufficient to remain productive and competitive. People have to face new domains and novel situations with increasing frequency due to the information explosion (Nash, 1994). The need to be a continuous learner is especially apparent in domains influenced by scientific and technological advances; these advances cause knowledge and skills to become obsolete overnight. To deal with today's complex workplace environment, employers need personnel who possess contemporary skills and knowledge, and are willing and able to proactively update their abilities to meet the ever-changing needs of the organization. Employees who are able to keep up with the information explosion are valuable assets; employees who fail to "grow with the flow" are restructured out of their positions. Therefore, lifelong learning is essential to staying current, competitive, productive, and innovative in today's workplace, and therefore employed and in-demand.

Following the prescriptions of the generative and intentional learning methodologies that promote the development of metacognitive and self-directed learning skills to support lifelong learning activities, a Web-based development tool was created. This tool was designed to help people in a workplace environment generate their own, individualized Web-based performance support systems (WPSS) to address the concerns described above by encouraging and providing a supportive structure for lifelong learning activities.

Lifelong Learning Defined

Lifelong learning is any purposeful learning that people engage in throughout their lives; it is an activity engaged in. to gain greater individual self-fulfillment and to improve the quality of life for the individual and the emerging society (Overly, McQuigg, Silvernail, & Coppedge, 1980). The knowledge explosion requires professionals to engage in lifelong learning if they intend to stay current — let alone evolve, advance, and remain competitive — in their profession. Therefore, lifelong-learning skill development is imperative if people are expected to learn over the full expanse of their professional lives. In order to better prepare for lifelong learning activities, learners must be exposed to learning activities that require them to take on and develop many of the responsibilities normally afforded to educators. To achieve this requires moving away from a view of learning that is controlled outside the individual — by a teacher, trainer, instructional designer, or subject matter expert — to a view of learning that is internally controlled by the individual (Overly et al., 1980). Therefore, in order to internally control the learning process, the development, and subsequent successful application, of two skill areas -- metacognition and self-directedness – is required.

Metacognition

Von Wright (1992) defines metacognitive skills as "the steps that people take to regulate and modify the progress of their cognitive activity: to learn such skills is to acquire procedures that regulate cognitive processes." Glaser (1984) describes metacognitive or self-regulatory skills as knowing what one knows and does not know, predicting outcomes, planning ahead, efficiently apportioning time and cognitive resources, and monitoring one's efforts to solve a problem or learn. More specifically, metacognitive skills that are required for lifelong learning include the (Ridley, Schutz, Glanz, & Weinstein, 1992):

- recognition of content and skill limitations;
- ability to set goals and create action plans based on those defined limitations;
- ability to activate the appropriate prior knowledge to achieve set goals;
- ability to accurately assess progress in learning and task performance and effectiveness of learning resources selected;
- awareness of what still needs to be completed to reach a set goal, and how best to allocate time and resources; and
- ability to modify strategies, tactics, processes, and resource selection based on the needs of the task at hand.

Self-directedness

Self-directed learning is:

> ...the process in which individuals take the initiative, with or without the help of others, in diagnosing their learning needs, formulating learning goals, identifying human and material resources for learning, choosing and implementing learning strategies, and evaluating learning outcomes (Knowles, 1975).

The domain of medicine provides a perfect example of self-directedness. When dealing with patients, the doctor has to begin assessing the patient's condition before having all of the data necessary to evaluate, diagnose, and treat the patient. Characteristically, the patient provides the doctor with fragments of information ("My stomach hurts. I can't hold any food down. No one else in my family is experiencing any problems."). The rest of the information needed to solve the patient's problem comes from the study of a variety of other resources: patient and family history, laboratory results, x-rays, other doctors' opinions, past experiences, similar cases in the case file, and current research findings on new diagnostic and treatment procedures. These skills utilized by the doctor to collect the necessary information to solve the patient's problem are described as "self-directed learning skills" (Barrows, 1985, 1986).

Barrows (1995) defines the process of self-directed learning as utilizing the following skills to solve a problem or fulfill a learning requirement:

- the ability to identify and define a problem/learning need;
- the ability to identify, find, use, and critique resources for solving the problem or meeting the learning requirement;
- the ability to capture and apply information from resources to the problem or learning need; and
- the ability to critique information, skills, and processes used to solve the problem or meet the learning requirement.

So, how do we develop lifelong learning skills?

In order to develop lifelong learning skills, the learners need to be directing and driving the learning process and activities based on their learning and performance needs. Two instructional methodologies that specifically address the development of lifelong learning skills are generative learning and intentional learning.

Generative Learning Environments

Generative learning environments require students — individually and collaboratively — to be responsible for creating, elaborating, and representing domain knowledge in an organized manner (Cognition and Technology Group at Vanderbilt, 1992; Hannafin, 1992; Scardamalia, Bereiter, McLean, Swallow, & Woodruff, 1989; Scardamalia & Bereiter, 1991). Through a this process of "generating" knowledge, instead of passively receiving information, learners develop structure, strategies, and habit for lifelong learning.

Generative learning environments require students to take responsibility for determining what it is about a particular domain they need to know, and then direct their activities accordingly to effectively research, synthesize, and present their findings. Schank and Jona (1991) describe a generative learning environment in their discussion on the research method of teaching. Under the research method of teaching, students are asked to research a particular topic and then present their results to others (the class, a collaborative group, etc.). In this way, students are taking over the responsibility of information gathering and synthesis and dissemination/presentation from the teacher. For this teaching method to lead to successful learning, students need to be allowed to select their own topics to research and report on, so that they have a real interest in proceeding with the assignment and have more control over their learning. Because the learning is student-directed, where each student makes choices and takes responsibility for those choices, the learning is more meaningful; "...in general, material that is organized in terms of a person's own interests and cognitive structures is material that has the best chance of being accessible in memory" (Bruner, 1961). In addition, because students are responsible for selecting a topic, developing a question to research, making decisions about how to gather information, analyzing and synthesizing information, etc., they are engaging in activities that help to develop high-level thinking and problem solving abilities.

Intentional Learning Environments

Intentional learning refers to the "cognitive processes that have learning as a goal rather than an incidental outcome" (Bereiter & Scardamalia, 1989). Intentional learning encourages students to take "an intentional stance toward cognition" (Scardamalia & Bereiter, 1991), which means that learners must learn how to monitor and be aware of their own learning processes, and take responsibility for pursuing desired and/or required learning outcomes. Intentional learning is learning that is actively pursued by and controlled by the learner (Resnick, 1989). Palincsar and Klenk (1992) describe intentional learning as an achievement resulting from the learner's purposeful, effortful, self-regulated, and active engagement. By encouraging students to take "an intentional stance toward cognition", intentional learning helps students learn how to not only monitor and be aware of their own thinking and learning processes (i.e., metacognitive skills), but also to take responsibility for pursuing individually-determined learning goals (i.e., self-directed learning).

The objective of an intentional learning environment is to create a supportive structure in which students can engage in cooperative knowledge building as they move towards greater autonomy. Addressing students' need for higher-order abilities in thinking and learning, intentional learning helps students develop the general metacognitive and self-directed learning skills that facilitate autonomous lifelong learning (Palincsar, 1990; Scardamalia et al., 1989). These skills are developed by engaging students in situations in which they need to build a body of knowledge based on their learning interests and needs using a variety of information resources. While building the knowledge base, students practice tactics for making claims, collecting evidence in support of their claims, and evaluating and responding to counterarguments from peers and teachers. Throughout this knowledge-building process, students reflect on specific aspects of their learning and thinking processes, and consider the effects of collaboration on each other's learning, such as the impact of opinion, bias, controversy, debate, and negotiation (Glaser, 1991).

Throw them all together and what do you get?: Web-based Performance Support Systems (WPSS)

Influenced by generative and intentional learning methodologies as well as electronic performance support systems (EPSS) technology, I developed a Web-based tool empowers learners to build their own Web-based Performance Support Systems (WPSS) to support their learning, professional development, and performance within specific domains. Similar to electronic performance support systems (EPSS), a WPSS uses the Web to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools that support high-level job performance. In fact, using the Web to create performance support systems is a perfect fit because the Web is actively used by professionals as a forum for the distribution of current and up-to-date references, instruction, and guidance.

By creating a structure that supports individualized and collaborative knowledge building by the people who will actually be using the knowledge, the higher-order thinking, problem-solving, and decision-making involved in the selection and utilization of appropriate learning materials and performance support is done by those who can get the most out of the process. In addition, because these activities occur in the workplace and are driven by the needs of the job at hand, the learning activities are contextualized, authentic, and meaningful. Enabling people to utilize an easy-to-use tool to develop their own WPSS accomplishes two goals:

1. they learn about the domain while they are locating, evaluating (which requires utilization of resources), and organizing resources to support their job performance activities and/or their generative and intentional learning activities; and
2. once the WPSS is completed it can be used to support performance and further professional development while working in that domain.

In this way, the WPSS not only enables learners to build a learning and performance resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent lifelong learning activities.

Overview of Original WPSS Development Tool Components

The WPSS development tool helps employees -- collaboratively and as individuals – organize, assess, and utilize Web-based resources. In order to build an effective WPSS, the development tool enables employees to organize Web resources into a variety of self-determined categories. Categories may include:

- cue cards: brief definitions, reminders, directives, job aids, best practices
- computer-based instruction: tutorials, case studies, practice activities
- wizards: intelligent demonstration/application functions; assistance
- coaches: response sensitive correction and feedback
- mentors: individualized responses to questions from experts in the field
- practitioner forum: access to other practitioners in the field
- examples
- tools

In order to build a WPSS that meet individualize, specific learning and job performance needs, employees engage in a number of generative and intentional learning activities including:

- determining their learning needs and goals
- developing a plan for action for finding resources to help fulfill those goals
- researching Web resources that meet the appropriate needs
- utilizing Web resources in order to evaluate usefulness, difficulty level, strengths and weaknesses
- updating links to Web resources when appropriate
- responding to other learners' comments regarding WPSS contributions
- developing Web resources via HTML pages and threaded discussion forums

In other words, employees practice and develop the very skills and strategies needed to engage in lifelong learning activities while they are learning domain-specific content and skills needed for thcir jobs.

Overview of New WPSS Development Tool Components: The Learner-Centered Resource Development Tool

Although the original implementation of the WPSS was successful, it had a major flaw: it relied on pre-existing Web resources. People using the WPSS had to rely on the WWW to provide the various resources needed to create a knowledge base that would support their learning and performance support activities. For the most part, the WWW provided the resources needed. However, especially in Intranet environments in which employees needed access to organizational specific resources that did or did not already exist, the WPSS failed to meet the learners' needs. Therefore, a tool was created to enable people -- as individuals or in collaborative groups – develop unique Web-based resources for inclusion in the WPSS.

The Learner-centered Resource Development Tool (LRDT) combines the technologies of document sharing and synchronous chat and whiteboard to create an environment in which people can develop -- from scratch -- their own Web-based resources. The LRDT uses synchronous chat and whiteboard features to provide a forum for group brainstorming about the contents of a new resource document. The document sharing feature:

- enables learners to track and archive various versions of new resource documents,
- utilizes asynchronous threaded discussion technology to allow reflective discussion around the development of new Web-based resources, and
- provides easy uploading and downloading of resource documents for revision purposes.

The LRDT, now in beta testing, extends the usefulness of the WPSS by empowering WPSS users to develop their own Web-based resources.

Examples of the WPSS in Use

Although still in a formative stage with enhancements being added all the time, there are a number of examples of the WPSS tool in action. These WPSS examples can be viewed for examination purposes only at the following URL: http://www.cudenver.edu/~jdunlap/wpss.html

Strategies for Selecting Technology for Education:

Choosing the Right Tool for the Job

Robert Fröhlich
Nanyang Technological University
School of Communication Studies
Singapore
tfrohlich@ntu.edu.sg

Abstract: This paper examines the requirements for choosing software and New Media technological solutions to facilitate future delivery platforms for Education. It outlines evaluation models and instruments for selecting software, and discusses various media, both current and future, which may aid pedagogic delivery. Through appropriate use of technology and software, selected in accordance with the models outlined, learning experiences may be enriched and learners may actively engage in their individual learning experience despite differing learning styles.

Introduction

The explosion of technology that has recently occurred, has forced many educators to be faced with the daunting problem of identifying appropriate technological solutions for Education. The task of selecting appropriate technology for the development of curricular resources for educational application, is something for which few educators have received any formal training, but are often required to undertake in the course of their employment. There are technologies that have been common place in classrooms for many years. These include the blackboard, over-head projector (OHP) and whiteboard.

New media technologies are not so common in educational institutions, although they are becoming more common as time goes by. One relatively new technology which has been employed by many educators, is computer projection using presentation software (i.e. PowerPoint) and LCD screens on OHP's or dedicated computer projectors. With the rapid evolution and convergence of New Media Technologies, educators are being told that they must adapt their delivery styles and make use of these new tools for education. Also, the entire delivery of education is said to be about to undergo a paradigm shift with the proliferation of distance education.

How do we go about selecting hardware and software for educational use, when we are not familiar with how it can be used? Do we just purchase the latest technology and then try to build a pedagogical paradigm around it. This approach may work if we have unlimited human and financial resources available to throw at these technological solutions, however, most educational institutions do not. Is it the technology that is driving pedagogy, or is the content available to make the technology merely a conduit for delivery? It is often beneficial to first look at what has not been successful in the past. Gayeski, D. (1989), identified a number of technologies which were hailed as being effective tools for education but failed to gain adoption. These include: Educational Television; Teaching Machines; Dial Access; Videotext; and to some extent Interactive Cable. Technologies were also identified with limited success, including: Video; and Visual Aids (Business Slides and Overheads). Questionable technologies were described, including: Teleconferencing; CAI; Interactive Video; CD-ROM; and AI. Now, some ten years later, these questionable technologies are undergoing a convergence to form part of the New Media Technologies.

We need to carefully evaluate technology before we adopt it. Learning paradigms can not be based on technology alone, but must be based on content. Information is not knowledge. It is not sufficient for educators to merely disseminate information to learners, who in turn may be able to recall this information when assessed and examined. The learners need to be able to apply the information in various situations for knowledge to indeed have been gained.

In evaluating technological solutions we need to take into account many factors, some of which are:

- Economic Viability - Capital Expenditure, Software Development or Acquisition, Operational Cost, Provision of User Help Systems, Maintenance, Upgrade Path.
- Software Availability - Suitability of Content to required learning environment, Development Cost
- Flexibility - Customisation feasibility.
- Reliability – Technical, Educational.
- Ease of use – Educators, Students.

When selecting technological solutions, the paramount concern must be to ascertain whether the pedagogical needs are best addressed by the tools under review, and whether they are economically viable. It is only through a carefully planned approach that it is possible to reveal the realisation of instructional objectives through their implementation.

Models

Different models have been developed for evaluating software, however, few are designed specifically for evaluating educational technology and software. Most of the existing models approach the evaluation from a wide perspective and, if anything, focus on user interface factors and not pedagogical factors. A pedagogical model for selecting educational software has been outlined (Komoski, P.K., 1995), which involves seven steps:

1. Analyse Needs	• Needs & Goals • Objectives
2. Specify Requirements	• Compatibility with Available Hardware • Cost – Multiple Copies? Site License Necessary? • User Friendliness • Level of Interaction Desired • Adequacy of Documentation • Access to Technical Support via Toll-Free Number • Direct Correlation with Instructional Objectives and Curriculum Requirements Identified in Needs Analysis *The following criteria should be applied within the context of the Objectives and Student's Needs.* • Content • Instructional Presentation • Demands Placed on the Learner • Technical Features • Documentation and Management Features
3. Identify Promising Software	• Educational Products Information Exchange (EPIE) • Listservs – AskERIC@ericir.syr.edu
4. Read Relevant reviews	• ERIC database etc.
5. Preview Software	• Observe Students • Are Educational Objectives Achieved? • Preview with own Students or Avoid Purchase!
6. Make Recommendations	• Select Most Desirable Software after Systematic Evaluation of all alternatives in terms of Educational Objectives and Constraints • Establish Quantitive Method for rating each alternative against the Selection Criteria established in Step 2 • Evaluate Relative Importance of each Selection Criteria – Preview should probably be rated high • Create Written Report
7. Get Post-Use Feedback	• Determine Conformance or Discrepancy to Enabling Objectives specified in Step 1

Software needs to be evaluated by educators before being implemented, in an attempt to enhance the learning experience of the students. Through the use of exemplary resources, students may then be offered a richer learning environment. However, to be able to truly evaluate technological solutions, including curricular resource software, one must first look at who the students are, and what is the desired knowledge to be conveyed. This investigation must be undertaken before we can look at the media available to support the curriculum.
Heinich *et al.* (1996) devised the ASSURE model as a procedural guide for planning and conducting instruction that incorporates media (technology and curricular resource software), specifying six stages:

A: Analyse the Learner
S: State the Instructional Objectives
S: Select Methods, Media and Materials
U: Utilise Media and Materials
R: Require Learner Participation
E: Evaluate and Revise

This model appears to be more useful because it involves the students from an earlier stage. It also facilitates a more iterative process through the inclusion of revision. An entire piece of software should not be ignored and discarded because it fails to meet all the instructional objectives. If it meets some of the objectives, better than the other products available, sections may be used as an effective tool to assist students with a particular segment of the topic.

Instruments

In order to be able to evaluate any software objectively it is good to have a well developed systematic instrument such as an evaluation form. This can be a quantitative instrument or checklist, where the evaluator simply ticks an appropriate box against a known grading scale or rubric (e.g. Poor, Fair, Good, Excellent) (Children's Software Review 1995). It can take the form of a questionnaire, where sufficient space is allowed for the evaluator to compare the software product to a known set of heuristics and write detailed comments; or it can be a combination of both.

A checklist is used by Children's Software Revue, where evaluators respond to items by ticking one of four possible responses (always; some extent; never; and N.A.-Not Averaged), to five categories of criteria. Through the application of evaluation rubrics, the California Instructional Technology Clearinghouse (CITC) have reviewed and categorised over 2,000 curricular resource software titles into a searchable database. Their evaluation is also divided into five broad sections, but in a much more pedagogical approach. The CITC provides for three levels of grading: makes an excellent case for recommendation; makes an good case for recommendation; makes an minimal case for recommendation. This approach seems to be a more quantitative approach, through the use of a checklist. The complete checklist can be viewed at: http://clearinghouse.k12.ca.us

New Media Technology

New Media Communication Hybrid Technologies, may facilitate learning to take place at any time and in any location. They may also enable the delivery of intelligent multi-layered interactive multimedia solutions which will help ensure that learners are absorbing the desired information, whilst not having to traverse subject matter which is already known. Some of the New Media Technologies, innovations, and devices which may shape.educational These technologies are paradigms and pedagogy in the new millennium are:

- Broadband Cable Data Networks and Satellite Data Transmission
- Video on Demand, High Definition Television, Digital Television and 3D/Omnidirectional Video Imaging
- Digital Versatile Disc
- Machine Translation
- Virtual Displays and Body Wearable Computers
- Intelligent Agents and Multimodal Interfaces

These technologies are outlined in Fröhlich (1998).

The facilitation of Education must always rely on content rather than the technology of the delivery medium. A well-drawn sketch on a blackboard can convey information much better than a poorly produced slide-show. The paradigms utilised in education have evolved over many years, however, it is only relatively recently that Multimedia has been able to fulfil an integral role in facilitating DL through being able to provide differing instructional techniques to suit different Learning Styles. Technology can be of great benefit in the delivery of Distance Education and DL, or it can become a barrier as well. Different people assimilate information through different cognitive paths and processes. Like a "Chinese Whisper" situation, re-transmission of information may continue, along with the addition of 'noise' and 'distortion', for a number of steps until the information transmitted bears little resemblance to the original information. This particular form of degradation of information rarely applies in Distance Education situations, because it is usually a single stepped process, however, the information may still not have been correctly understood by the learner. This may be through the addition of noise into the learner's cognitive process through the delivery of the information not aligning with their preferred learning style. To be sure that the information has been understood by the learner, it is best for them to have to put it into their own words or images, and transmit it back to the educator. This is usually achieved through the learner being subjected to answering questionnaires, completing exams and undertaking other assessment tasks.

In face-to-face delivery by a 'sage on the stage', the teacher usually has the benefit of having visual contact with the students and can gain feedback as to whether 'the lights are on' and whether the topic is being comprehended by the students. People rarely want to 'lose face' and appear ignorant by asking questions in front of their peers, so students are often inhibited in revealing that they are unable to follow the subject matter in front of the whole class. They may also be reluctant to make suggestions which may be perceived as incorrect (Koschmann *et al* 1995). Even experienced teachers are often unable to gain the required feedback as to whether they are teaching the students topics which they already know. The teacher is often unable to move on to another topic without boring and alienating some students by regurgitating information. Students usually respond to social pressure and complete classes even if they find the content boring and uninteresting. If the learning style of the student does not align with the manner in which the information is presented, the student may often leave with little more knowledge than when they entered. Even though students may have been presented with the required information, information is not knowledge. The cognitive transfer of information to knowledge may not have been facilitated through the style of delivery being mismatched with the student's learning style.

In asynchronous DL there is often no social pressure to stay and complete the class. Masie *et al* (1998) asserts that when students are on-line they are usually merely one click away from exiting the programme. Learners switch-off and leave for a number of factors, some of which are: "Been there, done that!"; "I'll never use that knowledge!"; "This site is SO slow!"; "I can't figure out what to do!" These factors need to be eliminated in order to keep learners motivated to complete the course. One way of maintaining interest in the learning process may be to utilise user-model based interfaces. A prototype form of user-model based interface, utilising adaptive link annotation, has been implemented on the WWW in the form of Adaptive Navigation Support (ANS). This has proved to be beneficial to student's learning as long as they accepted and followed the navigational advice provided (Eklund *et al*, 1998). In the future, more advanced user-model based interfaces should allow us to make use of styles of delivery which appear to the learner as being less didactic, but facilitate the absorption of information and the cognitive transfer of information to knowledge. The subject information needs to be designed for delivery in numerous ways to provide for different learning styles. These differing styles of delivery must be envisaged and planned for at the authoring stage of the courseware, and the delivery interface must also provide for this flexibility in delivery.

An intelligent agent (Woodnorth, 1998b) client interface may provide the learner with their prescribed topics in a controlled navigational environment. The learner may unknowingly be restricted from travelling to wherever they want, but would transparently be directed in their travels by the client. They may only be offered a limited choice of navigational paths and would be gently steered throughout the learning experience. The intelligent agent would constantly update a profile of the learners knowledge and preferred learning style through the use of audit trails and constructive evaluative exercises and tests. The pedagogical preference for Problem Based Learning (Camp, 1996) may be facilitated with students being given problems, then interacting with an intelligent agent to find a solution.

Conclusion

Communication Technologies and software, if selected carefully, may empower educators to construct rich learning environments where all learners can be actively engaged in their individual learning experience, despite their differing learning styles. Through the hybridisation of these new technologies the geographical barriers currently limiting the use of technology for education, such as lack of electricity, telephone and broadband infrastructure, can also be broken down so that learners universally may become more actively involved in their own education. It would appear that given the correct mix of technology and content, DL may finally come to the forefront of educational delivery. As education in the global village becomes more of a reality, and distance ceases to be the major limiting factor in the delivery of affective education, we need to exercise care so that the educational benefits are available to all citizens of the planet and that we do not further the creation of the new class system of information rich and poor.

Abstract: Producing an educational multimedia CD-ROM in a culturally diverse environment provides a number of challenges. Content collection and validation, client education, choice of multimedia consultants, research into cultural beliefs, cultural sub-groups, geographically dispersed subject matter experts and agreement between content experts from various para professional disciplines are but a few. This case study traces the development of a CD-ROM for Otitis Media, a middle ear infection which results in Conductive Hearing Loss in young children, particularly indigenous children, from as early as a few weeks old through to their teenage years and beyond. The recurring incidence of Otitis Media during a child's early years may result in permanent hearing loss and is thought to have a significant impact on a child's educational, social and emotional development. Experience gained from this project highlights the critical elements of a project that must be considered when developing a multimedia CD-ROM. These include educating the client, scoping the job accurately, determining content availability, choosing appropriate consultants and setting up clear communication and decision making strategies to achieve consensus between subject matter experts from diverse disciplines.

Background

Otitis Media has been recognised as a serious problem for indigenous children for many years. When associated with Conductive Hearing Loss (CHL), it is the most common ailment experienced by children of the 90's [National Center for Health Statistics, 1992]. In New Zealand alone Otitis Media is estimated to cost the community $704 million per annum, an increase of 150% since 1975 [Allen, 1993]. Otitis Media is known to affect children from as young as a few days old through to their teenage years and beyond.

While much debate still exists with respect to the overall effect of Otitis Media, it is widely recognised that CHL with Otitis Media can cause children to suffer difficulties with their auditory, linguistic, social and educational development [Hasenstab, 1987; Kavanagh, 1986; Webster, 1988]. As a result, it is suggested that these children will also experience significant social and emotional difficulties during their early development. [Jacobs 1993] stated "The real cost of recurrent Otitis Media must be counted in terms of low self esteem, children who cannot make friends or children who are in the vicious cycle of failure at school".

[Rockeley & Rhys-Evans 1986], estimated that "up to 80% of all children experience at least one episode of Otitis Media by the age of 5 years with a peak occurrence between 6 and 18 months of age". Research in

Australia has shown that up to 70% of indigenous children in a classroom may experience Otitis Media with associated Conductive Hearing Loss at any one time [Lowell, 1993].

Project Objectives and Scope

In 1996 the Education Department of Western Australia in conjunction with Edith Cowan University undertook to produce a CD-ROM to increase awareness of Otitis Media and present caregivers with guidelines on the early recognition and appropriate intervention strategies that could be adopted to support children with Conductive Hearing Loss. "PRISM Interactive", a Western Australian based Multimedia Company was commissioned to provide design and production services for the development of the CD-ROM.

When the project was initially commissioned the target audience was identified as three distinct groups:

- children [4-7 years]who experience, or have experienced Otitis Media;
- teachers/indigenous education workers; and
- parents of children in the high risk groups.

As the scope of the project developed, the target audience was extended to include other caregivers responsible for the well being of children in their care and a range of para-professional groups such as health workers, audiologists and speech pathologists.

The key objectives of the CD-ROM were to:

- identify the common causes, signs and symptoms of Otitis Media with associated CHL
- identify the educational, social and emotional difficulties experienced by children with OM;
- provide a series of guidelines on appropriate intervention strategies that can be used to support children suffering from recurring Otitis Media;
- provide a comprehensive data base of support agencies/groups and teaching resources that can be used to assist children with OM;and
- provide children within the age group 4-7 with an understanding of the cause of OM, self help strategies that they can employ and identify those within their immediate family/community that can provide support.

As part of the scoping process, the Education Department of Western Australia established a working party whose members were considered leaders in their field of expertise. It consisted of 15 people including teachers, speech pathologists, audiologists, health care workers, indigenous education workers, ear nose and throat specialists, surgeons, and nationally and internationally recognised researchers in the area Otitis Media.

To commence the scoping stage the Education Department convened a two-day workshop with the working party, which generated much enthusiasm and ideas. The workshop also highlighted the following:

- the scope of the project was much broader than first estimated and the original project time frames were not achievable;
- it would be difficult to achieve consensus among the members of the working party on both the objectives and content of the CD-ROM;
- the Education Department of Western Australia (the client) had very little useable content; and
- the original budget was not going to be sufficient.

Content Collection Issues

When the budget for the project was initially developed, only a small amount of funding had been allocated for content collection on the premise that the client would be able to provide the necessary content to allow the project to commence. During the scoping process it became apparent that the client did not have access to this content and that insufficient funding had been allocated to this stage of the project. This left the working party with the dilemma of how the required content would be identified and collected to enable the commencement of storyboarding and multimedia production.

While this would normally have seen most projects suspended, the working party who were very much aware of the impact that Otitis Media was having on the development of young children volunteered their services to ensure that the project could proceed. Without this support, and the expertise of this group, it is unlikely that the project would have been completed. Such was the commitment of the working party that on one occasion a surgeon left the operating theatre to answer a question, leaving his assistant to continue with the operation!

During the scoping process it also became apparent that many of the para professional groups represented on our working party had dissimilar views on some of the finer aspects associated with the impact of OM on a child's development. In the absence of any defined source of documented content, a literature search was initiated to identify any content and research that would support the views that would eventually be depicted on the CD-ROM. This was to take three months to complete. As relevant content was sourced or developed, it had to be filed, referenced and cleared for copyright. The information collected required careful cataloguing to allow designers to quickly retrieve information when they returned to this material up to three months later.

However, new research findings kept emerging that caused continual changes in storyboards and on-screen content. While this was having a significant impact on the scheduled delivery date the working party felt that the latest research must be reflected. At this point it was decided that a Web site would be developed to complement the CD-ROM to allow access to future research findings.

With up to five different subject matter experts across each of the professions within the working party it was often difficult to reach agreement on the critical elements and treatment of the content. To overcome this issue, it was decided that the instructional designer would take the role of content identification and assessment. This person was perceived as not having a particular bias towards any particular discipline and was able to communicate and collaborate with all the subject matter experts. However, obtaining agreement on content still continued to have a significant impact on the project delivery date. Many of the subject matter experts were living in different states across Australia, so feedback and approval of storyboards was time consuming, often taking up to two weeks to be returned. In some instances storyboards underwent no less than twelve iterations before all the subject matter experts would sanction commencement of production.

To help make the process of content collection and approval more efficient, it was eventually agreed that only two subject matter experts would approve the initial content. Storyboards would then be circulated to the whole working party for final approval. This helped reduce the time required to validate the storyboards and the stress on the instructional designers!.

Cultural Issues

Apart from the difficulties associated with the collection of content, this project was made more difficult to manage due to the wide cultural diversity of the main target audience, Australia's indigenous population. The client was aware that within indigenous populations there exists many different groups, each with different cultural beliefs which had to be considered if the final product was to gain acceptance and be actively used as resource. This presented a major challenge for the design team resulting in the need to work closely with many members of different indigenous groups to identify and reach consensus on the appropriate treatment, interface design, learning styles, graphics styles etc.

While the design team was aware of many of the more commonly known cultural issues, on a number of occasions various segments of the program had to be revised in light of the feedback received from indigenous groups. Examples included ensuring that graphics did not depict children looking directly into the faces of adults, skin textures and facial features were not indicative of any one group and that consent was obtained from parents and adults shown in the videos or photographs. In Aboriginal culture once a person dies it is taboo to view the face of a deceased person. Even the way photos were transitioned on and off the screen had to be carefully considered to ensure that we did not offend the beliefs of Indigenous people.

This cultural diversity, and need to be aware of many different customs required a much wider cross section of the target audience be sampled than would normally be needed during the formative stages of the project. While this would have a significant impact on the time frame of the project it was considered critical if the project was to be accepted in all the indigenous communities that it would eventually be used in.

Project Resourcing & Client Education

As mentioned earlier the client had no experience of multimedia CD-ROM development and had little knowledge of the resourcing implications of such projects. Originally it was anticipated that the project would take about three months to complete (it eventually took eighteen months), with the belief that content was readily available or could be easily sourced. On this basis, an Education Department employee was allocated 25% of their time to coordinate the project. Unfortunately, even after the full scope of the project was known (and lack of available content), the time allocation for the client coordinator could not be increased.

As a consequence, the project became dependent upon the energy of a few people who contributed many hours outside normal working hours to collect content. During the latter stages of the project this extra burden, compounded by dealing with diverse subject matter experts and the impact of continual changes to meet varying cultural needs, was the cause of considerable personal stress for some team members.

This highlighted the need for "Educating the client" about correctly scoping a project, and having content and appropriate resources available before commencing a project of this size and complexity. Lack of content is an important issue in multimedia production which must be considered carefully before undertaking a project of this size. In light of our experiences we would strongly recommend that when undertaking a project of this nature a separate contract for the identification and collection of content should be completed before attempting to estimate the budget and production schedule.

Contracting the right people was essential to complete this project. Consultants were chosen who had completed similar work in the past. In this case it was important that the main developer had instructional design and CD-ROM production expertise. Checking the quality of past productions and asking previous clients about their satisfaction level gave a good indication of which consultants were suitable. Other attributes that were required in selected consultants included communicating honestly, clearly and on a regular basis with reporting schedules showing allocated responsibilities, and excellent interpersonal and team skills.

"The client will want a quality product at the cheapest possible price, and the developers will want the biggest possible profit margin!"

Copyright Issues

Copyright clearances were necessary for all media, teaching activities and papers that made up the CD-ROM information database. In some instances the design team discovered that some of the materials provided were not the legitimate property of the source. This resulted in the need to implement a policy where all content providers were required to demonstrate proof of ownership of the materials that they were supply. If sufficient proof of ownership was not available, then the materials provided were not used. While this occasionally restricted the amount of useable content that was identified it was necessary to protect the interests of all parties.

Information had to be maintained about each media element (graphics, text, video, sound & voice) used in production i.e. the source, ownership, shipping information, loan duration, copyright status, licensing and other relevant attributes needed to be stored and maintained.

Implementation Issues

As part of the implementation of this CD-ROM a policy on Otitis Media in Western Australian government schools is being developed by the Education Department of Western Australia. Professional development programs have been conducted in the sixteen education districts throughout the state to ensure that all teachers, school health workers, indigenous education workers and other caregivers are aware of the implications of Otitis Media, the availability of this CD-ROM and the manner in which it can best be used to educate the wider community. This process also involves groups from outside the education sector i.e. health, allied health, Aboriginal Medical Services and other community groups must be invited to attend the professional development sessions. However, as occurred during the design and production phase of the project, implementation has been hindered by the lack of resources necessary to conduct professional development. Without additional resources, concern is also held for the maintenance of the program.

Promotional materials and copies of the CD-ROM have been distributed free of charge by the Education Department to all government primary schools throughout Western Australia and will be provided at minimal cost to all other education sectors around Australia.

The Education Department of Western Australia has received numerous letters of commendation from many professional groups both nationally and internationally, including the World Health Organisation.

Although no structured marketing has occurred demand for the CD-ROM has outstripped supply and resulted in the Education Department outsourcing the reprint, distribution and future marketing of the CD ROM.

Recommendations

From the experience gained in this project, the following recommendations are made for anybody considering the development of a computer based training CD-ROM within a culturally diverse environment:

- have a thorough understanding of the content required and the resources needed to collect it;
- consider issuing a separate contract to identify and collect content prior to finalising the scope, budget and time frame of the project;
- educate the "ultimate client" , subject matter experts and other stakeholders about the key facets of managing, developing, coordinating, and resourcing a project of this size;
- insist on sufficient dedicated time and resources for a client coordinator;
- ensure that a strong representation of the cultural groups that make up the target audience are included on the working party;
- have a clear understanding of agreed objectives and adhere to these at all times to keep the project on track;
- ensure that costings and time schedules are not locked in prior to a proper scoping of the project being completed;
- ensure that the client is made aware at the beginning of the project of the resource requirements required to implement and maintain the final product;
- use developers and consultants who are experienced in this type of development;
- use subject matter experts and consultants who have good interpersonal skills, communication skills and a "good sense of humour"!

Distance learning: the dispositions of students and the perceptions of colleges and employers to self directed learning and new learning technologies.

Dr David Warner, Director, Labor Market Research and Analysis, department of Employment and Training, Queensland, Australia
Email: davidwar@ozemail.com.au

Dr Gayre Christie, Senior Lecturer, Queensland University of Technology

Abstract. Distance learning has played a major role in Australian education for much of the 20th century as distance and remoteness made access to traditional facilities very difficult for many. Now, however, it has become a mode of necessity for many people whose life/work styles, rather than geography, dictate how they can access education and training

The Australian National Training Authority has developed a national policy on 'flexible delivery', with considerable focus on learning in the workplace or 'on-the-job' (ANTA, 1996). It defined flexible delivery as 'commonly uses the delivery methods of distance education and the facilities of technology'.

The development of this policy was on the basis of a number of unexamined assumptions. These assumptions suggested that vocational education and training clients are sufficiently skilled to access training programs offered through flexible delivery, including on-line delivery.

The research reported in this paper set out to examine these assumptions.

Background

Distance learning has played a major role in Australian education for much of the 20th century as distance and remoteness made access to traditional facilities very difficult for many. Over time it developed also as a mode of choice. Now, however, it has become a mode of necessity for many people whose life/work styles dictate how they can access education and training. It is less about choice and remoteness today, and more about the pressures of work and life dictating an only viable mode: distance learning method.

The Australian National Training Authority has developed a national policy on 'flexible delivery', with considerable focus on learning in the workplace or 'on-the-job' (ANTA, 1996). It defined flexible delivery as 'commonly uses the delivery methods of distance education and the facilities of technology'.

However, the development of this policy position was made on the basis of a number of unexamined assumptions. These assumptions included: That vocational education and training clients

- want to learn through flexible delivery and on-line and have the capacity to take advantage of this;
- are sufficiently skilled to access vocational education and training programs offered through flexible delivery, and;
- can learn in the workplace.

The research reported in this paper set out to examine these assumptions.

Subjects

Students: Questionnaires were distributed to professional, trade and para-professional students who were concurrently in employment (worker/learners). The students were chosen from a wide range of occupations and from small medium and large workplaces. No differences in response were found by sex, size of enterprise or course.

Project Methodology

The research used questionnaire surveys, and structured focus group interviews to address the research questions.

Questionnaire

This is a very comprehensive 130 item likert-type scale in two parts. Part one canvasses student opinions about their abilities as learners and about their perceptions of and experience with various forms of instructional communication, including technology. It also canvasses their perceptions about their own abilities as independent learners. Part two uses a commercially available scale to assess subjects' self-directed learning readiness (Guglielmino, 1977).

Structured Interviews

These were conducted in focus groups with a sample of the worker/learners' employers and a sample of the TAFE teachers who were involved in teaching the worker/learners.

Results

Surveys were completed by 542 worker-learners Three hundred and twenty particpants were male and two hundred and twenty one female with one participant not indicating gender. Sixty eight percent were under twenty five years of age. The breakdown for size of workplace in which they were employed showed that thirty four percent were in small workplaces with less than twenty employees, thirty eight percent in medium workplaces with up to five hundred employees and slightly over nine percent were in large enterprises with more than five hundred employees.

Data also were interrogated for age between those under 25 years and those above. There were no significant differences for Part 1 of the Questionnaire, but there was a significant difference in relation to self-directed learning readiness. This was surprising for Part 1 because general assumptions about technology use would suggest that the older age groups were less confident and competent. This was not the case, although it needs to be recognised that neither age group reported high levels of competence or confidence with technology.

Questionnaire Part 1

Participants reported a substantial (high or medium) degree of confidence in themselves as learners (93.8%), said they were self motivated (92%), and could work independently with little direction (91.8%). However, nearly one-third (30.8%) said they were not capable of self-directed learning, with only fourteen percent strongly agreeing that they were capable of self-directed learning. In other words, respondents in the sample seem confident working under the supervision of a teacher, but not under their own supervision. It is interesting to note in a related study that Australian and Scottish students were less at ease with teachers than their United States counterparts, but were more open to self-directed learning (Christie and Warner, 1999).

Preferred mode of Learning

Respondents reported that traditional face-to-face learning was their most preferred mode of learning. This is shown in Table 1.

TABLE 1: Most Preferred Mode of Learning

PREFERRED MODE	%
Face to face	42

Learning Packages	5
Electronic	3
Guided experiential	5
Combination, inc. face to face	43

Further, fifty-five percent of all respondents believed that their future learning would be delivered face-to-face.

Learning Technologies

In the emerging area of learning technologies, participants reports give cause for concern in relation to flexible delivery. Forty-one percent had no computer based learning experiences, fifty-two percent had not experienced CD Rom learning and sixty-three percent had no experience of the Internet for learning. Only the Internet is reported on in this paper.

The Internet

For the majority of participants, the Internet was a new medium for which they reported low skill, or no experience. Their self-reports of competence are shown in Table 2.

TABLE 2: Level of Reported Competence in Internet Tasks.

Task	No Experience	Low	Medium	High
Accessing	37	18	22	19
Browsing www	43	17	18	18
Emailing	46	19	17	14
Downloading programs	50	18	15	13
Chat groups	51	15	19	11
Database search	47	17	19	18

Despite the above, participants did report that they perceived that the Internet would be useful for their learning (66.8%).

While sixty-three percent had no prior experience of the Internet, some sixty-two percent said that they currently have access to it either at home (15.5%), in the workplace (6.1%), or through their course provider (19.2%),. Eighteen percent stated that they had access to the Internet through more than one location.

These results give some cause for concern. They show that about two thirds of respondents had either no competence or no skill in performing Internet-related tasks. These findings endorse the observation that students require progressive exposure to the use of higher-end technologies to support their learning.

Questionnaire Part 2

Part two of the questionnaire dealt with an assessment of student's learning preferences and used a commercially available scale to measure this dimension of student readiness for self-directed learning. "Self directed learning is a strategy or a process whereby the learner accepts the responsibility for planning, seeking out resources, and implements and evaluates their own learning" (Brookfield, 1984. p.16). Scoring norms for this scale are depicted in Figure 1.

TABLE 3: International Norms for Learning Preference Assessment (Guglielmino, 1991) and Australian VET Sample

Score	***Level of Readiness***	***AustralianVET sample %***
252-290	High	8
227-251	Above average	19
202-226	Average	32
177-201	Below average	29
58-176	Low	12

Results revealed information which may give cause for concern. For example, the mean score on this scale for the Australian VET client sample is 202, with seventy three percent of the Australian sample scoring 226, or below. Comparison with international norms reveals that our sample has only low to average readiness for flexible learning. Forty one percent of the sample score only below average or low on flexible readiness.

Half of the students in the present sample possess below average to low readiness for self-directed learning and the scores for three quarters of the sample are average or below. This indicates that despite massive investment in flexible learning technology and infrastructure, the skill level of students may have remained unaddressed. The VET sector has apparently failed to acknowledge that similar investment needs to be made to ensure that clients can cope with flexible learning demands. The results call attention to the fact that mandating a flexible learning mode for all VET clients will potentially disadvantage three quarters of the client population. This is poor pedagogy and poor business.

However, a significant difference for age was identifies between those under 25 years and those above. The latter indicated a greater readiness for self-directed learning with some 40% scoring above average and higher, compared to 21% of the under 25 year group. This has implications for how course developers and instructors differentiate between younger post-school students and mature age students in the workforce.

The research findings do point to a cohort of VET clients with above average to high dispositional readiness and also with a range of self-directed learning skills, including the use of learning technologies.

Those clients with the attitude and skills that are disposed to flexible delivery do want choice. This is not readily available to them now. However, a collaborative approach in establishing 'virtual' provision of training could support these clients and provide a new framework of 'learning efficiency'.

Structured interviews with teachers

Overwhelmingly teachers believe that face-to-face delivery is more successful as a college strategy than other modes of delivery in promoting student learning. Optimun training is achieved through a combination of face to face learning with college lecturers, and workplace training and practice with workplace supervisors. A further critical factor, perhaps the most important factor in any method of delivery was described as interactivity.

The teachers interviewed said that a range of skills are required of students to profit from flexible delivery. They feel that students may possess some or all of these skills to varying degrees but few possess all of the skills at a sufficiently high level. The skills nominated by teachers were:

- Time Management
- Goal Setting
- Self-direction Skills
- Computer Literacy
- Technology Skills
- Basic Literacy and Numeracy
- Comprehension and Meta-Cognitive Skills

They perceived all of these skills to be essential for flexible learning. They did not indicate any teacher or institutional responsibility for helping students actually develop these skills. They generally attributed 'blame' to the students and their previous learning experiences or institutions.

Structured interviews with employers

The majority of employers interviewed were familiar with the term flexible delivery but most had some difficulty or confusion with the precise definition of the term. Most saw flexible delivery as somehow giving more emphasis or focus to the learner, and they saw it as more focussed on the individual rather than on the group.

Employers, without exception, mentioned literacy skills and numeracy skills as the most fundamental skills required of employees to benefit from any kind of training. Among the essential skills for flexible delivery success are:

- Literacy and Comprehension
- Problem Solving and Information Retrieval Skills.
- Analytical Thinking Skills
- Keyboard Skills

They saw these skills as more important than for example, computer literacy skills which they believe can more easily be taught on a just-in-time basis. Above all, employers believe that trainees need to come to the training experience with high levels of motivation to learn and high levels of self-direction skills.

Employers from larger workplaces knew more about flexible delivery and the needs of employees in relation to training. Larger workplaces tend to have more equipment than do smaller workplaces. They also tend to have more text-based resources and are more likely to be technologically better equipped. Overall larger workplaces seem better able to support students with more non-human support.

Conclusion

This study has found that the assumptions on which flexible delivery and online delivery are based are untenable. On the basis of the current research, the assumption that students are ready for flexible delivery of courses does not seem warranted. Both disposition and skill for self-directed learning were low on an international benchmark scale. Differentiation, based on age, however, could provide better opportunities for mature aged workers. Further, there is evidence from the interviews with VET teachers and employers that the VET sector has a limited understanding of flexible delivery and what might be needed for it to be successful. Teachers and employers generally saw the problem as belonging to the student/employee and resulting from poor previous school experiences. They identified skills needed, but did not indicate any belief that they might have a major role to play in enhancing the capabilities of students/employees.

In terms of the use of learning technologies, people in the VET sector have limited experience and competency of them as learning tools. While basic computing skills were evident, their reports did not indicate any real sophistication in higher-order computing or Internet skills. For both present and future learning there was clearly a preference on the part of students for face-to-face traditional delivery in college.. There was little evidence that their VET experiences exposed them to learning using new technologies or developing the skills to be able to learn thus. However, there were some indications that, given opportunity and learning skill, the students might well develop the disposition to learn differently. Certainly, there is no evidence to suggest that VET clients could not develop the capability to learn through flexible delivery. What needs to happen is an attitude change on the part of students, teachers and employers and attention given to the development of skills associated with flexible learning, particularly skills associated with new learning technologies.

The Effect of Technological Paradigm Shifts on Established Educational Technologies: A Case Study of Audiographics

Allan Ellis
School of Social and Workplace Development
Southern Cross University, Australia
http://allan.scu.edu.au/ aellis@scu.edu.au

Roger Debreceny
Nanyang Business School
NanyangTechnological University, Singapore
http://www.ntu.edu.sg/home/adebreceny rogerd@netbox.com

Abstract: Audiographics technologies enjoyed a period of relatively widespread use and progressive refinement in the early to mid 1990's. Their growth and development was however paralleled by the growth and development of the Internet and the World Wide Web. Since the mid 1990s the functionality and appeal of collaborative Web-based tools has slowly gained favour amongst educators with the consequence that they have began to replace the more specialised functionality of established audiographics programs such as Electronic Classroom ® with the more diversified and increasing sophisticated Web-based programs. The low speed and poor reliability of phone line connections and congested Internet service lines are factors that can still give audiographics programs the edge in some non-metropolitan and remote areas. The results of a telephone survey of Electronic Classroom ® users indicates that audiographics use has at best stabilised and at worst is in decline in the face of an ever increasing array of Web-based collaborative tools. The detailed comments of Electronic Classroom ® users in relation to the decision abandon audiographics and move to another educational technologies will be presented as part of the conference presentation.

1. Introduction

This paper addresses the effect of technological paradigm shifts on investments in educational infrastructure, courseware and teacher skill sets. The paper reviews the paradigm shift that has occurred in educational information technology with the arrival of the Internet and the World Wide Web (the "Web"). The Web has literally affected all pre-existing educational information technologies to a greater or lesser extent. In this research we address the impact of the Web on one relatively widely adopted educational information technology: audiographics. This technology is a form of synchronous, distributed multimedia software. Audiographics is designed to support distributed learning across a range of educational levels. How have developers of audiographics software responded to the challenge presented by the Internet and the Web? Equally importantly, how have educational administrations, institutions and individual teachers reacted to the new opportunities and challenges presented by the Internet and the Web?

This paper proceeds as follows: In the next section, the nature of Kuhnian paradigm revolutions, or what are more commonly referred to as paradigm shifts, is discussed. The next section introduces audiographics educational technologies. We review the adaptation made by suppliers of audiographics software to Internet technologies. We then analyse the response of experienced users of a well-established Australian audiographics product, Electronic Classroom ®, to the changes brought about by the Internet and the Web. In the final section, we make some recommendations for further research into substantial changes or paradigm shifts, in educational technology.

2. Paradigm Shifts in Educational Technology

Kuhn (1962: 83), explains that a paradigm revolution in science occurs when a "continually resistant component of Science - an anomaly in the paradigm" occurs. He notes that a paradigmatic revolution "is complete when the profession will have changed its view of the field, its methods, and its goals" (Kuhn 1962:84). Paradigmatic revolutions "must occur all at once (though not necessarily in an instant) or not at all" (Kuhn 1962: 149). While the original Kuhnian view of a paradigm revolution was to describe the comprehensive shifting of plate tectonics in scientific disciplines, the more popularly accepted term of paradigm shift has come to represent a fundamental move in understanding and use of technologies or other human activity. For example, Capra (1982: 30) defincs a paradigm shift as "a profound change in the thoughts, perceptions, and values that form a particular vision of reality". The term has now entered into the public consciousness and has been used widely in a variety of disciplines.

There has been recognition in recent years of the importance of information technology in reshaping a variety of human endeavours. The work of Negroponte (e.g. Negroponte, 1995) and Tapscott (e.g. Tapscott 1995; 1997; and Tapscott and Caston 1992; 1993) have been influential in pointing to the fundamental implications of new computer-based technologies for the way that societies are organised. While the work of Negroponte, Tapscott and others have not been linked to any particular technology, we can say that the extraordinary move of the Web (Berners-Lee and Cailliau 1990; Berners-Lee 1997) from the relative confines of the high-energy physics community to the general global community, constitutes a paradigm shift, even a paradigm revolution, under any definition. In the space of less than a decade the Web has grown into an unfathomable multimedia resource. Intkomi Inc. estimates that there are more than 200 million publicly available pages on the Internet that a search engine can index. There are probably many more pages hidden behind corporate Intranets and database engines. The Web has affected the development of a wide variety of pre-existing information technologies from local and wide-area networks, to group decision support and collaborative systems to e-commerce and logistics.

3. Audiographics

Audiographics is a set of linked technologies that supports synchronous and distributed teaching and learning (Barker and Patrick 1989; Rehn and Towers 1994; Ellis, Debreceny and Crago 1996). In the "pre-Internet" period, an audiographic installation would involve computers at physically distributed teaching sites connected by modem and telephone line. The sites would also be connected by telephone line for voice. This is illustrated in Figure 1:

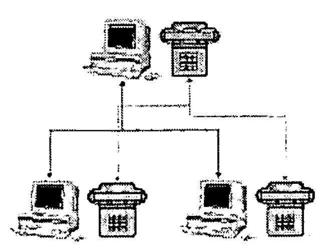

Figure 1: A basic audiographics installation

Typically, audiographics software supports one or more of shared whiteboards with graphics and chat features. In the case of the Electronic Classroom ® product, shared access to sounds and movies in QuickTime ® format was also provided. Audiographics was, for some time, the only multimedia computer-based form of educational technology that could support synchronous, different place interaction with graphical support. Of course, pre-Internet technologies such as bulletin boards and chat rooms could support such interaction, but in a text-only mode. The place of audiographics in the broader span of educational technologies is illustrated in Figure 2

	Spatial	
Temporal	same place	different place
Synchronous	Classroom activities - discussion groups, role playing	Audiographics, Distributed GDSS, Internet Pagers, Videoconferencing,

		Educational TV and radio, Teletutes
Asynchronous	Email, Listservs, Web discussion boards, RealAudio, Asynchronous TV	

Figure 2: Typology of Educational Technologies

Three products took the major share of the worldwide audiographics marketplace. These were Vis-à-Vis and Smart 2000 from Canada, both of which were in a Windows 3.11 and subsequently Windows 95 environment, and Electronic Classroom ® from Australia, which operated in an Apple Macintosh environment (Crago 1993). As might be expected, Electronic Classroom ® dominated the Australian marketplace, with substantial inroads being made in the Victorian and West Australian school system and, to a somewhat lesser extent, the NSW and Queensland school systems and higher education nationally. Electronic Classroom ® has provided the foundation for a number of experiments in distributed teaching and learning, many of which have been reported at previous ED-MEDIA conferences (for example; Ellis and Debreceny 1994; Arms 1997; Oliver and Lake 1997; Stoney and Oliver 1998).

Audiographics has been applied in a wide variety of educational environments, from primary school to higher and further education (Ellis, Debreceny and Crago 1996). Audiographics does, however, require rather intensive investment of resources. Each site traditionally required two telephone lines for voice and computer-to-computer communication. When there is long-distance synchronous teaching and learning, which has been the situation for many audiographics installations, there are additional communication costs. These costs may be substantial.

Ellis, Debreceny and Crago (1996) documented the progressive technical improvements in Electronic Classroom® functionality from version 1.0 in February 1990 to version 2.5.9 in June 1995. In April 1996, the release of version 3 allowed users to substitute point-to-point Internet connectivity for modem connectivity. This allowed users of try out IP networks instead of dedicated phone lines.

In contrast the Internet, has provided the promise of connection to local points of presence (POPs) at the cost of local telephone call. Further, with Internet support, only one phone line, for audio, is required. Migration to an Internet-based solution also opens up many opportunities for wider collaboration and alternative forms of collaboration. Synchronous teaching and learning can be integrated with asynchronous communication and collaboration by email, listserv or Web-based discussion board.

A large number of products have been developed to support synchronous and asynchronous collaboration on the Web. Products include chat tools such as ChatTouring, which, as the name suggests, is designed to support text-based synchronous chatting but with the ability to take participants in the chat to designated URL's. The chat participants' browser follows the lead of the URL that has been placed on the ChatTouring chat space. New synchronous tools have been developed in the Internet environment that was not possible with pre-Internet technologies. For example, the concept of a "pager" such as Mirabilis's ICQ allowed for participants to enter into dialogue with designated parties when those parties come onto the Internet.

Widely known products that most closely resemble "traditional" audiographics solutions in an Internet environment are CUSeeMe(TM) and ClassPoint(TM) from WhitePine, and NetMeeting(TM) from Microsoft. Each of these products supports audio, video, shared whiteboards and chat. Each is compliant with the ITU's H.323 standard on multi-point video conferencing. ClassPoint is also compatible with the T.120 standard on multi-point data sharing . Products based upon T.120 are designed to interoperate with H.323-compliant products. ClassPoint(TM) is an enhanced version of CUSeeMe(TM), which originated as a research project at Carnegie-Mellon University (Steele 1994). The product supports the multi-point audio and video of CUSeeMe(TM) as well as integration of Web-touring, along the lines of ChatTouring discussed in the previous paragraph. ClassPoint(TM) also provides for teacher control of the "classroom" environment as well as Web-based teaching and learning materials. NetMeeting has integrated audio, video, shared whiteboards, shared applications and chat. NetMeeting is, however, limited to two parties sharing audio and video, although others can share a chat room and shared applications. MeetingTools(TM) from DataBeam enhances NetMeeting(TM) to support a large number of users, albeit without audio and video support.

The pre-Internet audiographics products have made varying attempts to become Internet-friendly. None has, however, made the transition completely successfully. Developers of some of the products have tried to reduce the cost of ownership by multiplexing audio and data on the same telephone line (Klein, Pratap and Prestinario 1997). No evidence has been found for widespread adoption of such a solution. A product, which sits between

the traditional audiographics products and the newer generation of Internet products, is FarSite(TM), also from DataBeam. It does not support audio or video. FarSite(TM) has, however, extensive support for Internet-based collaboration tools.
In summary, the Internet now provides the promise of low cost synchronous collaboration with all the functionality of the pre-Internet audiographics products. At the same time, moving to an Internet solution provides the potential for teachers and learners to access the resources of the network and to leverage alternative synchronous and asynchronous Internet collaboration solutions. However it must be remembered that the reliability and speed of Internet connectivity varies widely. How did the users of pre-Internet audiographics respond to this paradigm shift?

4. A Case Study: Electronic Classroom®

4.1 User Telephone Survey

Format and questions
As discussed above, Electronic Classroom ® is a well-developed and widely used pre-Internet audiographics product. It has been in use in the secondary educational sector since 1990. Although most of the installations have been in rural and regional Australia, there have been applications of Electronic Classroom ® in urban environments. Typically, schools in a defined geographic area will collaborate to jointly offer classes that could not cost-effectively offered by individual schools in the consortium. By mid 1998 a total of just over 1000 Electronic Classroom ® licenses had been sold. This research was designed to track the decisions made by active users of Electronic Classroom ® in the period from approximately mid 1996 to mid 1998, that is, since the introduction of version 3, which allowed Internet connectivity to be substituted for modem connectivity, and over the time of rapid growth of collaborative Web-based tools.

A telephone survey of Australian users was conducted in August and September 1998. Revelation Computing, the developer and distributor of Electronic Classroom(R) supplied some contact details of users. Other contacts were added, based on the authors' knowledge of users from past research. The intention of the survey was to sample people who had not just purchased copies but who were known to have made some use of the product in the years prior to 1998. The survey was intended to be a simple pilot study. It was not designed as a comprehensive review of the entire product user base. Nevertheless the survey was stratified. It sampled metropolitan and country users in several Australian states. In Australia, primary and secondary education is the responsibility of educational administrations at the state level.

The majority of users were known to be active in the various state primary or secondary school systems. The age of students studying via Electronic Classroom ® sessions ranged from nine to eighteen years of age. The survey was not intended to be a detailed "product comparison" but rather an attempt to establish if any trends and changes were present and if so, how the trends and changes could be best characterised.

Some general points about the survey population and survey questions are relevant. By the very action of making use Electronic Classroom ® in their teaching and learning environment, users can be characterised as technologically literate, as innovators and as "early adopters" under the model proposed by Rogers (1983). Given this, it is to be expected that users would also be active experimenters with other related products and hardware that might be seen as offering similar features of perhaps even completely "new" instructional environments.

The structure of the survey involved a series of questions of two types: a number of optional, defined responses (e.g. Yes/No) or open-ended responses (a few sentences to a few paragraphs were recorded). The initial question was aimed at splitting the sample into two sub-groups:

Opening question: Are you still actively using Electronic Classroom ® in your teaching?

Possible responses: Yes or No

Depending on the respondents answer to this question one of two other sets of additional questions were asked.

If Yes:
1. Is your level of use: Possible responses: (a) higher then a few years ago, (b) about the same, (c) less than an a few years ago.
2. Have you looked for a potential replacement system? Possible responses: (a) Yes, actively, (b) No, but have checked out "similar" products, (c) No, not at all.
3. Have you considered any other products that might provide supplementary support? Possible responses: (a) Yes, (b) No
4. What do you consider are the current major strengths of Electronic Classroom ®? Give details.
5. What do you consider are the current major weaknesses of Electronic Classroom ® ?Give details.

If No:
1. What was your main reason(s) for abandoning Electronic Classroom ® ? Give details.
2. Has this move proved to be the right decision? Possible responses: (a) Yes, (b) No.

5. Results

5.1 The Yes group

The majority of users surveyed were in the Yes group, that is, Electronic Classroom ® was still being used by them and their organisations. However, the users reported that the level of use had stabilised or was declining. No one was actively looking for a replacement product but, as was to be expected, all were "checking out "similar Internet-based products that provided collaborative screen sharing facilities.

The majority of Yes respondents also reported they had considered, or even trailed the use of supplementary products. These included low cost, small window videoconferencing such as ClassPoint(TM) or CUSeeMe(TM). Use of such products was seen as a means of enhancing the feeling of personal contact between teachers and students and amongst the student population.

The features that were overwhelmingly reported as being the major strengths of Electronic Classroom ® were its tenacity at maintaining a continuous connection even over relatively poor quality telephone lines and its suitability for delivering a formally structured lesson based on already developed content. These comments come as no surprise as they represent the elements of the niche market that the product originally targeted.

In terms of major weakness most respondents said none. One respondent stated its inability to link with other similar products, in particular those that run on a Windows platform.

5.2 The No group

The main reasons for abandoning Electronic Classroom ® were related to the rapid spread and evolution of the World Wide Web and the availability of shared whiteboard and screen control software as well as the availability of low cost colour videoconferencing hardware and software. In metropolitan areas the availability of Internet connectivity, had clearly attracted several users into what they saw as a more information rich environment. This environment was seen as more popular with the respondents' students. Connection to the Internet was often centrally funded by the respective State Education system, and/or available, at relatively low cost, via commercial ISP's. This contrasted with the cost of phone connections with Electronic Classroom ® that requires expenditure of school budgets or the continuation of special grants from central administrations.

All No respondents believed that the move had been the right decision. Several did offer the comments that it had altered the structure of how online lessons were now delivered. The respondents felt that the "more direct control available when using Electronic Classroom ® had been lost". In contrast, the benefits of an Internet solution "were that the students were now searching for and creating more of their own resources". Clearly the popular appeal amongst the student population of creating Web pages had been a factor decision to move from Electronic Classroom ® to an Internet solution.

Details of individual responses to the phone survey will be incorporated into the conference presentation.

6. Conclusions

In this paper, we have introduced audiographics technology against a backdrop of a paradigm shift in educational technologies. We noted that new Internet-based products provided the functionality of pre-Internet audiographics applications. These Internet-based products allow users to use a single telephone line for video, audio and data as well as opening up schools to the cornucopia of resources on the Internet and the Web. At the same time, suppliers of audiographics software have not moved quickly to meet the demand for Internet solutions.

How did schools respond to these opportunities? The strongest supporters of Electronic Classroom ® remain users who want to deliver formally structured lessons and are located in areas where poor telephone line quality is unfortunately still the norm. Reliability of connection and poor bandwidth in a rural and regional environment mitigates against a change. Attempting to support audio, video, shared whiteboards and chat on a single telephone line requires high-speed lines and continuous quality. A product such as Electronic Classroom ® has a high level of Quality of Service (QoS). The QoS of the Internet cannot be guaranteed. Also this group has a major investment in prepared lesson content, which would not be easily exported to another environment.

The reason that usage levels have stabilised and the user base is not expanding is clearly related to the increasing number of Internet connections in schools, the availability of other screen sharing programs and the increasingly rich resource pool provide by the Web sites around the world.

Finding An Educational Role For Performance Support Systems

Martyn Wild
Senior Research Fellow, School of Information Systems, Edith Cowan University
Pearson Street, Churchlands, Western Australia 6018
m.wild@cowan.edu.au

Abstract This paper will report the findings of a second study[1] to investigate the value of a Performance Support System (PSS) for novices undertaking a complex cognitive task (lesson planning), within an innovative instructional model. The intention of the research was to investigate the value in using performance support as a strategy for engaging learning, by describing how learning might occur as a result of using a specific PSS.

INTRODUCTION

The rationale for this research lay in the paucity of instructional design models or approaches for the development of educational software products, particularly for tertiary education. Furthermore, it was completed in the shadow of seminal comments by Brown (1994), and Park and Hannafin (1993), amongst others, which are proving increasingly representative of the field of instructional technology, and which strongly advocate the need for new and better informed (ie. by a greater diversity in research findings) instructional design models.

This research hypothesised the value of using a model of instruction based primarily in the theory of cognitive tools and in the design methodology of (electronic) performance support systems (PSSs), but also taking appropriate account of other cognitivist principles in instructional design, such as mental models, situated cognition and authentic learning. There were two orientations to the research reported in this paper:

1. Investigate how novice student–teachers engage PSS components in the Lesson Planning System (LPS)—a specific PSS designed to support the production of lesson plans.
2. Investigate the effectiveness of the LPS as a PSS to support the completion of lesson planning.

The space allowed here prohibits a full reporting of the data collected. Further refereed articles reporting on this and other data are published elsewhere—for example, see Wild (1998a; 1998c; in press).

PERFORMANCE SUPPORT SYSTEMS

A Performance Support System is interactive software that is intended to both train and support the novice user in the performance of tasks. Raybould describes a PSS, rather widely, as a, 'computer–based system that improves worker productivity by providing on–the–job access to integrated information, advice and learning experiences' (Raybould, 1990). Traditionally, PSSs have been characterised by their structure and the software resources they provide, and these are usually determined to include: an information base (eg. on–line reference and help facilities and case history databases); interactive and learning experiences; productivity software (often used with templates and forms); and, an advisory system (eg. coaching facility) (Gery, 1995).

THE CONTEXT OF DESIGN FOR THE LPS

At the core of the LPS is a model of lesson planning required by Edith Cowan University, Western Australia, and wider afield. This model includes essential components of lesson planning such as writing learning objectives, developing learning experiences and planning evaluation (Barry & King, 1993). Each component is supported by activities that instructs the user about the task (eg. provision of information relating to reasons why objectives are necessary, criteria for quality objectives), and which also assist the user in performing the task (eg. provision of a database of verbs to assist in writing quality learning objectives). A set of software tools are available to support each activity. A full description of the LPS can be found in Wild (1998b).

PROCEDURE

In the second of two major studies[2], five students, all female, were identified to provide the focus for studying their patterns of LPS usage over a two week period. These students were volunteers and self–confirmed novices in lesson planning. The students were tutored in the use of the LPS, to the point at which they felt comfortable with their skill in the use of the technologies (ie. computer and software use). Students then used the LPS to plan a minimum of six lessons, over a period of two weeks—producing these lesson plans so that they might be implemented in their professional practice placement schools within a day or so of their planning, and also subject to evaluation by a university supervisor, classroom teacher, and/or school principal or representative, as part of the normal operating expectations in the professional practice period.

Observational data was collected by video tape recordings, providing a complete record of use of the LPS for each student for each session of use. From the observational data, it was possible to determine a count of students' interactions with instructional and performance components of the LPS, and the amount of time it took for them to complete the lesson planning task using the LPS. Also, from this data, an instructional–performance (IP) coefficient was calculated to more effectively represent the changing nature of LPS usage over all lesson planning tasks. This coefficient is calculated by dividing the total number of instructional (I) interactions for each lesson plan, by the corresponding number of performance (P) interactions. For example, an equal number of instructional and performance interactions for one lesson plan, would provide an IP coefficient of one (1). Whilst there is no optimum IP coefficient indice, when calculated over a range of lesson planning tasks, for each student–teacher, the IP coefficients can provide an indication of the development of expertise in students' lesson planning skills.

Individual follow–up interviews conducted at the completion of the two week period (ie. within 15 days of the completion of the final lesson plan observed), helped determine how all students managed aspects of the lesson planning task. Interviews were conducted one–to–one, and comprised a series of open questions which sought to identify how students perceived they completed the lesson planning tasks, and probed why students performed and managed the task in the manner they described. The sixth and final video tape recorded for each student, was played back to the student at this point, to elicit a delayed think–aloud procedure, acting as a prompt for each student to offer explanatory comment on their actions and behaviours in using the LPS, over their whole period of use, and particularly addressing the notion of change and/or perceived improvements in skill performance.

Further, each of the six lesson plans produced was evaluated by an expert lesson planner (ie. lecturer or teacher), as a measure of product quality; and, as a means of gaining an indication of the strength of transfer in students' learning over media, these lesson plans were then compared to a lesson plan produced by each of the students by 'pen & paper' means, following their use of the LPS.

RESULTS

Taken together, there emerges consistent and strong patterns in the data (see Table 1). For example, the reduction in the use of instructional components is strong (21–9, or 57.1%), although less so if the fifth and sixth tasks (#5, #6) are discounted as unrepresentative (for which only two students provided data), (becoming 28.6%). Again, the reduction in the time taken to complete the lesson planning tasks, (34–13 minutes, or 61.8%) is very apparent—although, again, less so if the latter two tasks are removed from the calculations (becoming 44.1%).

Table 1: Lesson plans 1—6.

Lesson plans	LPS Components			Time (mins)
	Instruction (I)	Performance (P)	IP Coefficient	
L1	21	20	1.0	34
L2	18	19	1.0	25
L3	14	20	1.4	20
L4	15	21	1.4	19
L5	11	17	1.5	17
L6	9	14	1.6	13

Perhaps of more interest are the figures for students' use of performance functions in the LPS: very little change from one task to another over the first four tasks; and being reduced only in the fifth and sixth tasks

(20–14, or 30%), for which data was available from only two students. However, the most telling figures lie in the IP coefficients: the trend here is of a gradual and positive change, rising from 1.0 in the first task, to 1.4 in the third and fourth, and then peaking at 1.6 in the sixth task. The story in all these sets of figures and particularly those for the IP coefficients, is of students who develop their cognitive strategies in lesson planning using the LPS by the fourth task, and then refine those strategies thereafter, improving upon them more gradually over the remaining two tasks. Indeed, Figure 1 reveals more of the same story, suggesting the interaction in the instructional and performance interactions data sets that occurs just before the second task (#2), is the point at which the development in expert cognitive strategies first takes hold; but is only refined and consolidated at, or after, the fourth task (#4). However, as a cautionary note, it should be remembered that generalising in this way, does serve to mask the differences in the sets of figures recorded and analysed for individual students.

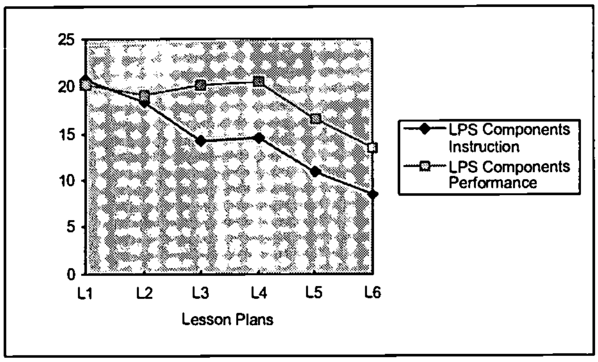

Figure 1: Lesson plans 1—6.

The temporal data, when plotted on a single graph (Figure 2), show that for all students, the time taken to complete a lesson planning task declined over the entire span of tasks (#1–#6). Also, for most students (ie. excepting students 2 and 3), this pattern of reduction is very similar: starting in the region of 34–46 minutes for the first lesson planning task; falling quite rapidly for the second and third tasks; and then declining more gradually for the remaining tasks. Of the two students (2, 3) who did not conform to this pattern, student 3 completed only three lesson planning tasks, making it more difficult to read patterns of any type into her data; and student 2 experienced a hiatus in the earlier data (where for tasks #2 and #4, the completion time rose by one to two minutes), but followed the broader pattern after task (#4). The data for all students increasingly converge over the last three lesson planning tasks, so that all students complete the final task in approximately 13 minutes.

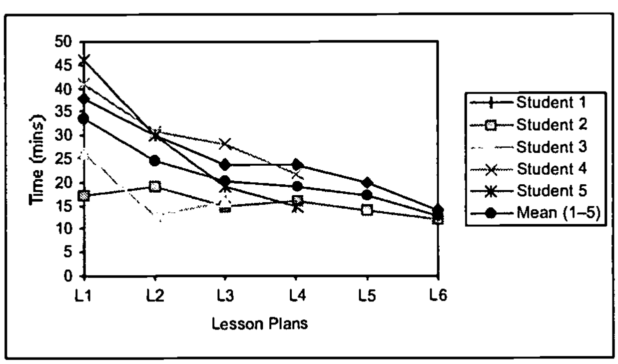

Figure 2: Time taken for task completion in the LPS for lesson plans 1—6.

Although there are similarities in both the interactions and the task–time data between the five students in their completion of the submitted lesson planning tasks, there are also some significant differences, described in full in Wild (1998b). Whilst each of the students experienced a reduction in the use of instructional components in the LPS over the series of tasks recorded, together with a strongly evident and corresponding reduction in task completion times, the patterns in their usage of performance functions are comparatively less alike—although, apart from two students, overall there are reductions in these interactions.

Beyond this, the data also suggest evidence of all students developing appropriate cognitive strategies for lesson planning using the LPS. For example, the data for two individual students (4, 5), when charted as line graphs (not shown in this paper), show interactions in the instructional and performance components interactivity data, at points somewhere between the second and third lesson planning tasks. It is at these points that the students have a ratio in the use of instructional–performance components, of one (1), and where their use of performance components begins to outstrip their use of instructional components. In addition, for these two students, the divergence between these two data sets that follows their interaction, suggests that such patterns in the data indicate the prevalence of cognitive strategies representative of expertise in the task. Even for those three students for whom there is no interaction in the instructional and performance components interactivity data, there is a pronounced divergence between these data sets at some point on individual students' interactions graphs (again, these graphs are not shown in this paper), a phenomenon which in itself is perhaps enough to indicate the development of expertise in the cognitive strategics being deployed.

Indeed, Figure 1, displaying the mean average in the interactions data for all students, suggests that the stage at which they begin to develop expertise in their cognitive strategies when using the LPS for planning lessons, (ie. the point at which there is an interaction in the instructional and performance components interactivity data) occurs very early on, at or just after the first task. However, it is evident that the phenomenon of the interaction in the data sets must be read in context, and in particular, that governing the nature and strength of the following divergence between these data sets. In this case, when all students are taken collectively, as represented in Figure 1, the pattern of divergence does not become soundly established until some point during or after the fourth lesson planning task (#4)—it is at this point on the graph, that the divergence pattern in the data stabilises.

INTERVIEWS

Interview data allowed for the richer documentation of students' cognitive processes and also increased accuracy (reliability) in interpretations offered in analysis of the video data. Whilst there is not room here to provide a detailed account of the analysis of each student's interview, it was clear from these analyses (Wild, 1998b) that the LPS supported a range of cognitive strategies, including that based in 'value adding', where there was clear benefits to be had from being able to word process to a template, to be prompted to check aspects such as lesson evaluation, and also to be able to provide well–formatted print–outs of lesson plans. There is additional evidence that students came to see their use of the LPS as a scaffold, which could be removed 'once you know what to do' (quote from student interview data). Furthermore, most students clearly evolved a confident, reflective and critical practice in their lesson planning, as part of the process of using the LPS: this is illustrated to a limited extent, in example statements for two students:

> After a couple of times, I really thought about what I was doing, about how I could make the lessons better. I used one of the... I copied one of the lessons in the program. Not really copied, I suppose... used it to get ideas from. It was really close to an idea I had anyway, of using cooking in science to get the kids to think about heat, the effects of heating water, evaporation. Once I had this lesson worked out, I used it as the foundation for my other lessons—objectives, evaluations. I started a new lesson plan each time, but I used what I did before to speed things up.

And:

> Yes, I'm thinking about the evaluation methods to use (here). I did take a lot of time, more time, thinking about what I was doing. I think I said this before. I thought more about what I was trying to teach, how I was teaching, you know, individual kids. My supervisor asked me to think about setting up groups for maths. This is what I'm doing. I tried to find out about groups (pointing to the screen). This helped. It was easy when I saw how to set out a plan for working with groups, so I used it in my lesson (plan). I can see I thought about what I wanted to do more. Yeh, OK. When I was finishing off, I went through the lesson again, here, like the computer said (when using the Reflection tool). It was good. It makes you think, to think about what you've doing, how things fit together. Yeh, (pointing to adding text on screen) I need to think about some of the special children in the class, there are quite a few really intelligent girls.

For all students, there were clear indications provided across the interview data to suggest the 'LPS experience' was a major benefit, in both supporting lesson plan writing directly, and in providing the skills and in particular, the confidence, to tackle lesson planning tasks without the use of the LPS. Furthermore, there were repeated indications in most interviews, that students were aware of the strategies they developed in using the LPS, as well as the benefits they perceived it bestowed. There were also indications of metacognitive skills being developed, of students consciously thinking of their own role in the lesson planning process, and of thinking about the best ways of working with the LPS to produce increasingly better lesson plans.

LESSON PLAN PRODUCTS

All lesson plans created by student–teachers here were subject to grading (F—A) by expert reviewers at Edith Cowan University. For use in providing a graphical representation of data in Figure 3, below, the grades were each articulated to a numerical equivalent (ie. a mark), 1—6 (see Table 2).

Table 2: Articulation of lesson plan assessment: outcome–grade–mark.

Outcome	Grade	Mark
Outstanding	A	6
Outstanding	B	5
Highly Competent	C	4
Highly Competent	D	3
Competent	E	2
Unsatisfactory	F	1

The grades for each of the five students over the series of lesson plans produced by use of the LPS and that were submitted and assessed, show an improvement, at best, of two grades and one major grade category (ie. from Competent to Highly Competent), (students 1, 4); and at worst, of no improvement at all (student 2). However, not all students experienced increasingly positive results in this respect, over the entire span of lesson plans assessed—for some (students 2, 5), their grades fluctuated both up and down, at different junctures in this span (see Table 3).

Table 3: Lesson plan grades [shaded areas indicate lesson plans produced by means of 'pen & paper'].

Lesson plans	Lesson plan grades					
	Student 1	Student 2	Student 3	Student 4	Student 5	Mean (1-5)
L1	2	3	2	2	3	2.4
L2	3	3	3	4	2	3.0
L3	4	4	3	4	4	3.8
L4	4	3	3	4	4	3.6
L5	4	2	3	4	3	3.2
L6	4	3	5	4	4	4.0
L7	5	3				4.0
L8	4	4				4.0
L9	5	3				4.0
Mean (L1-L9)	3.9	3.1	3.2	3.7	3.3	3.4
St. Dev.	0.9	0.6	1.0	0.8	0.8	0.6

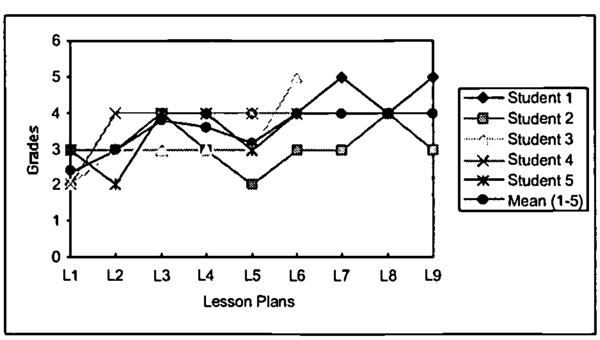

Figure 3: Grades for lesson plans 1—9 (where 1–6 corresponds to F–A).

Any improvement in grades achieved by the student–teachers over the lesson plans produced by use of the LPS, was maintained or bettered in the lesson plans subsequently produced by 'pen & paper' (see Table 3, and Figure 3). In the case of two students (students 1, 3) the improvements were by measures of one major grade category (ie. Highly Competent to Outstanding). Although it is difficult to argue a long–term trend or measure of learning or skill–performance transfer from these figures alone, there is clearly an inference here that some level of transfer did take place. In other words, removing the LPS from the student–teachers here, did not hinder or impair their performance in the lesson planning task; and it is likely, these students transferred their learning and their level of skill–performance in the task, achieved by their use of the LPS, to the same type of task, without the use of the LPS.

CONCLUSION

The study reported here illustrates how novice students used the LPS in a complex task (lesson planning) to reach levels of expertise in the completion of that task; and further, were able to continue to call on this newly acquired skill and knowledge base to complete the same type of task without use of the LPS. Whilst there are a range of cognitive strategies by which novice students developed expertise in their performance of lesson planning, it would seem that all students here benefited in particular from active participation in an holistic, complex yet supporting environment, organised around a single performance goal. In general terms, findings from this study included the following:

(i) Learning and performance in students was transferred substantively across media, so that when the LPS was removed as part of the task environment, learning and skill–performance in the same task continued.
(ii) Not all students learnt or performed effectively in a hypertext environment; and at least one student appeared to be specifically disadvantaged by the embodiment of instructional resources in a hypertext or hypermedia format in the LPS, as a task–based performance environment.
(iii) At least one student in this study was hindered in achieving meaningful and deep learning, by the design of the task environment in the LPS—where learning and performance was intended to be completed simultaneously or at very close proximity, (as in the philosophy of just–in–time learning).
(iv) Learning in a task–focused environment, such as that provided in the LPS, did not appear to promote cognitive strategies in students that were primarily guided by the motivation to perform the task better. Students were just as likely to form strategies guided by the motivation to obtain better understanding in the task.
(v) Students' learning styles or preferences appeared to be the primary factors influencing their adoption of cognitive strategies in learning and performing in a task. This was despite the fact that these strategies were not necessarily suited or optimised to the cognitive tools available for use in the LPS, or to the task–based environment in which they were applied.
(vi) The LPS provided strong cognitive support to novice student–teachers in their completion of lesson planning tasks.

It would seem that whilst PSSs like the LPS, are well–placed for consideration as an alternative instructional model, not all students are in a position to make the best use of them; and that individual learning styles are likely to be a strong determinant of students' success in their use.

Influence of Design Decisions on Student Explanations: An Example from *Seeing Through Chemistry*

Tricia Jones (triciaj@umich.edu)
School of Education, University of Michigan, Ann Arbor, MI
Gail P. Baxter (gbaxter@ets.org)
Educational Testing Service, Princeton, NJ

Abstract: We examine the relationship between design features, patterns of use, and the quality of student explanations generated in response to inquiry questions in a multi-faceted hypermedia environment "*Seeing Through Chemistry*." We see that some design features appear to influence student performance. In particular, incorrect answers and a model response seem important for helping students recognize the need to revise. What appears to be lacking are features which lead students to improve the explanation quality as they revise.

1 Introduction

Hypermedia systems may be particularly appropriate as learning environments because the associative knowledge structures of a topic or subject matter are made explicit. However, in creating hypermedia systems, attention must be given to design decisions that can support students in making appropriate connections in their own developing knowledge structures (e.g., McKendree et al 1995). Activities that will highlight the key concepts of a domain and engage the students in problem solving and reflection are especially important in this regard. Examples include guided tours which highlight concepts in a domain and how they are related, multiple possible paths through materials that encourage consideration of the same topics or concepts in differing contexts, questions that promote reflection on the relationships among topics or concepts, and opportunities to revise one's response as understanding develops.

In this paper, we consider the impact of various design features on student learning in a multi-faceted hypermedia environment "*Seeing Through Chemistry*." Psychological principles of learning, in particular, cognitive flexibility theory (Spiro et al. 1988) and principles of human-computer interaction (Dershimer et al. 1992) provided the theoretical and empirical basis for designing the *STC* learning environment. More specifically, *STC* integrates video, animations, and experimental simulations with text and pictures onto multimedia content cards to facilitate the development of students' understanding of topics in an introductory college chemistry course (Dershimer & Rasmussen 1990). Four interaction modes, distinguished by the level of structure and support, focus students' attention on the relationship among topics in each of the six modules and allow for multiple paths through the material to support individual styles and interests.

Inquiry questions form the primary instructional activity in *STC*. The questions represent a synthesis of topics or content cards, and the same topics may be relevant for several questions. Revisiting the same topics (e.g., concentration) in multiple contexts (e.g. pH, precipitation) promotes students' understanding of the relationship among related concepts. Students are asked to respond to the inquiry questions with an answer (select from among two or more choices) and a written explanation. Answers are scored right or wrong and then students are shown a model explanation. The software prompts students to revise their explanations and refer to content cards in that process. However, students are not required to revise their explanations nor does the software evaluate the quality of their explanations. Further, students make decisions on how the software is to be used – whether and when to read the content cards, selection and use of the four navigation modes, and whether and when to revise their explanations. The student makes choices in interacting with the software and it is this interaction that effects the extent of learning, more so than individual design features in the abstract. In what follows, we examine variation in *STC* modules (content cards and inquiry questions), variation in student patterns of use and their relationship to students' explanations to inquiry questions (used as a proxy for student learning or understanding). We conclude with software design implications.

2 Methods

2.1 Study Design

Each of the six modules in *STC* was designed with the same fundamental instructional goal. Nevertheless, characteristics such as the number of topics, content cards, and inquiry questions, and the nature and extent of supporting media influence the options students have to interact with the material. We reasoned that the nature and extent of opportunities to revisit content would influence student learning. To this end, we created visualizations showing which content cards are suggested for each inquiry question in each module and selected two modules that varied widely in coverage (see Figure 1). *Acids & Bases* has 6 inquiry questions, and was the fourth module completed in the semester. *Solubility* has 10 questions, and was the fifth and final module completed.

Acids & Bases
(53% topic coverage)

question	Topics 1-1	1-2	1-3	2-1	2-2	2-3	2-4	3-1	3-2	3-3	4-1	4-2	4-3	5-1	5-2	5-3	5-4

Figure 1: Coverage in *Acids & Bases* and *Solubility* modules

In Figure 1, bullets (•) indicate when a topic (one or more content cards) is suggested for each inquiry question in a module. Reading across the rows, one can see which topics are suggested for which questions. For example, for *Acids & Bases* question 1, *STC* indicates that topics 2-4, 4-1, 4-2, and 4-3 are relevant to this inquiry question (topics are named in the software, but names have been ignored for the purposes of this discussion).

Complete coverage occurs when each column has at least one bullet (i.e., every topic or content card is suggested at least once). Although neither module has complete coverage, *Solubility* has relatively more coverage than *Acids & Bases*. The columns indicate how many times the topic is visited; more bullets indicate the topic is suggested for more questions (i.e., repeat coverage). Overlap is determined by looking at the pattern of bullets: for example, *Acids & Bases* question 5 covers the same topics as question 2, and only overlaps any other question with one topic (3-2). *Solubility* question 10, on the other hand, overlaps with every other question in the module. Further, the *Solubility* module appears to contain distinct subsets of topics: questions 1 to 5 primarily rely on topics in Clusters 2 and 3, while questions 6 to 8 primarily rely on Clusters 4 and 5. Variety in overlap is important for revealing different facets of the topic; e.g. one question covers saturation and concentration, a second refers to saturation and dynamic equilibrium, while a third relates saturation and solubility.

Note that each module has a different number of inquiry questions and a different number of content cards. Modules with more inquiry questions provide more opportunities to visit a given topic: if there are 10 questions, a student has 10 opportunities to visit any given topic, but if there are only 5 questions, then the student only has 5 opportunities to visit a given topic. To facilitate cross-module comparisons, we report proportional visits: number of potential visits per content card per question. Across the six modules, the *Solubility* module provides the highest number of proportional visits (0.276) and *Acids & Bases* the lowest (0.177).

2.2 Methods, Procedures, and Measures

Participants. This study is part of a larger research project examining the use of *Seeing Through Chemistry* in an introductory chemistry course at a large Midwestern research university. Use of *STC* was required, but participation in the study was not: 201 of the 450 students enrolled in this multi-section lecture course volunteered to participate in the research project by completing additional instruments and giving researchers access to course and background data. Of the 201 participants, 180 completed the modules of interest in this study.

Context. The semester these data were collected, all students used the software regularly, for graded assignments. Students answered the inquiry questions for five of the six modules in *STC* and turned in the printed version of their responses. The printout shows the answer choice and the explanation (initial and final). Teaching assistants checked the assignments for completeness. Students received up to 6 points on each assignment for a maximum possible of 30 points (5% of the overall course grade).

Log Files and Inquiry Question Responses. STC automatically captures the sequence and duration of choices made by the student. This information is recorded to files known as log files, one per student, so that each log file captures completely a student's use of *STC* throughout the semester. The log file also captures transitions and navigation modes, as well as all answers and revisions typed in response to questions.

Explanation Quality. Because *STC* does not evaluate the quality of students' explanations, a post hoc scoring scheme was devised for this purpose, based upon student response data and the content in the model response. A student's explanation is assigned one of five scores, determined by its completeness, coherence, and correctness (cf. Chi, Feltovich, & Glaser 1981). The scores are 0–Inadequate; 1–Fragmented; 2–Partial, 3–Good, and 4–Elaborated. For example, a student who mentions two isolated facts but doesn't relate them to each other or to the question might be given a level 1 score (Fragmented). A student who mentions all the relevant concepts, including an explanation of "mechanism," and who adds ideas not found in the model response would receive a level 4 (Elaborated). The first author scored both initial and final explanations to the inquiry questions. A second rater scored a 25% random sample. Interrater reliability was 0.87 and 0.79 for *Acids & Bases* and *Solubility*, respectively.

Patterns of Use. A variety of software tools derive patterns of use from the participants' log files. Moves are extracted from the log files, and characterized by type (e.g. view question (q), view content card (c), edit response (r)). The sequence of moves is combined and then abstracted to form a pattern label that is assigned to each question.

Interviews with a target group of students (Jones, Berger, & Magnusson 1996) revealed two aspects to patterns of use: base patterns and revision patterns. Base patterns are characterized in two ways: students who look at cards before they read the question and students who look at cards after reading the question but before entering their response. Revision patterns consider whether students revise their explanation and whether students refer to cards between initial and final revision. The possible combinations of base and revision patterns are shown in Table 1. Base and revision patterns of use were identified for each of the 16 inquiry questions for each of the 180 students.

	Revision Patterns			
	do not refer after initial response		refer to cards after initial response	
Base Patterns	no revisions	revisions	no revisions	revisions
qr: read **q**uestion, **r**espond	qr_{init}	$qr_{init}r_{final}$	$qr_{init}c$	$qr_{init}cr_{final}$
cqr: read content **c**ards, read **q**uestion, **r**espond	cqr_{init}	$cqr_{init}r_{final}$	$cqr_{init}c$	$cqr_{init}cr_{final}$
qcr: read **q**uestion, read content **c**ards, **r**espond	qcr_{init}	$qcr_{init}r_{final}$	$qcr_{init}c$	$qcr_{init}cr_{final}$
cqcr: read content **c**ards, read **q**uestion, read content **c**ards, **r**espond	$cqcr_{init}$	$cqcr_{init}r_{final}$	$cqcr_{init}c$	$cqcr_{init}cr_{final}$

Table 1: Patterns of Use in *Seeing Through Chemistry*

Intuitively, we expect those who read the content cards to write better explanations. On the other hand, perhaps some students do not read the cards prior to responding if they think they already know the material. They may intend for the exercise to serve as a "self check" on their understanding; if they determine they don't understand, they will read further. Students may read the cards before they answer the question, or after they read the questions but before responding. The former is like reading the chapter before doing the exercises; the latter is like pre-reading questions on a reading comprehension test. Both are legitimate strategies, but one may be more effective in this setting.

3 Results

We believe that the design of instructional software can greatly influence the learning that occurs, through the nature and quality of the interaction that is supported. Because the design of the *Solubility* module is more robust and interconnected with respect to topic coverage than is *Acids & Bases*, we expected students to provide higher quality explanations for that module. In analyzing student responses, we first considered the answer choices and the explanation quality. We further examined these measures in light of the process students undergo while answering inquiry questions, both what they do before making their initial response (base patterns of use) and what they do while working towards their final revision (revision patterns of use).

3.1 Answer Choices and Explanation Quality

In analyzing student responses, we first considered answer choices. In general, the answer choices to inquiry questions were relatively easy for students: for 4 of the 6 questions in *Acids & Bases*, 80% or more of the students made the correct choice. The most difficult question in this module was Question 4, with only 20% initially correct. The *Solubility* module is similar in the sense that the questions were relatively easy for students to get correct on their first response. However, there was less variation in the difficulty of the inquiry questions. For all of the *Solubility* questions, 55% or more of the students answered correctly, and for 7 of the 10 *Solubility* questions, 80% or more of the students made the correct choice initially. Furthermore, in *Acids & Bases*, 146 students (~81%) got more than half the questions initially correct, while in *Solubility*, 174 students (96%) got more than half the questions initially correct.

	Acids & Bases Module (6 questions)						Solubility Module (10 questions)					
	Answer Correctness		Explanation Score Totals (max possible = 24)				Answer Correctness		Explanation Score Totals (max possible = 40)			
Response	min	max	M	SD	min	max	min	max	M	SD	min	max
Initial	20%	95%	7.34	(3.97)	0	17	57 %	97 %	12.01	(6.13)	0	34
Final	100%	100%	12.84	(3.68)	4	21	100 %	100 %	19.06	(6.44)	6	36

Table 2: Answer and Explanation Scores (n=180)

Explanations were scored on a 4-point scale. As shown in Table 2, in the *Acids & Bases* module, students average around 1 (fragmented) point per question for initial responses and move to a 2 (partial). Likewise for the *Solubility* module, students improve from an average score just above 1 to just below 2. In both modules we see that students generally select the correct answer choice but they do not provide high quality explanations for their choices. Moreover, students do revise their explanations and the change in the quality of explanations is statistically significant ($t(df=179)=18.65$*** and $t(df=179)=15.40$*** for *AB* and *Sol*, respectively) but the magnitude of the difference is small. Furthermore, contrary to expectations, there were no obvious differences between the two modules in overall quality.

3.2 Base Patterns of Use

In examining students' patterns of use we asked: do patterns of use affect explanation quality? To answer this question we characterize the various patterns of use and the consistency with which students use them within and between modules. In *Acids & Bases*, 119 students use only one of the four base patterns, a further 31 use one pattern for five of the six questions; therefore, 150 students (83.3%) use a single pattern almost exclusively. Similarly, in *Solubility*, 139 students use one pattern exclusively, while 19 more use one pattern for all but one question. So 158 (88%) use one pattern almost exclusively. Furthermore, only 20 students (11%) switched from a 'cards first' (cqr or cqcr) pattern to a 'questions first' (qr or qcr) pattern between the two modules.

In both modules, the qcr pattern is used by almost half the 180 students on each question, but the distribution of students amongst the other patterns varies considerably across questions. Furthermore, students are either in a 'cards first' group (cqr and cqcr) or a 'questions first' group (qr and qcr). However, the distribution of students within these pairs changes through the module. Finally, as the module progresses, students tend to refer to cards between the question and the response (e.g. the size of the qr group decreases while qcr increases, likewise for cqr and cqcr).

	qr		cqr		qcr		cqcr		sample			
question	M	(sd)	M	(sd)	M	(sd)	M	(sd)	M	(sd)	F	group differences
AB q1	0.98	(1.11)	1.87	(1.19)	1.81	(1.03)	2.24	(1.37)	1.65	(1.21)	8.47 *	qr < cqr, qcr, cqcr
Sol q2	1.02	(1.22)	1.66	(1.26)	0.62	(1.02)	1.73	(1.32)	1.12	(1.25)	9.58 *	qcr < cqr, cqcr
Sol q5	0.83	(1.29)	1.59	(1.30)	0.96	(1.06)	1.66	(1.14)	1.18	(1.22)	4.99 *	
Sol q7	0.87	(0.97)	2.06	(0.89)	1.70	(0.90)	1.85	(0.94)	1.69	(0.97)	8.43 *	qr < cqr, qcr, cqcr
Sol q10	0.43	(0.99)	1.24	(1.16)	0.90	(0.86)	1.17	(0.95)	0.96	(0.98)	3.95 *	qr < cqcr, cqr

* $p < .003$ (.05 / 16)

Table 3: Initial Explanation Quality Score by Base Pattern Group

In order to examine effectiveness of strategies, we examined mean scores within the base pattern groups. Initial explanation quality score means and standard deviations are shown in Table 3 (only significant results are shown, due to space restrictions). On each of the 16 questions, we conducted a within-subjects (base pattern group: qr vs. cqr vs. qcr vs. cqcr) ANOVA. Base pattern group effects were significant for 5 of the 16 questions. For 4 of these 5, significant group mean differences were found. For two questions (AB1, Sol 7), the qr group had lower mean scores than all other groups. For a third question (Sol 10), the qr group had lower scores than the two cards-first groups (cqcr and cqr). Consistent with our expectations, these results suggest that patterns of use are related to performance. Students who read cards (either before the question or between the question and response) generate better quality explanations than students who don't read cards prior to writing their response.

3.3 Revision Patterns

Students are asked to respond to each inquiry question by selecting an answer from among the choices given and generating an explanation to support their choice. Recall that students can then revise their explanations. Do they use this opportunity? What features might influence their decision? Do their revisions lead to improvement?

We examined whether students consistently applied revision patterns. In *Acids & Bases*, 20 students only use one of the four revision patterns, a further 28 students use one pattern all but once; therefore, only 48 students (26.7%) use a single pattern almost exclusively. Similarly for *Solubility*, 10 students use one pattern exclusively, while 25 more use one pattern for all but one question. Thus, only 35 students (19.4%) use a pattern almost exclusively in *Solubility*. Contrast this with the base patterns of use where the values were 83% and 88%. Base patterns are fairly consistent and revision patterns are less so. This suggests that the base pattern is perhaps more characteristic of the student, while the tendency to revise or refer is more a reflection on the design features of the software.

What software features might influence the quality or the revision process itself? We reasoned that feedback on performance would be an important determinant of students' performance. To examine this, we looked at the percentages who revise, and whether those revisions improve the explanation quality. Students are given feedback as to the correctness of their answer, but they are not given explicit feedback about the quality of their explanation. However, if their answer is correct, they are shown a "model" response or explanation to which they can compare their explanation as an indicator of quality. If the answer is incorrect, students are prompted to review relevant content cards; a "model" explanation is not shown. Students then made a decision—not imposed by the software—about whether and how much to revise their explanation, and whether to refer to cards.

3.3.1 Answer Correctness and Tendency to Revise

We expected students to revise their explanations when they provided an incorrect answer and as expected the questions that were the most difficult (i.e., the largest number of incorrect answers) had the highest number of explanation revisions. Virtually all students with a wrong answer revised their explanation. However, we also found that 20 to 60% of the students with a correct answer (depending on the question) revised their explanations. This finding suggests that students use criteria other than correctness of answer to judge whether to revise their explanation.

3.3.2 Model Response and Explanation Quality

One possibility is that students compare their explanation to the model response. As it turns out, one of the inquiry questions did not have a model response. An examination of responses to *Sol* q3 shows that the question was slightly more difficult than average; 80% of the students answered correctly. While all students with incorrect answers revised, only 20% of the students with correct answers revised. This is the lowest percentage of all the questions.

Why do students revise? Perhaps their explanations are quite bad, and their revisions only bring them up to the quality of those who don't revise. Furthermore, revising does not guarantee improvement; however, the data reveal that revisers tend to improve the quality of their explanations, although slightly less so in *Solubility* than in *Acids & Bases* (75% and 80% for *Solubility* and *Acids & Bases*, respectively). If we examine only those students who revise, the scores for explanations increase on average by about 1.5 points (on a 4-point scale). Their final scores are typically between 2 and 2.5, which is higher than the overall mean.

In both modules, there is one question where improvement is much less common. For *Solubility* question 3, only 42% of the revisers received a higher score. In contrast, 72% or more of the revisers improved their scores for all other questions in that module. Again, *Solubility* question 3 did not have a model response – this perhaps suggests that many students rely on the model response in their revisions. In *Acids & Bases*, 43% of the revisers on question 5 do not see an improvement. The reason is not immediately obvious, but it might be that students were unable to pick out the crucial concepts in the model response and instead latched onto surface differences.

4 Conclusions

We see that some design features appear to influence student performance. In particular, incorrect answers and the model response seem important for helping students recognize the need to revise. What appears to be lacking are features which lead students to improve their explanation quality as they revise. Furthermore, differences in coverage do not appear to influence explanation quality or revisions. Perhaps this is because students do not refer to much content in the first place, so any potential benefit from a more well-connected module is mitigated.

According to the *STC* designers, revision should be a key process when students answer the inquiry questions (Dershimer et al. 1992). Substantial revision in the sense of improved explanations is not taking place. Why not? We see that students revise when the inquiry question choice is hard (when they choose the wrong answer). Perhaps the questions need to be harder or trickier. But also, the nature of the interaction – merely expecting students to revise – does not seem to encourage engagement. Students need feedback on the quality of their explanations. A different response model can be seen in the Evolutionary Thematic Explorer (Jacobson 1997). In that system, students choose statements from a list and then have their answers critiqued with respect to two major theories of evolution. Experimental results show learning occurred. Perhaps similar activities here would help: students could assemble an explanation from sets of statements that either capture key concepts or highlight common misconceptions.

Furthermore, students need an incentive to revise. While the inquiry questions were used here as the primary instructional activity, they are in one sense just another navigation mode. Students are supposed to choose the mode that best helps them learn. Discussions with the primary designer indicate that reliance on inquiry questions might best be used in a classroom where considerable discussion takes place before the final explanation is written (Dershimer 1996). At a minimum, if these questions are to be used as an assignment, the graders need to pay attention to whether or not and what kinds of revisions students make. Without the external motivation of a grade that takes explanations into account, many students will not make the effort to learn the material or to express their understanding.

Our experience identifying the extent of criss-crossing would be a useful exercise for hypermedia designers. Visualizations such as we created can help identify the gaps in coverage at the design stage, rather than in a later analysis. When we began this study, we thought "criss-crossing" referred to the content design: are the content cards related and cross-linked? do the inquiry questions lead students to visit all the cards? But what we see instead is that the design of the questions itself – are they hard? do they reveal common misconceptions? – seems to have considerable influence over whether or not students make substantial changes in their explanations.

Abstract: A component framework for implementing Web-based learning activities, customisable for local discipline and teaching requirements, is proposed. The framework is based on a standard protocol for describing and recording the state of Web pages containing arbitrary arrangements of HTML input elements and/or interactive objects constructed in JavaScript, Shockwave or Java. The State Description Protocol lays the foundations for independent development and reuse of software components with which learner activity can be recorded, analysed and re-created. Learning activity pages may contain embedded references to previous tasks and provide conditional feedback to student input by way of additional components. The framework philosophy is to provide flexibility in educational design, multiple paths to adoption and to maximise collaborative sharing and reuse of both components & pedagogical techniques.

Background

The Multimedia Education Unit is a central academic unit supporting the University in its move to integrate technologies into 'transformed' curricula. It provides educational design, evaluation, media & programming services and runs staff development programs. The Unit is involved in the development of a range of faculty projects where local academic knowledge is the key to understanding learning and discipline requirements. The Unit has a central role in recognising, developing and promoting techniques that will facilitate effective utilisation and transfer of this expertise throughout the institution and further afield.

Educational technology is increasingly being focussed on the more open, flexible and apparently democratic world of the Internet. This move is not without its difficulties, given the wide range of possible solutions, the rapid evolution of technologies and challenges to individuals adjusting to new skills and roles. Finding a path through a complex and dynamic solution space involves broad consideration of educational, organisational, technical and individual needs. Integrated course systems such as WebCT and TopClass provide useful tools and templates for efficient management of learning and production of materials. In the process however, they also restrict flexibility of approach, for example in the use of customised discipline interfaces or in the richness of conditional feedback. The model proposed is intended to supplement the capacities of such integrated systems.

Customised Learning Activity Scenarios

We have tried to address the need for high quality interactive learning while ensuring that both software and pedagogical techniques are scalable and transferable. Educational requirements targeted include the capacity to support:

- *customisable user interfaces* to discipline knowledge;
- *responsive feedback* to a student's actions;

- exercises involving with *subjective knowledge*;
- customisable learning sequences that can incorporate *elements of face to face interaction;* and
- *reflective summaries and overviews of the learning experience* for both student and teacher.

Such requirements are derived from the experiences gained working with faculty teaching staff on real course projects. For example, a structured learning sequence might be proposed by a teacher as a useful exercise for students in a particular content area. Scenarios such as this from different discipline areas are of prime relevance to the formation of a generic implementation framework. More detailed ones have been described (Fritze, Johnston & Kemm 1998). It is the teacher's understanding of student, content and teaching strategy, predating technical implementation considerations, that we are keen to harness.

This scenario illustrates how a simple sequence of learning actions might take place between a student (S) and mentor (M). It represents one approach of a teacher in a face to face tutorial, seeking to encourage reflective thinking.

1) S is presented with an issue and asked to articulate an initial interpretation
2) M suggests one relevant factor and asks S assess their own response to that criterion.
3) M provides feedback based on this assessment (2 & 3 are repeated with different criteria)
4) M then recalls the initial view and asks S to re-examine this initial interpretation.
5) S receives a summary overview of key points, demonstrating how their initial interpretation has developed.

The learning sequence is expanded (Fig. 1). If such an activity were to be facilitated, not by face to face communication, but by an online computer, simple text entry fields and check buttons are probably adequate for articulation of responses 1a, 2a & 4a. A sequence of disconnected questions however, would not be sufficient to capture the full spirit of the dialogue. For example, analysis of the response 2a is necessary for useful feedback (3). In addition, the initial hypothesis is recalled in later tasks (2 & 4) and again in the summary overview (5). Knowledge of the student's actual efforts needs to be maintained for the life of the activity and could possibly be referred to in entirely different contexts in other areas of a course (6).

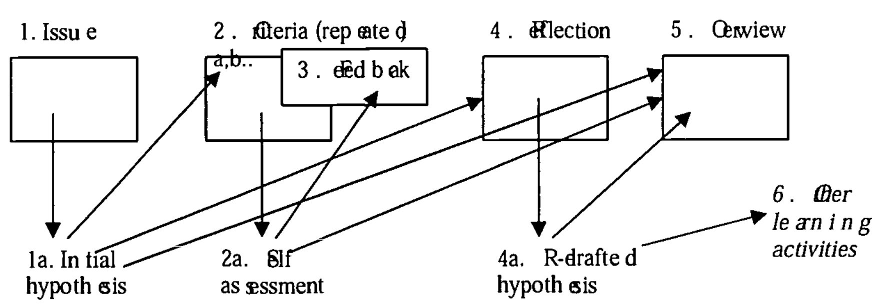

Figure 1: Stages of a reflective learning sequence 1-5. Student entries 1a, 2a, 4a are re-introduced to later tasks

This example represents a relatively simple face to face dialogue interaction to which many variations and extensions possible. We desire to construct such sequences within a practical online environment.

A Component Framework to Support Customised Learning Interactions

A component architecture to facilitate synthesis of online learning scenarios of the type above is illustrated (Fig. 2). This has evolved from an earlier work (Fritze & Ip 1998) in which a central 'activity manager' object running in the browser controlled the entire process. The new modular architecture has enabled the integration of components and techniques from other projects, for example the Virtual Apparatus framework (Ip et al. 1997) and Component-based Object Library (Ji et al. 1998). Web pages can now be light in weight, with simpler, easier to maintain software. Additional components can be created in whatever technology is appropriate.

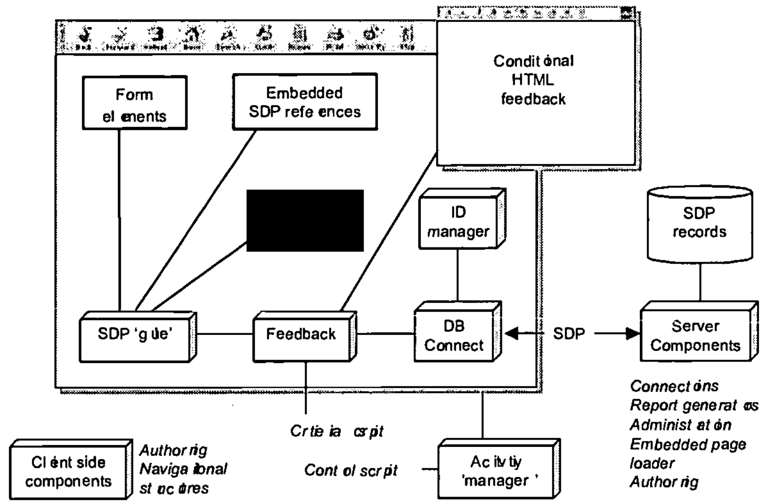

Figure 2: Learning Engines components and protocol framework.

A browser page contains visible user interface components such as forms elements and interactive Java or Shockwave objects. These are connected by a common State Description Protocol representing the state of the page as described below. SDP conforming components are supported by a 'glue' script and linked to a database via other components. Additional functions can be added to provide specialised feedback or management of page sequences, for example. Various page configurations are indicated (Tab. 1) with those required in the described learning sequence (Fig. 1) numbered.

Page Style	SDP glue	Interactive I/F object	DB/ID connect.	Feedback Comp.	Embedded SDP refs	Notes
Resource page	R	o				Page containing HTML form elements and/or interactive objects can be set to particular states on loading or by clicking different HTML buttons.
Basic saved page (1)	R	o	R			Page state is saved to and retrieved from a corresponding record in database.
Conditional feedback (2)	R	o	o	R		A feedback component analyses and responds to page state according to criteria statements.
Embedded SDP References (2, 5)	o	o	o	o	R	Page containing embedded references to SDP records of any activity. Rendered by a loader component as a summary document, activity map, progress log etc.
Redrafting task (4)	R	o	R	o	R	Previously submitted SDP entry inserted into a new task for redrafting.

Table 1: Possible configurations of page components for different learning purposes. Each page requires certain components (R), others are optional (o). Numbers in brackets refer to page structures used in figure 1.

Interface Components

In addition to HTML text fields, radio buttons, checkboxes, popup menus , framework Web pages may contain interactive objects developed in JavaScript, Shockwave or Java. For example, a large number of specialised components have been written in dynamic HTML for an online course in Chinese language (Ji et al. 1998). A Shockwave object for graph sketching is illustrated here (Fig. 3) and others have been described (Fritze & McTigue 1997). The essential characteristics for such interactive objects are that they:

BEST COPY AVAILABLE

- operate within a browser page supported by basic 'glue' scripts;
- register their current State Description to the controlling page in response to student actions; and
- can configure themselves to a certain State Description if instructed by the controlling page.

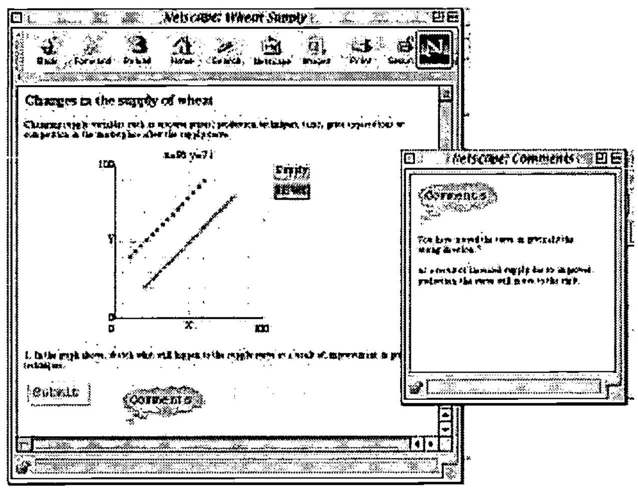

Figure 3: A Shockwave graphing object and assessment component combined on framework page to provide conditional feedback based on the State Description of an entered graph.

Representation of State – the State Description Protocol

The central element of the Learning Engines framework is the ability to record a snapshot of a learning activity page containing any combination of forms elements or conforming external interface objects. This is specified in terms of a State Description Protocol (SDP) that can be used to record the student entries, restore previous page states and for analysis of students input. The SDP is a 'list of lists' consisting of property/value pairs, where a value may be a string, a number or another list as in the following form:

{prop1:value1, prop2: {subprop1:value3, subprop2:value4 }}

The SDP syntax relates closely to object structure representations in both JavaScript and Director Lingo as well as to the pedagogical learning elements. Not immediately obvious is that the SDP string format requires no special database configuration for different page configurations and rich descriptions of the customised pages and embedded objects can be readily defined. For example, the SDP for the above page (Fig. 3) containing a single 'graph' object set with one curve supplied by the question ('supply') and another entered by the student ('answer') is:

{graph:{supply:{style:"growthline", X1:20, Y1:20, th1:40, th2:220, X2:80, Y2:70},
answer:{style:"growthline", X1:10, Y1:40, th1:45, th2:225, X2:60, Y2:90}}}

Assessment and Feedback Components

The use of SDP facilitates analysis of a student's input and formulation of appropriate responses. The SDP string above contains detailed information with which to interpret the curve entered by the student (Fig. 3). The 'Submit' assessment component on the illustrated page (Fig. 3) has established that the style of the curve 'answer' is correct (graph.answer.style = 'growthline'), its gradient is correct (graph.answer.th1 = 45), but that its coordinates place it incorrectly.

A number of feedback components have been developed, ranging from very simple JavaScript functions that compare the SDP of a page with a preset value, to one controlled by an XML criteria specification to progressively reveal feedback comments and provide access to further tasks. Further feedback mechanisms can be developed as required for particular purposes.

Embedded SDP References

The learning sequence (Fig. 1) requires that page states be carried forward into other pages. This is achieved by embedding references to the stored SDPs within the HTML of a page. When displayed by a loader component, these references are expanded with the latest state information from the corresponding database SDP record. In this example the overview page (5) refers to text entered as the initial hypothesis 1a, as well as to the self-assessments 2a and the redrafted entry in 4a. The embedded reference could be contain text, HTML, or even the state of an interactive object such as the curve entered in a graph sketcher above. This capacity to refer to any element of work submitted makes possible a range of useful learning functions, such as progress reports, entries in learning 'journals', summaries of key points or dynamic content maps. Such a page could serve multiple purposes such as an overview of the issues and a navigational menu (Fig. 4).

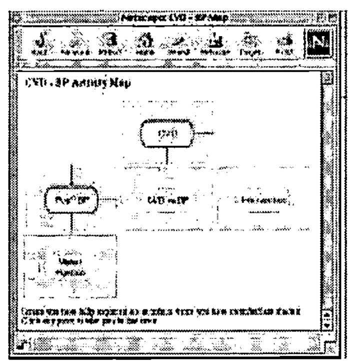

Figure 4: A map page representing the progress of a student as a 'jigsaw'. Each piece is an embedded reference to the SDP of an exercise page and is filled in as the student completes the activity. The pieces contain links to the relevant activity.

Conclusion

We have attempted to relate closely to coal-face educational requirements in building the foundations of a framework for customised on-line learning interactions. Such requirements relate at least in part to the features of face to face dialogue. Central to the pedagogical and technical operation is a protocol for memorising and analysing the states of Web pages containing an arbitrary arrangement of input elements or interactive objects. These records of student activity are accessible from any other page, enabling the construction of simple but useful learning structures.

Since the initial writing of this paper, the Learning Engines framework has been incorporated into OCCA, an Online Courseware Component Architecture under development at the Multimedia Education Unit. OCCA formally brings this work together with other online technologies developed at MEU: the Virtual Apparatus framework (Ip et al. 1997) and Component-based Object Library (Ji et al. 1998). During 1999, over a dozen internally funded University projects will use this architecture. Work in MEU will concentrate on facilitating the direct involvement of Faculty academics in the production of materials. This will involve collation of exemplars of interactive question configurations, the running of workshops and the evaluation of techniques developed.

While online interactions do not replace face to face dialogue, they can usefully supplement and enhance other approaches to teaching and learning. The flexibility offered by the framework can empower academics to think beyond what might be offered by more rigid delivery methods, for example, by integrated courseware systems and traditional lecture/tutorial environments. The intention is to encourage conception of novel learning interfaces and interactions that will operate in conjunction with other such approaches. It is hoped that the uptake of OCCA into the University and wider community will provide a productive environment in which components and learning techniques can be developed and shared.

Abstract: This paper discusses cultural factors in user acceptance of human-computer interfaces and presents findings from the first phase of the development and evaluation of two versions of a multimedia program *"Learn About PCs"* (British version and Kuwaiti version).

The purpose of this study is to evaluate users' perceptions and opinions about two versions of *Learn About PCs*, its usability and suitability to the users' culture, highlighting some issues which designers may consider when designing multimedia programs for different cultures. The study was able to uncover several interesting findings and to make recommendations which are useful for redesigning the two versions of *Learn About PCs* . The overall results of this study confirm that most of Kuwaiti students preferred the Kuwaiti version of the multimedia program while most of British students, British experts, and Kuwaiti experts preferred the British version of the program compared to the Kuwaiti one.

1.0 INTRODUCTION

It is believed that culture is a discernible variable in interface acceptance, and that interfaces should be designed to accommodate users' culture (Del Galdo 1996, Fernandes 1995, Uren et al 1993, Nielsen 1990). Since there has been little research in the area of designing multimedia learning programs for different cultures, this study is intended to underline and see where the issues lie and how they might be investigated.

Two versions of *Learn About PCs,* a multimedia learning program, have been designed, one for British and one for Kuwaiti Higher Education (HE) students. They carry the same content and structure, but they are different in the way that media elements are presented on the screen. The two versions have been designed and developed not only to look at how the interface worked and how successful it was, but also to examine some presentation and screen design differences which accommodate both the British and Kuwaiti users. The program does not give a detailed knowledge about computers, but rather provides learners with all-round grounding in the concepts involved which serves the intended outcome of the study. The objectives of this study are as follows:

1- To identify some presentation design issues when developing multimedia programs for different cultures.

2- To evaluate the usability and the suitability of the two versions of *Learn About PCs* for the British and Kuwaiti HE students, and to provide some recommendations for future designs.

2.0 THE DESIGN OF *"LEARN ABOUT PCs"*

Learn About PCs was designed and authored using *Asymetrix Multimedia Toolbook version 4.0.* The process for designing the program were identified as information design *(defining the content and the audience),* interaction design *(defining the navigation, types of interaction, and control),* and presentation design *(defining the style and the layout of the elements).* Theories and issues which contribute to an effective interface design were taken into account, such as: ease of use, consistency, visual representations, etc. The prototype of *Learn About PCs* was originally designed to suit British HE students. The design intentionally followed a set of theories and guidelincs outlined in the British literature (Boyle 1997, Vossen et al 1997, McAtter and Shaw 1995, Davies et al 1994, Leonard 1994, Preece 1990).

3.0 DESIGNING THE KUWAITI VERSION

In order to achieve the objectives of this study as outlined in the introduction part of this paper, the initial program *(British version)* was redesigned producing a version of the program which suits Kuwaiti HE students *(Kuwaiti version).* Since there is not much work published about designing multimedia interfaces for Kuwaiti or Arabic cultures, the researchers have identified some presentation design differences based on their investigations and their knowledge about the Kuwaiti and British cultures. Some differences were identified as: *Buttons and icons, Background Colours, Frames and Borders, Graphics, Music, and Speech.* Based on these differences, *Learn About PCs* was redesigned while other issues such as: content *(in English language),* structure, functionality, navigation links, and screen layout were kept the same.

4.0 METHODOLOGY

The procedure followed in the evaluation of *Learn About PCs* consisted of various phases which have been identified by (Catenazzi et al 1997). These phases are: *Selecting the technique; Preparing the evaluation; Conducting the evaluation; and Elaborating data.*

4.1 SELECTING THE EVALUATION TECHNIQUE

The first step of *Learn About PCs* evaluation was the choice of the most appropriate evaluation technique, taking into account the stage of development of the prototype and the research context constraints. It was believed that the most suitable way for evaluating the program was a limited survey technique, in which a semi-structured interview was used.

4.2 PREPARING THE EVALUATION

The preparation of the evaluation involved *selecting the participants; arranging the semi-structured interview; and defining the tasks* which are necessary to obtain feedback from the participants.

4.2.1 PARTICIPANTS

With respect to the selection of the evaluators, the researchers took into account the *Learn About PCs* evaluation objectives, that is to verify that the two versions of the program are suitable for the users' culture. Therefore, two groups of potential users were required (Experts and Students). Seventeen experts *(6 British and 11 Kuwaiti)* and nine HE students *(4 British and 5 Kuwaiti HE students).*

4.2.2 INTERVIEW

The semi-structured interview was arranged to elicit evaluators' opinions with the aim of assessing the usability and suitability of the two versions. The interview form was divided into four parts: Part One was concerned with participants' personal information; Part Two was concerned with common design issues and the usability of the program; Part Three sought evaluators' opinions about the differences between the two versions of *Learn About PCs* and their suitability to their culture; and Part Four was concerned with evaluators opinions about the preferred version and their general comments and suggestions for improvements.

4.2.3 TASKS

With respect to the task selection, taking into account the objectives of the study, users were asked to navigate and interact with the two versions of *Learn About PCs* by turning pages, activating links, playing media, etc. insuring that they went through and interacted with the whole program. They were asked to observe the differences between the two versions which were identified in section 3.0. It took about one hour to complete all of these tasks. It was considered useful to have their comments and opinions about the program's usability, utility, and suitability directly, by asking them a number of questions while they were interacting and recording their feedback immediately before the semi-structured interview which was planned to be accomplished after completing the tasks at the end of each session.

4.3 CONDUCTING THE EVALUATION

After the preparation had been completed, the evaluation process started. The evaluation took place both in Kuwait *(Kuwaiti experts and students),* and in Britain *(British experts and students).* Subjects were informed that they are not being tested, rather it is the system that is being tested. The evaluation execution was conducted individually, that is, one user at a time in order to follow and observe them during their interaction, stopping them when needed, asking questions, and taking notes about their comments and suggestions. The evaluation process lasted between one hour and one hour and a half including the task and the interview at the end of the session. The evaluation time varied, that is because some evaluators were interested in the program, giving more comments and suggestions and raising many questions, while others, *(mainly students),* were strictly accomplishing the tasks, and finally answering the interview questions, giving some comments and recommendations.

4.4 ELABORATING DATA

The data produced were elaborated, in order to transform them into findings and recommendations for improvement. The evaluation results are reported in the following section.

5.0 RESULTS

Significant differences were found between evaluators opinions about the two versions of the multimedia program. The results of the evaluation are summarised in (Tab. 1) through (Tab. 8). Note that the scale used for (Tab. 1) is represented by *(Scale: 5 = very much and 1 = not at all).*

Questions	Kuwaiti Students	British Students	Kuwaiti Experts	British Experts	Average
1-Are buttons and icons in the British version meaningful?	3.8	4.5	4.1	4.3	***4.2***
2-Are buttons and icons in the Kuwait version meaningful?	2.9	3.4	2.7	2.9	***3.0***
3- Did you like background colours in British version?	3.8	3.5	3.4	4.2	***3.7***
4- Did you like background colours in Kuwaiti version?	3.6	3.5	3.3	2.8	***3.3***
5- Did you find frames and borders in the British version appealing?	3.8	3.8	3.4	4.0	***3.8***
6-Did you find frames and borders in the Kuwait version appealing?	4.0	3.5	3.1	2.8	***3.4***
7- Did graphics and images in the British version reflect British culture?	4.0	3.3	4.2	4.0	***3.9***
8- Did graphics and images in the Kuwaiti version reflect Kuwaiti culture?	4.0	3.8	3.9	4.0	***3.9***
9- Did you notice the differences in "graphics" in the two versions?	4.4	3.8	4.1	4.3	***4.2***
10- Is music appropriate in the British version?	4.0	3.3	3.7	3.0	***3.5***

6.0 DISCUSSIONS

This study was able to uncover several interesting findings and to make recommendations to designers when designing multimedia programs for different cultures. The overall results, as shown in (Tab. 8), confirm that most of the Kuwaiti students, taking their comments and suggestions into account, preferred the Kuwaiti version of the program while most of the British students preferred the British version. In addition, most of the British and Kuwaiti experts preferred the British version of the program stating that "It has a standard and simple look and feel" compared to the Kuwaiti one. The following is an interpretation of the tables shown above.

6.1 BUTTONS AND ICONS

As shown in (Tab. 2), participants were more positive about buttons and icons in the British version than the Kuwaiti version, mainly because they believe that buttons and icons are more simple and clear. (Tab. 1) reveals that the average score of participants' opinions about buttons and icons in the British version is 4.2, while in the Kuwaiti version is 3.0. Out of evaluators' responses, it is learnt that it is essential to improve buttons and icons in both versions with emphasis on placing drawn graphic icons *(rather than the bitmaped icons)* for the Kuwaiti version keeping them as simple and standard as possible, and design them to better reflect the Kuwaiti culture.

6.2 BACKGROUNDS AND COLOURS

The dominant background in the British version is textured grey as suggested by (Boyle 1997), and for the Kuwaiti version is textured dark brown, as it is the norm for most of the Kuwaiti Press which represents the Kuwaiti desert environment. As shown in (Tab. 1), the average score for background colour in the British version is 3.7 while for the Kuwaiti version is 3.3. (Tab. 3) reveals that British and Kuwaiti students have similar degree in liking background colours for both versions, while British and Kuwaiti experts were clearly positive about background colour in the British version.

Although the use of colours can carry different meanings for different cultures, there have been, as noticed from participants comments, a lot of contradictions which indicates that colours should not be a cultural issue, but rather a personal taste when developing multimedia programs. In addition, background colours should fit with the domain which the application covers.

6.3 FRAMES AND BORDERS

The British version was designed with normal borders which were represented by lines around both the main screen and the information area. However in the Kuwaiti version, two Islamic frames *(borders)* were used, one around the screen, and one around the information area. The objective of the use of frames in the Kuwaiti version was to add Kuwaiti cultural taste to the program.

As shown in (Tab. 1), the average score for participants' response was 3.8 when they were asked whether the frames in the British version were appealing. On the other hand, their average score for the Kuwaiti version was 3.4. (Tab. 4) reveals that the majority of Kuwaiti students and Kuwaiti experts preferred the Kuwaiti version in terms of the use of frames and borders, while the majority of British students and British experts preferred frames and borders in the British version. This part of investigation shows that Kuwaitis liked the use of Islamic colourful frames in the program, because their eyes are used to, however, they suggested to improve frames' quality, and to make better selections.

6.4 GRAPHICS AND IMAGES

Graphics and Images were scanned and imported in the two versions. They were used in the British version to reflect the British culture *(Such as British people or places),* while some graphics and images were used in the Kuwaiti version to reflect the Kuwaiti culture. (Tab. 5) reveals that the majority of Kuwaiti students and Kuwaiti experts preferred graphics and images in the Kuwaiti version, while most of British students and experts preferred graphics and images in the British version.

6.5 MUSIC AND SPEECH

Kuwaiti music were incorporated with the Kuwaiti version and British music were incorporated with the British version. As illustrated in (Tab. 1), the average score for evaluators' opinions about the appropriateness of the use of music in the British version and Kuwaiti version were 3.5 and 3.7 respectively *(Scale: 5 = very, 1 = not at all).* (Tab. 6) reveals that most of Kuwaiti students and experts preferred music in the Kuwaiti version, while British students and experts liked music in the two versions equally. Some British evaluators suggested the selection of better music, while others suggested to improve the quality of the music for the British version.

In addition, speech was performed by a Kuwaiti person *(speaking English)* for the Kuwaiti version, and a native British person for the British version. As illustrated in (Tab. 1), the average score for evaluators' opinions about the appropriateness of the speech used in the British and Kuwait versions were 4.2 and 4.0 respectively, *(Scale: 5 = very, 1 = not at all).* (Tab. 7) reveals that all of the Kuwaiti students preferred the Kuwaiti speech while Kuwaiti experts preferred speech in both versions *(could be because most of Kuwaiti experts have studied English abroad and lived with native English speakers).* On the other hand, most of British students and experts preferred speech in the British version.

7.0 RECOMMENDATIONS FOR NEW DESIGN

As the two versions of *Learn About PCs* are going to be redesigned based on the results of this study, we will summarise recommendations when redesigning the two versions. The objective is to increase the suitability of the two versions to users' culture:

1- Use standard icons for the two versions, however, remove the scanned images which were used as icons in the Kuwaiti version and replace them with drawn graphic icons which reflect objects in the Kuwaiti culture.
2- As participants have different perceptions about colours in general, and as colours seem to be a personal taste rather than cultural issue in this matter, background colours should be similar in the two versions. Light blue, light brown, or light grey background could be convenient for the two versions.
3- Improve the frames in the Kuwaiti version, choosing better and more culturally related, using only one or two types of frames throughout the program.
4- Improve the quality of graphics and images used in the two versions, add more graphics and images which are closely related to British and Kuwaiti cultures.
5- Change the type of music in the two versions, improve their quality, and make better selection.

Abstract: In 1998 a tool called the "Virtual Constructing Tool" (VCT) was developed within the Faculty of Policy Sciences. The VCT aims to facilitate the process of reading, discussing and producing papers with construction and communicating tools and is completely based on the use of the Internet. Each course in which the VCT is used is divided into two parts. In the first part, students construct their own knowledge system. In the second part, personal findings and opinions merge into a joint presentation. In this presentation, the leading part is played by the structuring of information with the help of hyperlinking. This paper shows the fundaments of the VCT and describes its main features. More information can be found on http://www.kun.nl/vct.

Introduction

The Faculty of Policy Sciences attaches significance to teaching in small groups with much student involvement and interaction between students and teachers. Students frequently work on co-operatively assignments, which result in a joint paper. The advantages of group work (see for instance, Eurelings and Rontelkap (98)) are strengthened by the use of hypermedia. Because of the increased user-friendliness of the Internet, a window has been opened to the development of a learning tool, which is completely based on the Internet standard. This tool is called 'Virtual Constructing Tool' (VCT). The VCT aims to enrich learning processes within groups and finally, it is "just as any co-operative learning method, a unique solution to the problem of how to structure a classroom" (Kagan 85).

Communication and action

Years ago, Bateson (51) distinguished the 'report aspect' and the 'command aspect' within communication. In the 'report aspect' communication is reduced to the transmission of information between people. For instance, a teacher recites new theoretical insights with respect to a subject. There is no need for action as a response to the information. The receiver of the information only has to remember the information and to be able to recall it on demand.

The transmission of information from one person to another also can be interpreted as a regulative act. The teacher's announcement that theory 'X' is most common, might result the studentswriting this down in their notes. It is the 'command aspect' that is responsible for this change in students' behaviour. Changes in behaviour can influence the different actor's interests. If information threatens the interests of the receivers, they will not only reconstruct the message but also question its content. They might reject its behavioural consequences and opt for a discussion with the sender of the message.

Critical social theory (CST) recognizes this possibility. This theory views people as intelligent actors who assess the truthfulness, completeness, sincerity and contextuality of the message they receive. A listener or reader can go beyond achieving a mutual understanding with the speaker or writer. This is accomplished by critical reflection, which assesses validity claims which pertain to what the speaker or writer means. The listener questions these validity claims and sees that it is incomplete, false, unclear or inappropriate. What CST offers is the recognition that communication among everyday actors also involves their need to assess the validity or justification of what is being communicated in the first place Ngwenyama and Lee (97).

Two stages

The CST has many applications. In this paper CST is a point of departure in the exploration of the contribution of hypertext in collaborative learning in general, and in the production of group papers in particular. Two stages can be distinguished in the accomplishment of a paper: reading and writing.

The reading stage

In the initial stage of the production of a paper, the reading of articles and books is a common phenomenon. The preliminary problem-formulation acts as guide. Reading is a process in which relevant facts and different views are listed. Gradually different insights are related and a view of the authors themselves arises. In the reading stage hypertext is used to collect and present information. In particulary, hypertext is a useful tool in relating different texts. Many authors claim that hypertext is superior to conventional texts in representing the interconnectivity of concepts (Berk and Devlin 91, Jacobson 93, Mayes 90) and therefore, the production of knowledge. Knowledge is taken to be a semantic network of related concepts. During the reading stage a personal classification of pieces of information grows. Research into the effect of the reading of hypertext documents on the integration of knowledge is an ongoing process (Jonassen 89, Siemon 95, Eklund 95).

An additional advantage of the use of hypertext is that articles quoted can be made accessible as a whole. By making hypertext links to summaries of relevant parts of their sources, students increase the clarity and solidity of their argument.

Some authors stress the role of hypertext in the process of the construction of meaning. Hypertext forces the reader - more than in the case of conventional reading - to actively relate different pieces of information (Landow 92, Jonassen 89). The resulting individual web of knowledge serves as a point of departure for communication with other students. However, effective communication requires a logical structure of information. The individual web has a logical structure for the individual student but not for the other group members. Structuring information in a logical order for members and other readers is one of the main targets of the writing stage.

The writing stage

If a certain threshold in the reading stage has been surpassed, then the writing stage will commence. Authors usually aim at convincing their audience and therefore papers take the form of an argument. The delivery of this argument requires restricting the readers' freedom to jump from one part of the argument to another. Instead, the author should present a degree of structure and sequence. The necessity of putting structure in a paper constrains the otherwise desirable network structure of information. A network structure offers only limited possibilities of determining what the sequence of an argument is. As a consequence, in the writing stage a structure based on hierarchical branches is preferred. Hypertext is deployed to facilitate this kind of structuring. Structuring based on hierarchical branches has several advantages:

The paper may contain many details and side-steps without damaging the main line of argument.

Students are forced to distinguish between bits of information according to their rank of importance in view of the argument.

The copying of pieces of text form others, schemes and definitions can be omitted. Hyperlinking to the original sources (of excerpts) suffices. More time and space are left for the student's own line of thinking and supporting facts and arguments.

Hierarchical branching offers lengthy possibilities for validation by the readers who feel its necessity. Those who prefer the reader's argument for its own sake will skim over additional elaboration.

The CST proposes that while reading a text, conveying of the meaning may include more than just understanding the writer's argument. The reader is entitled to critical reflection / validation (Kunneman 83). According to Habermas, each type of social interaction brings about a set of validation claims of its own. Ngwenyama and Lee (97) differentiate between instrumental, communicative, discursive and strategic action. Writing a paper is considered to be a communicative action. The main objective of writing a paper is discussion which possibly results in agreement. The possibility of validating the writer's claims is important while reading an argument. Hypertext is a tool 'par excellence' in the case of two kinds of validation claims: completeness and truthfulness.

Completeness: In writing papers with hypertext, it is no longer 'What is the content?' which is the main question but 'Where should I put this piece of information?'. Recording several types and quantities of information is allowed. The number of pages is not a significant restriction to the content of a paper anymore. Redundancy in the inclusion of facts and visions is also allowed. Each paper contains virtual archives which can be used for validation purposes or just for curiosity"s sake.

Truthfulness: Hypertext allows references to an abundance of articles, statistics and books. By enabling the reader to consult original sources, the verification of the validity of their application is within reach.

This option is not meant in the first place to discover deceit. However, it is commonly known that authors unconsciously interpret their sources in a way which is more advantegeus to themselves. In addition, more insight is offered in thc contextuality of the sources. Rasker et al. (98) talk about 'activity-based transmission of information'. Anderson's ACT-R theory explains the power of hypertext. This theory poses that the delay between the content of someone's reading and the reception of feedback influences learning. The bigger the delay, the less learned (Anderson 93). Hypertext allows for immediate feedback in a number of cases. For instance, incredible views can be checked immediately if supporting hyperlinks are provided. In the case of written texts, the threshold for consulting sources is usually unpermeable and only a few readers will engage in the painstaking search for sources in libraries. The addition of original sources increases their accessibility.

Reading the authors' sources adds to the understanding of the writer's line of thinking and contributes to the development of meaning and the reader's own personal interpretation. Reconstructing the writer's argument, he of she turns to the construction of his of her own insights (Schank 94).

In the case a of disagreement between the readers and the author of a paper, the readers should ideally also become writers too, and express their lines of thinking, by using hyperlinking as well. The original writer can respond and so forth.

Hypertext and the structuring of information

According to Beeman (Mayes et al 90), hypertext learning systems can fundamentally change students' learning. While building a hypertext system, students organize information in a non-linear way. Structuring information in a non-linear way stimulates the processes of integration and contextualisation. By making hyperlinks, existing knowledge and new information are consciously integrated. Students are constantly stimulated to construct new knowledge structures. Interchanges between the old and the new structures signify an increase in learning.

Pointing out the advantages of hypertext does not necessarily mean taking a position in the debate between the devotees of linear versus non-linear representation of knowledge (Ess 96). In fact, it is the degree of linearity or structure that counts. Jonassen divides hypertext into twe catogaries, structured and unstructured hypertext. In unstructured hypertext linking has no rules (Jonassen 89).

A fundamental belief behind unstructured hypertext is the desirability of relating information by means of association (Berk & Devlin 91). However, readers will comprehend the coherence within the information only if they share each other's associations. Because of a personal bias in regard to associations, this will not often happen. Maybe this is the reason why many users feel lost in a hypertext network (Mayes et. al 90)

Unstructured hyperlinking is allowed only for private purposes. Our students are urged to build a knowledge web of their own. Hypertext is used here in order to collect information and to relate pieces of information together. In the realisation of a group paper, unstructured hyperlinking is not tolerated for reasons of communicating effectively and the necessity of logical arguing, which implies imposing some direction and sequence.

According to Landow (92), linearity is not only typical in the traditional presentation of papers but it can also be found in the building blocks of a network structure. A network structure offers the possibility for readers to choose a sequence themselves. The more the author's goal is to convince readers of his or her argument, the more structure and guidance is implied. Within a predetermined structure, hyperlinking is a usable means for indicating alternative paths and viewpoints.

A predominantly linear structure is preferable in case of an argument, in a situation in which convincing another person is of essence. A non-linear structure offers more possibilities if an inventory has been made of knowledge structures or belief systems.

The role of the teacher

The value attaches to hypertext is based on the acceptance of constructivist principles in regard to teaching and learning: In a constructivist view, teaching is the facilitation of the rediscovery of knowledge and the conveying of meaning to various parts of the world. It is not the delivery of information. Students acquire knowledge if they become involved in an active construction process. They have to read texts, to compare various views of diferent authors and to be able to formulate their own views. The writing of an argument is a useful tool in reaching these objectives. The teacher can support students' construction activities by formulating an argument first and then inviting students to respond critically if it is necessary that they assume a perspective view themselves. To reach this goal hypertext is used, for instance, to admit students to the sources of the teacher's argument (Schank 94). Divergences from the teacher's thinking patterns, by reinterpreting his or her resources, deepens understanding.
A construction process, such as the one indicated above requires a permissive and discovery minded atmosphere in the classroom. The Virtual Constructing Tool (VCT) which is illuminated below offers ICT support in the students' collaborative reading and writing activities.

The composition of the VCT

The Virtual Constructing Tool has three different levels: the general level, the group level and the personal level.
General level: The general level is accessible to all visitors of the Internet. Everyone who deliberately or incidentally passesby can become acquainted with the course. E-mails can be despatched to the teacher and to the students. Students in their turn, will find schedules, learning materials, news items and answers to FAQ.
Group level: Students can log in to the group level by using a password. Only members of the group are admitted. The tools for writing a group paper are accessible from this level.
Personal level: The personal level is reserved for personal items, for instance, references, summaries, relevant links, messages to news groups and notes. As these items are all accessible from the Internet, students always have them at their disposal, regardless of the PC they use.
On this level, students make their own knowledge web, which consists of Internet pages dealing with their specific themes. These pages are the building blocks of the group paper.

Students are invited to design personal pages. It is a useful exercise, which contributes to the social atmosphere of the group. "Whether or not software tools designed to support collaborative learning will actually do so, depends mainly on to which extent the instructor and the students are able to create a social structure which supports these processes." (Keynes 97). Photographs of the group members also contribute to this goal.

The devices of the VCT

The devices of the VCT are divided into Construction tools, Communication tools and Help. All devices enable time and place independence. Obviously, students may have meetings or use more conventional tools such as a telephone or a faxmachine.

Construction Tools

The construction tools support students in designing Internet pages. Students have at their disposal style sheets and the so-called 'html bank'. Style sheets are ready-made Internet pages, in which students only need to type their own texts. A professional lay out and background is provided.
The html bank offers pictures, buttons, symbols and other graphic tools, so that students can use these to prepare their papers.

Communication tools

In addition to all the usual communication facilities, the students have course conferencing and the so-called 'mutation form' at their disposal. Course conferencing enables students to communicate with all the course members. They can type in a message or respond to messages they have received. All messages are presented in sequential order. It is possible to include links to the group level or to external Internet sites.
Students use the mutation form in order to propose mutations in other students' papers. Mutations may concern parts of the text of the inclusion or exclusion of links. The proposed mutations usually lead to discussion.

Help
Students' computer abilities differ considerably. The Help function offers a manual, answers to FAQ and a guide for seeking on the Internet. Of course, contacting the Webmaster is also possible.

Conclusion

The VCT is used during four different courses. In all of these courses, additional changes have been made in the use and appearance of the VCT. We should gain more experience before sustaining the possible advantages for using hypertext in writing papers. For the time being, these temporary findings can be given:
Students and teachers are used to strictly linear thinking. In using the VCT, they must abandon this way of thinking and become used to connecting pieces of information through hyperlinking. It takes time before they become accustomed to structuring information in this way. Afterwards, the assignment appeared to not be suitable enough for structuring information by means of hyperlinking. However, writing a paper in this way was not experienced as being more difficult than was usually the case.

In addition to all usual communication facilities, students can use the facilities within the VCT. However, in true practice, no one used these facilities. The reasons were mentioned, which were lack of speed and interaction. Insufficient computer equipment at home (whether they had an Internet connection or not) was also seen as a limitation.

Abstract: Technological diffusion in schools is a complex process that has not met expectations. The paper identifies a model adopted by a K-10 school of distance education: the *Multi-Dimensional Emersion Model of Technology Diffusion*. It analyzes the process, including technical, pedagogical, and coercion and commitment issues. Evaluation of the outcomes of the whole school approach of the first year of adoption revealed general approval of the process, some disquiet concerning overt recognition by administration, and a majority who were able to move outside their comfort zone.

During the last decade we have witnessed a significant rise in the number of computers in schools. However, the integration of educational technology in school curricula still lags behind earlier expectations. Reports and researchers have tried to explain this gap, usually in terms of a failure by colleges of education to expose students to educational technology and to train them adequately in this area, budget limitations, the teachers' fear, reluctance, and often resentment to incorporate computer technology in their classrooms, and infrastructure organizational difficulties. Effective technological innovation is such a complex process and so difficult to accomplish within school cultures that the literature identifies "islands of excellence" (Willis, 1996). This paper reports the first year phase in a Pre to Grade 10 school of distance education's journey to create such an island. The specific aims are to identify the model of technological diffusion adopted, analyse the processes, procedures, and conceptual frameworks that were utilized, and evaluate the outcomes.

Methodology

A qualitative research methodology was employed. The study utilized the initial workshop evaluation, a needs assessment survey, a post 53 five point Likert Scale questionnaire, open-ended structured questionnaire, teacher project documentation, observational data from the teachers' presentations of their WWW project to their peers, and anecdotal evidence from the technology coordinator. The documentation contained teacher evaluations of computer software and WWW sites as well as unit plans detailing the incorporation of their selected piece of software and WWW site into their curriculum.

The Charters Towers School of Distance Education (http://www.chartowesde.qld.edu.au/) previously, School of the Air, is situated in North Queensland, Australia. It provides education to preschool to Grade 10 children, anywhere in Australia, who live at a distance to the nearest state school, are in hospitals, belong to travelling families, or are taught at home. The School's Development Council decides the strategic direction policies of the school but not its operations; it comprises equal representation from parents or caregivers and school staff. The school uses traditional means of communication like mail and telephone as well as radio for daily half-hour synchronous lessons between the teacher and students, video, television, and, since the beginning of 1998, the Internet to cross the barriers of distance and create the bonds of a school community. Where possible, face-to-face contact with students is achieved through structured student-family camps at the School when formal lessons are conducted and informal learning and socialising occurs between family and school, and by teachers through excursions, home visiting, and outreach activities.

All 37 teachers (Preschool through to Grade 10; one teacher-librarian, and two Languages Other Than English) were involved in the technology project. There were five male teachers and 32 female teachers ranging in age from 22 years to 50 years. Some had been in the school for up to eight years and were therefore experienced in distance education, while six teachers were appointed from regular urban public schools to the distance education school in 1998. Most had not extended their knowledge beyond the wordprocessing applications and the majority had had little experience with E-mail and even less with the WWW prior to 1998.

Results and Discussion

Our model of technological change, the *Multi-Dimensional Emersion Model of Technology Diffusion*, was identified from the data. Nevertheless, it is not surprising that it echoes theoretical models of school change or includes elements that other projects have identified as fundamental for successful diffusion. Understandably, it also contains innovative facets that incorporated aspects and shapes of existing practices and values particular to the Charters Towers School of Distance Education. The paper proceeds to discuss the model highlighting elements of similarity to, and difference from, other paradigms of technological diffusion and school change. The model is a combination of what we term, "markers-of-significance", that were put in place at the beginning of the technology diffusion project or evolved as it proceeded.

One of the markers identified in the model is the ***decision-makers.*** As the decision to focus on technology diffusion was made by the School Development Council, which involved teachers, it was not perceived as a "top-down" imposition by any of the teachers (Post Likert Questionnaire). The Council made certain global decisions or big picture decisions to do with school change. These global why, what, when, and how decisions involved a funnelling effect to the other stakeholders.

The "why" decisions involved the rationale and aims for the school to be at the forefront of computer information technologies so that the students would be well-served for the present and future. Effective school aims need to become the "common ground, the shared vision that compels all involved" (Meacutendez-Morse, 1992). All but four teachers supported the technology infusion in their professional lives and their teaching: "I embraced it as it is the way of the future for me and the students"; " I found it exciting as I could see its potential in student learning"; I enjoy the challenge of learning about technology" (Open-ended Questionnaire). In this respect the multi-dimensional emersion model reflects the re-educative/culture/fix-the-system attributes of Hord's (1992) generational model.

The "what" decision embodied aspects of the "fix-the-parts" and "fix-the-system" change model (Hord, 1992). It involved resourcing the vision or putting dollars where they would make a real difference. The school funded equipment, such as a laptop computer with a standard suite of software for each teacher, an Internet infrastructure and online costs, and a computer laboratory for in-school camps. Students' families were provided the opportunity to either purchase or lease a computer and printer from the school, including the standard package of software. The resourcing decision also resulted in the appointment of a teacher as a half-time information technology (IT) coordinator-half-time teacher. It was a significant resolution and commitment to change. This decision, which teacher representatives were party to, highlights the teachers' corporate commitment to the school's vision; their 100% agreement (Post Likert Questionnaire) meant they had to cover the IT coordinator's half-time teaching load when he wore his IT coordinator's hat training and mentoring the school community: staff, students, and home tutors. The multi-dimensional emersion model therefore did not lack appropriate resources which Boyd (1992, p. 25) argues has been "a major barrier to sustained change efforts".

The "when" decision resulted in a two-year time-line for information technology diffusion to be the school's major economic and pedagogic focus. This "fix-the-system" approach eschewed a global linear approach where step two did not start till step one was completed (Carr & Duchastel, 1998). For example, the school did not wait till all the staff had a laptop (the last few teachers received their laptop towards the end of the research) before commencing induction programs or appointing the IT coordinator. Twenty-one percent of the teachers (Post Likert Questionnaire) voiced a "too much, too soon" concern in their questionnaires. They would have preferred a linear approach so that they would only have had to cope with frustrations on one level, their own computer skill progress, rather than on a number of levels, including coming to grips with the pedagogic changes needed for incorporating the WWW into their teaching and technical failures (Open-ended Questionnaire). According to Geoghegan (1994), such a preference for incremental change as opposed to discontinuous and often disruptive breakthrough alterations in core processes is not uncommon.

The "how", fix-the-people - fix-the system (Hord 1992), decision resulted in an emersion model which involved all the teachers rather than a slower approach to training volunteers who would enthuse other staff to adopt the necessary pedagogic changes to their teaching. Louis and Miles (1990) preferred such a slower evolutionary method and cautioned that it's non-adoption could mean death to innovation. The teachers perceived the opposite with only 7% disagreeing with the items: "A small number of enthusiastic or knowledgable teachers should have been involved first" and "The Grade 6-10 teachers [the only grades whose students were provided with a home computer] should have been inserviced first" (Post Likert Questionnaire).

The major input into the nature of these global decisions came from the school principal, who also had the job of operationalizing them. One aspect of this was communicating the administration's and the School Development Committee's expectation that the staff would become meaningfully involved in the diffusion of technology. That expectation was accompanied by a high level of trust that this would naturally happen because trust meant recognition and acknowledgment of the teachers' professionalism. These sorts of elements appear to echo the empirical-rational and power-coercive strand of Hord's (1992) generational model. Operationalized, this meant the principal adopted a direct hands-off approach. The data reveals that the principal was definitely perceived by the teachers as a necessary catalyst for change. However, 21% of the teachers (Post Likert Questionnaire) would have appreciated an increased level of direct involvement, particularly in terms of individualized praise and understanding of what they were accomplishing.

The second marker of significance in our model of change was the ***IT coordinator.*** Casey's (1992) distributed expertise model emphasized the importance of leadership in school change, not just from the principal but also from others, such as an IT coordinator. This role was a two-way conduit-facilitator between the principal and the teachers. This duality was probably a significant factor in how the IT coordinator exercised his expertise. The teachers reported that he helped them develop images of "how to get there" that were tied to a workable reality. This is one of the factors that Boyd (1992) argues helps teachers develop a sense of ownership of the diffusion process. This perception suggests that all three generations in the "normative-re-education - culture - fix-the-system" model (Hord 1992)were in operation.

The how and what of inservicing staff was left to the IT coordinator. A multi-faceted model of professional development was adopted. According to Topp, Mortenson, & Grandgenett (1996), this is an important factor in school change because no one method of staff development works for all teachers. The Consortium for Policy Research in Education (1995) maintained that the most promising professional development programs are those that stimulate and support site-based initiatives because they are not isolated from classroom realities. The multi-dimensional emersion model certainly contained this ingredient. It was based on a needs analysis the IT coordinator conducted with the staff to ascertain their requirements and concerns. Inservicing involved traditional workshops, provision for peer collaborations, mentoring, and residential workshops.

The professional development program followed a linear time-line unlike the overall project which overlapped the phasing in of key elements. The reasons were specific to the school's context. The program capitalized on the division of the Australian school year into four terms of approximately ten weeks each. Each term had a distinct focus. The first phase of the inservicing was a series of non-compulsory workshops dealing with wordprocessing, spreadsheet, database, desktop publishing, E-mail, and WWW access and search skills. These were held weekly for most of the first term. According to the data, 93% agreed that this was a sensible approach (Post Likert Questionnaire); it allowed the IT coordinator and other new teachers to settle into teaching at a distance and all teachers to obtain a comparable level of technology skills. It also afforded staff a welcome distance from the networking hassles. In effect, it gave the teachers valuable time to begin to internalize what the school vision would mean in its actualization. Compulsory workshops were conducted in second term and third term to explore the pedagogy involved in evaluating and using educational multimedia software and the WWW, respectively, as teaching and learning tools. Each of these sessions involved three compulsory after-school workshops that addressed theoretical and hands-on practical issues. Teachers were not overly-disgruntled about having to spend their own time after a long day, being re-educated (Post Likert and Open Ended Questionnaires and Anecdotal Records).

The teachers consistently reported a very high rating on items ascertaining the facilitative effectiveness, level, and type of support of the IT coordinator with only seven percent undecided about the appropriateness of the level of support (Post Likert Questionnaire). During the whole process, the IT coordinator provided "just-in-time" mentoring and support for individuals and groups as either he or the teachers saw the need (Open-ended Questionnaire). Many teachers reported that they perceived the IT coordinator's praise and enthusiasm for their achievements as motivating and rewarding with a few explaining their belief that this attitude was not tokenistic as it was blended with useful critique (Open-ended Questionnaire). Sashkin and Egermeier (1992) concluded that the "more personal assistance and continuing support from a skilled and knowledgable local agent, the more likely that the innovation will be used for a long duration" (p. 7). Hopefully, long-term evaluation will prove this correct.

The third marker-of-significance in the model is the ***teachers***. For a variety of reasons, teachers are not particularly malleable to change (see Hord, 1992). Thc school principal made it clear to staff that the school's two year focus on the integration of technology this would involve commitment to the inservice that the IT coordinator devised. This certainly contains elements of the power-coercion - political - fix the people change model (Hord 1992) yet it also involves the re-educative - fix the system model (Hord 1992) because a majority of the teachers had taken on board their personal commitment to their re-education (Post Likert and Open-ended Questionnaires). The innovation involved exemption from non-project commitments, such as a residential workshop based off-campus at the district university, and after school hours workshops. Interestingly, few teachers commented negatively on these compulsory after-hour workshops (Likert Questionnaire). Many reported that the time was more than compensated by the chance "for working together and learning together" (Open-ended Questionnaire). It is not only technical resources that count but also the time and energy demanded of people to plan, share, observe, and take action. (Boyd, 1992).

Teachers were offered the opportunity to work individually, in pairs, or in a small groups on their curriculum units. Only four teachers and the teacher-librarian worked individually. Most opted to work in pairs for the interactive multimedia CD-ROM activity with most working as groups of three on the WWW activity. There appear to be four major reasons for their collaboration: (a) it permitted the pre-school and primary teachers to brainstorm ideas for their common grade levels while the secondary teachers collaborated in discipline areas; (b) time constraints meant collaboration allowed a reduction in individual time spent resource hunting and unit preparation; (c) it provided security through peer support; and (d), it divided the responsibility for designing units that incorporated the software and WWW site in meaningful contextualized ways. The data reflects what Boyd (1992) reported: skill building and training are part of the process of change and, hence, learning to do something new involves initial doubts about one's ability and incremental skill development.

Outcomes are obviously another marker of significance. The teachers' self-reported outcomes included: increased confidence; improved competency in computer skills and Internet usage, particularly search strategies; recognition of self and others efforts; ability to integrate CD-ROMs and the WWW as learning tools in their curriculum; using CD-ROMs and the WWW with students and witnessing their growth and enjoyment. A number still acknowledged their need for continued improvement due, in part, to not utilizing the skills or implementing the strategies regularly. There appeared to be little technofatigue. Three months after the first year, all but three teachers (one was indifferent) reported that they still found learning about technology and its incorporation into curriculum enjoyable and were "not getting tired of it": "No way!"; "To live is to learn"; "I 'm still learning and enjoy the challenges" (Open-ended Questionnaire).

Examination of the documentation data, their unit plans and the teachers' presentations of the WWW units, revealed that most teachers treated the professional development tasks seriously and professionally. The others handed in tokenistic work. A majority of teachers appeared to change their pedagogy to integrate new ways of teaching and learning into their curriculum. They had grappled with the necessary pedagogical changes to their thinking and practice. The Open-ended Questionnaire reported an acknowledgment of their successes and, for many, a current determination not to "backslide", as one respondent worded it. The outcomes of the minority group of teachers can be depicted as a brief sojourn out to the world of the Internet and interactive multimedia CD-ROMs. Overall, for the majority, the data revealed that their world was not the comfortable status quo oyster where a minority of the teachers still positioned themselves.

CONCLUSION

Any change paradigm, like the multi-dimensional emersion model of technology diffusion, will always incorporate elements of coercion, pressure, and support. It is getting the weightings and timing of them about right that is often crucial. The key to any change strategy is the word "persistence". Resource provision, professional development, teacher commitment, ongoing assistance, and recognition can not be one shot events or quick fixes (Hord 92; Beer, Eisenstat, & Spector, 1990). Currently, at the end of phase one, it seems that the change effort was more than an illusion for a majority of teachers. Implementation of phase two needs to monitor the "persistence" factors if long-term success is to be the outcome.

Towards the Virtual Class: Technology Issues from a Fractal Management Perspective

Philip Uys
Hydi Educational New Media Centre
Wellington, New Zealand
philip.uys@wnp.ac.nz

Abstract: This paper addresses the research question: *What are some of the key information and communication technology issues from a fractal management perspective when implementing the virtual class in conventional higher education?* It also suggests effective management strategies for dealing with the identified issues. The specific manifestation of the virtual class referred to in this study is when the virtual class is based on Internet and Intranet technologies. The term "networked education", coined by the writer is used to describe this expression of the virtual class. The study concludes that the implementation of the virtual class in conventional higher education has an extensive and profound impact on, and demands new ways of using and managing information and communication technologies.

1. Introduction

"The single most frequent failure in the history of forecasting has been grossly underestimating the impact of technologies"
Anon

The research question addressed in this paper is: *What are some of the key information and communication technology issues from a fractal management perspective when implementing the virtual class in conventional higher education?* This paper attempts to identify what some of the key technology issues are when the virtual class is implemented in conventional higher education and ways to address these.

Tiffin and Rajasingham (1995) argue that communications have a fractal dimension that is "a node in a communications network can prove, on closer examination, to be a communications network itself (p. 37). The technological issues are also viewed from a fractal management level that is to acknowledge the various levels and dimensions of management the management processes of the institute, administration, the departments (both academic and administrative), the design, development and delivery of teaching materials, the student's learning and so forth. "Management" in tertiary education does not refer to "administration" only. To limit management to administrative practices only and thus excluding the teaching area would be to argue that planning and decision making, organising, leading and control do not occur in the area of teaching, but only in administration. "Management" refers therefore to management on all levels of the organisation, both in the teaching and administrative.

2. Creating Visibility in A Virtual World

Rayport and Sviokla (1995) summarise the essence of the virtuality of the virtual class when they write about a corresponding phenomenon in the business world that they term the "marketspace" that is a virtual market place. They characterise it as being "virtual" because the value-adding processes "...are performed through and with information".

Tiffin & Rajasingham (1995) first used the term "virtual class" to refer to the learning process that is enabled solely by telecommunications. Tiffin & Rajasingham (1995) distinguishes the concept of the virtual class from the "Virtual Classroom" coined by Roxanne Hiltz (1986) as "...it suggests that the place a virtual class is held is an electronic simulation of a conventional classroom" (p. 10) because Hiltz described it as the use of computer-mediated communications "...to create electronic analogue of the communications forms that usually occur in a classroom including discussion as well as lectures and tests" (p. 95).

The virtual class can be described as the process that occurs when teacher, learner, problem and knowledge are joined solely through communication and information technologies for the purpose of learning and teaching. It is an educational experience of real people in a virtual dimension. In the virtual class the teaching and learning is performed without the movement of physical objects (eg getting students and lecturers into a physical venue).

The specific manifestation of the virtual class referred to in this study is when the virtual class is based on the Internet or Intranet technologies. The term "networked education", coined by the writer is used to describe this expression of the virtual class. Networked education emphasises the high level of connectivity that it enables through creating a network between student en student, student and teacher, student and resources, teacher and resources as well as the past and the present (through availability of on-line resources of one course occurrence for a next occurrence). It also indicates that the education is network-based (Internet or intranet) and computer-mediated, that it includes teaching, learning and research ("education"), and emphasises the distribution both of the control of learning, as well as the on-line learning and teaching materials among the students and teacher(s).

The virtual nature of this type of learning can remove the conventional prompts to assist the learner to focus on their studies for example when the lecturer starts to speak in a face-to-face on-campus lesson, or the arrival of study materials in paper-based distance education mode. It is therefore essential in the virtual environment to build in prompts to assist in this area for example automatic e-mail based on the course schedule as well as on the participation of each individual student.

3. Providing Mobility in the Virtual Class

The most significant loss students often experienced in an on-line environment are the lack of mobility of the study materials.

The affordability and weight of portable computers such as Laptop computers and notebooks negate these technologies from being an adequate provider of mobility. Smaller hand-held palmtop computers with infrared updating capabilities are a positive step in re-creating the mobility for on-line students.

Another development which is currently experimented with by MIT (Nicholas Negroponte at the 1997 ICDE Conference) and by commercial companies in the US, is to address and program pixels on paper which has all the characteristics of wood-based paper except that it is made of specialised materials. Pages in such a book can be loaded with information form the Web or other electronic sources and copied and pasted into other applications. Each page has a huge capacity to store information and can be continuously updated and reloaded. This will be a major breakthrough to provide students of the virtual class with both mobility and a totally new level of flexibility.

4. The Pervasiveness of Communication and Information Technologies in the Virtual Class

A complete set of technologies, which have become transparent through their pervasive integration into every-day life is required to make conventional on-campus or distance education possible. This set of technologies include roads, vehicles, electricity, air conditioning, buildings, ducting, clothing, aids such as spectacles, food preparation technologies, piping, systems dealing with waste, entertainment systems and so forth. At the same time these technologies require skills and knowledge which in most cases have become totally transparent through our frequent and natural use of it for example navigating buildings and roads.

The virtual class is per definition based on communication and information technologies. Education in this environment similarly needs a whole range of technologies, which often corresponds to the ones described above. At this stage the technologies required to enable the virtual class are however not only in its infancy and undergoing revolutionary changes, but the full complement of what is required is not even fully clear yet. In the current phase of establishing the virtual class, there are often new realisations of totally new technologies needed or significant changes required to existing technologies (like Word-processing HTML documents). It might be that the virtual class at this stage is creating more questions than being nicely tied down according to our traditional conventions. In this scenario communication and information technologies can be seen to be more of a hurdle than an enabling agent.

The virtual class therefore requires of both student and lecturer to assume a sophisticated level of computer literacy and use. While the on-line lecturer may have support within the tertiary educational institute through a computer department and a network of colleagues, the students often may not have the same advantage. It is therefore essential to provide technical assistance not only via on-line help information, but also through a technical help desk function which can be reached by telephone and fax.

A conventional tertiary educational institute interested in using technology-based education like the virtual class seems to require therefore an extensive use of CIT throughout the organisation. At the University of Melbourne, Australia, where a campus wide information system (CWIS) was implemented, Goldenfarb (1995) noted that one barrier to the successful implementation of the CWIS was low IT skills. Goldenfarb also notes that "...if the problem is identified, it can be overcome and the department can become a successful adopter".

In embracing the virtual class, an organisation per definition also embraces communication and information technologies on a wide base and with it the requirement for higher and new levels of computer literacy of their academic an administrative staff as well as their students.

5. Managing Discontinuity in the Virtual Class

In networked education the materials and teaching process is in a state of continuity while these are in a state of discontinuity in conventional tertiary education. Once a course is on the Web, it remains available and no special arrangements need to keep it continually available; special arrangements however have to be made to discontinue availability.

Effectively managing the discontinuity of on-line materials as a result of the discontinuity of human involvement is vital to meet student expectations and provide ongoing support, and in so doing avoiding that the institute comes in disrepute. An example of discontinuity is when a course is in a specialised academic area and the lecturers discontinue their involvement with the course. The on-line course materials will still remain on-line and might become obsolete, or when removed causes frustration to on-line users when unsuccessfully attempting to locate it.

In a paper-based distance education environment or a face-to-face physical teaching environment, the discontinuity of a lecturer can be addressed by the discontinuity of the mailings or the classes at an appropriate point. Two factors contribute to the problem. Firstly the on-line materials are often registered with search engines and guides on the Internet. The URL is then bookmarked within a web browser by users who may also share the URL with others in a network of contacts. Secondly the on-line materials need to be kept up to date if it needs to remain available.

The virtual class thus needs special approaches to ensure a seamless discontinuity like de-registering the materials with the search engines and guides, replacing the course materials with clear notices to that effect or contacting those whom the institute know have bookmarked the materials.

6. Effective Data Management in the Virtual Class

It is quite staggering to see how many computer products for the development of on-line courses take the notion for granted that course elements ("course objects") - including media elements - are to be stored in flat directory structures.

Often the HTML files media elements and scripts are being stored on servers in an organised flat directory structure, which is reminiscent of how data was stored before the 1980's. Since then relational databases and object oriented databases have clearly emerged as more effective and sound ways of storing information in computer systems.

Some comprehensive and specialised databased software have been developed for on-line course generation eg "Hyperwave" (initially developed as "Hyper-G") (Hyperwave 1998) and TLM (The Learning Manager) and Lotus Learning Space.

7. Bridging Transactional Space in the Virtual Class

A major challenge in the virtual class is addressing the issues of dialogue across the response and psychological distance between teacher and learner. "Distance" in the virtual class however is no longer defined in terms of physical proximity but in response time (comment made by Nicholas Negroponte at the 18th World International Council for Distance Education Conference in June 1997).

There is also another type of distance which Caladine (1993) explains as 'transactional distance' which is the psychological distance between learner and learner, and learner and teacher. Caladine indicates that transactional distance in technology-delivered education is greatly impacted by the technology itself: "...one of the most important determining factors is the medium of communication". Terry Evans and Daryl Nation (1992) seem to agree when they state that virtual class practices "...do not eliminate the problems of distance between teachers and learners but create their own" (p. 9).

Complicating this issue is a changing relationship between student and lecturer. In the conventional class, the teacher often has a one-to-many relationship with the students, which is based on the conventional teaching model as well as on convenience for the students. Students in a course will often relate with the academic community solely via the convenor of the course when seeking clarification, feedback, additional instruction or wish to challenge ideas. The on-line student however is "...no longer confined to our campus and its teachers and students and activities" Tiffin (November 1996). The student now has various teachers accessible by e-mail and geographically located anywhere in the world. This was vividly illustrated when the writer wanted to clarify an aspect of Roger's (1983) diffusion of innovation theory and was able to use electronic mail to contact Everett Rogers personally and received clarification within 24 hours through a reply electronic mail (Rogers, E. Re: Top-down approach. everett rogers <erogers@unm.edu>, 10 July 1998). The student in the virtual class, through an extended group of on-line teachers, can therefore be more challenging and also more knowledgeable than the conventional student. Furthermore, lecturers might have to deal with a new relationship with their students which is not one-to-many but *one of many*.

Synchronous on-line communication facilities like Internet Relay Chat (IRC), voice, video-conferencing and shared whiteboard facilities over the Web provide social interaction in a more natural way, and also build some accountability into on-line courses. Asynchronous mechanisms like electronic mail, hypermail-threaded message and newsgroups are effective in bridging both time and space.

Addressing the social needs of on-line students and on-line teachers are critical. Strategies like newsgroups, electronic mail discussion lists, synchronous on-line meetings, arranging some kind of meetings in the physical realm with other students, designing courses with a high level of interactivity and using photographs and video clips of students and lecturers within a course can all be used to address these needs.

8. The Nature of Change Required When Implementing the Virtual Class

Taylor, Lopez and Quadrelli (1996) comments on the work of Morrison believe it to be improbable, as technology becomes more pervasive in all aspects:

> ... and suggests that our thinking about those issues itself must recognise that a 'smooth evolutionary transition' to the widespread use of more flexible modes of delivery is not likely. Indeed, his work suggests it may be far more productive to conceptualise the process of evolution in terms of dislocations, dilemmas and uncertainties rather than projections from 'what is' to 'what is needed'.

At the University of Melbourne, Australia, where a campus wide information system (CWIS) was implemented, (Goldenfarb 1995), a research project looked closely at the first ten departments adopting the use of CWIS and set out to test if critical success factors in diffusing innovations, identified in the literature and at other universities played key roles in diffusing the CWIS in this University. Goldenfarb found that:

> In the final analysis of departments against criteria measures for successful adoption, the departments that recognised the low skills as barrier found solutions to this problem and rated highly in the ranking order. On the other hand, the department that had very high IT skills but did not see a clear advantage in adopting ranked last. The department that did not see a clear relative advantage didn't have full commitment from the head of the department. Many other departments reported success in obtaining commitment from the leader, when clear benefits were demonstrated in trial/pilot projects.

Understanding the benefits of the virtual class, like possible productivity increases of academic staff, is therefore essential for administrative managers and academic staff to take a positive interest in the implementation of the virtual class.

9. Conclusion

The possibility in the virtual class to work collaboratively has become a strong motivation to consider networked education. This is not surprising if one considers the nature of the underlying distributed technologies of the virtual class that is the Internet and intranets - the purpose of which in essence is to enable connectivity - be it to share resources or contact other people. This fundamental characteristic of the virtual class needs to be fully explored in areas like on-line communication, use of on-line resources, collaborative research activities and the transnational recognition of prior learning and qualifications.

Does conventional tertiary education have the ability to change as dramatically as the new media seem to demand> Can it respond in such a flexible, dynamic and adaptable way? Thomas, Carswell, Price and Petre (1998) argues for the "transformation of practices (both teaching and administrative) to take advantage of technology in order to provide needed functions, rather than superficial translation of existing practices".

Taylor, Lopez and Quadrelli (1996) believe it to be improbable:

As technology becomes more pervasive in all aspects of teaching and administration, both academic and general staff roles are being transformed. New positions and skills are required across all key areas. From the diversity of staff development strategies and activities that universities are adopting, we identified three approaches to deal with this challenge. These approaches will need to support an accelerated shift from teaching to learning, delivered not by individual lecturers but by multi-functional teams. Universities are poorly equipped and under resourced to manage this strategic change.

It is important that the future must not be inhibited by what we have been doing in the past; we have a great opportunity to rethink teaching, learning and research; to uncritically replicate in the virtual class what happens in conventional on-campus and distance education would be a tragedy.

"In a time of drastic change it is the learners who survive;
the "learned" find themselves fully equipped
to live in a world that no longer exists"

Eric Hoffer

SHORT PAPERS

Collaborations in Educational Multimedia: Realizing a Culturally-authentic, Contextualized Image Database for Spanish and French Instruction

Oscar Retterer, Director of Academic Technology Services, O_Retterer@fandm.edu
Kimberly Armstrong, Associate Professor of Spanish, K_Armstrong@fandm.edu
Franklin & Marshall, Lancaster, PA USA

A major benefit of incorporating multimedia and technology into foreign language learning is that it can provide students with something resembling, albeit loosely, an immersion experience. Linking the classroom to authentic sounds and images engages the student in the learning process; it makes language learning more than a series of verb conjugations, and instead a richer experience. If we can engage the student, then we have a better change of making him/her a successful language learner.

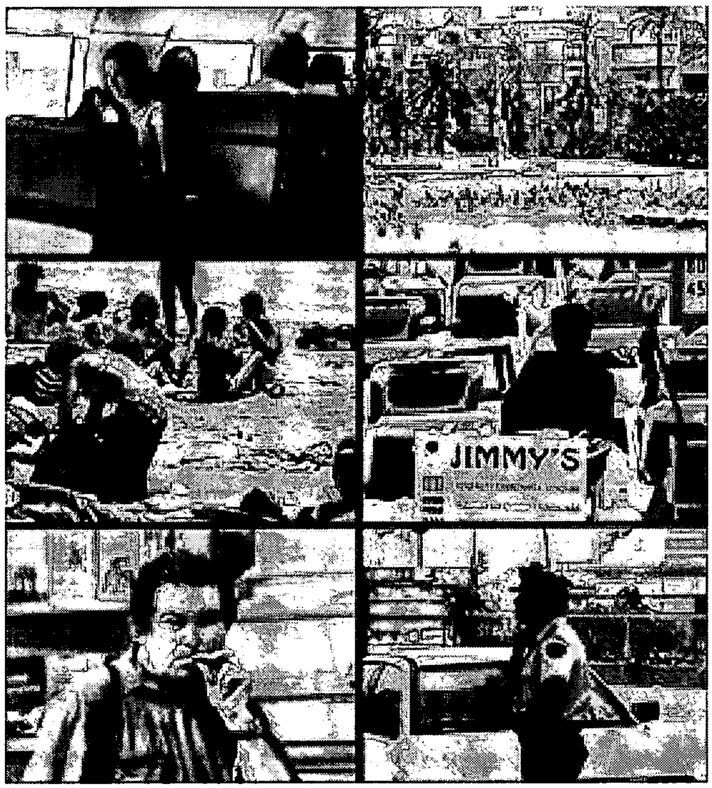
One of the goals of our language programs is to help students achieve advanced levels of oral proficiency in the foreign language while giving them as much exposure as possible to authentic cultural information. In order to enhance language learning possibilities, we decided to take advantage of advanced digital imaging technology to provide culturally rich virtual learning environments for our students. A special program at Franklin & Marshall, the Academic Technology Venture Fund for Curricular Innovation, allowed us to create an intra-departmental archive of culturally authentic French and Spanish digital images. We are using these images to create innovative activities which can be tailored to various levels of language learners.

The Academic Technology Venture Fund for Curricular Innovation was established to promote faculty initiatives that enhance opportunities for curricular innovation through instructional technology support that foster teaching and learning. Through a competitive application process, the Venture Fund awards several mini-grants of up to $5000 each to support curricular project design, development, and implementation. Collaborative projects exceeding $5000 are also possible. One of the advantages of the Venture Fund is the collaborative nature of the projects. Content experts can rely on technology experts to help create the applications needed in order to deliver the class materials in systematic, efficient, and professional package to students.

The first priority of this project was to establish an archive of culturally rich images; we sent a student who was fluent in French and highly proficient in Spanish armed with both a digital camera and a standard 35mm to Spain and France in order to record these images. We provided him with a "shot list" that included items from monuments to bidets to couples holding hands. We expected the student to return with about 1000 pictures -- he returned with nearly 2000, including those of Paris after the 1998 World Cup! Approximately 1200 of these images were recorded digitally while the remaining 750+ were taken with print film and then transferred to Photo CD™.

Upon the student's return, our second priority was to create a database and categories for that database in which to insert information about each image. This included information about where the picture was taken, the elements within the photo, and a series of keywords. This aspect of the project will result in a searchable web site that instructors can use to create classroom applications and that students can use to research both oral and written projects.

While the images have already been used for multiple purposes, one specific project that we have developed promotes oral proficiency. As we began to view the images, it became clear that they could be used to create narratives, a key feature of advanced level speakers. One of the most difficult leaps that a language learner makes is the progression from being an intermediate level speaker with the ability to describe the here and now to an advanced level speaker who is able to talk about events which occurred in the past. Textbooks at every level spend time talking about how to talk in the past, but students are rarely given enough time to really work on this aspect of acquisition before they are moved on to another grammar point. The "storyboards" that we create for students give them the opportunity to further practice this skill using authentically appropriate images that are linked to the vocabulary that they have been studying. These storyboards can be a brief as four images or as long as eight. For intermediate level speakers, there is a logical sequencing to the pictures and a common theme. For instance, one storyboard (below) contains six images: a young woman on a plane, a picture of a beach in Spain, a close-up of sunbathers, a young man renting out lounge chairs on the beach, a shady character smoking a cigarette, and a police officer. Students have the opportunity to create a story using these images so that their language creation also occurs within a context. Students also record their stories orally without the opportunity to write anything down since our goal is to improve oral proficiency with this project. We expect that students will complete five to six of these stories throughout the semester with the instructor providing feedback for each story. Students access the storyboards via our campus network, and eventually they will be able to do so via a website.



This classroom application is something that we would not have been able to do within a traditional classroom. We would need to either spend classroom time passing the pictures to each student or create 20 different storyboards so that students could take them home and work with them. Given the fact that we intend to have students complete five of these narrations, that would involve over 100 storyboards and at least 400 pictures. Technology has given us a tool to deliver this application to students in an efficient manner and has already provided us with essential information about how non-native speakers tell stories in a foreign language.

The Effect of Hypermedia Delivered Modeling On Learners' Self-Directed Study during Problem-Based Learning

Susan Pedersen, University of Texas at Austin, Department of Curriculum & Instruction
sped@mail.utexas.edu

Douglas C. Williams, University of Southern Louisiana, Department of Curriculum & Instruction
dwilliams@usl.edu

Min Liu, University of Texas at Austin, Department of Curriculum & Instruction
mliu@mail.utexas.edu

1. Research Framework

Problem-based learning (PBL) is an instructional approach that uses problems as the stimulus and focus for student activity (Baud & Feletti,1991). Research suggests that PBL may help students develop the skills necessary to pursue learning independently (Aspy, Aspy, & Quinby, 1993).

In PBL, instruction begins with the presentation of a complex problem situation and all learning occurs as a result of students' efforts to solve the problem. As students realize that they lack information necessary to develop a solution, they identify learning needs, then engage in self-directed study to meet those needs (Barrows & Tamblyn, 1980). During self-directed study, learners must sift through information, distinguishing that which is pertinent from that which is not. Yet, inexperienced problem solvers tend to focus on the surface features of a problem, failing to recognize what information is useful (de Jong & Ferguson-Hessler, 1986). Even in the field of medical education, both faculty and students have expressed concern that students may not be able to determine what should be learned (Barrow & Tamblyn, 1980). When attempting to use PBL with young learners, support for the development of self-directed study seems warranted.

Responsibility for this support can be left to the classroom teacher, but the extent and variety of supports needed can be overwhelming. One of the potential benefits of computer technology in educational environments is that it can share the responsibility for this support with the teacher. Collins (1991) argues that technology can offer good process models of expert performance embedded within the situations in which they are useful. The purpose of this study is to determine if the provision of hypermedia based models of expert cognitive processes can support students' work during self-directed study.

2. Research Questions

1. Does hypermedia delivered cognitive modeling affect students' use of a cognitive tool during self-directed study?
2. Do students transfer strategies taught through hypermedia delivered modeling to other tasks?

3. Design of Study

3.1 Sample

Two sixth grade science classes in a suburban school district in the southwestern United States participated in the study.

3.2 Treatments

Alien Rescue, a hypermedia PBL program dealing with the solar system, was used with both classes.

Two treatment conditions were developed. In the *cognitive modeling* treatment, the character of an expert scientist appeared in a video in the hypermedia program to model the cognitive processes she would use in collecting information pertinent to an identified learning need. In the *help* treatment, the expert scientist explained the function of the same tools used in the modeling treatment, but without modeling how she would use these tools to meet a learning need. Most students worked in pairs, though some worked individually.

3.3 Dependent Variables

Students' notebooks and a log of their tool access were used to examine the effects of the modeling on their work during a three day period of self-directed study. To examine transfer, a problem situation unrelated to the problem presented by the software was given to students at the end of the self-directed study period.

3.4 Data Analysis

The notebooks were analyzed descriptively for evidence of the effect of modeling during self-directed study. For the transfer measure, six relevant facts (needs) and ten irrelevant facts (non-needs) provided in the measure were identified. Students received one point for each relevant fact they identified, and one point for each irrelevant fact they did *not* include, and these were added for a total score. Three one-way ANOVAs were conducted with the needs, non-needs, and total scores as the dependent variables.

4. Results and Discussion

The descriptive analysis of students' notebooks showed differences in students' work during self-directed study. These results are summarized in Table 1.

	Cognitive Modeling	Help
Average number of words in notebook	207	188
Average number of times notebook was accessed in three weeks	73	63
Average number of meaningful sections created by 4^{th} day of study	4.1	2.8
Percent of notebooks containing evidence of lists	91%	25%
Percent of notes that represented relevant facts	68.6%	47.0%

Table 1: Results of Descriptive Analysis of Notebooks

For the transfer measure, the analysis of variance for the needs and total scores showed non-significant results, while the ANOVA for the non-needs score was significant ($F= 4.869$, $df = 1, 39$; $p < .05$).

The results of this study suggest that students' self-directed study is impacted by the provision of a hypermedia based tool in which an expert models the cognitive processes she would use, and that students will transfer skills modeling during PBL to other problems where they are useful. Of particular note, the results suggest that students who received modeling were better able to distinguish information useful in solving a problem from other, less useful facts. This suggests that problem-based learning software should be designed to include tools that provide expert modeling of the cognitive processes used.

Introduction

The University of Alberta's Faculty of Education has undertaken a restructuring process with the goal of better preparing teachers to effectively integrate technology into their teaching. A major component of this restructuring process is the development of a program of courses that make extensive use of Web-based technologies. This paper describes one course development project: the transformation of a traditional Lab-based instructor led course, on multimedia technology tools, to a "Wed-Mediated Instruction" (WMI) course that exploits various communication features of the Internet. The underlying goal of this transformational process was to preserve the constructionist learning environment (Nicaise & Barnes, 1996) of the traditional course while at the same time optimizing the course delivery mode to make it more accessible to a wider audience of students.

Project Overview

A course on multimedia in the classroom (Carbonaro, 1997) taught entirely in Lecture/Lab format was transformed by moving the course resource materials onto the World Wide Web (Web) and by making extensive use of Internet-based telecommunications. The course (now called EDPY 485 - Multimedia Tools for Teachers) employs what we like to call Web-Mediated Instruction (WMI). A course delivered by WMI is not necessarily delivered completely over the Internet, rather the Internet serves to provide resources and facilitate communication. Face-to-face (F2F) instruction and F2F student collaboration are still important components of our course. This allows for increasing student accessibility (Internet-based support) while simultaneously maintaining a constructionist collaborative learning environment that incorporates multimedia tools for creativity and problem-solving.

The Course

The theoretical considerations of the project resulted in the development of a course that made heavy use of hypermedia construction applications and Computer-Mediated Communication (CMC) which are viewed by Jonassen (1996) as superlative Mindtools. The course website (http://www.quasar.ualberta.ca/edpy485dev) provides a great deal of flexibility in that students can proceed through the course experiencing varying degrees of F2F instruction. Some students like to be helped in person, so they attend scheduled lab times. Others choose to work more independently, from home, work or wherever. Some students collaborate via telecommunications while others prefer in-person collaboration. Another factor in our particular course is that few students can afford the wide array of application software and peripheral devices available at the on-campus lab facility. This course requires that the students utilize special hardware and software including: scanners, digital cameras, postscript printers, video digitizing hardware, ZIP drives, and high-end video and graphic editing software. Thus, in our course, economics dictates that students must work on-campus for certain assignments. In any case, the website provides the information the students need in order to understand what is required of them to complete the course: course outline, schedule, list of required materials, explanation of assignments, marking criteria, tutorials, supplemental reading material, etc. The course requires that six modules be completed, they are: Internet tools, multimedia tools, digital poster, presentation software, hypermedia, and webpage construction.

The EDPY 485 course is continuously undergoing many changes to enhance the instructional environment. These include: (a) modifications to the Web-based resource center; (b) greater use of the Internet for course communication; (c) allowing greater choice in the time and location of instruction; and (d) improving the assessment of student performance. In particular, we have devoted considerable effort to developing the course website in support of course objectives. The course website is not just a syllabus representing the instructor's own perspective (Duchastel, 1997). There is a vast amount of educational material available on the Internet that is very useful to pre-service or in-service teachers. A website makes it easy to point the students to resource sites, and to Internet-based search tools which aid them in finding additional resources on their own. A lot of the information presented in this course is very dynamic. A website enables us to constantly enrich, update, and disseminate this information. The course website also enables us to easily show students exemplary models of previous students' work, which students can view whenever they wish, from any computer with Internet access.

Conclusions

After some initial offerings we obtained feedback from students via an online anonymous survey and from informal conversations. The survey was developed by adapting the online questionnaires currently in use in two other Web-based educational technology courses to assess students attitudes and course quality (Montgomerie & Harapnuik, 1997; Szabo et al., 1997).

Initial results indicate that we have largely managed to combine the best of these two very different worlds (both traditional F2F instruction and individualized Internet-based instruction). Students have appreciated the personal support offered by the traditional component of the course (particularly computer novices) and the flexibility and access to resources offered by the Web-based component. Hopefully, this course models how the needs of a wide range of students can be answered by supplementing traditional teaching methods with an individualized, self-paced component. For example, some students take the website and run with it, others like the instructor to accompany them on a slower walk through the course content. This course also demonstrates how a website can dynamically provide suggested resources to students and therefore models a WMI approach to learning and teaching. Student feedback indicates that the constructive, collaborative, student-centered nature of this course has proved to be a very engaging learning environment. There appears to be support for the idea that the incorporation of CMC into EDPY 485 furthers the Mindtools cause by providing teachers with a glimpse of how WMI technology can contribute to the creation of engaging and relevant learning environments.

Background

In 1995 the School of Post Compulsory Education and Training at the University of Greenwich piloted the use of Computer Mediated Communication (CMC) as an Enterprise in Higher Education project in support of the In-Service Distance Certificate in Education (Lewis, T., Gould, M., Ryan, M., 1997). The reasons for wanting to use CMC were to provide students with regular access to their peer group and tutors through conferencing and e-mail. A virtual learning environment was created using the groupware product, Lotus Notes (Ryan and Culwick, 1997). A customised desktop was created which included a set of virtual classrooms for each of the units of study, an electronic resource centre and student common room. We believed, and it was subsequently confirmed, that improved access would reduce the feelings of isolation often associated with distance programmes and provide opportunities for peer exchange and enhanced tutor-student interaction (Singletary and Anderson, 1995). Following the success of this pilot, the use of CMC as a support tool was offered to any distance student who had the necessary equipment and computer literacy skills.

It is our experience that those students and staff who are aware of and exploit the technology find it rewarding and beneficial to both their learning and teaching. If the use of information and communication technologies (ICTs) is integrated into curriculum thinking, planning and delivery from the start then we believe it is likely to be beneficial. Whilst providing a highly structured and integrated learning environment, a Notes desktop did not seem to be an appropriate technology when potentially large numbers of students (exceeding a thousand) would need to be supported within the newly validated Certificate in Education programme.

The New Certificate in Education

This new programme includes students who are studying a common set of units in full-time, part-time and distance modes. The majority of materials are print based and form the core of both content and mediation for all modes of study. We believe that tutor and peer support is fundamental to all teacher education programmes and ICTs are known to be effective delivery methods. It is important that students, tutors and mentors, remain up-to-date in their knowledge of relevant policies, practices and uses of ICTs in education and training. One way of addressing this is to integrate the use of ICTs, including hybrid CD-ROM technology, into the delivery of the new certificate programme.

Proposed Structure of On-Line Campus (OLC)

Building upon our earlier success in using Notes, a web-based, virtual campus has been established to support all students irrespective of mode of study consisting of:

- a Discussion Forum,
- Electronic Resource Centre,
- Student Common Room.

The Discussion Forum allows any registered student to pose a question, share an experience or ask for guidance. If they wish, tutors may set up activities to support the delivery of their unit that can then be accessed by students irrespective of mode (providing they have the skills/equipment). The Resource Centre can be used to store copies of files created by tutors in a range of software applications, (enabling easy access by both students and colleagues), and links to other web sites and OLC pages can be easily created for the benefit of all (Rohfeld and Hiemstra, 1995). The concept of a Common Room has been established as benefiting distance students and can provide opportunities for virtual, social interaction between students irrespective of mode, time or place (Mason, 1993; Moore, 1989).

One of the principles established by our use of CMC in support of Continuing Professional Development (CPD) programmes, is the need for a range of skills to be employed when designing and using an on-line environment. Consequently, this project draws upon the expertise of the Notes developer, the curriculum designer and the subject specialist. It is also intended that students, who are themselves a valuable resource (Knowles, 1990), will contribute dynamically to the content, nature and role of the OLC.

Training and Development

The need for staff and students to have the appropriate skills and confidence in order to exploit technology is well documented. A number of staff have experience of working with Lotus Notes and a growing number are able to 'surf' the web. A Notes desktop provides more features and greater control over the placing of documents and management of the discussion forum. It is envisaged that during this coming academic year all unit co-ordinators will be equipped with and supported in using Notes, enabling them to be more effective managers of and contributors to the OLC. Other staff and all students will access the OLC via a web browser. Training in the use of the web is already available to all centrally which will remove the problems previously associated with inducting even small numbers of students into the use of the Notes desktop.

What Next?

A major reason for employing an OLC at this time is that it allows us to promote the appropriate use of ICTs in the delivery of our teacher education programmes and to support colleagues in exploiting its potential. It is likely that IT competence will be a core component of future teacher accreditation schemes and we should prepare ourselves, our students and programmes to incorporate the technology strategically. As a relatively large scale pilot project we are interested in examining such factors as:

- the extent to which the learning community exploits the technology
- whether the mode of 'attendance' determines the use of the OLC
- what 'additionality' is brought to the certificate programme
- its cost effectiveness
- the merits of Lotus Domino as a web development tool
- the relationship between hybrid CD-ROM products and the OLC

Answers to these questions will help us to plan a longer-term strategy for the use of the OLC in support of other programmes from certificate to doctorate studies. This will form part of an integrated approach to the use of ICTs in teaching and learning which ignores time and distance (Berge and Collins, 1995) and focuses on quality and value.

This document is a very brief summary of a larger paper and presentation. It is not possible to discuss the issues presented two pages, so we will restrict ourselves to providing an annotated outline of the topics here, and invite you to download the larger document. More information about the hypertextbook Visual Design for Instructional Multimedia, including previews of most sections of the book, is available from http://members.home.net:80/m4.multimedia/. A complete version of the paper, presented earlier this year, is available for downloading as a PDF file [190 KB] from www.extension.usask.ca/Papers/Misanchuk/EDMEDIA99/EDMEDIA99paper.pdf.

Large-scale hypertext implementations designed to provide information are common enough (especially as websites); however, large-scale instructional equivalents are, at this juncture, more rare. The complete paper and presentation include the following:

- Description of the design and development of a CD-ROM-based hypertextbook, entitled Visual Design for Instructional Multimedia, which consists of more than 3,100 HTML, JPEG, GIF, and MOV files
- Morphology of the project through several stages, highlighting issues arising from developing the product with HTML rather than with a more hospitable authoring program
- Description of a number of things we learned from the "school of hard knocks"—some profound, some mundane—in the hope that by sensitizing you to some of the problems we encountered and decisions we made (and sometimes re-made), we can help you avoid some of the pitfalls we encountered.

Outline of the Paper and Presentation

Need for the Book
Content and Scope.
Structure

The "modified linear" design
Mainstream text and diversions

- reference citations
- examples
- elaborations
- navigation links

Diversions from diversions
Orientation and location cues

Process

Getting started
The distance factor
Working together and apart
The overall process

Work Methods

Pages on the Fly
Document First, Pages Later
Outline, Just Like Mr. Hankel Says
The Traditional Book Publishing Approach

Design Issues

Settling on a Visual Design
- The impact of technology on design options and the design process.
- The impact of usability testing and technology on navigation design.

Navigation Schemes and Screen Geography
- Hypertext advantages with simple navigation.
- Linking to the same page from different locations in the text
- Image map menus vs. frames
- Cues for different types of links

Academic Writing and HTML
- Formality of language.
- Editorial issues.

Web or CD-ROM versus Print for Distribution
- Why not a printed book?
- As long as it's electronic, why make it essentially linear?
- Why HTML instead of another authoring environment?
- Why then, a CD-ROM and not the Web?

Expert Review and Usability Tests

Concerns of Designing Distance Learning Environment

Tel: 909-880-5692, E-mail: aleh@csusb.edu

The current education scenario appears to place the Internet as a timely tool for educators who are interested to reform education delivery (McLain & DiStefano, 1995). The technology sophistication, compatibility and user friendliness to education environment makes education more accessible from distance. In fact learners may receive academic degrees without stepping on university ground. In addition, Kinner and Coombs (1995) found that utilizing computers in the classroom can reduce communication barriers and facilitate interaction among learners that are inhibited in the traditional classroom. However, the differences between classroom instruction and computer-based learning are very significant (Steinberg, 1991), therefore educators should address the issue very carefully. If it is planned, designed and executed correctly, and learning can be placed in a meaningful context, then the learners will be actively engaged in the learning situation (Bridges, 1992).

This paper will report concerns for conducting on-line courses, including instructional format, methods of instruction, methods of interactions, methods of communication, instructional media, and participants. It will address some of the concerns when conducting an on-line course. The intention is to share the information, recognize and realize the challenges for professionals to be better prepared for the electronic learning environment.

Instructional Format

Using the traditional class instructional format such as preparation, presentation, application, and summary may be considered for an on-line course. However, its affect on student's concentration, motivation, thought, mastery, and comprehension (Verduin &Clark, 1996) could be a big challenge without the right strategies to transfer classroom activities into on-line activities. Among these factors, on-line educators are most concerned about the assessment process, especially when looked at in the context of traditional classroom environment or exam oriented learning formats regarding the validity of student's works.

Methods of Instruction

Brookfield (1985) contended class facilitation will promote greater student involvement in the learning process when compared to lecture method. However, in an on-line environment the method can be very challenging, especially when students have different learning styles. The factors that determine how, what, and when to interact are the most critical factors to be addressed in order for the teaching and learning to be efficient and effective.

Methods of Interaction

In an on-line environment the discussion, group work, and question-answer sessions can be accomplished by means of both asynchronous and synchronous modes. Anderson (1993) discussed these factors for effective, successful teaching and learning in a classroom. However, the absence of physical presence in an on-line environment makes the execution of such factors more challenging, especially when much of the success of the on-line delivery method using these factors depend on both the capability of computer system and software, and the ability of the instructor to manage the class effectively.

Method of Communication

In a traditional classroom visual, verbal and non-verbal communications are readily integrated in the teaching and learning process to express the meanings of actions, words, and texts (James & Blank, 1993). Cochenour (1994), however, explained the difficulty to integrate these factors in electronic environment such as on-line course. There are many variables that have to be considered for the integration to be successful such as capability of system networks, students' and instructors' computers, software, and course design.

Guest Speakers

In a traditional classroom instructor, students and guest speakers are common participants (James & Blank, 1993). On the contrary, in on-line environment, guest speakers are absent. Among the reasons are, they have to face the challenges of learning computer operation skills, managing the software, availability of time, log on process and so on. Their involvement is more difficult when the primary communication strategy is mainly based on text like the asynchronous mode of delivery. The lack of or no physical contact, facial expression, and social cues that could promote normal relationship as in the traditional classroom will contribute further to the absence of the guest speaker in an on-line environment.

Instructional Media

Miller and Clouse (1993-1994) contended the role of technology is significant to disseminate primary course information in the education settings. It can be applied as the main instructional strategy or as a supplement to enhance learning and teaching. In an on-line course the use of technology is a must. However, finding the right technological tool to enhance learning and teaching can be very challenging. Among the variables that have to be considered in the selection process are the capabilities of the system networks, end user machines, compatibility and accessibility of software, support personnel, and policy. These will determine to what extent media can be used to conduct communication, interaction, and instruction.

Conclusion

This shift of new education paradigm with regard to the advance of technology is altering educators' perceptions about teaching and learning strategies. Many educators are involved with the new paradigm of teaching. The concern of (1) using appropriate instructional format, methods of instruction, methods of interactions, methods of communication, and instructional media, (2) encouraging participants' involvement, and (3) requiring the correct strategies should be the primary issues for on-line educators. Some questions have been answered but many are still unsolved. Educators should share their ideas with their colleagues and continue the debate for a better practice.

Implications of the Electronic One Minute Paper

Steven Hornik
Department of Accounting and Information Systems
Xavier University
United States
hornik@xavier.xu.edu

The One-Minute Paper (OMP) has been used to generate feedback to instructors for some time (Harwood 1996; Ludwig 1995; Kloss 1993). Traditionally this has involved having students spend a few minutes at the end of a class session writing down what was understood and what was still unclear from a particular classroom session. Bryan et al. (1993) reported that instructors had favorable perceptions about the timely feedback of OMP's obtained from accounting courses. In addition to providing feedback, the cognitive effort that is required by students to complete the OMP has been shown to positively effect learning under certain conditions. Bryan et al. (1993) reported that students from various accounting classes reported a perceived augmentation to learning as a result of the OMP.

Although the empirical effectiveness of the OMP are sparse some studies do indicate a beneficial relationship between the preparation of an OMP and learning. Almer et al. (1998) has shown that accounting students completing an OMP performed significantly better on quizzes than students who did not complete the OMP[1]. Similar results have been found with economic students (Chizmar and Ostrosky 1998) studying microeconomics.

The OMP is typically performed in class, at the end of a lecture. This research will examine what effect if any will endure by having students complete their OMP electronically (or electronic OMP) some time after the class lecture has finished Having students complete the OMP electronically can change the nature of the OMP in several ways. First, if students do no have access to a computer in the classroom for which the OMP is to be completed the benefit of the immediate recall of the class contents may be lost. However, an added benefit of completing the electronic OMP (or e-OMP) is that the students' e-OMP can be made available to other students, thereby providing students with feedback similar to what an instructor would receive from a traditional OMP. In addition, the e-OMP lends itself to the possibility of having students provide comments and/or explanations to other student's e-OMP about unresolved questions. In other words the e-OMP can become a virtual component of class discussions in which students from a class can post questions about areas that they do not understand and have their fellow colleagues help them by providing explanations.

Numerous questions stemming from the use of the e-OMP can be formed. The first, will the cognitive effort used in completing the e-OMP result in better performance? Also, will the e-OMP completed up to a day after a class session, be as useful as the e-OMP completely shortly after class? The second, what effects will collaboration have on learning within the OMP framework? That is, will students who have responded to an e-OMP with helpful suggestions outperform students who have only completed the e-OMP without responding to any fellow students? Third, will the e-OMP have distinct effects depending on exam type (multiple-choice, problem solving or essay)?

Experimental Procedure

The e-OMP data presented here was gathered during the fall 1998 semester from 54 MBA students[2]. The e-OMP was implemented using Learning Space and Lotus Notes. Students were told that the posting of e-

[1] Further analysis by Almer et al. (1998) indicated that the benefit of the OMP was only significant for essay-type quizzes vs. multiple-choice type quizzes.

[2] The students were from two separate *Financial Statement Analysis* classes. One of the groups was from an off-site MBA program. Analysis of the two groups indicated no significant differences between them so the results from the two groups are combined.

OMP would be anonymous, but that if any inappropriate comments were posted the person responsible could be determined. The e-OMP contained the following questions: 1) *I am most confused about the following point that was brought up in class tonight; 2) If there is one thing I completely understand now, it is the following:; 3) I would like to learn more about the following topic:; 4) Finally, please rate your perception of understanding for this weeks materials: Got It!, On my way to getting it, or Oh boy I'm Lost*[3]. The response to the e-OMP was worded as follows: *I believe that if you consider the following points, it might help clear up your confusion.* The response to the e-OMP was not anonymous and was used in the determination of the overall participation grade for the student.

Data Analysis

To examine the relationship between the e-OMP and student performance the students overall grade (scored on a 1000 point scale) was divided into its component parts: exams and mini-cases. Pearson correlations were run to determine any relationship between these components (and their totals) with either the e-OMP or the responses to the e-OMP. Results indicate a positive relationship between the e-OMP and students total overall grade (.378, $p<.005$). With respect to the e-OMP response, results indicate a positive relationship between the response and students overall score[4] (.569, $p<.000$), the total exam score (.349, $p<.01$), and the combined exam and mini-case score[5] (.389, $p<.004$).

Next ANOVA was used to examine if the differences among the students' performance could be attributed (in part) to the e-OMP or responses to the e-OMP[6]. The results indicated that even though a significant positive relationship existed between the use of the e-OMP and overall student performance there were not any significant differences that could be ascribed to the number of e-OMP completed. However, the results indicate a significant difference between the number of responses to the e-OMP and the total exam score ($F=2.382$, $p<.064$), the combined exam and mini-case score ($F=2.934$, $p<.03$) and the overall score ($F=7.619$, $p<.000$). Post-hoc analysis on the overall score indicated a significant difference between 0 responses and any response (either 1,2,3 or 5 responses). Of practical importance the differences were as follows: 5 responses: 122 points ($p<.001$), 3 responses: 103 points ($p<.000$), 2 responses: 63 points ($p<.039$), and 1 response: 51 points ($p<.034$). Post-hoc analysis of the combined exam and mini-case score also indicated a significant difference between 0, 3 and 5 responses. These differences were as follows: 5 responses: 63 points (p<031); 3 responses: 51 points ($p<.019$).

Introduction

In a recently developed series of training materials designed to help school personnel work with youngsters with behavioral problems, *Teacher Problem-Solving Skills in Behavioral Disorders*, interactive multimedia case studies were combined with electronic performance support system (EPSS) tools for teachers. Funded in part by a grant from the U.S. Department of Education (Semrau & Fitzgerald, 1993-1997), the goal of the project was to develop interactive training programs to enhance problem-solving skills of teachers to better serve children with social, emotional, and behavioral difficulties. Through authentic, case-based problems, users learn to plan therapeutic instruction, design behavioral interventions, and create cognitive-behavioral intervention materials to teach children self-management procedures (Fitzgerald, Standifer, & Semrau, 1998).

To supplement the training materials for educators, initiatives are underway which attempt to extend the real-world use of the training materials by developing a companion series of EPSS software programs for children to use in classroom settings (Fitzgerald & Semrau 1998). The software programs for kids are compatible with the cognitive-behavioral strategies in the instructional materials for teachers. The self-management materials provide a set of electronic tools that children and youth can use to create their own behavior plans for self-management. By helping children take responsibility for their own behavior, internal controls for behavior are established and the need for external control of behavior are reduced.

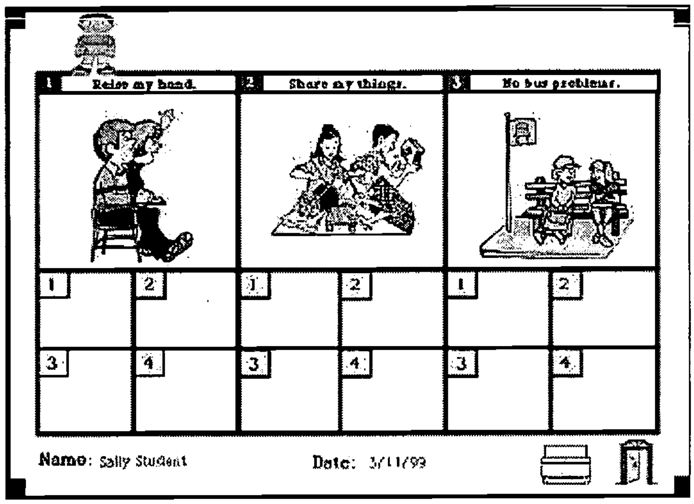
Computer-based training and support mechanisms are an innovative approach for helping students gain control over personal behaviors. Although there are limited data on the use of computer-based instruction to support behavior change in students to date, research results are promising. Fitzgerald and Werner (1996) reported success with a computerized verbal mediation essay as a cognitive retraining procedure to assist a student with significant behavioral disorders in changing his behavior; the computerized essay provided consistent practice and focused the child's attention and thoughts on behavioral choices and consequences. In another case study, the same researchers reported a procedure in which software templates were developed for a student to create self-monitoring materials. This study was the pre-cursor to this work to develop and investigate the use of EPSS tools with children.

Instructional Design of Program

The EPSS programs are designed as easy-to-use templates that can be individualized by children and/or their teachers. To use the templates, the child simply clicks on "hot words" on the template form to enter personalized content and then print it for use in the classroom. The program automatically enters the child's name, the date, and establishes a datapath for recordkeeping purposes. When complete, the templates will be appropriate for youngsters at two levels: elementary and middle school/junior high. The programs are created with *Authorware 4* and operate on both Macintosh and Windows platforms.

KidTools incorporate several literacy-related design features to make them suitable for children's use. The teacher tools were modified, making the templates child friendly and incorporating the use of natural language of children. Graphic characters were added to serve as "guides" to the different tools. Audio support now supplements simplified text instructions.

The following graphic displays an example of a KidTool. This is a *point card* for monitoring success on three behaviors. The child selects pictures from a graphics library to represent the behaviors. Each behavior is given a simple descriptive name. The monitoring grid is printed on the card to allow the child to monitor success on the behaviors four times during the school day.



Formative Evaluation

Teachers from three elementary schools in rural and urban areas in Missouri participated in designing and evaluating KidTools. A small cadre of teachers in each building shared the materials with interested teachers and contributed suggestions for template adaptations as well as additional forms needed in their schools. Project staff observed children's use of the software using think-aloud techniques. User datapath records were examined to determine common template usage and to gain samples of natural language from children. At the close of the school year, interviews were conducted with teachers who implemented the materials. Based on formative evaluation data, KidTools will be revised during the summer months for full implementation in the schools during the 1999-2000 school year. Recommendations will be forthcoming regarding effective implementation of EPSS tools with elementary-age youngsters.

The Wake Forest Strategic Plan for Technology

David G. Brown, International Center for Computer Enhanced Learning
Wake Forest University E-mail = brown@wfu.edu

All incoming Wake Forest University freshmen students receive new laptop computers upon entering, exchange them for a more powerful laptop upon returning for their third year, and take their second computer with them upon graduation. In Fall 1999 the computer will be the IBM Thinkpad 390 with Pentium II, 333 Mhz, 6 GB Hardrive, 128MB Ram, 4.1" active matrix screen, DVGA video, ethernet, and CD Rom. Standard software will include Windows 98, MS Office Professional 97, Netscopae 4.5,Dreamweaver, SPSS 9.0, and Maple V5.1.

All Wake Forest faculty and staff are on a two-year refresh cycle. All students, faculty, and staff therefore have 24-hour, 365-day, worldwide access to one of two standard computers with standard software packages. Standardization enables round-the-clock staffing of knowledgeable help desks, coaching by roommates and office neighbors, loaner pools, and (most meaningfully) teaching with the knowledge that all students have access to powerful electronic tools. The methods students learn for one class (e.g. creation of a web page) are transferable to other classes and to all types of community activities (e.g. fraternities and special interest clubs).

This ubiquitous computer environment has transformed the quantity, quality, and character of teaching, learning, and campus life. Frequent surveys confirm that more students are more intensely involved with more subgroups over more months, even when subgroup members may be farther apart. Surveys show that faculty are in touch with more students more frequently, as well as with more professional colleagues in more countries and for more years. The capacity for network conferencing, for sharing videotapes, for synchronous and asynchronous threaded conversations, for sophisticated archiving and indexing of messages, and for random access of images now contributes to a much, much richer community of learners. Students in a freshman writing course exchange rough draft essays with a similar class in Canada. Shakespeare students participate in fortnightly, live, two-way video conferences with the archivists at London's Globe theatre. Business students view and review cyber-lectures so that class time can be reserved for discussion and analysis.

Because Wake Forest was one of the first to implement a ubiquitous computing program, we have been visited by individuals and delegations from over 300 U.S. colleges and universities and over 40 colleges and universities in other countries. In Winston-Salem, Southeast Asia, and Europe we have been sharing "the Wake Forest Story." Our intent is to catalyze other institutions to implement ubiquitous computing for the benefit of their students. This story includes a multiyear financial plan, the steps followed toward achieving faculty and trustee votes for a standardized computer initiative, faculty development initiatives, printer and network strategies, etc.

In COMPUTER ENHANCED LEARNING (http://iccel.wfu.edu) nineteen leaders of the implementation have collected this list of lessons learned:

- PC's are only 10% of the Challenge (support/networks/policies/train/expose)
- Most sunk costs can be ignored
- Expectations need management
- Develop a comprehensive plan first, and quickly match it with a multiyear financial plan
- Standardization pays rewards well beyond those anticipated; non-standard configurations require 3-4 times support
- Students/Faculty want specific computer training that is centered around a task-at-hand; general classes don't work well
- Be prepared to outsource challenges
- Reliability is critical, especially the Help Desk
- Provide academic units staff of their own & plenty of equipment without hassle
- Defer wiring every seat and every classroom
- Provide printers to every student
- Adopt a common course shell
- Avoid mandating the use of computers by all faculty
- Insist upon at least a three year refresh rate
- Improve communications weekly; rumors fly faster
- Spread the gains from & ownership of innovation throughout all units

This beginning list is cited for the purpose of catalyzing a sharing of lessons learned by other early implementers of ubiquitous computing, and thereby enabling others to avoid some of the missteps others have made.

Faculty Development Strategies

David G. Brown, International Center for Computer Enhanced Learning
Wake Forest University, USA. Email = brown@wfu.edu

One of the last, yet most important, stops along the road to utilizing powerful and newly available multimedia technologies is motivating and training the nation's faculty. Now, more than at any time in the last fifty years, the academic disciplines are focused upon quality teaching. Faculty must be encouraged to start with their educational objectives and their successful learning experiences, and then consider how technology might allow the pursuit of these objectives in more effective ways. In this "teachable moment" we must efficiently provide faculty with the ability to use an array of new tools--- from downloading clips from the internet, to accompanying lecture-discussions with PowerPoint slides and creating animated videos to illustrate difficult-to-understand concepts.

The infrastructure must precede everything. A first challenge faced by faculty development specialists is assuring access to appropriate computers. To be fair, all students must have easy and equal access, and faculty will insist upon fairness before they ask students to rely upon computers. Equally important is a reliable network, for without it faculty will have to prepare failsafe assignments which means double-work. Classtime is too precious to risk losing.

A second challenge is assuring access to appropriate advice. Required is "just in time" training when there is a "need to know." Alternatives include subsidized summer workshops, special classes available upon demand, computer-based training modules, well-trained help desk personnel, course designers, and single-purpose seminars. At Wake Forest we have come to rely most heavily upon STARS (well-trained students assigned for semester-long periods to help individual faculty members incorporate computer enhancements into their teaching), Academic Computer Specialist (Ph.D.'s in the discipline hired by departments to spend full time helping departmental colleagues design and implement computer enhancements in their teaching and research), and RTAs (trained students residing in residence halls and available for face-to-face consultation especially in the evening). .

A third challenge is motivating faculty to make the time to learn how to use these new tools. While assuring faculty that they will not be penalized for deciding against the use of computer enhancements in their teaching, multiple programs encouraging exploration are essential. Some of the most successful programs are release time grants, summer fellowships, technology fairs, innovations awards, and collecting information about teaching innovations in conjunction with promotion and tenure decisions.

A fourth challenge is dissemination strategies, especially sharing information about successful adoptions. Swap and share seminars, benchmarking trips, guest lecturers, subsidy for attendance at national computer meetings, computer-assisted learning newsgroups, and "computer tip talks" by students are among the more successful programs for dissemination.

The real key to success is a faculty culture that supports experimentation and encourages each faculty to do his/her best for the students. Such a culture is most likely to thrive when most faculty are using technology in some way, and when colleagues can share knowledge.

Nothing is more important than keeping it simple! By shortening faculty learning curves and standardizing campus practices, widespread adoption is greatly accelerated. Specifically, two practices are advocated:

1. When possible, standardize. Enable all students and faculty to use the same machines, hardware, and software. Friends and neighbors will teach each other. Once a crisis is fixed for one machine, it may be applied to all. Once a student learns how to use the computer in one class, the knowledge is relevant for the next. The negative consequences of physical breakdowns can be minimized by backup systems. Training is greatly simplified.

2. Emphasize "high benefit- low cost" uses of the computer. Specifically, train faculty to use the computer to improve communication, both instructor-student and student-student. Encourage the use of group e-mail, URL citations, and course web pages. At first, discourage the time-consuming development of on-line exercises and of fancy visualizations. That can come later.

The nation's faculty is eager to do well by students. Strong networks, early successes, and standardized systems can be the backbone for effective dissemination strategies. It will not be long before courses without computer enhancements will be as unfamiliar as courses without textbooks. The faculty is ready! The students are there!

Exploring Curriculum Delivery

Yanlu Xu
Wrexham Business School
North East Wales Institute

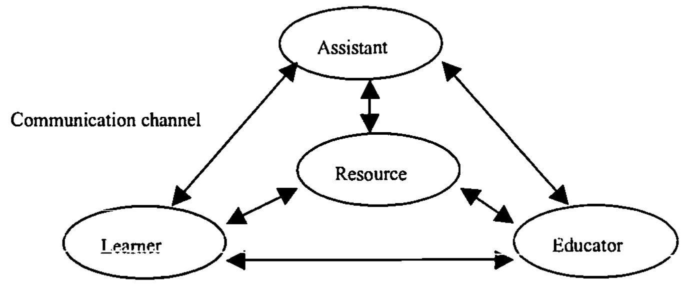
xuy@newi.ac.uk

Three Parameters of Curriculum Delivery System

This paper reports on an attempt to conceptualize curriculum delivery within the framework of new technology. When we analyze the differences of curriculum delivery in a social context, we see there are three main parameters that strongly influence the curriculum delivery paradigm. These parameters can be set into a social context along with human history either vertically or horizontally. The three parameters are *knowledge, pedagogy, and technology*. First we discuss the three parameters in a vertical time dimension which represents human history. *Knowledge* based on human beings' understanding of the real world has developed as different self-contained disciplines, such as: physics, medical science, chemistry, social science, engineering, computer science. The different disciplines nowadays have much more to offer their learners than in the past due to the development of the disciplines themselves. Knowledge is the basis of any curriculum delivery system. It is the content of delivery and it affects the richness of the curriculum delivery system. Another parameter is *pedagogy* and we conclude that the present curriculum delivery system in education puts much more effort into pedagogical issues than before. Educators are concerning more about how students learn and, consequently, how they themselves teach. Many institutions have set up instruction design centers to improve and enhance curriculum delivery. Pedagogy has been paid much more attention as the discipline has matured. This parameter affects the flexibility and reflects the methodology of curriculum delivery. The third parameter is *technology*. This has had considerable influence in the past and we can project an immense future impact on curriculum delivery. Projects such as China's TV University and the UK's Open University are both good examples of technology bringing new ways to teach and learn. Future technology will allow us to provide a more open and flexible curriculum delivery system. Now we consider those three parameters in a horizontal dimension. A horizontal time dimension implies the same point in history and the same society. We could see that different institutions might offer different standard curricula at the same historical point. Thus Harvard University might offer better management curricula than others do. In other words even if we consider the same historical point, institutions have their own practice in the context of the three parameters. The knowledge parameter reflects the capabilities and experience of staff. The technology parameter represents the extent of use of teaching technology. This can include such things as multimedia curriculum delivery, online Internet platform course delivery, CNC distance learning and ITV distance learning. At one extreme some institutions may have not even have started the use of transparent slides! Finally, the pedagogy parameter affects the effort an institution puts into its instructional design. The ones that put in more effort should have better outcomes for their curriculum paradigm than others that have perhaps put in less effort. There are a number of articles arguing that we should pay more attention to pedagogy, but how can those pedagogical issues be integrated into instructional design along with the use of technology? This remains unclear. Overall, with these three parameters we can build a three-dimensional paradigm of curriculum delivery that can reflect its current standing.

The CLEAR Curriculum Delivery Framework

We have concluded that we can construct a curriculum delivery paradigm with these three parameters. The CLEAR framework (see the figure below) offers guidance on *how* to make this system work. It is a mechanism that can provide an open and flexible access and approach to curriculum. And it has been designed keeping these ideas in mind. In the CLEAR framework there are five basic components, namely, *Communication channel, Learner, Educator, Assistant, and Resources* (CLEAR). Four of those components are based on an initial investigation (Xu, 97) of the current framework of the Wrexham Business School. The *assistant* component was derived from a literature review.



The CLEAR Framework

In the framework figure, the lines indicate the communication channels. The bubbles indicate the other four components. The *communication channel* component (also referred to as the 'knowledge transfer routine') always links any two of the other four components together. When the five components are set into one framework and if somehow the resources transfer routine can reflect the openness and flexibility of access to the curriculum, it is not hard to arrive at the conclusion that the traditional approach has very little openness and flexibility for the learner. This is because in the traditional process, the educator draws knowledge from the resource, and mediates mainly by face to face communication in transferring knowledge to a learner. In the CLEAR framework, the knowledge transfer routine has been expanded by added the role of an assistant into the delivery system. Also the communication channels mean more than just face to face communication in the CLEAR framework. They also include all the possible communication methods relying on advanced technology. In consequence the resource becomes richer and easier to access in the sense of content and format due to the contribution of the assistant, the learner, and the educator.

Future Research

In comparison with traditional methods, the CLEAR framework can provide more opportunities to learners, since it sets curriculum delivery into an open and flexible framework by adding transfer routines and communication channels and it also enriches the format of knowledge resources. However, it is admitted that these goals can be achieved only if we can find ways to take advantage of technology, because the framework relies heavily on the use of advanced technology. Therefore future research in this project aims at developing a suitable technology platform. Currently the links between technology and the five components are being mapped. The components of educator, learner, assistant, and resource will centralize on their own roles in the system, and the communication channel will maximize the possibility of assisting their different roles. The main activity for the educator is to facilitate, for the learner it is to explore, for the assistant it is to cooperate and for the resource it is to be retrievable. The communication channel will have a key role in extending and supporting the system functionally. The system will be implemented into an object-oriented paradigm of the methodology of software development. The roles played by educator, learner, assistant, and resource can all be integrated as objects and attributes into the system by different communication methods to interact with the system. This work will be reported in more detail at a later stage.

Department of ECECS
United States
chia.han@uc.edu

Introduction

Learning styles are approaches to learning and studying (Dunn, 1987). We all have learning preferences, which enable us to learn more effectively. When introduced into a learning environment that supports our learning style(s), learners have a higher level of understanding the material. The learning styles theory implies that how much individuals learn has more to do with whether the educational experience is geared toward their particular style of learning. In a traditional classroom environment, there is one instructor and several learners, which is an one-to-many relationship. The instructor presents information with his/her personal style of instruction. If the instructor's style of instruction is conducive with the majority of the learner's learning style, then the class as a whole will perform well. In the general case, the instructor's style is conducive with most of the learner's, but not a perfect match. In this case, the majority of the class will have an average performance with fewer people doing either very well or very bad, which establishes a bell shaped grade distribution.

Imagine a classroom full of instructors and only one learner, which is a many-to-one relationship. Each instructor is an expert in the same field of study, but each uses a different style of instruction. Hence, the learner's chances of doing well in this classroom would appear to be significantly better than in a classroom with one instructor because each learner would adapt to the instructor(s) that would facilitate his/her learning style. In the sections that follow, we will introduce an implementation of the many-to-one relationship.

Arthur

We have developed a web based instruction system that provides adaptive instruction, Arthur. Arthur takes several different styles of instruction from several different instructors and makes them available to each learner, which defines a many-to-one relationship. A group of instructors with different instruction styles from the same field collaborate to create a course map, which is similar to a syllabus, for the course content. The course map is divided into small sections that are called concepts. A concept is a basic unit of instruction or a fundamental concept that must be covered within the course. In a traditional class, the topics that are listed on a syllabus would be considered course concepts. After creating the course map, each instructor will create a web deliverable course module, using their own personal instruction style, that adheres to the course map. Upon completion of their individual course modules, each instructor will add their course information into Arthur via the web. This creates an instruction pool of course modules accessible from the world wide web. Each course module represents a unique method of delivering instruction via the web utilizing a different instruction style. Upon entry into the system, learners will be assigned course modules from the instruction pool.

Learning Experience

When a learner enters Arthur using a login and password, Arthur will deliver the first concept of one of the course modules from the instruction pool. The courses are initially selected at random. Therefore, each student will be assigned their first course module by chance. Each concept is terminated by a short evaluation quiz entered by the instructor. Learners will take the quiz at the end of each concept. They are expected to pass each section with a score of eighty percent or better in order to continue within the current course module. This evaluation method introduces the term *Mastery Learning*, which is used by Arthur to adapt the instruction style.

Adapting Instruction

Mastery Learning is based on the assumption that, given enough time and proper instruction, most students can master any learning objective (Bloom 1968). The normal distribution of scores learners exhibit on any performance test arise from the use of one instruction style given by one instructor and the practice of holding instructional time constant for all students and allowing learning to vary. Bloom (1976) suggest that learning should be held constant and time allowed to vary. Arthur uses mastery learning to adapt instruction for each learner. When a learner completes a quiz at the end of a concept, Arthur employs mastery learning to adapt the instruction based upon the learner's score for each quiz. If the learner scores 80 percent or better, Arthur will allow the learner to move onto the next concept using the current course module. Otherwise, Arthur will force the learner to repeat the same concept under a different course module, which utilizes a different instruction style.

Conclusions

The theory of learning styles states that people have different approaches to learning and studying (Dunn 1987). Several studies show that there is "No Significant Difference" when technology is applied to instruction (Gerhing 1994, Goldberg 1996, & Moore 1996). The most commonly used instruction environments use an one-to-many or one-to-one instructor/learner relationship. We have developed an environment that utilizes technology to deliver a many-to-one instructor/learner relationship. Before the recent use of technology, this type of education experience would have been too expensive to implement. Using the world wide web and supporting technologies, we can deliver a many-to-one instructor/learner relationship such that individual learning styles can be accommodated.

Introduction

Web-based learning environments can offer learners an opportunity to participate in real-world, authentic situations that can provide them with exciting learning experiences. Anchored, authentic, and situation learning environments such as MayaQuest, Net-Frog, Jasper Woodbury, and Voyage of the Mimi, provide learners with a unique opportunity to participate in complex-real world learning experience. In these learning environments, learners collaboratively participate in experiences within meaningful contexts to permit the learner to become independent and develop problem solving and reasoning skills that can be transferred to other situations. Learners participate in activities to develop skills that involve the analysis, synthesis, and evaluation of information and strategies used to solve a wide variety of problems (CTGV, 1990). In turn, learners help define and refine the learning environment to create a multi-dimensional microworld.

Reform and accountability measures across the nation have challenged teachers to alter the ways in which they teach (e.g., SCANS, Goals 2000). Integrated curriculum and technology-rich learning environments meet these challenges. In Florida, responses to these measures are seen in the Florida Sunshine State Standards which describe skills that students should attain in eight subject areas (in four grade level clusters PK-2, 3-5, 6-8, and 9-12): Language Arts, Mathematics, Science, Social Studies, the Arts, Health and Physical Education, and Applied Technology. Both national and state standards involve a wide range of high-level outcomes that require students to work cooperatively to solve problems, apply solutions, and reflect upon their experiences.

Development of the Learning Environment

The Search for Luna was anchored around the framework of an Archaeological Field School. A team of professional archaeologists, elementary school teachers, instructional designers, and technology experts worked together to develop and implement the expedition. In Northwest Florida, there is a rich archaeological tradition, both on land and sea. Nautical archaeologists have found and excavated a sixteenth century Spanish ship in Pensacola Bay and believe that there are six additional sunken ships still to be found. Field School participants worked with archaeologists to make meaning from artifacts of the current find and assist in the exploration for and excavation of other ships. Two major themes guided students through the expedition experience: Become an Archaeologist, and The Expedition Challenge.

In "Become an Archaeologist," Field School participants learned the basics of becoming an Archaeologist through four thematic weeks: 1.Exploration, Immigration, and Colonization (History), 2.How Does Archaeology Help Us Learn About Our Past (Searching), 3.What's the Scientific Method? How Do Archaeologists Use It? (Excavation), 4.What Happens to Artifacts? (Conservation). For the Expedition Challenge, learners were encouraged to form an expedition team and plan, organize, and pretend to carry out their own expedition to explore and colonize a new territory. For both the Field School and the Expedition Challenge, learners were encouraged to collaborate with other learners throughout the State of Florida through a Share Network.

To support the constructivist nature of the learning environment, extensive resources were available to the participants. Learner resources were required to develop the necessary knowledge skills to solve the designated problems (Wilson, 1996). The Field School resources, for learners, included: an Artifact Database, Glossary, Web Sites, and Books. These resources formed the background materials that learners needed to answer expedition problems. To help teachers during the experience, materials were also available to provide assistance such as additional resources, sample in-class activities, and assessment and data collection techniques. Teachers also had access to a sample model unit, available through the EPSS, STEPS, that outlines standards alignment, integrated curricular activities, resources, best practices, and technologies that can be used in a Nautical Archaeological Unit (Northrup, Pilcher, & Rasmussen, 1998; Support for Teachers Enhancing Performance in Schools, 1998). Teachers were kept up-to-date on expedition status through online newsletters. All teachers were part of a listserv that was used for group communication.

Implementation of the Learning Environment

The expedition, which consisted of both live and simulated elements, permitted learners to participate in student-centered learning activities along with their classmates and other learners across the State of Florida from October 12 through November 6, 1998. Approximately 150 Florida teachers joined the expedition, participating in a variety of ways. Some classrooms completed the "Become an Archaeologist" sequence; others worked on the Expedition Challenge. Participants included teachers and learners from public school systems, private schools, home-bound students, and home-schooled students.

Many tasks involved a focus on cooperatively-determined problems and the solving of complex, real-world problems, that permitted an interaction with archaeology experts. Learners and teachers corresponded daily with the Expedition Team to receive approvals for class teams, equipment lists, and answers to the daily Mystery Artifact and Help Find It! (a Florida geography quiz). There were also four live broadcasts where learners were able to e-mail or call-in questions to historians and archaeologists. Archival records have been retained so that teachers can use the materials in their classrooms for years to come.

Conclusion

Web-based learning environments can be exciting experiences for both learners and teachers. Learners can help construct the learning environment to meet their individual learning needs and teachers can take advantage of pre-developed and emerging materials to enhance their curriculum. The development and implementation of virtual learning environments is a complex endeavor that requires a strong theoretical framework to permit effective development and implementation.

ushijima@csce.kyushu-u.ac.jp

Introduction

Multimedia technologies have made rapid progress in recent years. By using these technologies advantageously, we can create more powerful and effective educational teaching materials. However, developing multimedia teaching materials requires computer programming, which may be an insurmountable obstacle for ESL teachers who want to develop such materials, but are unfamiliar with computer programming. As a solution to this problem, we are developing a tool that helps a teacher create Web-based exercises and quizzes for their classes without requiring any programming. An ESL teacher will be able to create various types of exercises by preparing teaching materials, according to a simple format, without the need for any programming code. Our tool will be able to automatically create the appropriate HTML/JavaScript forms and pages by extracting necessary information from the prepared materials. The tool now under development is called A-MATE: A Multimedia Authoring System for Teaching ESL. We first began the A-MATE project in order to incorporate the option of creating individualized ESL teaching materials into our "Hypermedia Pronunciation Power Program," (Matsuno & Tsutsumi, 1998). "Pronunciation Power" helps ESL students improve their English pronunciation. However, we have found that A-MATE also has great potential as a stand-alone program, and would be useful to ESL teachers.

Strategy

The user interface of A-MATE should be as easy to use as possible, so that an ESL teacher can devote his or her main energies to developing teaching materials, rather than struggling through a computer program. After our analysis of TOEFL and TOEIC exercise texts, as well as ESL textbooks, we found several types of exercise patterns. Those patterns are: 1) Presenting pictures, 2) Presenting spoken dialogues, 3) Presenting sentences, or 4) Presenting (playing) videos, and then giving questions. Additionally, there are several question/answer patterns: A) Choose one answer from -n possible answers, B) Connect -n to -n items, C) Complete sentences, and D) Arrange -n mixed-up items into the proper order.

To sum up, we can abstract typical ESL exercise activities as follows:
1) Present example problems utilizing a (multi-)media type and format.
2) Choose one out of a group of question/answer patterns.

We have plotted our program strategy to produce student exercises based on above two ESL development activities adopted in general:
1) A teacher chooses one exercise pattern from the group of exercise types.
2) The teacher also chooses one question/answer pattern from the question/answer groups.
That is basically all that a teacher has to do. We will describe A-MATE in more detail in the following section.

Description of A-MATE

A teacher prepares his or her teaching materials in advance. The teacher may collect these materials via the Internet, or capture them from other media formats such as CD-ROM, Laser Disk, and/or VCR. As we mentioned above, A-MATE internally treats each type of exercise in a similar way. However, A-MATE offers several types of exercises for the teacher's convenience. Figure 1 shows the A-MATE Menu. In Figure 1, if a teacher clicks the "TOEFL" button, the menu for TOEFL exercises pops up. Then, the teacher can choose an exercise type from three options as follows: "Listening Comprehension," "Structure and Written Expression," or "Reading Comprehension." In Figure 1, if a teacher clicks the "Other Exercises" button, Figure 2 pops up.

If a teacher clicks the "Next" button after choosing menu items as in Figure 2, another card appears, and then the teacher is urged to input his or her specific questions, the number of possible multiple choice answers, and both the correct answers and the incorrect answers for each multiple choice question. We think the more the number of correct/wrong answer combinations grows, the more students can enjoy the variety of quizzes. This is due to the runtime randomization function of A-MATE. At runtime, A-MATE chooses one correct answer, and chooses n-1 wrong answers randomly from the group of wrong answers that a teacher has prepared in advance, and mixes up the correct answer with the wrong answers. This means students can try different patterns of quizzes, and A-MATE should automatically judge if students' answers are right or wrong. Table 1 shows how A-MATE's actions correspond with each exercise type at runtime:

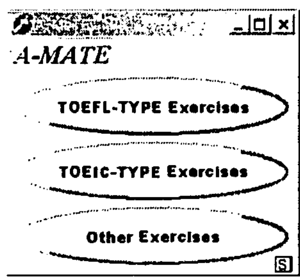

Figure 1: Main Menu

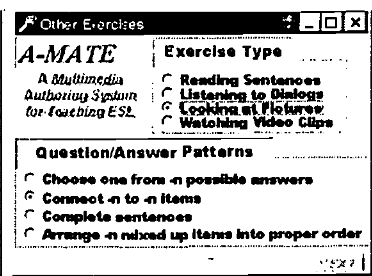

Figure 2: Sub Menu of "Other Exercises"

Table 1: A-MATE's Action

Type	*Required Inputs*	*A-MATE's Action at Runtime*
Choose one from -n possible answers	-n, one correct answer, and at least n-1 wrong answers	Choose one correct answer and n-1 wrong answers, and then mix them up
Connect -n to -n items	-n and at least -n pairs of items	Chooses -n pairs of items and mix them up
Complete sentences	Input sentences, and then mark words a teacher wants to hide	Hide marked words
Arrange –n mixed up items into proper order	-n sentences in proper order	Mix -n sentences at random

Discussion

There are several excellent authoring tools such as Macromedia Director and Asymetrix Toolbook. However, these packages demand a certain degree of programming knowledge and expertise, and can be difficult or time-consuming to effectively utilize. Nonetheless, such tools are quite useful for courseware design. If our goal were to make more complex courseware programs, with many additional options, A-MATE would not adequately serve the goal, and authoring tools such as those above-mentioned, would be preferable. However, with A-MATE, it is not necessary for the ESL teacher to acquire any knowledge of scripting, as the design parameters can cover most of the commonly used ESL exercise patterns, without any additional programming on the teacher's part. In the future, we also plan to develop software solutions for recording and calculating students' exercise results, and add methods for student grading optionally.

The Educational Technology Professional Development Program

Michael Szabo, Ph.D., University of Alberta
Mohammed Aly, Ph. D., Northern Alberta Institute of Technology
William Fricker, Northern Alberta Institute of Technology
Richard Poon, Northern Alberta Institute of Technology
Clayton, Wright, Ph. D., Grant MacEwan Community College

Abstract: Postsecondary Institutions (PSI)s in Alberta, Canada are exploring ways to promote the development of educational technology for on-campus, multi-campus and distance delivery of instruction. It became apparent that professional development was the way to harness the intellectual capital of the instructors and to provide the critical mass to carry out the enormous task before them. A collaborative initiative was proposed to develop a common set of instructional materials on the topic of educational technology for professional development in all PSIs in Alberta. Phase I resulted in the production and validation of 25 print-based modules on key topics in educational technology. Faculty and staff from 13 of Alberta's 27 technical institutes, colleges, and universities participated in developing and validating one or more of these modules. Participants may obtain certificated credit from a university and/or continuing education credit from their home institutions. Phase II, scheduled for completion by the summer of 1999 will involve the transformation of the original 25 plus an additional 5 modules on leadership training to interactive, multimedia format suitable for delivery via the World Wide Web. In addition, one educational technology facilitator has been hired at each of the principle institutions to provide professional development opportunities for faculty and staff using the print-based modules at their respective institutions.

Overview

In 1997, the Department of Advanced Education and Manpower established a series of grants to post secondary institutions (PSE) in the Province of Alberta. The grants are designed to promote the use of instructional technology in order to increase achievement, learning efficiency and most of all access to a broader range of residents of Alberta. A secondary goal is to foster cooperation among the institutions in the Province.

For Phase I, the Northern Alberta Institute of Technology (NAIT) and Grant MacEwan Community College (GMCC) formed a consortium to create a series of 40 print-based modules for professional development of faculty and staff in the area of educational technology. The modules were produced and validated by faculty and staff from over a dozen institutions during the 1997-1998 academic year. Faculty may opt for certification from the Faculty of Extension of the University of Alberta.

Phase II begin during the summer of 1998 under the leadership of NAIT, GMCC and the University of Alberta (UA). The first of two goals is to enhance the print modules with interactivity and convert them to web-based instructional delivery (WBI) for increased access and to model WBI as part of the professional development of faculty. The second goal is to hire a trainer at each of the 3 lead institutions to train faculty in educational technology concepts using the print- and later web-based modules.

To date, the print modules are being heavily used and the trainers from each of the three institutions are actively conducting both large and small group training.

Development of the ETPD Print-Based Modules

The Province of Alberta has been on the leading edge of educational technology since the early 1960s when the UA acquired an IBM 1500 CAI System. The tradition has continued with subsequent applications at many other Alberta PSEs. The application of educational technology proceeded through many research and development initiatives from 1965 through to the late 1980s. At that time, recession and budget cuts reduced the availability of resources to continue on the cutting edge. In the middle 1990s, however, the government of Alberta began to return some funding from the major cuts of previous years in the form of targeted grants. These grants were aimed at development of educational technology systems which would increase access to all citizens of the Province, rather than just those who could physically attend one of the many campuses.

At the same time, the demographic trends began to be recognized; older adults who want basic and relevant skills, minimal career interruption, corporate training competencies, and concerns over non-traditional institutions beginning to take over training.

The Educational Technology Professional Development (ETPD) Project was established in recognition of the need for training of faculty and staff in the use of educational technology. Secondarily, it is recognized there is a need for faculty of institutions to come to grips with the issues of change and reform which, some argue, educational technology can provide (will bring?). To accomplish the training, the consortium identified the necessary content, format, and expertise within the Province to design, develop and validate the modules. The modules are organized into the four areas of Computer Literacy (9), Institution-Specific Topics (7), Educational Technology Core (9), and Specialization Areas (15).

Examples from Computer Literacy include Basic Keyboarding, Basic Word Processing, Image Scanning, Creating WWW Searches, Basic Spreadsheet and Database Management. From the Institution-Specific topics include Electronic and Voice mail, Knowledge of Printing and Support Services, and Network Familiarity. The Educational Technology Core includes such topics as Instructional Design, Survey of Educational Technology, Independent Study and distance Education, and Layout and Design for Print Materials. Specialization Areas include things such as Web Page Design, Advanced CD-ROM, Presentation Graphics, Audio-Teleconferencing, and Introduction to Computer-Assisted and -Managed Instruction.

The modules were created and validated by faculty members from ten different PSEs in Alberta and are available through GMCC. Interested faculty may arrange to complete a specific number of these modules in a program operated by the Faculty of Extension of the University of Alberta. Several of the PSEs are using selected modules as part of their graduate and undergraduate programs in Instructional Technology/Distance Education.

Development of the ETPD Web-Based Instruction Modules

Phase II recognizes the need to provide the modules in modern electronic format using the WWW. At the same time, using the WWW must include adding value to the modules in the form of interactivity, ease of access, and finally to provide a model of what WBI can do for the faculty users. Funding was obtained by NAIT, GMCC and UA to re-design and develop 30 of the modules into WBI format.

As of this writing, standards have been established and development of modules is underway. Issues such as who, how, where and what are being resolved. In addition issues of platform, servers and telecommunications links and speeds have been resolved.

In recognition of the fact that training is a necessary but insufficient condition to bring about change in the use of the innovative nature of educational technology, a series of 5 modules on dealing with the change process in the context of educational technology is being developed. These will complement and be a part of the 30 WWW modules. Example topics in this series include Dealing with Mental Models, Sharing a Vision (for Educational Technology-Driven Change) and Long Range (multi-year) Planning.

Also in Phase II, a full time trainer has been hired at each institution to provide group and individual support to faculty with respect to the use of educational technology. During this presentation, an update on the usage and WWW development (scheduled for completion for summer 1999) will be provided. In addition, sample modules will be made available for examination of structure, content and methodology.

Multidisciplinary Development of Sophisticated E^3 Learning Models

robert.hinks@asu.edu

Introduction

Many people - including legislators and governing boards of educational systems, college and school administrators and faculty, owners of learning technology companies - are searching for a signpost that indicates the best way forward for education. Appreciating the fact that knowledge is being reorganized, none can say with certainty how education will be done ten years from now. One crucial question, the answer to which would provide an important clue as to what may lie ahead, is "what should be the role of modern computer and communication technologies in the future of education?"

Considering the fact that effective communication is at the heart of good teaching and learning, interactive multimedia CD's and resource-based learning using the Internet would appear to have a bright future in education. Moreover, advances in these and other technologies continue to change many aspects of modern life, often in very significant ways. Notwithstanding these facts, just how far new technologies will move us along the path towards more effective, enjoyable and efficient learning (**E^3 learning**) is an interesting question to contemplate. It is possible that the use of modern computer and communication technologies in education might not advance far beyond their current role as useful additions to traditional methods of teaching and learning. However, the same technologies *could* lead to the development of entirely new learning materials and learning environments that, if successful, would require a large-scale reassessment of the function of educational institutions.

The E^3 Learning Model

The answer to the question of where education goes from here might be another question: "what (technological) developments in the quest for E^3 learning will capture the interest of students?" Most current educational applications of computer and communication technologies do not demonstrate the full potential that they possess to improve learning. For an effective demonstration, it will be necessary to create a highly developed "whole product" - an *"integrated learning system"* - that includes *all* components of a course and facilitates the human interaction necessary to create a supportive environment for learning. Integration of new, comprehensive and sophisticated methods of communication into an optimal technology-driven learning environment is a prerequisite for the success of advanced technology-driven E^3 learning models at the post-elementary levels.

It is quite possible that the reaction of students to new learning systems will be the signpost that legislators, administrators and others pay most attention to. Appropriate technology-based systems providing complete, flexible learning experiences will attract students. When these systems also demonstrate the potential to be well integrated with other school or college activity then institutions will shake off uncertainty and nervousness and become enthusiastic about their future in a new learning environment.

The transformation of conceptual components of a new technology-driven model of learning into products that have worldwide appeal to students requires a clear objective and a sound plan to achieve it. The objective, broadly defined, is as stated above. That is, to create an integrated learning system by combining the latest computer and communication technologies with the desirable components of traditional education. If development of new computer-based learning products is the force driving this work, then the first requirement of the plan - an element that is crucial to the success of the entire endeavor - is to have the appropriate mix of people on the technology research and development team. Persons with a vision of what education could become, and possessing not only creative talent but also relevant (good or bad) experience of current education systems, these special people will possess vital components of the knowledge and dedication necessary to achieve the objective. The "appropriate mix" will draw from many disciplines, and include persons from traditional populations of the academic community as well as further afield. This is a very important point. Whereas many educational applications of technology have been developed by college faculty or specialists employed by learning product companies, sophisticated "whole products" will result from the combined efforts of people with diverse talents. Faculty, *students*, *alumni* and others having knowledge in the area of learning being redesigned, or with expertise in computer or communication technologies, or the learning sciences, communication arts, etc., etc., must work together to create the highly-developed products having potential to reinvigorate education at all levels.

To emphasize this point even further, some school and college faculty learn the elements of multimedia or other types of computer software in order to develop learning "modules" that illustrate parts of courses they teach. Faculty and students in media arts use the same software to develop creative works that typically communicate something quite different. When education technologists utilize the software they do so primarily from a learning sciences viewpoint. All of these talents must be combined - *at a higher level than ever before* - to create the new technology-driven E^3 learning methods!

The CoBaLT Team

In 1995 the author created an informal partnership of students, faculty and alumni of Arizona State University to explore the use of advanced multimedia software to develop computer-based learning modules for college-level engineering courses (Hinks & Lerman, 1996). Members of the partnership, named CoBaLT for *Computer-Based Learning and Training*, has ranged from 3 to 7 persons representing a number of academic disciplines, including computer science, engineering, chemistry, architecture, education, music and the media arts. The members have had extensive discussions on the shortcomings of traditional education and the best ways to improve learning. Our experience has underscored the importance of research and development taking place in an interdisciplinary setting, and "hands-on" experience has led to a high level of confidence in the use of advanced multimedia software. Several prototype multimedia modules have been developed and demonstrated. Perhaps most importantly, an appreciation of the opportunities and challenges offered by the new computer and communications technologies has been gained.

Findings

The CoBaLT team believes there are three aspects of E^3 learning model development that are critical to success, namely:

1. The project manager needs to pay constant attention to the interaction among all members of the model development team. This requires every participant, regardless of area of expertise, to fully understand and support the team's objective. Regularly scheduled, well-planned meetings are essential, and must include the full participation of all team members.
2. Another significant challenge is to establish a viable model of the multimedia design necessary for optimal E^3 learning. The goal here is to develop a clear and concise understanding of the entire multidimensional framework that replaces the traditional linear approach to the presentation of knowledge. High-level software, representing the latest in integrated media technology, has to assemble the knowledge contained in each module of the framework using a standard – but flexible – "skeleton", the components of which allow connections among the multiple formats of integrated media to be represented in the same way from module to module.
3. The third component of optimal model development is efficient utilization of computing hardware and identification and use of the most suitable multimedia software. Software for sound (including music), text, graphics (including animation) must be compatible. In our experience, it is advantageous if more than one team member is familiar with any given software.

Introduction

Instruction through the World Wide Web is a viable alternative to the traditional, formal classroom environment. Students from kindergarten through post-graduate classes take advantage these opportunities to enhance their learning experiences. One of the criticisms directed toward WBI is that there is lack of interactivity and this lack of interactivity consequently reduces instructional effectiveness. There is a perception that students are isolated and that there is a lack of communication among instructor and students. However, using interactive instructional strategies can facilitate the development of intellectually motivated students.

The Fundamentals of Interactivity

Over the past two decades the term interactivity has been used in many contexts. Interactivity, in the 1980s, referred to the hardware required for Levels I-IV of interactive videodisc technology. In the past few years, researchers began examining the nature of the interaction rather than the capabilities of specific hardware. Schwier (1993) proposed a taxonomy of interaction that incorporates levels, functions, and transactions for a multimedia environment. The three levels of interaction proposed were reactive, proactive, and mutual. Reactive interaction is basically used for responding to given questions. Proactive interaction emphasizes generative activity and construction of new and meaningful knowledge. Mutual interaction is reserved for artificial intelligence and virtual reality environments.

Based on this earlier research in multimedia design, proactive interaction is of most interest in the design and implementation of interactive WBI. Self-awareness, self-regulation, problem-solving, and decision-making skills are most supported by a generative environment (Bruning, 1994). Instruction created for the web environment can be developed that is generative in scope and interactive in nature through a student's active involvement in the instructional process. Interaction and subsequent communication levels are facilitated through three different modes: (1) student-to-content; (2) student-to-student; and (3) student-to-instructor. Each mode is not mutually exclusive as a combination of interaction types actually strengthens the learning environment and promotes multiple instructional strategies for communities of diverse learners.

Designing Instruction for Interaction and Communication

Answers to the question, "what is the role of instruction," suggest prominent instructional strategies to facilitate modes of communication and interaction within web-based instruction. A sampling of activities and instructional strategies should be used to facilitate the different modes of interaction and levels of communication. For each mode and level, unique strategies can be developed within the context of the web-based learning environment. As web sites are developed to facilitate the instruction, appropriate design elements can be incorporated that assist students in the interaction and communication processes.

Student-to-Content Interaction Strategies

Instructional. One of the primary ways that students participating in WBI receive information is through interacting with the lesson content. Comprehensive electronic lectures may be used to present information. Organizing strategies, such as advance organizers, tables of contents, and lists help guide the student through the lesson. Students may also explore teacher-included web links for elaborated information or information from a various sources and opinions. Embedded questioning techniques can help to keep the learner on task and engaged in the learning activity. Questioning frames can also be used to direct students through searching, discovery, and exploration activities. Summaries of the lesson can refocus the student on important points and prepare them for supplemental activities that promote retention and transfer of information.

Web Page Designs. Strategies for interaction are important for student-content interaction; however, design of the web page is equally critical. Pages should be aesthetically pleasing and appropriate for the learning situation and should follow appropriate screen design/layout principles. For example, relevant graphics can be used as needed. The text can be formatted so to permit students to follow the lesson and to motivate them to continue working through it. Lines and lines of text should be avoided to prevent information overload. Instructions and directions need to be clearly stated and highlighted so that they are set apart from the instructional material. Likewise, web links should be distinctly noted and return instruction included.

Student-to-Student Interaction Strategies

Instructional. Student-student relationships are difficult to generate by the very nature of WBI itself. Students are never actually in the same room with each other and, consequently, traditional ways of building a cohort (e.g., personal communication, before, during, and after classes; in-person group activities) are not possible. Discussion and responses take place over extended periods of time, reducing spontaneity and conversation flow. Strategies such as early formation of groups, changing groups often, and mentoring among novice and expert students can be used to assist students in developing effective group techniques.

Web Page Designs. When building group discussions, activities such as chats, threaded discussions, e-mail, listservs are typically used to facilitate student-student interactions. Other technologies such as web boards and desktop video conferencing can be also used.

Student-to-Instructor Interaction Strategies

Instructional. The student-instructor interaction in WBI is potentially very personal and can be viewed as a mentor-student relationship. Through e-mail, personal communication is promoted; instructors can develop one-to-one relationships with their students that may not be possible in a traditional course.

Web Page Designs. As with suggested designs for student-student interaction, student-instructor design elements include consistent location of communication links and easily available help and frequently asked questions. Strategies that instructors may use to facilitate student-instructor interaction include: automatic response (sending receipt acknowledgements) and responding to all when asked a question by one.

Conclusion

There are many instructional strategies can be used to facilitate interaction in a web-based environment. Effective use of these strategies permits students and instructors to actively engage in the learning process and develop positive, meaningful relationships that build generative, interactive learning environments.

Pedagogical Challenges for the World Wide Web

Tony Fetherston
School of Education
Edith Cowan University
Perth, Western Australia
t.fetherston@cowan.edu.au

Universities are showing increasing interest in raising the standard of teaching that occurs in their courses. There is a growing awareness that the traditional model of lecture/workshop/tutorial/assignment may not be the best approach in promoting learning in students. Concurrently with this change, there is increasing use of the World Wide Web(WWW) to deliver courses to internal and external students.
It is timely then to examine the role of the WWW in moves towards better teaching and learning for internal and external students at university.

Learning approaches

The first challenge is to begin regarding the use of the WWW not as a delivery medium but as teaching and learning tool. Once viewed this way we can allow pedagogical constructs to be applied to the use of the WWW rather than just examining the technical issues surrounding the use of the WWW.
The usual approach in most internal courses at universities involves a lecture/tutorial format in which material is delivered at lectures and discussed at tutorials. The unspoken assumption is that delivery of the material (lecture) results in learning of the material. This approach is called transmissive and assumes a strong link between the means of education and the ends. That is, having delivered the material then students are assumed to have learnt.
For external students, materials delivered by the web offer access to easily updated textual materials, some limited interactivity with programs on the WWW and access to audio and video that can be streamed in real time. This makes it technically possible for them to watch a lecture in real time without attending the university. This is also a transmissive mode of learning.
Approaches that encompass collaboration and build a sense of community would seem to be ideal for support by the use of the WWW and are becoming an important focus of research (McMahon, 1997; Dillenbourg & Schneider, 1995; Walker &Lambert, 1996).
If we start to regard the WWW as a teaching and learning tool that can support social constructivist approaches to learning, then University lecturers will need support as they undergo personal, social and professional change.

Joining the community

The WWW has probably been the main influence that has changed the way we conceive of computers. They are no longer machines which have to be conquered or commanded but have become transparent (though maybe some operating systems and browsers make them translucent!) windows into an information world. Students need a sense of this world, a sense of the audience participating and an understanding of the mostly unwritten rules that govern its behaviour in order to successfully use the new medium. The second challenge facing the use of WWW then is to equip our tertiary students with the conceptual models and practical skills to enable them to participate in this community. This is necessary because, according to a social constructivist view, participation can result in good learning. Once they can participate then we face the challenge of equipping our students with the critical thinking skills necessary so that they can confidently use information on the web for learning purposes..

Using the technical features for learning

Students can fill in forms, watch video, complete a multiple choice test, have it marked, watch live video, listen to live broadcasts, watch animations, submit written assignments, email other students, talk to other students and look at other students through the use of the WWW. These capabilities represent clever technical achievements and there is no reason to think that development in this area is likely to slow. However these achievements pose a third challenge (related to the first) of how to best implement technical capabilities so bring about meaningful learning. Which means finding good pedagogical practices that will build on the inherently engaging nature of the web and produce good learning.

Assessment

To answer this question would require a consideration of a broader range of assessment techniques currently used at universities in order to uncover differences in learning. Such consideration is likely also to occur if universities contemplate outcome-based approaches. Assessment should be reconsidered in most university courses with the advent of the use of the WWW and this presents a fourth challenge of how to best use the web for good assessment. Good assessment is valid and authentic and would mean practices like providing opportunity for assessing student's procedural skills, allowing students to critique set problem and allowing students to make up their own questions.

Learning to learn

The fifth challenge facing the use of the WWW in universities is to how best use the web to encourage good learning behaviours in students. As an example of the kind of behaviour to be encouraged, metacognition is universally regarded as an essential attribute of good learning. If students have good knowledge of the nature of their learning, of their effective learning strategies, of their learning strengths and weakness and can be given some control over their learning then better cognitive and affective outcomes will result. Further, conceptual change requires metacognition and metacognition helps recognition, evaluation and revision of personal views (Baird & Northfield, 1992). The WWW with its essentially individual approach to education has potential in this area to meet this challenge if appropriate design strategies are employed. If the design of courses allows individual exploration coupled with reflection and the comparison of views with others then metacognition can be enhanced and good learning can result.

Change

A final challenge to the use of the WWW is faced by lecturers themselves. Using the WWW means that lecturers will have to change their usual practice. Change to embrace the WWW and to meet the above challenges would probably be driven by a belief that learning in their courses is not as good as it could be and that assessment could be improved. It is likely that the use of the WWW for distance education students is likely to be restricted initially to its use as a delivery platform as good instructional design is required to meet the above challenges. It is far more likely that the challenges can be met through the use of the WWW to support the internal delivery of courses as lecturers can more easily implement a different approach. For this reason the WWW is likely to be used in good teaching and learning mostly in internal courses.

Supporting Primary and Secondary Education Through a Centre for Distance Training

G. Papadopoulos, A. Gogoulou, E. Gouli, H. Houssou
Pedagogical Institute of Greece, Department of ICT
E-mail: {gpap, rgog, lilag, ehous}@pi-schools.gr

Introduction

The rapid evolution of science and technology causes changes in all aspects of every day life. It has become necessary for everybody to develop learning skills and have the opportunity for life long training in order to conform to the demands these changes impose. Especially for the teachers who play major role in the application of the educational system, mechanisms providing continual training and daily support need to be established. In our country, the teachers' training is facing a lot of difficulties due to the fact that there are a lot of distant and secluded regions and islands. The use of the information and communication technologies opened up new opportunities for accessing educational material and participation in distance courses, which can be better adapted to the trainee's needs, offering greater interactivity, providing more possibilities of individualisation of the learning process, in which the trainer is not a mere transmitter of knowledge and the trainee is not just a passive receiver. The Hellenic Pedagogical Institute has introduced a Distance Training Centre, called "Hellenic Distance Training Centre" (HDTC, http://hdtc.pi-schools.gr) which provides new ways for training and collaboration between scientists, teachers and students.

HDTC Services

In the context of making the teachers active members of a world-wide educational community and giving them the opportunity to find out the educational potential of the new technologies (ICT), the HDTC aims at the: a) provision of in-service, distance training; b) elimination of teachers' and schools' isolation; c) removal of barriers to learning, ensuring accessibility for the majority of teachers and students; d) provision of collaborative opportunities via the Web; e) development of added-value services utilising the existing technological infrastructure at schools; f) contribution to the formation of new attitudes towards the teachers' training and the exploitation of new technologies for the improvement of teaching and learning.

The implementation is Web based, incorporating all the necessary tools for interpersonal communication. The provided services are based on the following three scenarios i) *supported self-learning* ii) *collaborative learning* iii) *virtual classroom*. These services are structured as follows:

Training material: It is very important for teachers and students to learn about the role of ICT and its implications. The use of ICT has significant advantages both for the students who may gain a lot in information handling, motivation, problem solving, etc, and the teachers who have more opportunities for individual teaching and group work, for rethinking and applying new teaching and learning strategies, etc. This material concerns: a) *information and communication technology in learning*; b) *basic technical knowledge*; c) *scenarios - lesson plans for the use of ICT in the classroom*; d) *educational software*; e) *research projects*.

Curricula – textbooks: The teachers have the possibility to be informed in time for the new curricula and textbooks and contribute to their development by sending their comments and suggestions. They can also send relevant questions or ask for clarifications in order to be prepared before their application in schools.

Discussion fora: The discussion fora environment intents to promote and facilitate the exchange of information among teachers and contribute to the solution to common problems. The educational community, through this environment, has the opportunity to join several on-going discussions relevant to either specific curriculum subjects (e.g. Mathematics, History, Physics) or cross curriculum subjects (e.g students' assessment, use of ICT in education), raise issues to be discussed or answer to existing ones.

Educational web-sites and Conferences: A "guide-list" of Web sites is provided to the teachers and students which focuses on those Web sites that mainly offer lesson plans, additional educational material and collaborative activities. Also, bulletin boards for educational matters and conferences are presented.

Collaborative activities: Through several activities, the teachers are motivated to use ICT. These activities include evaluation of Web sites according to specific criteria, design of lesson plans, development of Web pages with educational material etc. The results of their work are presented via HDTC.

Help desk: This is a service of major importance, which aims at supporting effectively all the teachers to get over minor or major every day problems. It concerns the following: a) *tools and techniques*; b) *pedagogical issues*; c) *FAQs*; d) *submission of questions*; e) *mailing lists*; f) *bibliography search*; g) *comments- suggestions*.

Virtual classroom: The Training Centre has the necessary infrastructure to organise telecourses. It is responsible for the choice of the subjects, taking into account the teachers' preferences and needs. A group of experts from the academic community may be invited to engage in the telecourse. The communication is bidirectional, so that questions can be raised, clarifications can be given and collaborative activities can take place. The careful choice of the subjects, the trainers, and the effective management of organisational issues can result to active trainees' participation and the overall success of the telecourse series.

Conclusions – Future plans

The first conclusions, as these are drawn from the comments sent by e-mail as well as from the questionnaires that were completed by teachers are very positive and encouraging and point to the overall usefulness of such a centre. Unfortunately, in our country, it seems that the ISDN technology is still immature to be widely used at schools - the ISDN connection cost is high and the technical support is inadequate. Pedagogical Institute's forthcoming plans are focused on the following:

- the qualitative improvement and the renewal of equipment and services in the light of technological advances. More specifically we will work on a) the enrichment of the educational material b) the minimisation of the response time to the users' requirements, questions c) the best fulfilment of the teachers' needs and d) the promotion of public awareness and discussion about the HDTC and its benefits.
- the development of a reliable model for organising telecourses.

STUDENT PERCEPTIONS: INFUSING TECHNOLOGY INTO TEACHER EDUCATION THROUGH ELECTRONIC PORTFOLIOS

Carla Piper, School of Education, Chapman University, USA, piper@chapman.edu

Dr. Susan Eskridge, Benerd School of Education, University of the Pacific, USA, seskridge@uop.edu

Preparing teachers for the 21st Century has been a concern for educational leaders in this country during the last two decades. The National Council for Accreditation of Teacher Education (NCATE) issued a report called "Technology and the New Professional Teacher: Preparing for the 21st Century Classroom" in 1997. The NCATE technology task force suggests that perhaps the best way teacher education faculty can inspire future teachers to use technology is "to cast themselves as learners and to experiment fearlessly in the applications of technology," making themselves "role models of lifelong learning" (p. 9). The task force states that re-educating the existing teaching force requires extensive professional development, but that the problem will be compounded if future teachers are inadequately prepared to use new technology (p. 7). NCATE has challenged higher education to incorporate technology across the entire teacher education program, not just as a "computer literacy" class added to the existing curriculum (p.7). The task force states that "today's teacher candidates will teach tomorrow as they are taught today" (p.4). NCATE states that teacher education is in a time of transition, calling for experimentation and a new attitude that is "fearless in the use of technology" (p.6).

The U.S. Department of Education states that technology offers "numerous possibilities for integrating assessment into the daily life of the classroom" (1997, April, p. 6). Portfolios have been helpful, not only in assessing student performance in teacher training courses, but in helping students reflect upon and organize the material learned in the courses. Developing portfolios electronically provides students with new ways to demonstrate a broad range of abilities, as well as give them greater awareness of the unique capabilities of technology in creating meaningful forms of alternative assessment. A well-designed electronic portfolio system can support this approach and offer expanded potential for collecting different kinds of records of students' work. Final products in a variety of media (text, graphics, video, multimedia), students' oral presentations or explanations, interviews that capture students' development and justifications for their work, and in-progress traces of thinking and problem solving processes can now be included using video and computer technologies.

This study focuses on the use of technology as a tool for portfolio assessment of teacher candidates as evidence of achieving course objectives. Students from a small California university created multimedia portfolios as a final assessment for a reading methods course. Course objectives were linked to state teaching standards, as well as the Reading Instruction Competence Assessment (RICA) goals. Initial attempts to use an HTML web format caused problems due to the students' lack of computer experience and expertise. Templates were pre-designed using Hyperstudio in order to provide a more workable framework for inexperienced students. A separate stack was created for each course objective and a menu stack provided space for personal artifacts and a philosophy statement. Each objective stack included a cover sheet text box for self-reflection and self-assessment. Artifacts were evaluated in terms of meeting course criteria and cover sheets were examined for evidence of student self-reflection and self-assessment. Students were interviewed to gain insight into the experience of collecting and preserving artifacts electronically.

Generally, the students responded positively to the electronic portfolio experience despite the initial concern over the technological expectations. Several students expressed frustration at having to work with computer technology in a reading methodology course. One student stated: "I was scared of the whole assignment at first because I didn't know how to use any other programs than word processing basically." Another student described her change of attitude toward the electronic portfolio process as she progressed through the semester:

> I was really negative about it at first because it was technology and I didn't know how...I didn't see how it really related to the English and Language Arts class and I didn't want to do it, because I

didn't see how it related to that. But, after I did it, I saw the relation and how it correlated. Actually I'm glad that I did it.

Students generally responded favorably to the use of templates. One student said: "I liked having the prepared one (template). That was great, 'cause I was getting started." Another student said: "The first one (disk) that we had was of the templates, which were good. I really liked the templates. Those were helpful..." Some students indicated an interest in developing their own design in the future. One student stated: "I liked having the template. I could change things later to spice it up." Another student described how she would improve her process in the future: "I would use Hyperstudio but I'd design my own template. The ease of the template took the stress off for the first time, but I'd do my own next time."

When students were asked what they saw as the purpose of the electronic portfolio project, one student replied: "I saw it as primarily a reflectionary tool. It was helpful to know you were gaining what you should get out of the course. It fulfilled various purposes, but I used it more for reflection on goals. It could also be a tool for interviews." Another student stated: "One of the purposes was to get me used to a new computer program, because I know that's one of the big things that we need to start getting used to now is all the technology. The other purpose was to show that I had met the necessary objectives for the class and that I understood that I met the objectives."

Students generally indicated a positive response to the use of portfolios for assessment. According to some students, electronic portfolios offered a more creative means of demonstrating evidence of meeting objectives.

> As with any portfolio, I was in the position to review all my work and the initial objectives of the course. In doing this I was able to assess my work and reflect upon how the work I completed met these objectives just by being able to tell you what I did for all these objectives or what stuff I put in there. I think I got more out of it than if I would have if I'd had to study for a test and just basically memorize and cram into my brain a bunch of stuff for just a couple of days, and then just spill it out on a piece of paper.

Evidence of self-reflection and self-assessment was present in all portfolios examined. One student stated: "The class really helped me feel prepared, but I think sticking it all in one place and making connections between the objectives and the things helped me say, oh look, I am prepared. Not only do I think I am, but I can tell you why." Another student explained the electronic process:

> As with any portfolio development, you are critically examining your work to determine which way you have met the selected criteria, and how you can best example or highlight your work. The process of developing the portfolio is a constant self-assessment. However, I don't feel that the electronic portfolio was more of an assessment than a hard-copy portfolio would be. The process is the same, it is the final output that is different.

NCATE states that teachers need new understandings about how technology has changed society as a whole and new approaches to using a wide range of tools and software as a part of their own "instructional repertoire" (p. 6). In the year 2000, NCATE expects to present new accreditation standards that make effective use of technology a central requirement for teacher preparation. Infusing technology into teacher training presents a challenge to educational institutions due to the ever-expanding accreditation requirements and time limitations. Student perceptions provide greater insight into the strengths and weaknesses of the electronic portfolio as a tool for assessment and as a viable means of integrating technology into teacher training.

New communications and strategic planning

Communication is a fundamental concept in educational practice. The attitude of professional educators and students towards distance education is influenced directly by the quality of the communication methods available [Price 1995]. The technological developments in the television, computing and communication industries are having a major impact on all aspects of life. The convergence of these technologies is bringing about new business opportunities, new home entertainment possibilities, new learning opportunities in traditional classroom teaching, self learning and distance learning. Developments in personal computer and interactive video techniques make it increasingly possible to demonstrate, experiment, analyse and simulate complex processes on screen. The World Wide Web, for example, provides new opportunities for quality distance education over the Internet. The Web, combined with other technological advances such as digital video compression, video systems, multimedia networking, voice activated computers, virtual reality, etc will offer a wide range of high quality on-line distant learning opportunities [Underwood & Underwood 1994].

Many research activities have been carried out over the years in the area of *strategic planning* and *scenario methodologies* (see for example [Georgantzas & Acar 1995]) but no great efforts have been devoted to facilitating their fruition by advanced learners. Enormous attention has been paid over the time to theoretical aspects of formal strategic planning but the gap between analytical details of the ensuing findings in various application fields and the necessity of easy-to-learn knowledge has not been adequately bridged. Therefore, methodological and technical efforts have to be made in order to make these disciplines easier to be learned during advanced education courses. These attempts can be made even by exploiting the tools offered today by technology, in particular by the "networked hypermultimedia" epoch which we are entering, characterized by the evolving global digital superhighway infrastructure and dominated by the huge planetary diffusion of the networked hypermedia World Wide Web.

In this context, *scenario engineering* includes a general corpus of scenario methods and techniques for strategic planning and pre-planning. Scenario engineering can be regarded as a pragmatic approach arisen in the area of scenario methodologies which has been conceived and developed for the construction of scenarios to be produced even by exploiting multisectorial technology resources.

NET-SIMULAB for advanced education

NET-SIMULAB [Nicolo' & Sapio 1998a, 1998b] is an advanced work environment suitably arranged to carry out research activities in the field of scenario engineering and to handle multimedia information in an interactive way. As regards the hardware configuration of NET-SIMULAB (Figure 1), there are three main workstations. Workstation 1 and workstation 2 are basically used for scenario generation and analysis. Workstation 3 is used for scenario presentation and documentation. A portable workstation is used for remote elaboration and can be connected to fixed workstations. Additional hardware includes external mass-memory units, hi-fi devices, video equipment and digital photographic facilities.

In particular, *scenario transfer* [Nicolo' & Sapio 1998c], a subset of scenario engineering specifically devoted to make scenario studies easy to use, can be oriented to education objectives. To this purpose, the instructional pattern for learners may include advanced navigation hypermedia tools and allow distance learning over the global network. Thus, NET-SIMULAB based scenario-engineering training management can be performed. As an example, instructional projects concerned with scenario transfer methodology could be addressed to scenario modellers, decision makers as well as scholars and students in the field of strategic planning. In this context, NET-SIMULAB is intended to serve as a knowledge and expertise centre oriented to "produce" scientific methodology for scenario transfer. This task can be significantly facilitated and strengthened by the access of NET-SIMULAB to the Web.

The success of advanced education in strategic planning greatly depends on the effective transfer of information about application hypotheses and methodological outlines as well as about results and findings to learners. Clear (intrinsically), comprehensible (for non-specialists), concise and correct (as to formal aspects) information can assure immediate and time-saving catching of key aspects by learners. We can call this important requirement the "four 'C's rule" (due to the initial letters of the words clear, comprehensible, concise and correct) and we consider it as a basic principle of an efficient and effective scenario transfer.

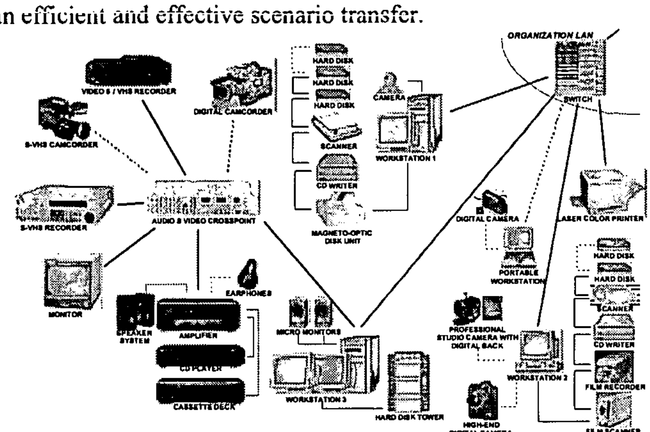

Figure 1: Technical configuration of SIMULAB

In this context, multimedia technology can provide powerful capabilities that should be suitably employed. Exploitation of sound and images (still images and full motion pictures) can significantly contribute to delivering easily understood, synoptical studies and therefore to facilitating their utilization. Furthermore, scenario documentation, presentation and communication are more effective if they are research-engineers—driven (i.e. modellers-, analysts-, simulationists-, methodologists-driven) through the use of multimedia facilities. As a matter of fact, such capabilities provide modellers with flexible technological tools which are suitable to calibrate and modulate the complexity level of the transfer contents according to the circumstances and the category of learners.

Introduction

In many educational organizations, networks are used for educational support. On the other hand, there are many traditional classes that have no educational support using computer networks. When one intends to utilize computer networks or the Internet for traditional classes, he will suffer from problems such as time for investigating teaching materials, manpower, arrangements of equipment and preparation of presentation data. In this paper, taking above points into consideration, we propose a method of introducing educational support using computer networks for traditional classes.

The method of educational support for traditional classes using computer networks

We set following goals for the proposed method. First, the purpose of the method is review and self-studying. Second goal is that the method could preserve the various teaching style of teachers. Third goal is that the method should be simple so that the number of staffs and a budget should not be large. Fourth goal is that the method is able to be adopted to traditional lectures and computer exercises. Last goal is that more than one simultaneous classes should be supported using the method. To satisfy these goals, we adopt the following means:

- *The scene of a class is recorded on video tape as it is. Afterwards the video is opened to the students through networks.*
  In this way, teachers do not have to make additional preparations for classes. Watching the video is enough for students to relive the class.
- *A written material or a computer screen of the teacher operates is also recorded on another video tape. This video and a teacher's video are synthesized to a single image for publication.*
  In this method, as the written material is created during the traditional class, teachers need not prepare anything than the usual lecture and need not change their teaching style.
- *The camera for recording teacher's movements has fixed view and never follows of teacher's movements.*
  Written material is more important than the teacher's movements. Especially for reviewing and self-studying, precise movements of the teacher are not necessary. Only the feeling of actually being in the class and the motion that the teacher points to something are necessary.

Implementation

There are following three steps to implement our proposed method. First step is to record the class. In the case of a class in which the teacher uses a blackboard, he must use a visual presenter instead of a blackboard. The output from the visual presenter is recorded and presented to students using a projection device. Another video camera records movements of the teacher from the rear side of the classroom. The view of the camera is fixed and it is left during the class as it is. In a case of a computer exercise class, we use a scan converter to record a screen of a teacher's computer. Another video camera records a keyboard and a mouse that the teacher operates. Second step is to make digital video data. Video of the teacher and video from the visual presenter are captured into a computer and merged into a single video. For image compression, we use the MPEG-1 format. Figure 1 shows an example of an MPEG video picture. Voice data is compressed in MPEG Layer II form. Third step is making digital video data public to students. We use the WWW as user interface for viewing MPEG-1 video. The WWW page contains names, syllabuses, titles and hyperlinks to MPEG-1 video for each class.

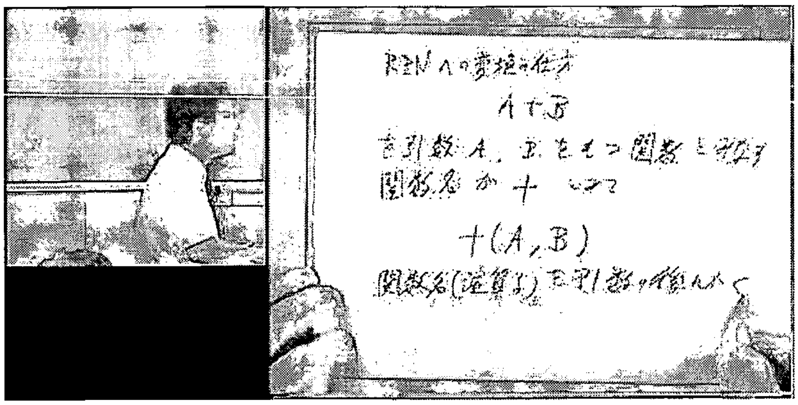

Figure 1: An example of an MPEG video picture.

Results

As experiments, we applied our proposed method to following two subjects in 1998. The number of supporting staffs was only two.

- "Exercise for information processing" course. This subject teaches a computer literacy for freshman students in the Japanese culture course. Each student uses a computer in the course. We applied our method to this course from April 17 to Jun 26 1998 (10 classes). The number of access times to the videos was 84 until July 1 1998. This number is fairly large because the number of absentee of each class was less than 10.
- "Computer literacy" course. This subject aims to introduce the computer science to freshman students in the information science course. Explanation of this subject was mainly carried out by speaking and writing. We applied our method to this course from Jun 9 to Jun 23 1998 (three classes). The number of access times to the videos was 134 until July 1 1998.

In both courses, teachers commented that this method was effective as an educational method for students who were absent from a class or students who had not understood well. Students who actually watched the video commented that this service was good because the points, which were difficult to understand during the class, were able to be reviewed. They also commented that self-studying watching the video was necessary since one might be absent from class because of compelling reasons.

Introduction

In Hong Kong there has been positive support, from educationalists, academia, and universities, for the integration of computer-based pedagogy in classroom teaching and learning (Li et al 1998). This study is in an attempt to support those initiatives by investigating the effective uses of computerized presentational tools (CPT) for enhancing teaching and learning. The central focus was to explore the potential benefits and usage the CPT for classroom teaching and learning and its contribution to the preparation of teaching materials.

There were two-fold objectives of this study. They are: 1) to gain feedback on classroom teaching and learning through the use of a CPT from the perspective of both students and teaching staff; and 2) to explore the possibility of using CPT as a standard tools for the preparation of teaching materials at the university. Triangulation methodology was used with combination of semi-structured questionnaire survey and in-depth qualitative interviews. The results are then used as the reference to enhance the teaching and learning through the use of educational technology.

In focusing on the effects of classroom learning, the components of the assessment were divided into six aspects. They are: the organization and structure of teaching material; clarity and legibility; visual stimulation; vertical interaction; efficiency in delivery of information material; learning environment and atmosphere. A sample of 300 students ranging from Diploma to Master Degree level in the field of nursing and health sciences was studied through questionnaire survey together with in-depth interviews on 30 students.

In exploring the experiences using CPT for improving classroom teaching and its potential to become a major foundation tools for developing teaching materials, the lecturers representing 3 different health disciplines (i.e. nursing science, biomedical science and behavioral science) who involved into this study were recruited for an in-depth interviews.

Conceptual framework

This framework was comprised with the components indicating the flows of knowledge transformation through classroom teaching and learning as shown in the following Fig. 1.

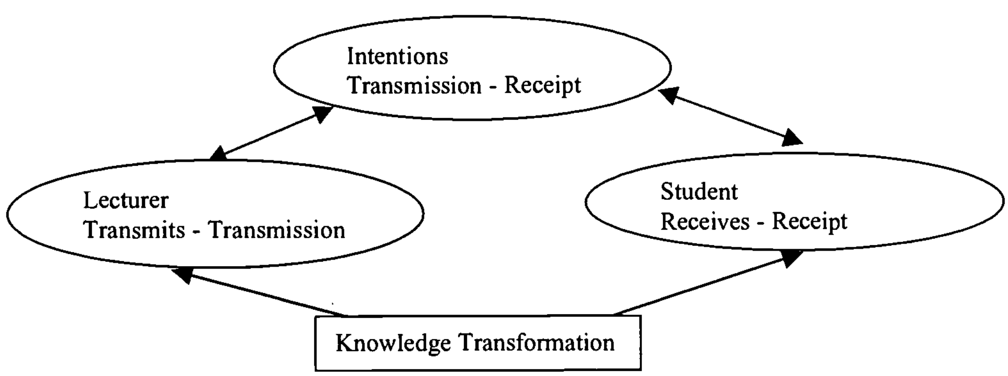

Fig. 1: Flow of knowledge transformation through classroom teaching & learning

Part of knowledge transformation can only be achieved through the process of teaching and learning within which the intentions is believed as one of the major factor to affect those outcomes. However, these intentions could be enhanced through the six dimensions of domains as mentioned previously (i.e. organization & structure of teaching material; clarity & legibility; visual stimulation; vertical interaction; efficiency in delivery of information; enhancement of learning environment and atmosphere).

Procedures

All students from 7 different classes ranging from Diploma to Master Degree level received CPT instructed classroom teaching. The contents of those teaching material were made by their subject lecturers and accordingly to their subject areas and academic levels. Questionnaires were given to each of these classes immediately after lecture. Feedback was received from 300 students. In addition, in-depth interviews were conducted with 30 students regarding to their opinion on the uses of CPT for classroom learning and teaching. The lecturers involved in using CPT instructed material for teaching were interviewed.

Findings

Apart from the descriptive statistics, the combinations of the statistical methods was used for the quantitative data analysis by using SPSS while NUD.IST package was used for the qualitative data analysis.

The results indicated that the computerised presentational packages for classroom teaching were well received by the students as effective tools to enhance the process of learning. The study also indicated some problems in enhancing a vertical interaction between the lecturer and the students, and feasibility of performing a computerised presentational package classroom teaching. The score comparison for the six domains on an overall reaction to a CPT instructed learning were shown in Fig. 2.

Interviews with lecturers reflected that they felt the CPT instructed classroom teaching would contribute to the process of teaching as well as the students' learning. They found the combination of different text fonts and colours display, which makes for the production of high quality teaching material in the textual format as well as integrating other formats such as pictures, graphics, sound and video. The flexibility in arranging the sequence of the presentation allows the lecturers to have a better organisation of the teaching materials and also serves as an information bank for learning materials.

In summary, they felt that CPT allowed better organisation of teaching materials in logical sequences combined with speedy display of the teaching contents to enable a smooth delivery of lectures. That also helped the lecturer to keep the time at their required pace. Consistency of similar lecture contexts for different classes can be maintained through this standardisation in the format of teaching materials being presented. It also facilitates the future development of modular or credit based system in our university.

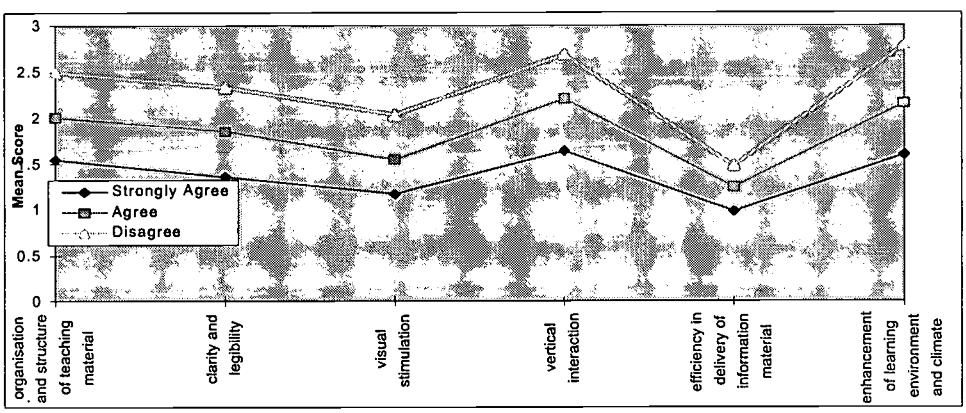

Fig. 2: Score comparison for the six domains on an overall reaction to CPT instructed learning.

There were some situational constraints imposed on the CPT instructed teaching. The lecturers expressed that the physical environment of the classroom, such as the size of the classroom, lighting arrangement and its intensity, will directly affect the quality of the display or projection. The technical set up of that equipment was also relatively time consuming. In addition, they pointed out that the operation of CPT instructed teaching required practical computer skills in order to ensure the smooth running of the lecture. In operating such educational technology, many lecturers are still green in experience.

In conclusion, the indicated factors influencing the perceived effectiveness of CPT instructed classroom teaching from the students and lecturers may serve as indicators for the future improvements of teaching strategies. We are optimistic that additional resources and support from the university can make computerised presentation teaching valuable for students and teachers.

DESIGN AND EVALUATION OF A DISTANCE LEARNING COURSE ON THE WWW

Ana Amélia Amorim Carvalho
Institute of Education and Psychology
University of Minho
Portugal
E-mail: aac@iep.uminho.pt

The World Wide Web has been largely used on distance learning, but some problems arise, mainly related to students' feelings of loneliness [Schrum, 1997]. We decide to focus on this problem and also applying Cognitive Flexibility Theory principles to a 19th century Portuguese novel "Cousin Basilio" [Carvalho & Dias, 1997a] available at the following URL: http://www.iep.uminho.pt/primobasilio

On this research we focus on learners' feelings and opinions about the web course structure, and communication between learners. We also attend to subjects' attitude towards the computer and to their knowledge as users, and also to their "Learning Preferences" based on a scale that we developed [Carvalho, 1998a & 1998b]. Finally, we describe their opinion about being enrolled in other courses on the web.

"Cousin Basilio" Design

During the design of this document we had two main concerns: first of all to apply Cognitive Flexibility Theory principles to the novel "Cousin Basilio" from Eça de Queirós and secondly to recreate the 19th century ambience on the interface. If you access to the URL mentioned previously you will see an ancient book and on its cover you read "*O Primo Basilio*: múltiplas travessias temáticas" ("*Cousin Basilio*: multiple thematic criss-crossings"). Then you have some information - a Help function "Ajuda" - about the function of each button and the functionality of each path as soon as you press them.

Each page has some objects (buttons) available that recreate a 19th century atmosphere. All information and instructions to the user appear in blue, using a well designed handwriting. It has two menus: the main menu is on the left side top corner, and looks like an ancient street plate; the complementary menu is under the main menu. The information available on this second menu is dependent of the path chosen on the main menu, nevertheless it gives access to "Themes" (a general description of each of the nine themes selected for analysing the novel) and to the "Bibliography" (authors mentioned on "thematic commentaries" or on the description of the general Themes). At the end of the page there is a black pen that, when pressed, allows the learner to write his/her own notes. On the bottom, near the pen, there are three coins that when pressed give access to the content material and, later on, allow the user to quit the document properly. When this button (coins) is pressed in order to quit the document, some possible links related to the novel and to the author appear. The texts of the novel have a light yellow background that imitates old stationery. All comments that help to understand the texts appear on a blue background (this resembles an ancient official Portuguese stationery) that is sealed.

The main menu is always available and shows all the possible paths to the learner. The first path named "Casos" (Cases) presents five sequences of the book, each sequence containing several small texts (mini-cases) of the novel. According to Spiro and Jehng (1990: 181) "the mini-case (a segment drawn from a larger case) is the starting point for all instruction". Advanced knowledge acquisition has significant context dependent variations, so it is important to analyse several mini-cases according to multiple representations. The second path "Tópicos de Reflexão" (Topics for Reflection) has five topics. For the study of each Topic, several relevant mini-cases and thematic commentaries have been selected. "The notion of 'criss-crossing' from case to case in many thematic dimensions serving as routes of traversal, is central to our theory" [Spiro et al., 1987: 187]. The third path "Travessias Temáticas" (Thematic Criss-Crossings) allows the user to do a personal search, choosing the themes and cases. The last option is "Tabela de Conteúdos" (Table of Contents) with all cases and respective mini-cases and the indication of the applied themes for each mini-case.

Distance learning course procedures

This distance learning course on the web sets a pre-requisite on the subjects' background: they have to be undergraduate students or teachers of Portuguese literature.

This course integrates three packages to be sent to each subject with several instruments like Questionnaires (a Questionnaire about subjects' computer literacy and a Questionnaire of Opinion about the web document), tests, a "Learning Preferences" scale (containing the following dimensions: 'complex knowledge acquisition', 'autonomy in learning', and 'preference for complex knowledge'[1] [Carvalho, 1998a & 1998b]), guidelines for the session, participants' e-mail addresses, and

[1] The "Learning Preferences" scale has three dimensions: F1: alpha=0.83; F2: alpha=0.73; F3: alpha=0.63; the scale has a Cronbach's alpha =0.81 (Carvalho, 1998a &1998b).

researcher's contact. Exchange e-mail is not compulsory, but recommended if they like to share some ideas or some doubts. At the end of this distance learning web course, we ask the subjects to write a report commenting on several aspects like the document design, the structure of the course and their opinion about courses on the web for lifelong learning.

When they finished to answer all instruments on package 1, they had one session on a computer laboratory at the university with the purpose of making them feel comfortable to use and explore the document on the Web. At the end of this session, they received the second package. After having read all the descriptions on the general themes, and done the first path on "Cases" and the first path on "Topics", the users were challenged to try to build their own knowledge that they could check on the document. This kind of challenge has been successful in another study (Carvalho & Dias, 1997b). Each subject worked at his own pace. They were applying the packages according to their pace of learning.

Sample characterisation

We had nineteen subjects, 1 male and eighteen females, 3rd year undergraduate students enrolled in Portuguese Literature, ranging from twenty to twenty-nine years (the mean was 22.5 years and the mode was 20 years). We realised, when analysing the Questionnaire of Computer Literacy, that 2 subjects never used a computer, all the others were using it, but not often. Most of them had never explored an interactive environment, only 6 subjects had (31.5%) explored the Internet. We analysed their attitude towards the computer according to two parameters: attitude and feelings. The correlation obtained in these two parameters is high (.71). Most of them, thirteen subjects, liked to work with a computer, four subjects didn't like and two avoided it. Most subjects (15) felt comfortable when working with a computer, eleven of them liked to work with it, but four did not. Only two subjects felt "a little bit nervous" when they needed to use a computer. Finally, two subjects felt nervous and avoided to use a computer, but anyway they accepted to participate in this research. The results on the "Learning Preferences" scale pointed out a positive attitude[2] in all three dimensions.

Results and Conclusion

Although subjects' computer literacy was low, they felt it was easy to use the web document and to navigate on it. In addition, not only their opinion about the web document as a whole was favourable, but also in what concerns its structure, interface, orientation and its content.

All of them accepted positively the suggestion of having access to documents like "Cousin Basilio" on the web, as a support to their learning modules in the university and for further education. Some of the subjects that accepted the challenge of constructing the possible explanations of the applied themes to each text in the path "Cases" and to select the texts that support a given "Topic", said that "it helps to a deeper study", another one mentioned that she "realised that, when trying to explain thematic commentaries, some of her ideas were wrong, but others only need to be completed". Learning by doing (constructing) takes a great effort and strong involvement that are rewarded in the learning achieved.

All orientations and tasks to be achieved have been considered clearly enough. Most of the subjects used the university computer laboratories. Some went to the lab with a peer (12 subjects), others alone, but usually they met someone there with whom they shared some ideas. Only four subjects never shared ideas with others in the lab or after the sessions. They did not use the e-mail facility because they knew each other and they met regularly at the university.

We think that it is important for learners to have a face-to-face meeting with the teacher responsible for the course. In this way, they have the opportunity to see each other and to know the people to whom they are going to send a message, to clarify any doubt they have about the course, besides the introduction to the web document functionality. With this methodology, even those subjects that never used a computer or that seldom used it have the opportunity to learn to use it properly. The participants must be comfortable with the system and the software, so that they may concentrate on the academic tasks.

Finally, we think that if we want to have a real Information Society our undergraduate students have to explore the web for their study. The USA President's Advisory Panel recommend that "teacher education should focus on learning with technology while emphasising content and pedagogy" (Davis, 1997: 221). Today's undergraduate students are the teachers of tomorrow and they will know how to use the web with their students, if they are used to explore it.

Introduction

A great amount of information is conveyed, during the communication, by means of verbal and non-verbal elements. The relationship of these various components is so pertinent and consistent that we might fail to converse if we cannot understand those non-verbal elements or use them appropriately (e.g., Bateson et al., 1981). Multimedia-based materials have a great potential to present both verbal and non-verbal elements and to combine them efficiently for language education. Moreover, the Internet has been increasingly utilized as an effective instructional tool for language learning, since the Web can become a multimedia-based content provider with versatility and interconnectedness (Harasim et al., 1996; Khan, 1997; McManus, 1995; Owston, 1997; Ritchie & Hoffman, 1996). The purpose of the present study was to design and develop a Web-based multimedia instructional system for French language learning. The instructional system was designed to encourage students to actively participate in the learning process by providing students with a learning environment that is flexible, individualized, interactive, and efficient.

The Content Structure

The content structure of the instructional system was designed to be adaptive to individual learning situations on a non-real time basis. Students can navigate the hyperlinked multimedia contents without a pre-ordered learning schedule. Through their exploration and navigation, thus, students can design their own instruction. The contents are divided into two levels: beginning and intermediate. Each level consists of 15 lessons developed to be easily integrated into the school curriculum in Korea. As shown in Figure 1, each lesson is composed of eight components: listening, reading, speaking, grammar, drills, games, pronunciation, and reading comprehension.

The Interaction facilities

The interaction facilities of the instructional system consist of four components: help, bulletin board, announcements, and e-mail. These interaction facilities were designed to provide various types of asynchronous communications among three different user groups: teachers or tutors, students, and system administrators (Boverie et al., 1998; Laney, 1996; MacKnight, 1998; Repman & Logan, 1996).

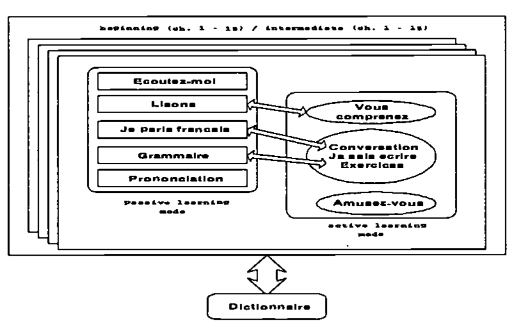

Figure 1: The Content Structure

The User Interface

In designing and developing the user interface of the instructional system, a special emphasis was placed on user-friendliness and efficiency. The user interfaces are differentially provided to each of the user groups, depending on their authorization status, since the user groups need different modes of interaction. For the consistent and systematic delivery of information, the subsequent hyperlinked information is presented in the same page. As shown in Figure 2, the navigation bar on the left side of the screen provides a cascaded pull-down menu from which students can easily choose their lessons and appropriate interaction facilities needed. The position indicator on the upper side of the screen allows students to locate themselves during navigation and exploration.

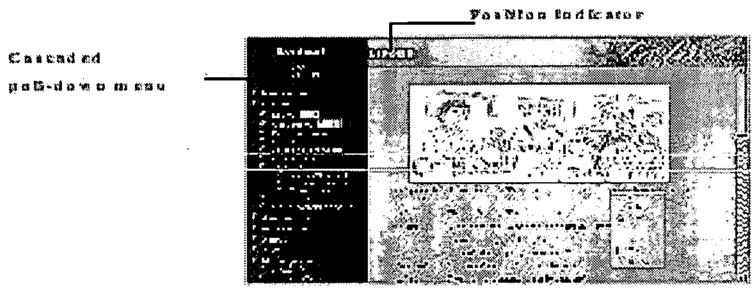

Figure 2: The User Interface

Conclusion

In conclusion, this study has presented the design and development of a Web-based multimedia instructional system for French language learning. The instructional system developed in the study appears to be one of the first instructional systems for computer-assisted French language learning in Korea. It can provide a learning environment where students can actively participate in the learning process through exploring and navigating the hyperlinked multimedia learning contents. This system has been successfully integrated into the existing curriculum and has been currently used in the foreign language courses. Furthermore, the interaction facilities of the system will be more expanded to make synchronous as well as asynchronous communications possible. Finally, an experimental study is underway to examine the effectiveness of the instructional system with regard to students' learning process and product.

Very clearly multicultural education is an important concept for both preservice and inservice educators. The U.S. macroculture is shared by all our the nation's citizens. Many cultural groups or microcultures are also part of the American Society. A goal of multicultural education is that a process of thinking will develop. Thus the authors have categorized several variables of multicultural education: age, belief, social class, exceptionalities, gender, language, ethnicity, and sexual orientation. The authors have carefully selected websites which represent various points of view in order to assist the student or educator in the process of thinking and in developing a multicultural perspective.

Addressing the Changing Roles ofTeachers and Learners in Internet-Delivered Materials

Yin Leng Theng
School of Computing Science
Middlesex University (United Kingdom)
y.theng@mdx.ac.uk

Introduction

Since its release in 1991, the World Wide Web (or Web)has changed the Internet to the extent that it has become almost synonmouswith the modern use of the Internet. In recent years, we are beginning tosee more and more open learning materials, distance learning programmes, virtualinstitutes, *etc.* springing up across the globe to cash in on these seemingly attractivebenefits. Organisations such as schools, professional bodies and businessesrecognising the benefits are also turning to internet-based mode ofteaching to enhance their learning programmes.

But, before we get so hyped up with this novel mode of teaching andlearning, we should really take a step back and askourselves these questions: how has internet-based teaching and learningchange the roles and relationships of teachers and learners? What are thesechanging roles? How can teachers and learners be helped to cope with thesechanging roles so that effectiveuse of internet-based materials can be realised?

Gone is the traditional concept that the teacher is thesource of all knowledge. In internet-based teaching, the teacher is nolonger the dictator of content and pace of learning.In other words, face-to-face teaching in the classrooms is replaced bylearners' interaction with learning materials through the Internetvia the computer monitor, replacing the teacher (Forsyth, 1997).In internet-based teaching, there is a shift towards learner-centredness,transferring the ownership of learning to the learners. Producing internet-delivered materials is not just simply putting coursematerials on the Internet, we need to address these changing roles andprepare teachers and learners for them, in order that the Internet iseffectively used for teaching and learning.

We learn from experience that many computer projects failed not onlybecause of poor *design* but also poor *delivery* in terms ofpreparation and training of people involved in the final systems(Ellington, Percival and Race, 1995; *etc.*). To address the changing roles of teachers and learners, this papersuggests doing things well both in the *design* as well as the *delivery* of internet-delivered materials.

Design Principles

Very often the criticism against internet-deliveredteaching is that the human element, that is the teacher, is absent andlearning becomes impersonal. A real challenge to designers is to retain asmuch of the traditional classroom"features" as possible in the design ofinternet-delivered materials, and to ensure that teachers and students seeits benefits, and to accept it as an effective, alternative form oflearning.

The second challenge to the design of internet-basedmaterials is to incorporate the well-accepted ingredients for successfullearning by (Ellington, Percival and Race, 1995): (i) making the materials stimulating and interesting enough to makelearners *want to learn*; (ii) incorporating sufficient activities tohelp learners experience *learning by doing*; (iii) providing sufficientchannels of *feedback* to the learners; and (iv) enabling learners to *digest and relate* whatthey have learned to the real world.

Theories in instructional design, constructivism, minimalism andhuman-computer interaction can be applied to translate these basicprinciples for successful learning experience into practical design:

- *Instructional design* represents asystematic, coherent approach to the design of computer-based instructionalmaterials. GagnŽet. al. (1979) propose thatlearning materials must include nine instructional events that shouldnormally be followed in sequence: (i) gaining attention; (ii) informinglearner of lesson objective; (iii) stimulating recall of prior learning;(iv) presenting stimuli with distinctivefeatures; (v) guiding learning; (vi) eliciting performance; (vii) providinginformative feedback; (viii) assessing performance; and (ix) enhancingretention and learning transfer.
- *Constructivism* proposes that the knowledge of the worldis constructed by the learner, making learning rather than instruction thefocal issue. If learning has a constructive character inherently, then it follows that teaching practices need to besupportive of the construction that occurs. Cummingham et. al. (1993) propose seven principles of instructional design: (i) embedlearning in realistic and relevant contexts; (ii) embed learning in

socialexperience; (iii) encourage the use of multiple modes of representation;(iv) provide experience and appreciation of multiple perspectives; (v) encourage ownership and voice in thelearning process; (vi) provide experience in the knowledge constructionprocess; and (vii) encourage self-awareness of the knowledge constructionprocess.

- *Minimalism*'s central idea is to minimise the amount of explicit instructionalmaterials, and that learning takes place in small steps (Carroll, 1990).Therefore, learning materials should be structured in a highly modular wayof self-contained units, allowing learners' strategies and preferences to drive the selection andstructuring of contents.
- Knowledge in *human-computer interaction* is important in helping designers to take into account human capabilitiesand limitations, and predicting how design choices might affect human.Design guidelines from human-computer interaction on text, graphics,colours, *etc.* are useful in helping designers to create interfaces that are clear,consistent, simple and uncluttered so that complex information can beeffectively perceived by learners.

The designprinciples discussed above have been used to teach ninety second-yearcomputing science students at Middlesex University (London). As part of theassessment, these student designers were asked to design and develop ahypermedia, computer-aided learning package incorporating established principles in human-computer interaction,learning theories and instructional design, and translating them intopractical design. These principles have, in general, been useful in guiding these novice student designers in the design anddevelopment of their learning packages.

Delivery

In a recent conference on "Educationaluses of the Internet and European identity construction" held in Strasbourg (France) in September 1998 (seehttp://in-tele.u-strasbg.fr), teacher representatives at the conferencefrom across Europe voiced their concerns that not enough is done to prepare teachers and students to use theInternet effectively. There is a general sense of fear and apprehensionamong teachers because they are not trained to use the computer andInternet for teaching.To avoid rejection of this new medium by teachers and students who are moreaccustomed to traditional classroom teaching, and find it difficult to giveup, education and training should be provided to address the lack ofconfidence in using the Internet as a teaching and learning tool. Teachers as well as students should betaught appropriate skills to use the Internet which include knowing how to search and query, transfer materials and files, use ofe-mails, chat and bulletin boards, computer-aided materials, *etc.*

Conclusion

This paper examined the changing roles of teachers and learners ininternet-based teaching and learning. Effective design and careful deliveryof the materials are some ways suggested to address these changing roles.Future work involves drawing up a framework for an application design modelfor developing hypermedia materials for teaching and learning. The aim ofthis framework is to provide designers with some sort of a checklist toensure thatdesign issues crucial to the successful delivery of internet-basedmaterials are considered.

Evaluating collaborative telelearning scenarios: A sociocultural perspective

Frode Guribye & Barbara Wasson

Department of Information Science, University of Bergen, N-5020 Bergen, NORWAY
Frode.Guribye@ifi.uib.no Barbara.Wasson@ifi.uib.no

Introduction

In this paper we discuss work in progress by describing the conceptual framework we are using to identify patterns of collaboration in collaborative telelearning scenarios within the Norwegian project DoCTA (http://www.ifi.uib.no/docta/). Project DoCTA focuses on the design and use of artefacts in collaborative telelearning scenarios aimed at teacher training. Various scenarios utilising the Internet are used to engage the students in collaborative learning activities. An ongoing exploratory study is analysing four different scenarios.

In the first scenario, a pilot study is analysing the use of Teamwave Workplace (http://www.teamwave.com/) for collaborative activities in a graduate university course[1] at the University of Bergen (UiB). The next two scenarios involve European inter-cultural simulations where the goal is to design a textual artefact (such as a treaty or policy statement). In IDEELS[2] teams of Norwegian students at UiB and Nord-Trøndelag College (HiNT) collaborate with teams in Germany, Spain and France to develop a treaty. In Demeter[3] Parliament, Norwegian students at Stord/Haugesund College (Stord) collaborate with students from 13 countries to contribute solutions to contemporary problems facing the European community. In VisArt, a fourth scenario being designed, developed and deployed for use between Norwegian educational institutions, the goal is to design a visual artefact to be used in teaching a subject of choice. In this scenario, teams will comprise students from the three Norwegian participating educational institutions (UiB, HiNT and Stord).

Collaboration Patterns

From a research perspective, the exploratory study being carried out within DoCTA will provide us with insight into the processes of collaboration enabling us to identify collaboration patterns and further our understanding of how instructors, students and other learning facilitators organise their learning and work.

The community of study includes teachers, learners and facilitators participating in the various collaborative telelearning scenarios. The main research question has been formulated to ask how these students, teachers and facilitators organise their learning and work given the different scenarios. The four collaborative telelearning scenarios vary with respect to: (1) actor characteristics (e.g., within a common community vs. disparate and divergent cultural backgrounds; similar knowledge and preparation vs. different knowledge and preparation; etc.); (2) aspects of the learning activity (e.g., text based vs. visually based; well-defined learning tasks and goals vs. ill-structured tasks and goals; etc.); (3) the kinds of artefacts they have access to (e.g., the artefacts provided in the various internet environments[4]); and (4) the kinds of artefacts they are to design (e.g., textual or visual).

Conceptual approach

The underlying conceptual framework adopted in this research is taken from three different, although closely interrelated approaches, namely: activity theory (Leontev, 1978, Engeström 1987), distributed cognition (Hutchins, 1995), and situated action (Suchman, 1987, Lave, 1988, Mantovani, 1996). One of the goals of this research is to argue that, together, these approaches make up a rich framework for describing, evaluating and analysing collaborative telelearning scenarios. All three approaches underscore the need to look at *real activities* in *real situations* (Nardi, 1996, our italics), and always, in some way, include the context in studies of human activity.
The rationale for combining these three approaches as the conceptual foundation of this study, is that they all fall under what is called a sociocultural perspective (Wertsch, del Río & Alvarez, 1995), that highlights learning and thinking as phenomenon that can not be studied in isolation. Rather, they are complex processes situated or distributed in an environment — it is impossible to separate them from the context in which they occur. The different approaches each emphasise slightly different elements of the framework that is important to be aware of

[1] http://www.ifi.uib.no/staff/barbara/courses/host98.html
[2] http://ftp.uni-bremen.de/wwwgast/fzhb/ideels/public_html/index.html
[3] http://hugin.hsh.no/prosjekt/demeter/index.htm
[4] E.g., in IDEELS the artefacts they have access to include their own email system, Teamwave Workplace, and OPUSi a web-based conferencing system developed at the University of Bremen, Germany.

in these kinds of studies. Situated action emphasises the emergent, contingent nature of human activity, the way activity grows directly out of the particularities of a given situation (Nardi, 1996). Distributed cognition on the other hand, asserts as a unit of analysis a cognitive system composed of individuals and the artefacts they use (Hutchins, 1991, Nardi, 1996). This approach underscores the distributed nature of cognitive processes, and the role that different artefacts play in these processes. Activity theory also emphasises the mediating role of artefacts, but stresses that these artefacts carry with them a particular culture and history, thus, focuses on the institutional and cultural elements involved in the learning activity (Kuutti, 1996). Adoption of these approaches provides a strong and fruitful conceptual framework that informs the evaluation of collaboration patterns in collaborative telelearning scenarios.

Evaluation approach

The evaluation aims at a naturalistic study of how participants in collaborative telelearning organise their work and learning activities. Ethnography (e.g. Hammersley & Atkinson, 1983) influences the design of our evaluation approach including the choice of data collection (e.g., participant observations, unstructured interviews, video recordings) and analysis techniques (e.g., discourse analysis, video analysis). This means that the evaluation is an iterative process where an ongoing analysis guides the data collection emphasis in successive phases.

In order to collect data about the activities that the students engage in during their participation in the scenarios, different methods and techniques will be used. The most important sources of information will be derived from observing the students as they collaborate and interviewing them, and also from electronic logging of artefacts used for collaborating (e.g., email, shared whiteboards, chats, to-do-lists) and artefacts designed (e.g., a web page) during the collaboration. It is a challenge to carry out the participant observations since a large number of the students are geographically distributed over Norway thus direct observation of all the students is unrealistic and too costly. Rather, an alternative technique consisting of immersing ourselves in the virtual environment in order to observe their activities will be used. For this reason, the electronic data logs will be an extremely important supplement to the "online" and "offline" observations. The data being logged, is not just statistical data recording who is logged on when, but includes a periodic chronological recording of all artefacts in the environment. This means that we can recreate versions of the environment to study the use of artefacts over time and the creation and development of the artefacts produced in the collaboration process. Data collected in the fall of 1998 has been analysed and used to inform the data collection in the spring 1999 scenarios. At EDMEDIA'99 we will be able to provide a preliminary report on our findings.

1. The Transformations of the Individual

Historians of technology show us in myriad ways how the arrival of technology changes the conception that individuals have of the world, the relationships with the objects that surround us and social relationships (Delfgaaw 1975). We can distinguish different levels of transformation, depending on the impact of the technology itself (Attali 1985). Information technologies are already announcing a veritable revolution: the information revolution. This is an unfinished revolution that forms part of the worldwide tendency toward societal acceleration, a re-figuration of identity and our place in the world (Morin & Kern 1993), and a reduction in the restrictions of time and space, at least, in communicational transactions (Tiffin & Rajaasingham 1996).

Our relationship with information has two basic dimensions: operation and representation. In both cases, the information refers to the object being spoken of, and also to what is being said about the object.

In the *operational dimension*, we manipulate information to extract data on the object being referred to. We operate the information in order to get more information; in this way, information is understood as "a difference that makes a difference" (Bateston 1985). Operating information requires a previous question that imposes intention upon the action of operation.

The *representational dimension* has to do with the products that result from operating information; it is its expressive dimension. The representation contains an internal reference to the intention of the individual expressing it and another external reference linked to the questions of the individual receiving the information. In both cases there is an object of information constructed multi-dimensionally according to the socio-cultural codes of the people involved. In this way, information is a communication bridge between individuals that are expressing the world, and therefore, expressing themselves. Here is where a first level of transformation appears, in the relationship with others derived from information technologies: what it allows us to represent.

A second level has to do with the way it allows us to represent. Information technologies are intrinsically linked to the communication technologies that enable communicational expressions to take place a different way: the object expressed by one person can be manipulated by another, using the representation itself.

So our relationship with information (operation and representation) and with others (communication transactions) is transformed by information and communication technologies in all aspects of our lives. That is why we consider it important to identify the elements that make an individual computer literate, so as to propose an appropriate literacy process.

2. Computer literacy

In the human-computer interaction, we find a process that begins with a casuistical exercise of action upon the tool, and that leads up to the integration of the tool as part of the environment of "action upon the information". We understand this process in the following way:

The process of computer literacy begins with a casuistical interaction of the person with the tool, which manifests itself as "I want to... How can I...? Do it..." In time, the individual begins to identify a set of patterns that organize his actions when interacting with the tool.

Several patterns organize interaction with informational tools on a level at which these tools are seen and operated as artifacts for completing tasks without necessarily being integrated into daily activity as an integral part of the individual's environment.

The *organizational and representational patterns* refer to the interface structures that allow us to understand what can be done with the artifact. These are structures that appear in such a way that they make clear how the computer functions internally. In this way, we find "iconic" organizations in the graphic environments that describe what is immediately possible, and indicate the most common actions.

The *patterns of objects and their structures*. Computers contain objects, each one made up of defining attributes and other objects. A document is an object whose attributes are those definitions applied to each of its parts. It might contain sections with specific attributes that are different from the attributes of other parts of the document. One section contains paragraphs each paragraph contains words, and these contain letters. An object's attributes affect all of its parts except those made up of objects with their specific attributes

As for the *pattern of processes,* they allow individuals to organize the set of actions that they carry out to achieve what they want. There is a process pattern that we could call "second-level" inasmuch as it refers to the process for knowing the process for doing what I want to do. It is the search process we apply every time we do not remember all the steps for obtaining a specific result.

On this second level of patterns constructed by the individual for interacting with information tools, one might be skillful at operation without necessarily being computer literate. This is achieved on a third level where among other things, the person consciously proposes the production of different representations of the object in question in order to know it better, to know more about it.

This level is made up of the combination of two patterns: the handling of information in such a way that implies intentional action upon the object referred to, which is an exercise in reorganizing and processing information; and the pattern of metacognition that allows individuals to account for the way they produced what they produced. This third level, organized on the basis of the individual's intention, implies opening new horizons of possibility.

So the computer literate are those who can conceive of information and communication tools as part of their environment and operate them as such intentionally in the search of more knowledge about the objects referred to by the information they are manipulating and expressing.

3. The computer literacy process

The essence

The computer literate that we are describing is basically an apprentice, intentionally looking for more knowledge. This leads us to take a look, especially in formal education, at the way the individual conceives and operates "how to know". We identify two key elements, and educational strategies must be devised to activate them: 1. The individual's intention., as the origin of any process. 2. Metacognition. As a substantial element that gives the individual a reference point in his or her process of knowing.

Skills for handling information

We are talking about an individual that searches for more information: he or she proposes various representations of these objects in order to know them better. In this sense, we cannot conceive separately computer literacy from information literacy. If a person is not already information literate, then when educating for computer literacy, we have to educate for information literacy as well.

Tool work in spite of technological change

In the computer literacy process we should recognize that the capacity for tool work should be immune to technological change. The patterns described conform a model that should be worked on three different levels:

1. Identifying the patterns: Individuals approach to technologies is quickly and systematically.
2. Operating patterns: Individuals use the tool for their particular purposes. It implies that the individuals have the capacity to build and rebuild work strategies around their own purposes.
3. Appropriating, rebuilding and applying the model and the personal way of operating it: Individuals move among different platforms and continue to operate in spite of technological change.

Project Description

This paper is a case study of the technical trial for the development of mobile multimedia technology to create a virtual learning space on the World Wide Web (NOMAD – New Online Media Alternate Delivery). The subject of the trial is the genius loci, or spirit of place, of rock art to support a college level Architectural History course. The fundamental notion is that architecture is the 'gift of creating places for ritual' (Kostof, 1995) and that the act of creating a place with a handprint is the beginning of architecture. In part, this project is an exploration and contrast of the first notion of 'place' (Casey, 1998) as created by the first technologies with the current notion of 'place' created by current technologies, for example cyberspace (Meyrowitz, 1985).

The format in which the material is presented is intended to generate interest and enhance participation. Real time processing and presentation of material through the web is used to create a sense of participation in the adventure. The journey unfolds as a story in serial form: Like a novel by Dickens published in weekly installments, and is intended to whet the appetite and create expectation for the next installment. The general structure is in the form of a serial narrative (Murray, 1997) with a beginning, middle, and end but with each phase indeterminate, unfolding as a journey in real time. The NOMAD Project is similar to a number of on-line virtual adventures, for example, Terraquest's Virtual Antarctica, but is focused specifically on the significance of place and ritual in the making of architecture.

Architecture

Architecture as the 'first art' is a gift of the gods. Inspiration is the 'breathing in' of the 'genius', the spirit of the Muses (Frye, 1957). Both Humans and animals live in caves but animals do not have architecture. Homo Faber - Man the Maker changes his environment to support his activities, understanding the distinction between utility and meaningfulness expressed linguistically as the difference between "in order to" and "for the sake of"(Arendt, 1958). For example, making a fire pit to support cooking and heating is more than just functional. The technology creates a place of social gathering forming a group with a hierarchy as expressed in each individual's relationship to the fire. Caves are perceived as connections to the underworld and the womb of mother earth. By placing one's handprint on the cave wall, one participates in the mystery of life. The simple act of making rock art marks the place as special spiritually and elevates the cave to the realm of architecture.

The Cartesian notion of space and its relationship to time (Casey, 1997) is distinct from my use of the notion 'place' and its relationship to 'event' which is fundamentally phenomenological. Cyberspace is a misnomer. All that is required for the concept of space is the definition of boundaries and limits. The universe as limitless space is curved conceptually providing a boundary. Place always involves human agency, even if it is as minimal as giving a name to a space. Death Valley has a history and image that makes it a 'place' in our culture. Any material intervention that supports this iconography is architectural. Cyberspace does not meet the physical requirements of space but it can be thought of as place, or Cyberplace as it meets the phenomenological requirements.

The Aesthetic of the Digital Environments

Murray (Murray, 1994) has documented the three principal notions that enhance the experience of digital environments as immersion, agency, and transformation. Immersion is the ability for consciousness to get 'lost' in the environment as in being 'buried' in a book. Agency is the ability to impact outcomes. Transformation is the ability to 'play' at being something else, often with cathartic effects. How can these pleasures be exploited in NOMAD and to what end?

Immersion is a measure of interest in the content (Murray, 1994). It can be enhanced through quality graphics and text and the narrative structure of a journey that generates a beginning, middle, and an end. The unfolding nature of the serial delivery generates expectation in what comes next. Key is the timely generation of data and its mounting on the web site.

Agency promotes ownership (Murray, 1994). It is enhanced through quick responses to online queries with answers from the field and participation in the online forum. A notion of the project is that students will do research in specific areas that will generate questions for field investigation and therefore have an impact on what happens next. Agency in the interface can be enhanced through the use of QuickTime VR which allows the user manipulation of view and through the use of live video of locations from which the participants can capture images as they chose.

Virtual transformation often produces cathartic effects that generate real transformation (Murray, 1994). The hope is that by being a virtual traveler one will become a real traveler and go to the sites visited virtually. By researching a specific area of the content, participants break down the barriers between student and teacher. By being a member of the virtual team, the participant develops real team skills.

Responding to the aesthetic of the new media and enhancing notions of immersion, agency and transformation in the construction of the digital environment will, I believe advance pedagogical objectives through increased participation and user satisfaction.

Further Research

The unique elements of NOMAD include:

- Using multimedia in near real time to communicate sense of 'place'
- Using a narrative structure to organize course material
- A roving or mobile instructor developing and delivering content from remote locations
- Integrating a variety of relatively new multimedia applications and wireless technologies
- Operating under remote and technology challenging conditions

Introduction

The computer has come a long way from a device that merely performs mathematical calculations for science and engineering to a device such as multimedia systems that can mimic the mental and sensory abilities of a human (Dannenberg, R. and Blattner, M 1992). Multimedia systems have made possible the different representation of information in a variety of ways. Through its interface, multimedia has made possible the interaction with these various forms of information through the various human senses. Multimedia interfaces uses multiple media viz. language, graphics, animation, video, non-speech audio, to communicate with users (Roth, S. and Hefley, W. 1993). Research in this area consist of a few studies involving the effect of using various combinations of media on the user's performance offering little for clear cut designs for mixing media. Multimedia generation entails the following processes:

1. Selecting the content of the information to be communicated
2. Choosing what media to use in order to communicate the information
3. Deciding how to present the media
4. Coordinating the presentation of the various selected media

Just like in a movie where the effect of the medium depends highly on the proper mix and relationships of the script, choice of characters, storyline, cinematography, music and setting, multimedia processes raise issues on the optimal mix and relationships between the various formats, use of models, metaphors, navigation, input and manipulation, synchronization and exploitation of new media (Blattner, M. 1994). This is because historically, design of interactive multimedia is driven more by intuition rather than empirical research (Park, I. and Hannafin, M. 1994; Faraday, P.M. and Sutcliffe, A.1997). This is exacerbated by the designers not being aware that design principles exist. This optimal mix issue is dealt with through empirically guided principles formulated by Park and Hannafin, Faraday Sutcliffe and, through tools for presentation with embedded expert systems in the field of artificial intelligence.

Multimedia Interface Design Principles

Park and Hannafin formulated 20 research-based principles for designing interactive multimedia. These learning principles are empirically rooted in the psychological, pedagogical and technological domains. The psychological principles provide important insights into how individuals think and construct meaningful learning. These are based on theories such as schemata, meaningful learning, elaboration and situated cognition. The pedagogical principles combine's Gagne's taxonomy of learning and learning outcomes, Ausubel's theory of advance organizer and Mayer's theory of meaningful learning. Together they form the structure for multimedia teaching and learning environment. The technological principles are meant to provide a vision on how future technologies will influence the teaching-learning systems and the changing role of the teacher and the student. These serve to suggest improvements for creating more powerful and efficient technologies for the future. These 20 principles are intended to root and strengthen multimedia in contemporary research and theory without unnecessarily constraining the multimedia designer's creativity by limiting them to conventional thought. However, it would be equally unwise to allow multimedia designer to continue their design approach without due consideration to human processing and cognition (Park and Hannafin 1994; Blattner, M. 1992).
Peter Faraday and Alistair Sutcliffe (1993) drew up guidelines for designing multimedia interface for the Esprit INTUITIVE project consisting of four components viz.:
1. creation of a task model with information requirement specifications

2. Resource Model describing the media available
3. Selecting the media appropriate for the task
4. Scripting a coherent dialogue combining information in different media

In another project, 'Etiology of Cancer', Faraday and Sutcliffe (1997) tackles the design at a micro-level through a "moment-by-moment selection of appropriate media in response to specific cognitive needs and task requirements".

Intelligent Multimedia Interface

An Intelligent Multimedia Interface such as the Intelligent Multimedia Presentation System IMMPS basically assists the multimedia system designer by collecting the information and the goal for communicating that information to the user which are then matched up with IMMPS archive of alternative media and presentation techniques (Roth, S. and Hefley, W. 1993, Shih 1997a and Shih 1997b, Bordegoni, M. et. Al. 1997)). The laboratory prototypes developed are of the type that generates coordinated multimedia presentations such as WIP which presents and understands combination of graphics, text and pointing gestures with the capability of interpreting questions and designing multimedia answers (Andre, E. 1997). The PPP Personalized Plan-Based Presenter which creates a script with an accompanying method to present the material (Andre, E. 1997). There is the Columbia Operations and Maintenance Explanation Testbed COMET which automatically designs integrated textual and 3-D information (Shih, T. 1997). The SAGE automatically creates business graphics display. The TEXTPLAN provides narrated animations of directions over an object-oriented map. AIMI involves the user into a multimedia dialogue and produces graphics that the user can interact with.

Conclusion

With a complex time-varying nature of multimedia elements, issues for further research and investigation of multimedia interface will continue to be multimedia input and output (Roth and Hefley 1993, Blattner and Dannenberg 1992), navigation , visual design (Hannafin, M. and Hooper, S. 1989, Grabinger, S.1989, Lucas L. 1991), media allocation (Maybury, M. 1993; Arens, Y., Hovy, E. and Vossers, M. 1993; Faraday. P.M. and Sutcliffe, A.. 1997) and integration of media (Roth and Hefley 1993). To be generalizable, the already existing models and tools need to be validated and tested on a variety of design settings and on different types of users.

Some visitors of a website, browsers, simply want to become acquainted with a topic. They browse the home page and click topics to see what further information the site has to offer them. The success of the site partly depends on enticing these visitors to continue the exploration. The success also partly depends on conveying the site's underlying structure. The browser should get an impression of the ways in which the topic is treated.

Other visitors come to the site with a distinct question in mind. These visitors, searchers, are focused on getting a specific answer to their question. They want an immediate answer and they do not want to have to click through several layers of information or (sub)topics to get it. The site is a success for these visitors if it gives a comprehensive and correct answer without requiring an inordinate amount of energy in delving it up.

Its not easy to serve both audiences as what attracts the browser may repel the searcher. In this paper we sketch our attempt to handle the browser-searcher paradox in designing a website on technical documentation. The design approach we have adopted for dealing with this issue is known as minimalism. Minimalism has been used predominantly for supporting the (new) user of software programs such as word processors and object-oriented programming languages. Due to the limited space that is available for describing our design, we discuss only the major design principle to anchor the topics in the task domain. Also, we concentrate on a single topic within the domain, namely screen captures.

A key design principle is that the site structure - the number of levels and the division within levels - should reflect the underlying domain structure. Some topics about technical documentation can be treated in a single level. For example, the statement that quality writing evokes quality reading is treated simply as a nice-to-know fact appearing only on the Home Page to entice browsers. Other topics need stratification. Screen captures are such a topic. Screen captures can be characterized according to their general appearance (i.e., design) and function (i.e., role). Typically, the design or role of screen captures requires further specification to support the work of a designer of technical documentation.

The treatment of screen captures begins not on the first or on the second level of the website but on Level 3, the Theme Page (see the Figure). The reason is that the topic represents a rather specialized part of technical documents. Along with other parts such as a goal statement, one or more action steps, and possibly some problem solving information, a screen capture - or some verbal equivalent - is a constituent element of a procedure. The main function of a screen capture is to support the joint handling of manual, software and input device. For example, a screen capture may give feedback with which the user can check whether (s)he is still on the right track. In other words, screen captures give coordinative information. As this kind of information can also be given verbally, there is a need to compare and contrast these modes in delivering coordinative information in procedures. This explains the rubric and its organization on Level 3.

The stratification on the levels 3 and 4 complies with the taxonomy of screen captures. The Theme Page gives a comprehensive treatment of screen captures, briefly describing and illustrating the main design dimensions and roles. The Case Page details each of the four dimensions or roles. For example, users who turn to this Page for information about coverage see a page with an identical lay-out and structure as the Positioning Case Page. In addition, the organizer with brief descriptions of the four design dimensions remains on top of each of these pages to convey the impression that these dimensions all lie on the same level in the hierarchy.

A special problem with the presentation of screen captures on the Theme Page and the Case Page is that there is a conflict between the preferred technical solution for displaying pictures on the website and our design philosophy. All experts that we consulted on the question of how to display the (many) pictures (screen captures) along with the explanations suggested that we use clickable thumbnails on the Page. Clicking the thumbnail would then display the larger picture. This is strongly advised against in our design approach. What belongs together should also be presented together. Thus we sought for another (technical) solution. One of the two design options that we have come up and that keep picture and explanatory text together is using an expandable thumbnail. That is, the visitor can simply enlarge the picture by clicking and dragging a corner. The result is that the text is pushed downward, but still remains on the same Page (or level).

Surely, there is a need for people to see how screen captures fit into a wider context. For screen captures this context is a procedure which is always a main component or chunk of information in technical documentation. Therefore, the topic is treated on level 2 which is characterized as a Procedure Environment to signal the wide variety of topics that one should expect to be discussed here. Screen captures also make their appearance on the first level, on the Home Page. On this Page the browser is given a preview of a set of rather diverse screen shots - in thumbnail format - to enhance the attractivity of that page and to invite the person to explore that (or another) element of a procedure.

Website level & Name	Description	Content
Level 1: Home Page	Visitors are informed in an attractive way of what this site has to offer. All Environments are introduced. Some themes and Cases are illustrated with an example.	Environments - Testing - Design approaches - ***Procedures*** - ***Screen captures- preview***
Level 2: Environment Page	Visitors are shown how each Environment is structured or organized. Typically, these structures are based on validated taxonomies or typologies.	Procedures - Conceptual information - Constructive information - Corrective information - ***Coordinative information***
Level 3: Theme Page	Visitors can get to know the main topics within a Theme. Typically there is an overview, a limited set of examples, a recap of the wider context, a discussion of research, and a preview of 'more details'	Coordinative information - Textual variants - Screen captures - roles - ***Screen captures - designs***
Level 4: Case Page	Visitors receive the basic facts about the topics in a theme. There is a definition, an exhaustive set of (annotated) examples, a discussion of design variations and related research findings, and a section on design considerations	Screen captures - designs - Cueing - Size - Positioning - ***Coverage*** - ***Full vs partial screens*** - ***Use of context***

Many topics are still to be resolved. One of these concerns finding a way of making it easy to access information found on the deeper levels of the site (we limit the site to four levels, as shown for screen captures). An option we are considering here is using a special form of a preset query system to direct searchers quickly to the relevant Level and topic. For example, the searcher should be able to reach level 3 or level 4 directly from Home by responding to the query "I want information about ..." with respectively "screen captures", or "positioning screen captures".

In creating our website we have led our choices be affected by the following main factors: usability issues (e.g., what is the audience, what do visitors want) topical or domain characterizations (e.g., taxonomies or typologies), the minimalist philosophy with its corresponding design principles and heuristics, and finally, technical considerations (e.g., the decision to abstain from using plug-ins to serve a wider audience). We have found the approach meaningful but also progressing only slowly. This is what can be expected in minimalism. It simply takes a lot of time and effort to create a website that allows people to do more with less.

DATABASE-DRIVEN WEB APPLICATIONS FOR TEACHING & LEARNING

Daniel Y. Lee
Department of Economics & Coordinator, the Virtual University
Shippensburg University, Shippensburg, PA 17257 USA
DYL@ship.edu

1. Introduction

Although many instructors now utilize the Web to supplement their courses, the Web pages they create are mostly "static" in nature. These HTML documents are written and then posted onto the Web server, where they sit until requested by a browser. Materials on these documents are outdated overtime until the Web developer revises them one page at a time, which requires considerable time and effort, especially as Web pages multiply. In the long run, a better strategy to maintain a Web site is to use "dynamic" pages linked to databases. These Web pages are "dynamic" in the sense that they are created "on the fly." They don't exist until a browser makes the request. Upon the information user's request, the database inserts the requested information into preformatted HTML templates. If the information in the database is updated, the Web page will display the new information the next time it is requested by the user. The purpose of this paper is to provide an overview of how educational Web sites can be more easily administered, modified, and customized by using Web-database connectivity.

2. Developing Database-Driven Web

2.1 Advantages of using database-driven Web

Web browsers provide a Graphical User Interface (GUI) that can be used to access many things, including a database. Unlike the traditional database management systems, the user would not have to configure and learn to program database client software. Instead, using a Web browser's built-in forms capability, users can access a database by simply filling in the data they want and pressing a button. The returned data can then be presented in an easily readable format. Furthermore, the Web's cross-platform support allows users on many different types of computers or platforms (Windows, Mac, Unix) to access a database from anywhere in the world. Information can be disseminated with a minimum of time and effort, without having to solve compatibility problems (Lee and Liu, 1998).

There are several advantages of using database-driven Web development over the conventional "static" Web pages. First of all, Web pages can be created "on the fly" by querying current information stored in the database. New and fresh information can be presented to the user at each visit. This technology also makes it easier to administer, modify, update, and customize a Web site. In addition, users can tap into vast existing databases including many legacy systems through Web-database interaction. This allows for cross platform access without requiring custom client applications. Furthermore, database-driven Web makes it possible such useful functions as maintaining user state, i.e., user's preferences and other user-specific information can be stored between visits for various uses. In addition to these benefits, database-driven Web renders particular advantages to educational Web sites. Databases are "an excellent way to manage the media components of a Web site … instructional Web sites comprise huge numbers of media objects and multiple of content creators; databases make managing this information and longer-term maintenance issues easier to address" (Ashenfelter 1998).

2.2 Mechanism of database-driven Web

Typically, the Web server delivers a block of text written in the HTML to the browser, which parses the HTML and may request additional content, such as graphical data. The model works well for static data, but what about live data? For example, how would a Web server deliver content that it generates based on user input? One answer is to use a CGI (Common Gateway Interface) script to handle the database queries. CGI scripts are programs that let Web servers execute other programs and incorporate their output into HTML documents. The Web server executes a CGI program as a separate process to fulfill a user's request, which can be as simple as a Web page hit counter or as complex as a database query. Because a CGI program is external to the Web server, it can be written in virtually any language, whether compiled or interpreted. Some Web servers provide libraries and interpreters for Java and Visual Basic for use by CGI programs.

While CGI programs can handle basic Web-database connectivity functions, programming requires a steep learning curve. CGI programming is also subject to such limitations as input data validations and weak security. Recently various "middleware" products have been developed to minimize the CGI programming time and additional features of Web-database connectivity, including superior security, input data validation, e-mail protocol, etc. Middleware is a general term for any programming that serves to glue together or enhance two separate programs. Users now can create Web-database applications by using a fourth generation language middleware products such as Cold Fusion or Active Server Pages.

Database-driven Web publishing involves three major components: the Web forms, CGI or middleware, and database system. The mechanisms for Web-database interaction are shown schematically in Figure 1. There are four major stages in this interaction. First, the user fills the Web form using the browser, requesting pertinent information. The browser submits the request to the Web server. Second, the server invokes middleware or CGI scripts, accessing and querying the database. Third, the middleware or CGI retrieves or produces a HTML document. Finally, the Web server sends the result to the browser for display. CGI script or middleware makes it possible for the operations such as opening and updating appropriate database tables to link form objects to a database structure specified in the database design. The Web server and database server can be hosted in a single computer or two separate machines connected through the Internet.

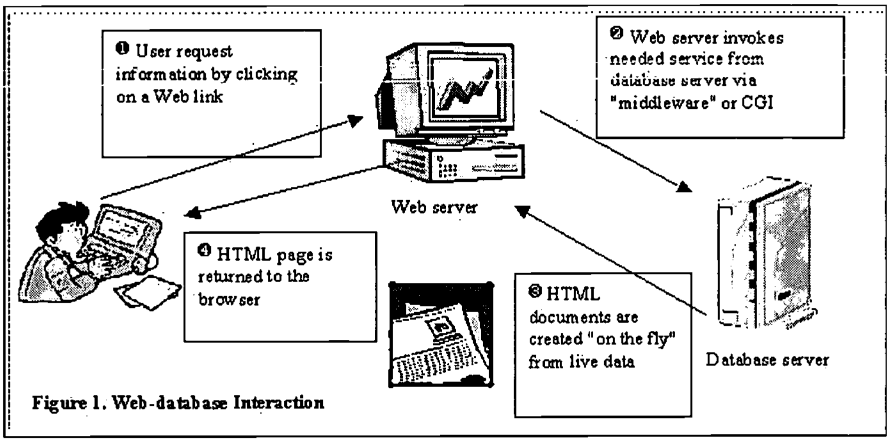

Figure 1. Web-database Interaction

2.3 Design of a database-driven Web

To design an effective database-driven Web, three major design activities must be performed, including Web form design, database development and CGI or middleware programming. Web forms are necessary as a user interface for a database-driven Web. The information user can send a request to a database by submitting it via Web form. A relational database is composed of rows (for records) and columns (for fields) in table format. Compared with a flat file structure, database approach has the advantages of minimal data redundancy, information sharing, and data consistency. Finally, some programming is required to connect the Web forms and databases. For example, Active Server Pages utilize extensively Visual Basic programming knowledge. Visual InterDev utilizes more user-friendly graphical interface. Cold Fusion eliminates some of the complex CGI coding by combining standard HTML with a server-side markup language called the Cold Fusion Markup Language (CFML). For example, the CFML tag <CFQUERY> can replace many lines of CGI programming codes. In addition, Cold Fusion supports such advanced features as security integration, dynamic Java forms, data entry valuation, e-mail integration, Lightweight Directory Access Protocol (LDAP) support, and advanced SQL (Structural Query Language).

3. Conclusion

Static Web documents are cumbersome and time-consuming to maintain. Whenever part of the contents is changed, the Web pages need to be updated. While dynamic Web development may require greater up-front costs, these database-driven Web pages will minimize the cost of providing up-to-date materials to the information user in the long run. Instructors can simplify the means of adding and updating materials on the Web by connecting their Web pages to databases. Carefully designed database-driven course Web sites can significantly enhance student-teacher interactions without taxing heavily on the instructors' valuable time and effort.

CHEMISTRY ON THE WEB

Dr. Leon L. Combs
Department of Chemistry
Kennesaw State University
U.S.A.
lcombs@ksumail.kennesaw.edu

This paper will focus on two applications of web technology to learning chemistry: the development of web sites for students to use for the understanding of particular topics in a physical chemistry course, and the use of web supplements for students in freshman chemistry and physical chemistry lab.

I. WEB SITES FOR UNDERSTANDING PHYSICAL CHEMISTRY CONCEPTS

The author is developing several different sites for use in the teaching of a two-semester course in physical chemistry. There will be a physical chemistry main site called the web "handbook" for the course and there will be many other sites called introductory sites. The on-line "handbook" being developed will reference introductory sites so students can make optimum use of their on-line time. The "book" will include the use of many topics which the students can "click on" to go to one of the introductory sites for further study.

students who do not know the topic can go to the site for an in- The introductory sites will contain rather complete introductions to concepts involved in the physical chemistry course, and will include examples of applications of the concepts. The author is particularly concerned with the students' metacognitive development, and these introductory sites will attempt to clearly show how the understanding of the concepts is developed so that further applications of the concepts should be easier. Those students who are already familiar with the particular topic can ignore the site or go to it for a quick review. Those depth study of the concept.

To help students judge their level of understanding of the introductory topic, java-based concept tests will be available which provide instant feedback to the student. A certain level of understanding is recommended before the student should proceed to further studying in the handbook. If the student performs below the recommended level then he/she should return to the introductory topic for further study and a retaking of the concept test. Once the student has achieved a satisfactory score on the concept test then he/she should be prepared to proceed to the topic development in the handbook. The handbook will also have problems for the student to work in applying the concepts.

For an example, one may go to this site (http://stern.kennesaw.edu/~lcombs/inter) and see how intermolecular forces are discussed for those who need a review or for those who seek a more complete study of an introduction to this concept. This introductory site would be referenced from the on-line handbook which further develops applications of the concept of intermolecular forces.

Will there continue to be a hard textbook for the course? At this point the answer is yes for the "handbook" is presently being developed as a supplement to a standard textbook. However as the "handbook" further develops it is possible that it will become the only text and it may be in the form of a web site or a CD, either of which would reference the introductory sites. The author envisions the introductory sites remaining as web sites since they can easily be modified as the need arrives.

It is possible that this method of study can be extended for use in courses taught entirely, or mostly, via distance education. We are developing videos of pre-lab lectures so that students can view the pre-lab lectures at any time and from any place, and as we develop our techniques of video presentation over the web, we plan on making use of the technology for lectures also. The web-based video lectures will use an Elmo for showing what would be done on a chalk or white board. Although it is difficult to imagine physical chemistry being taken totally as a distance education course, it is possible that a market for such could develop. We do anticipate offering a course in Chemical Literature and a course in General Chemistry about 90% over the web by next fall using this video technology and web-site technology such as will be described in part II. The students will have to come to campus or other proctored sites for tests.

This short talk will show portions of the "handbook" and portions of some of the introductory sites. It is hoped that by the time of the meeting that some video portions will also be ready to demonstrate.

II. Web Supplements in Chemistry

The author has been using a platform called Web-Course-in-a-Box (WCB) for a couple of years. WCB is being developed at Virginia Commonwealth University and a commercial company has been formed for further development and sale of the product. The author has used WCB for freshman chemistry, a senior seminar course, and for physical chemistry labs. WCB contains six components: a section on the class roll which allows for e-mail to be sent to all students and allows the students to develop portfolios for the course, a section for announcements, a section for the class schedule, a section which allows the students to make their own web page and to obtain help using WCB, a section on class information which can be anything relating to the class including web sites or class notes, and a section which can contain multiple bulletin boards and a fully developed lesson for the course. The section for the bulletin boards is very useful in that many bulletin boards can be formed by the professor. Separate bulletin boards may be formed for each small group within the class so that only members of that group can use the bulletin board. The small group boards are very useful for group projects.

The author has found WCB particularly useful for a university such as KSU which is a commuter university of about 13,000 students. Most of the students work and they find WCB a very helpful way of working on small group projects, taking concept tests, and finding notes for classes that they have missed. They can assess the web site after they leave work at 3:00 a.m., read missed notes, send e-mail to a study partner or to the professor, and work on the bulletin board project with their partners.

KSU is changing to WebCT this summer but all of the advantages of WCB are applicable to WebCT which has more functionality and is easier to administer.

During this portion of the talk, the author will demonstrate the use of WCB in several courses with particular emphasis upon applications in a freshman chemistry course being taught the spring semester of 1999. The corresponding WebCT site will also be demonstrated. The author has found that it is most useful to construct a web page for the course which contains the course syllabus, homework assignments, lecture notes, old tests, and other such information and have links to WCB or WebCT from this web site. It is much easier to do the necessary housekeeping from semester to semester with the items stored on a separate web site rather than to the course supplement. The author's general web site for a freshman chemistry course will be briefly discussed.

Distance Learning with MACS

D. Sturzebecher, O. Brand, M. Zitterbart
Institute of Operating Systems and Computer Networks, Technical University of Braunschweig
Bültenweg 74/75
38106 Braunschweig, Germany
{sturze|brand|zit}@ibr.cs.tu-bs.de

Introduction

Distance learning is a fast developing field with many different aspects to it. One commonly accepted differentiation is between the synchronous and the asynchronous aspects of distance learning. The synchronous aspect refers to learning scenarios such as study groups or class rooms. Asynchronous teaching is mainly represented by exercises (Zitterbart et al. 98). To provide a complete environment for distance learning it is necessary to consider both aspects. Asynchronous learning has been investigated to a great extend and many, mostly WWW based systems have been devised to support it. Synchronous learning in this respect is still less developed. There are a number of systems available, but these do not completely cover the needs of synchronous learning, as many underlying topics are still open to research.

The Modular Advanced Collaboration System (MACS) developed at the Institute of Operating Systems and Computer Networks (IBR) of the Technical University of Braunschweig aims at providing a flexible, scalable and easy to use system for synchronous distance learning. New ways of visualizing interactions among learners and teacher provide network-based learning that is similar to real life scenarios. Asynchronous aspects of distance learning are covered by the WWW-based learning environment Tele online/offline Learning (To/oL) also developed at IBR (IBR 98).

Structure of MACS

MACS offers an open framework for Computer Supported Collaborative Work (CSCW) applications as needed for synchronous distance learning. Due to its modular design, MACS can easily be configured to serve different scenarios, e.g., study groups or class rooms. The study group scenario assumes a small number of participants with equal rights, while the class room scenario provides extended rights to the teacher. Larger scenarios to model other environments, e.g., a conference with hundreds of participants, are thinkable.

MACS consists of three different levels: **network**, **tools** and **control**. At the **network** level the best suited protocol for the chosen scenario can be configured by taking the number of participants, the type of media and the available infrastructure into account. The number of participants is mainly determined by the type of scenario. The type of media involved can result in drastically different requirements (e.g., a text tool/chat vs. high quality audio/video). The infrastructure available to the participants has to be considered, as this might limit the choice of media (tools) and suitable protocol, thereby, limiting session size (i.e., number of participants). The **tool** level contains the main functionality of the available/used tools. A session is created or joined without any tools activated. Once in the session it is up to the learner to start a selection of tools and, thereby, create/join the corresponding media stream. An example for the motivation of not automatically joining all media streams is a mobile participant, who due to the bandwidth limitations of the wireless connection may not be able to support video streams. The **control** level is responsible for system and session administration. The system administration includes the maintenance of databases listing the current sessions, known users and available applications. Mechanisms to create, join, conduct, leave and terminate a session are offered, as well as mechanisms to invite or expel a participant. The session administration and visualization is performed by a session controller. This is necessary, as it is possible to simultaneous participate in more than one session.

Session Control

In MACS session control is performed by a session control module, such as the Visual Session and Floor Control module (ViSCO). ViSCO performs session and floor control in a virtual meeting room, in which participants are represented by thumbnails (Fig. 1). Various state information about the participants is provided through the thumbnail and symbols associated. An example is the participants multimedia (e.g., audio and video) equipment, represented by the symbols above the participants thumbnail. A camera symbol means that the participant has a camera available and can, therefore, source a video stream.

Floor and session control are also performed within the virtual meeting room. If a learner requests the audio floor, a *speaking bubble* is displayed on top of the corresponding thumbnail. This can easily be recognized by the other participants, especially by the current floor holder who may decide to release the floor. This type of visualization of social situation within a session helps participants to interact in a more natural way, just like in a conventional teaching and learning scenario. The graphical representation depends on the learning scenario. For the study group scenario (Fig. 1) the participants are arranged around a simple table, while the class room scenario puts the teacher in front of his class.

The integration of the session control into the virtual room provides a consistent user interface and a strong grouping of control elements. This prevents the well-known problem with complex user interface due to a large number of buttons, sliders and other control elements (e.g., MBone-tools) (Kuma 96).

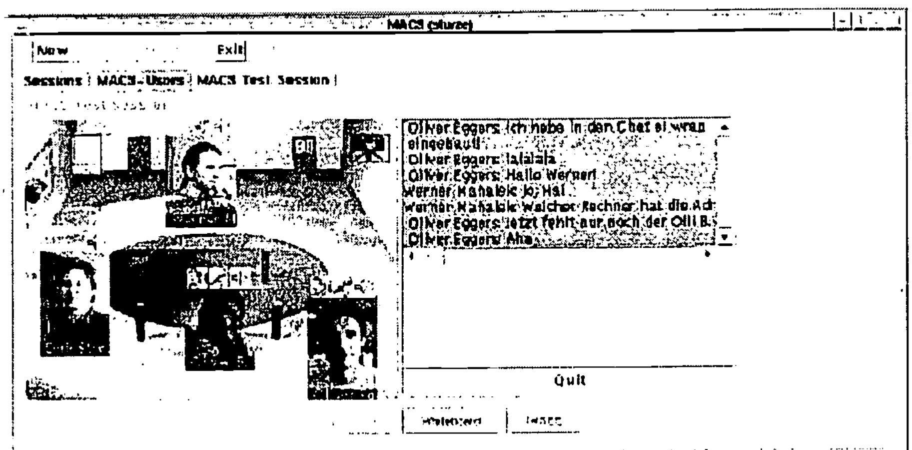

Figure 1: MACS user interface.

Conclusion and Outlook

There are different scenarios in distance learning, each with its own set of requirements. MACS provides a flexible and modular system which can easily be configured to fit the scenarios needs. A strong emphasis is placed on ease of use to help novice learners and teachers to learn the system. Feedback about the current session situation is provided by VISCO, allowing for more natural learning. Further extensions are planned and other scenarios, besides study groups and class rooms will be investigated. For further details please visit the MACS homepage at htttp://macs.ibr.cs.tu-bs.de/.

Multimedia Cases in Teacher Education: Towards a Constructivist Learning Environment

Ellen van den Berg
University of Twente
P.O. Box 217
7500 AE Enschede
The Netherlands
berg@edte.utwente.nl

Introduction

This paper is about the integration of multimedia cases in elementary science teacher education. These cases have been developed within the framework of the MUST-project (MUltimedia in Science & Technology). The MUST-project is a joint venture on behalf of three Teacher Education Colleges, the National Institute for Curriculum Development and the University of Twente in the Netherlands. The project aims at developing multimedia cases for the professional development of prospective teachers in elementary science and technology education. In the first project year two working prototypes on CD-ROM were developed. During this year the MUST-team became increasingly aware of the significance of the implementation of multimedia cases in teacher education programs. This paper ends with the notion of flexibility-in-use that in our opinion is a promising way to reconcile the voice of theory and the voice of practice.

Multimedia cases and a constructivist learning environment

In this section the design of the MUST multimedia cases are described according to principles for the design of constructivist learning environments (cf. Honebein, 1995). This description is not limited to the cases themselves, but, if appropriate, also the broader scope of teacher education programs is taken into account.

Embed learning in a realistic and relevant context

Non-scripted edited video of (an) elementary science lesson(s) forms the core of every MUST-case. These video clips are both a realistic and relevant context for prospective teachers. The clips are edited in a way that they provide ample opportunity for practising analysis and contemplate action (cf. Merseth, 1996). So, they are not meant to follow uncritically. On the contrary they intend to stimulate reflective thought and communication. These activities are also supported by assignments in which prospective teachers are encouraged to analyse the video from different perspectives and use these knowledge constructions in planning and implementing elementary science lessons themselves.

Different perspectives and multiple modes of representation

The MUST CD-ROMS include comments on the lesson by the video-teacher, experts, and prospective teachers. So, students are provided with experiences from different perspectives. However, there is some controversy among specialists in case-based instruction about whether or not to include experts' comments into a case. For instance, Merseth (1996) thinks those comments may inhibit the construction of knowledge by novices. When novices have read what "experts" say about the case, they may tend to abandon or suspend their own beliefs in favor of the "delivered wisdom" (p. 733). On the other hand, Shulman (1992) argues that, for example, experts' comments provide additional perspectives or lenses through which to view the events of the case. So, they add complexity and richness that gloss rather than simplifying or trivializing the events (p. 12).

In the MUST-project the use of multiple modes of representation has been applied in different ways. Firstly, the earlier mentioned edited non-scripted videotapes and audio comments on the video represent science lessons in elementary classrooms in different modes. Moreover, other modes of representation are depicted by all kinds of textual information.

Ownership an voice in the learning process

A third design principle is to warrant ownership and voice in the learning process by prospective teachers. This implies that they are encouraged to reflect on their knowledge construction processes and take responsibility for setting learning goals and pursue learning processes. In the design of the CD-ROMS of the MUST cases this principle has been applied by constructing an open non-linear interface. A second, and more important, way to account for this design principle is to formulate assignments that have an open character and stimulate the users to reflect on their learning processes.

The voice of practise: teacher educators

Especially the four teacher educators in the MUST-team refer repeatedly to the issue, that students are not familiar with working in a constructivist learning environment. The teacher educators question how much responsibility their students may handle. Moreover, they are worried about their role both in terms of their responsibility and in terms of practical implications. The former point may be illustrated by a remark of one of the teacher educators: she stated that it is her responsibility to do her utmost that students will reach the predefined learning objectives, so she wants to implement one of the multimedia cases in a rather traditional setting. This setting consists of a science method course, which is assessed by a uniform test for all students.
The latter point consists of concerns of teacher educators to assign all different types of more open assignments, such as portfolios. Or as one of them formulated it: For time reasons it is simply impossible for me to grade all these assignments.

Conclusions: towards flexibility-in-use

In this paper a dilemma is sketched between the ideal of multimedia cases in a constructivist learning environment and the reality of teachers and students in teacher education programs. In order to overcome this dilemma, the MUST project introduced the notion of flexibility-in-use. This notion implies that, especially, teacher educators have a considerable freedom in the way they want to use the multimedia cases, because from an implementation perspective it is neither possible nor desirable to impose a change in practice on teacher educators. By doing so, we take the warning of Louden and Wallace (1994) seriously. They warn reformers not to fall into the trap of the constructivist paradox. This means that reformers press teachers to make the transformation from conventional to constructivist practise in a single step. We opt for a more realistic reform agenda in which learning to teach with multimedia cases is perceived as a process of gradual reformation and elaboration of teacher educators' established patterns of teaching.

Enhancing Web-based Materials with Video Clips

Susan Mehringer
Cornell Theory Center
Cornell University
Ithaca, NY USA
susan@tc.cornell.edu

Background: CTC Education and the Virtual Workshop

The Cornell Theory Center (CTC)* began offering asynchronous distance learning over the Web in 1995, with its first offering of the Virtual Workshop. The Virtual Workshop is a Web-based set of modules used to provide distance education in high-performance computing. To date, we have conducted ten Virtual Workshops for about 1000 participants from academia, corporations, and government offices.

A goal in the Virtual Workshop evolution is experimentation with techniques intended to provide more interactive components, as well as options for participants with different learning styles. Features we have added include a glossary, interactive quizzes, personalized navigation via frames, animations, audio-tagged foils, discussion forums and whiteboard conferencing, and a web browser interface to lab exercises.

One interesting new technique we are currently incorporating is the use of video clips. We are working with two types of clips. The first type is screen and audio capture for tool demonstration. The second is using a film clip of a speaker in conjunction with other Web-based materials. The video clips will be used to enhance existing online materials. The clips are intended to improve our online educational materials by making the content more engaging and easier to understand.

Tool Demonstration Video Clip

The tool demonstration video clip is a screen recording, with a speaker voice-over. Previously, our online materials covering use of graphical tools such as a debugger or execution analyzer would use text and screen stills followed by a tutorial which walks the reader through the steps of a simple use of the tool. This is very tedious. We feel that providing a method analogous to looking over the expert's shoulder while s/he explains the steps of using a tool is a faster, more effective introduction.

Design Issues

- Web page composition: This video clip is presented alone in the web browser so that the viewer focuses fully on the screen. The clip will include typing, mouse movement, and menu selection. Too much information or activity on the screen might lose the viewer.
- Video clip length: If the topic cannot be covered in less than the ideal web video length, how should the parts be made available? Our ultimate goal is to provide an index into the video, which will allow the viewer to either jump into the desired part directly, or to view the whole segment in one piece. Other possibilities are to leave it as one long clip, and let the viewer fast forward as desired, or break it up into logical pieces, then play one at the time. In practice, we found that the clip for one topic is short enough that the index is unnecessary at this time.

Additional enhancements we hope to include in the near future include offering several clips on a single topic to cover different scenarios and programming languages, and making supporting material available, such as a text version with relevant hyperlinks.

There are several design options that we have decided not to address at this time, due to tool constraints and development costs. They include slow motion, additional screen highlights, and offering to execute a lab exercise synchronized with the demonstration.

The tool for the clip should be able to stop, start, pause, resume, forward, rewind, and show length and current time through the clip. These are common features that are readily available. Other desirable features include editing and file compression. We are currently using HyperCam from Hyperionics.

Speaker Video Clip

The second type of video clip is a speaker talking for approximately five minutes. Reasons to add this type of clip to our web-based materials include:

1. Give the materials a human look and feel. Most of the people who use our materials never see the developers and consultants; many have never seen Ithaca. Adding a "Welcome to the Virtual Workshop" clip or a clip that introduces Virtual Workshop participants to the consultants would serve to put a face on the materials, and hopefully, to make them more comfortable interacting with us by email or chat room.
2. Help in understanding a difficult concept. Supplementing words and pictures with an expert speaker might provide additional help for difficult points.
3. Break up the monotony. Although the materials have interactive elements, such as animations, diagrams, quizzes, simulation programs, and lab exercises, they can still benefit from an interlude of this type.

Design Issues

- Web page layout has almost unlimited possibilities. In contrast with the tool demonstration clip, a speaker clip should be paired with other activity on the screen. One possible usage would be to show the speaker next to the html page, with the html page keyed to advance at the proper time in the video. This picture most closely simulates a live lecture, and has enough activity to keep the viewer's attention. Early efforts may concentrate on having a content expert introduce a new topic.
- Length is also at issue for this type of clip. If the topic cannot be covered in less than the ideal web video length, we will again pursue an indexing solution.

As with the tool demonstration clip, the tool used for the speaker clip should be able to stop, start, pause, resume, forward, rewind, and show length and current time through the clip. We will also need encoding, to pair the video with html pages, and acceptable file size. We plan to experiment with a method to highlight portions of the screen at the appropriate time, used sparingly to focus attention, but not to the point of annoyance. We are currently experimenting with RealPlayer from RealNetworks, which appears to have the best combination of availability to our workshop participants and desired features.

Production and Evaluation Plan

We are continuing to research design issues and prototyping. We expect to evaluate both types of clips in production workshops in 1999. Evaluation will include questions on whether the layout is both clear and aesthetically pleasing, if the use of video clips enhance understanding, and if it is clear how to use and navigate the page. Early responses show that over 75% of respondents feel that the tool demonstration clips would enhance the materials, but less than half feel that speaker clips would be helpful.

The three legs of the stool: Teaching, Scholarship and Service remain the three-pronged pitchfork by which professors are raised high to receive promotion and tenure or pitched out of the barn and sent on their way to find another position. Historically, scholarship has been judged by the number and quality of publications and the level of prestige of the journal. Service, the weakest of the legs of the stool, is measured in terms of dedication to thankless positions on committees or in furthering other university goals. Recently, partnerships with school systems and community organizations has been a goal of many universities seeking financial support from federal and state grants which emphasize collaborative partnerships between universities and business or community and human service organizations.

In the past, and even today, the quality and quantity of scholarship and service can be estimated, to some extent, by a paper trail, including books, journals, and a well designed vita. But, how can teaching be evaluated? For too long, end of the term student evaluations have been the major source for judging the quality and effectiveness of teaching in higher education. As many professors and administrators realize, this form of evaluation, administered near the end of the quarter or semester, is often reduced to a popularity contest. Year after year, merit pay and promotion and tenure decisions are often based to a great extent, on these popularity polls. Short of video taping professors in interaction with students, there seems to be few alternative methods to document and subsequently evaluate teaching effectiveness.

For several years, authentic assessment has become an increasing priority in the field of education for teachers, administrators, and curriculum developers. There are many models available for use with K-16 students. Children in preschool and primary grades make judgments with the help of their parents and teachers to choose their best work and place it in a folder or expanding file. Students in the middle and upper grades may continue this method and may take pictures of their projects to place in their growing portfolios. With increased availability of computers in the schools, students in third and fourth grade may begin to use simple multi-media software to document their best work and projects. Goodlad, Comer and other proponents of educational reform recommend that schools and colleges of education provide future educators with multiple experiences in classroom settings beginning early in their educational careers. This proposal further emphases the need for authentic assessment as professors attempt to evaluate the pre-service teacher's growing levels of expertise in the educational process. Whether the decision is to develop a paper or an electronic model, the concept of portfolio development is a solid one.

The College of Education and Human Services (CEHS) of Wright State University has been recognized nationally as a leader in teacher education. A primary concern CEHS is that pre-service teachers develop skills of authentic assessment to document their own professional growth and, in turn, be able to apply in their classrooms in the future. CEHS has, for several years, assisted pre-service teachers to develop hard copy portfolios. These portfolios are constructed during the foundation portion of the education program, added to during the methods and materials classes and groomed during the student teaching experience. More recently, the authors have offered pre-service instruction in developing electronic models of professional and teaching portfolios, including CD ROM format and web page format.

For the pre-service teacher to the president of a university, the professional teaching portfolio is becoming an integral part of the educator's professional files,. A professional portfolio could be constructed to document all three areas: scholarship, service, and teaching, or any one of the three in isolation. Professional portfolios may be constructed in several ways, but to be used for authentic assessment, the portfolio must be more than a scrapbook, containing stubs from movies or basketball games. An educator could begin with a hard copy and easily develop this into a CD-ROM by simply scanning the documents and pressing them on a CD-ROM. Modern technological advances allow for use of multi-media to enhance the format. For example, a simple portfolio could be constructed using commercial software packages, such as Scholastic's Electronic Portfolios or the Grady Profile. Indeed, any multimedia presentation software may be used to develop a template for student portfolios. Multimedia programs such as Hyperstudio, Astound, Podium, Chisel or Powerpoint could be used to develop a portfolio which might include actual video and audio footage. This addition would provide a glimpse of the educator in the classroom or in individual interaction with students. Many books, as well as the World Wide Web itself may be utilized as models in for the development of a portfolio. The resulting document might then be stored and, in turn, viewed from a CD ROM or disk. One disadvantage with a CD-ROM is that it does take special equipment to press and it cannot be readily updated. Current technology, however, does provide for re-writable CD-ROMS.

A web page may allow for the greatest flexibility in creation, storage, updating and presentation. In the past, web design through programming and required knowledge of html limited the widespread use of the web page as a professional portfolio. Now that programs can be downloaded from the web and software purchased at a modest price, web authoring has been simplified and made understandable to a larger population. A web search engine will identify a number of on-line tools which would assist the user in webpage development. Some World Wide Web sites have been dedicated to housing references on web authoring such as:

... WWW Authoring Information (http://www.netspace.org/users/dwb/www-authoring.html)
... The Virtual Library of WWW Development (http://www.stars.com/Vlib/)
... Educators familiar with Clarisworks will adapt easily to Claris Homepage.
... Current versions of Pagemill offer the novice a path to webpage production.

More flexible, but advanced programs might include:

... Lotus eSuite DevPack (http://esuite.lotus.com/preview/preview.nsf/Content/Home+Page)
... GoLive CyberStudio 3.0 (http://www.golive.com/three/gogetit/index.ehtml)
... Virtual Media Technology's /) Virtual Media Publishing Suite which includes HDK3, INTRAWEB, Web*lite, and Hypershelf 3.0.(http://www.virtualmedia.com.au)
... Matterform Media - HTML Grinder and Theseus(http://www.matterform.com/design/)
... E-Publish (http://www.stattech.com.au/)

Educators may design their portfolios to document items included on their curriculum vita in the areas of scholarship, teaching, and service. In the area of scholarship, text files with grants received, and proposals which have been accepted for presentation at professional conferences might be included on the web page. Educators might provide hypertext links to their articles published in journals or to the professional organization's web page announcing a annual conference at which they are presenting a paper. In the area of teaching, examples of assignments and projects might be included as a hypertext file or as a scanned photo with sound bytes allowing the students to talk about their projects. Students' individual web pages might be accessible through a professional portfolio of their professor, documenting the student's professional growth even after graduating. Service could be documented on a professional educator's webpage by providing links to community resources and information on local events. Again, text files of grants which involved partnership schools and other community agencies could be included. Letters of appreciation from students and others might be collected and stored in an electronic portfolio format. The choices of what might be included in the portfolio are limited only by the creativity of the educational professional and the knowledge of the software available to make it happen. As an exemplar of authentic assessment, the professional educator's electronic portfolio may become a template used to document individual and professional growth in the business world.

Hematology Web: Supporting the Transition from a Disciplinary Medical Curriculum to an Integrated, Application-Driven Curriculum

Douglas Mann, Ph.D., Ohio University College of Osteopathic Medicine, USA, mannd@ohio.edu

Scott Jenkinson, D.O., Ohio University College of Osteopathic Medicine, USA, jenkinson@exchange.oucom.ohiou.edu

Andrea DeMott, M.A., Ohio University College of Osteopathic Medicine, USA, demotta@ohio.edu

Dan Johnson, M.A., Ohio University College of Osteopathic Medicine, USA, djohnson1@ohiou.edu

Ann Kovalchick, Ph.D., Ohio University Center for Innovation in Technology for Learning, USA, annk@ohio.edu

Introduction

Many medical school curricula have been reorganized in the past 20 years to incorporate problem-based, application-driven learning (Norman & Schmidt, 1992). Similarly, several MBA programs have been developed with projects rather than separate disciplinary courses as the primary learning activity (e.g., Stinson et al., 1998). However, faculty at any level of education may fear that a curriculum organized around problems or projects will not provide an adequate grounding in the individual scholarly disciplines that are the basis of course sequences in a traditional curriculum. Providing students with access to interactive web-based disciplinary resources (chosen or developed by faculty) for independent study and as a problem solving resource is one way to address faculty concerns about disciplinary coherence in an application-driven curriculum.

In medical education, the recently-developed "clinical presentation" approach to organizing curriculum content capitalizes on the motivational value of problem-based learning while providing a framework for learning based on an expert's organization of the knowledge (Mandin, Harasym, Eagle, & Watanabe, 1995; Mandin, Jones, Woloschuk, & Harasym, 1997). The clinical presentation approach provides students with a concept map for each of a series of common problems (e.g., anemia, chest pain, difficulty swallowing, fever) that shows how an expert's knowledge is organized, linking basic causal mechanisms and disciplinary concepts to specific diagnostic categories in a problem-specific manner (for an example, see Dane, 1997). Knowledge learned in this framework does not have to be reorganized in order to be applied. When the causes of a problem are learned in logical groupings that help learners to distinguish among the causes, diagnostic judgments are improved (Klayman & Brown, 1993).

The Ohio University College of Osteopathic Medicine (OU-COM) is reorganizing its traditional disciplinary curriculum into a Clinical Presentation Continuum (CPC) for implementation in Fall of 1999 for first-year medical students.

Project Goals and Design

The general goal of the Hematology Web project is to provide a complete online medical hematology course outline with slides that can be used 1) in a disciplinary curriculum for large-group presentations or independent study, and 2) in a new integrated curriculum via links to application topics. Hematology Web should deliver images of medical quality usable on a low-bandwidth connection, and the user interface should support comparison and contrast of any two images from the entire project.

Hematology Web's user interface was designed to emulate the menubar and pull-down menus of a standard computer program in order to make efficient use of screen space and to provide consistent, simple navigation. Two pull-down menus support navigation between and within topics. The 16 course topic titles are always available in one menu, and the web page anchors for the currently-selected topic appear in a second pull-down menu.

Images in Hematology Web are available in three resolutions: thumbnail, medium, and large (600 x 400 pixels). Space on the right side of the screen is reserved for two medium-sized image windows. After two images have been loaded, the next requested image replaces the "older" of the two current medium-sized images. This design makes it relatively simple to compare and contrast any two images in Hematology Web. Clicking on a medium image loads the large version of the image in a new centered browser window.

For independent study, the thumbnails are embedded in context in each topic's textual outline. For presentations, a slide list at the end of each topic contains just the image names and thumbnails with no other text.

The user interface was created with Javascript and frames. Javascript programming manages the pull-down menus and the loading and sequencing of images and labels in the image frames.

Eighty second-year medical students using Hematology Web as a course supplement in Fall 1998 were surveyed concerning user satisfaction and suggested improvements pertaining to use of the program in large-group, computer lab, and home settings.

Hematology Web has met its design goal of providing a user-friendly presentation and independent-study program for the content of an entire medical school course for a conventional or application-driven curriculum.

email: smcneil@uh.edu

Introduction

The purpose of the research study was to observe the application of learning theories to cross-functional teams in new product development and how individuals acquired skills and competencies as a result of their collaboration. A cross-functional team consists of individuals with specific but different skills, who work together toward a common goal, have a common purpose and follow a common approach (Katzenbach, 1993). For purposes of this study, skills were defined as those relating to design and development. Competencies were defined as the ability of the team members to communicate effectively, their perceptions of working in a collaborative environment and their level of confidence. The new product development process referred to the process of designing and developing an innovative product for the market.

Theoretical Framework

The theories of learning and cognition included in the study were cooperative learning, collaborative learning and situated cognition. Cooperative learning is an instructional strategy which proposed that when learners are teamed up for attaining a common goal, their cognitive learning gets enhanced (Slavin, 1991). Collaborative learning is a learning process where the team members through interacting with one another define the learning process (Bruffee, 1993). Situated learning is a theory dealing with the acquisition of knowledge in a given context. (Brown, Collins & Duguid, 1989).

Method of Inquiry

The research study was conducted using the naturalistic research design (Guba & Lincoln, 1985). In naturalistic research, the researcher assumes that it is difficult to understand any phenomenon outside its context. This research design was chosen because it would offer a rich understanding of the process of learning of individuals involved in the new product development process.

Participants

The participants for the research study consisted of 18 team members of cross-functional teams working in software; hardware and telecommunications related companies. Out of the 18 participants, 12 were core team leaders and decision-makers.

The Instrument

The instrument for the research study consisted of a researcher-developed questionnaire with open-ended questions. After each interview was transcribed, case studies were prepared.

Results

Most of the team members expressed the view that the collaborative environment offered them a window into the product development process as a whole and not just their part. The team members who were software engineers were able to understand the marketing aspect of the product development since in most cases the market defined the specifications for the new product under construction. The team members were usually brought forth skills for their particular area of expertise but often times had to learn new skills during the course of the project as and when the need arose. These skills, like design and development skills, were learned in collaboration with their peers. Team meetings were considered crucial since in some cases it became a platform for getting feedback from one's peers on the work done. These team meetings then became a learning board for the team members. It was deemed important to leave the lines of communication open at all times. Once the team members felt that their opinions counted they had a sense of ownership towards the project and attitudes changed for the better.

One aspect that came up time and time again was the fact that cross-functional teams were the way to go in today's market. The products were complex and the time frame short, which made it imperative that a cross-functional team be put together for meeting the deadline for the product. Also it was felt that no single person possessed all the skills needed and hence the need for a team of people with specific skills.

Importance of the Study

The study leads one to believe that there is a need for cross-functional teams in any product development because no single person could provide all the necessary skills needed. The study leads one to wonder if successful collaboration is due to good facilitation or due to the team selection process or due to the projects being challenging. It also leads to the question of whether we need more cross-functional teamwork among the faculty in the field of education. And if so, how will the design and development of curriculum be and how will this affect the delivery of instruction. Finally, in the area of Instructional Technology, collaboration of skilled people from different content areas will result in the creation of innovative multimedia instructional materials. With the rapid growth of the World wide-web, it becomes imperative to study the impact of collaboration among learners spread in different parts of the world. How will this impact classroom teaching and learning remains to be seen. What adjustments will be made to the existing classroom structures in order to deliver the instructional materials in an effective manner remains to be seen.

Development and Evaluation Design of Physics Learning Modules within the Lilienthal Web-Based Theoretical Flighttraining

Rolf Zajonc and Prof. Dr. Lutz Schön
Didaktik der Physik, Humboldt-Universität zu Berlin
Invalidenstr. 110, 10115 Berlin; Germany
zajonc@physik.hu-berlin.de

Introduction

The Lilienthal project arose due to both the emerging interest of several European pilot schools for computer aided learning and the decision of the European Community to foster European educational multimedia applications.

Apart from six pilot schools[1] three universities and the Fraunhofer Institut für Arbeitswissenschaft und Organisation participate in Lilienthal. The latter and the University of Stuttgart do the project management. The other two universities advice with their theoretical background the development of the "Virtual European Pilot School" and care for the research. Hereby the University of Amsterdam is responsible for socio-economic concerns whereas the Institut für Didaktik der Physik of the Humboldt-Universität zu Berlin focuses on pedagogical aspects. Lilienthal started '98 and will last for two years including demonstration and evaluation. A pilot study will be carried out in March '99 and it is foreseen to present its results at this conference.

Lilienthal

A complete pilot training takes about two years and involves several examinations with differences between the different nations. The whole training requires about 750 hours of instruction and some hundred hours of flight training. The Private Pilot License (PPL) as the base of all other licenses, is handled with up to 100 hours of instruction and approx. 40 hours of flight training. This varies from nation to nation. The participating pilot schools in this project develop an European-wide accepted instruction material focusing on the approx. 100 hours of PPL-Instruction to reach the open European market of private pilots. This instruction material is basically developed as an computer-mediated system not only in order to make didactic use of the new technical possibilities but also in order to reduce the costs for the students as well as for the often recently privatised schools. This system will finally result in an internet based Distance Learning Platform (DLP). It offers HTML-pages as well as multimedia CBT lessons, which can be run through and discussed asynchronously (Newsgroups, email) or synchronously (Electronic Classroom containing audio conference).

The Course

Sense-Giving-Structure SGS is a term used within Lilienthal for the idea to build the PPL course not subject divided but in interrelated stages, which partly run parallel to the practical instruction. Currently the number of subjects that are taught for the PPL varies from pilot school to pilot school but this number is adjusted to the nine subjects of the general European-wide requirements defined be the Joint Aviation Authorities (JAA). These are foreseen to be integrated into the national laws. If you write the 9 subjects like Navigation or Meteorology into 9 columns and 8 stages of the practical instruction like First Touch or First Flight in 8 rows a matrix emerges. Into this matrix were provisionally placed the 108 topic titles suggested by the JAA. Corresponding learning objectives were formulated. These were discussed in a Delphi-process [Dalkey&Helmer 1963] and finally led to an European Curriculum based on agreed detailed learning objectives.

The two-dimensional structure takes the opportunity not to be restricted to a weekly timetable any more. The student finds himself in semi-organised environment, represented by the matrix-structure. He is free to follow links within the subject, to a Basics course about the science behind some phenomenon or to external links for additional information.

[1] Lufthansa Flight Training, Ecole de Pilotage Amaury de la Grange Societe Anonyme (with two subcontractor schools), KLM Luchtvaartschool B.V. and Horizon Swiss Flight Academy Ltd.

The Knots in Hypermedia Environment

For the SGS in addition to the subject matter experts stage responsibles were determined who crosscheck the learning objectives for possible strong relations and intersections. These central points match in particular the possibility of hypermedia: *"The idea converted in hypertext is to organise a topic's content in single information units and to electronically represent these in a network database in form of knots and links between knots."* [Tergan 95, translation]. Research will focus on the way students work with these knots. In Lilienthal most have a scientific content like the concept pressure. The student will meet the term pressure at various occasions during his way through the course. The expectation is that the medial representation of multidirectional knots assist the linking of knowledge. A hint for this assumption could be drawn from mc-tests with three different groups of students. The first group will meet these Science Modules via links from the SGS as described, while the second will be given the modules as precourse and the third will be taught in traditional classroom teaching. The test will enumerate topics and ask for subjects which contain these topics.

Learning Modules

All modules will have three levels. The student will always enter a module on the "mandatory" level. This starting page is an overview about the linear sequence of "recommended" learning steps. By using optional links (the links are marked according to their level) the student can enter the "nice to know" level. This might be an external homepage, an historic anecdote, a discussion group. The "nice to know" level shall serve as the *"motivating narrative element"* [Waraich 98]. If its pages assist the learning process is open for investigation.

Links

The important difference between learning in a hypermedia environment and traditional learning with a book or in a classroom is the easy and comfortable use of links. *"There has been insufficient time for the field to formulate a detailed theory of learning from such systems"* [Shapiro 1998] Hence explorative investigations of the new medium's possible advantages are needed to increase our understanding hypermedia learning. In Lilienthal research will focus on the assumption that students look up something they already met before but feel uncertain about more often when they use the comfortable and direct link to the corresponding information. It is to prove whether this assumption is true and if so whether this really leads to a safe basic knowledge.

Evaluation Design

The evaluation methods will be threefold: questionaires, tests and protocols. Questionnaires are needed to receive the students' impression of the learning modules and their personal opinion about their learning progress. It will be based on the questionnaire used by the EuroMET-Goup for the user evaluation results [Phelps and Reynold 1998]. Pre- and posttests are carried out in order to measure the learning progress. Of course there is no guarantee though, that individual gain of knowledge origins from the corresponding learning module, when students can interfere with all kinds of information sources for a period of 3 months. Hence the learning success must be related to the learning paths through the whole course. With individual learning protocols hypermedia offers a unique opportunity to recheck the students actual use of the learning media.

Introduction

Web-based instruction (WBI) is an emerging delivery system used by public school systems, postsecondary institutions, military training centers, and business and industry to provide learners with education and training opportunities. There are literally millions of web sites on the Internet which use a variety of themes on almost every topic from antiques (http://www.antiquesonbroadway.com/) to zoos http:/www.zooatlanta.org/), providing global users with a wealth of information on almost any topic. In the great majority of cases, these sites are designed for information sharing rather than for instruction. Today, educators use the web for a wide variety of education and training purposes such as having students locate sites to gain information about instructional-related topics (Ackerman, 1996; Garner & Gilingham, 1996; Kehoe & Mixon, 1997; Reddick & King, 1996). Others have used the web for sharing information through listservs, newsgroups, chat rooms, MOOS, MUDs, etc.

WWW & Instructional Design

To harness the WWW for instruction rather than just gathering information, web-based learning environments must be created following principles of instructional design. Models such as the ADDIE model, as well as other traditional design models, follow a fairly linear path to the design and development of instruction. When developing instruction for the WWW, alternative views of design and development must be employed, taking into consideration the unique capabilities and characteristics of the web.

A critical component of successful instruction delivered through the WWW involves the active engagement and promotion of interactivity in the learning environment. Instruction that provides for active engagement depends on a careful plan that integrates strategies that attend to various learner characteristics and WWW features. This precisely planned instruction leads to the design and selection of appropriate performance objectives, instructional strategies, and technologies (even with selecting the WWW as the medium, there are other media selection considerations) for the delivery of the instruction. This integrated approach to analysis and design ensures that the development of the resulting instruction meets the desired goals, or purposes of the lesson.

Emerging technologies such as the WWW can be used to facilitate and promote learning in web-based environments. Learning is promoted through the use of instructional strategies which, in turn, provide a framework for presenting instructional materials. The learning environment is defined by the boundaries of an instructional situation – class session, part of a course, or an entire program or course of study. The integration of a variety of instructional strategies within a learning environment facilitates the successful learner. It is critical for designers to remember that these technologies serve as our tools that help students learn and instructors teach. The designer's skills and creativity, as well as capabilities of the delivery systems being accessed, are the only limits on how these technologies can be used in the development of instruction.

There are a plethora of instructional design and development models within the Instructional Design and Development field. Typically they cover from the point of design (micro level) to those that look at the entire process (macro level). Andrews and Goodson (1980) conducted an analysis of the basic models and described specific attributes of characteristics of over 60 models. Since that time, other design models have been revised (Dick & Carey, 1995) and new ones have been developed (Smith & Ragan, 1994). Commonalties among models in terms of elements revolve around the notion that they are systematic in process, have several stages of design, development, and evaluation, and have an initial stage of analyzing goals, learners, and context.

Web-Based Instructional Design Model

Web-Based Instructional Design (WBID) contains the basic stages of analysis, design, development, implementation, and evaluation that are also found in other models. However, the arrangement, or structure, of these stages is less linear than in some of its predecessors. The design and development process using the WBID model is an iterative and ever-changing and evolving process. The WBID model begins with an analysis stage, moves to a combined design/development stage, followed by the implementation stage. What makes WBID unique is that once the analysis stage is completed, the evaluation stage also begins. Evaluation is continuous through the design and development stage and is carried through the implementation stage. Because evaluation is such an important element when designing effective instruction and learning environments, it must be planned and conducted throughout the product design and development stages.

Each stage of the model contains and culminates in decision points, action plans, or products, so that the shift from one stage into another and back again is relatively seamless. This seamless shift is especially seen in the design-development stage where prototypic materials and products are developed initially before moving into production of a finished product.

This model is a natural way for instructional designers develop materials for learning as well as providing a constant refinement and enhancement of the product based on thc evaluation information. Evaluation, then, is no longer viewed as an add-on or tail-end stage, but an integral part of the design and development process. While most designers say that they conduct periodic reviews of materials and formative evaluation, they may not make it as integrated as our model suggests.

Conclusion

The World Wide Web offers many challenges and opportunities to those who design and develop web-based instruction. Traditional models of instructional design do not meet the needs of designers who are designing instruction for this emerging technology. The WBID Model facilitates the design of web-based instruction.

The Pedanet Project
Implementation of Schoolnet in Central Finland - Tools and Contents

pentti.pirhonen@jamsa.fi
valijarv@piaget.jyu.fi

Introduction

Pedanet Project:

1. Supports schoolbased projects
2. Developes web based services for schools
3. Implements more advanced telecommunication infrastructure for schools in Central Finland
4. Implements the Peda.net Schoolnet in Central Finland

Pedanet is a R&D project for utilizing the opportunities of modern information technology in learning and communication as a part of the operation of educational institutions. The target of Pedanet is to contribute to all the educational institutions and the municipalities in Central Finland by setting up, and advancing the performance, compatibility and economy of their telecommunication networks.

The essential objectives of the Pedanet project are:
1. To activate and to support the schools in the planning, development, and implementation of their own projects.
2. To promote equal access to information technologies in all schools regardless of current levels of resources and community support. Our primary concern is giving small schools the same opportunities currently available to larger schools. Through the schools, we reach out to include the community as a whole through continuing education and the provision of public access workstations.
3. To evaluate the use of data networks in the schools; and evaluate co-operation between schools.

Goals and Methods

The goal of the project is to build, by the end of the year 1999, an integrated, user-friendly, and pedagogically enriched electronic network for the use of all the nearly 60 000 students and 300 schools operating in the region of Central Finland.

The Pedanet project supports the development projects of the educational institutions in helping them create their own innovative ways of utilizing telecommunication networks in teaching and learning. Teachers are offered opportunities to disengage from the daily teaching work for a certain period to work in their own Pedanet-related projects. All projects include research activities that connect the projects to international discussions about the utilization of information networks for pedagogical purposes.

The purpose of Pedanet is not to externally guide the school's activities in their own development work but to support and advance the implementation of these projects through training, evaluation, research work and resourcing by offering pedagogic and technical expertise in form of various information network services.

How Pedanet supports school based projects

Finds experts
We locate experts in the use of information technology in each region. These experts try to identify potential projects that would be valuable to communities in their region.
Starts projects

Ten pilot projects were selected for Pedanet support. These projects may be specific to a region or may cover all of Central Finland. Projects subjects include: teaching methods, teaching contents, materials, and processes that have the potential to reform pedagogical practices in the schools involved.

Supports project development and disseminates project achievements to others

Pedanet facilitates contact between project participants and experts that may provide them assistance. We provide teachers with release time so that they may concentrate on their projects. We also provide project participants software and other technological support for instance establishing small services for schools on Internet.

When projects near completion, we will publish the results on the web and sponsor conferences to share what project participants have accomplished: their successes, the problems they encountered, and anything they have learned as a result of participation in their projects.

Tools and Contents of Peda.net Service

Origo, the Heart of Peda.net Service and the Main Tool for Virtual School in Central Finland

All the 300 schools in Central Finland will have an access to Peda.net Origo.

The Peda.net Origo is developed by The Future Learning Environment (FLE) project, coordinated by Medialaboratory / University of Art and Design, Helsinki, University of Helsinki and Sonera Ltd.

Origo includes modules for learning with new technology. These modules are called FLE-tools. (The working title). The FLE-tools are designed to help the students engage in productive work with knowledge objects and artefacts and generate new objects and designs. FLE-Tools is a groupware system designed for supporting collaborative knowledge building over the Internet. FLE-tools consist of several modules that are designed to facilitate collaborative knowledge building through a constructive process.

The Webtop; The environment provides each user with a personal open 'Desktop' in the web ('webtop'). The webtop is used to store digital materials and to share them with other students.

The Discussion Module is a shared space for discussing topics and concepts generated by the users.

The Jam Session module is a space for the collaborative construction of digital artifacts.

The Library is an adaptive medium to publish and browse multimedia learning materials.

Other Peda.net Tools and Services:

Interactive OnLine Magazine

A tool for pupils to publish shared web Magazines online.

Net Publishing system for schools

A tool for schools to publish information and notices on Web

"CUR-PRO" CURriculum PROcessor

Internet accessible application for Curriculum development

Document conferencing service

Voice Chat - Text Chat applications, internal IRC server
Mailing lists, Open Discussion forums, Thematic Discussion forums
Notice Boards, Web Calandars
Pedanet Commercial – E-Shop for schools
Information and News service for schools

PROFESSIONAL DEVELOPMENT GOES ONLINE: ITÕS ABOUT TIME

Angie Parker
Educational Technology
Gonzaga University
U.S.A.
aparker@soe.gonzaga.edu

Introduction

Its about time professional development is seen as something other than teachers sitting in a stuffy room, drinking cool coffee from styrofoam cups and listening to a speaker who may or may not be an expert. Furthermore, instruction online and instruction Òon-demandÓ is about time - time that teachers have in small segments before and after school and during preparation periods. And finally, the nation has entered the Information Age, itÕs about time professional development joins the revolution and participates in the move from physical space to cyberspace for the continued training of its teachers.

Rethinking Professional Development

With ever shrinking budgets, schools and school districts are no longer able to provide quality professional development in the traditional manner. With budgetary constraints in mind, many people are realizing that professional development must be delivered differently and must be constructed differently.

In addition to changes in delivery, professional development requires revisions in the way it is constructed. First, professional development in the Information Age must include a wide array of learning opportunities that encourage active participation in experiencing, creating, and solving real problems (Jakson, 1997). Second, professional development must not only be available to teachers 24 hours per day, seven days per week, but must take into consideration the audience of learners created by those teachers. Finally, professional development must provide the opportunity for teachers to reflect critically on the material and to fashion new knowledge and beliefs about the content, the pedagogy, and the application in the classroom.

Moving inservice training from stuffy rooms to the endless expanses of cyberspace allows all three criteria for revision to be accomplished and for professional development to be delivered into the hands of the Information Age. The following article will present not only an overview of a professional development project, entitled *Excellence thru Linkages*, but also illustrate how the professional development was re-constructed.

First a Brief Overview

Excellence thru Linkages was a two year, funded project designed to deliver technology inservice training to a Native American school in the northwestern United States. The first year of the project involved traditional training and focused on the hardware and software available at the school. Although instruction and discussion both included the integration of technology into the classroom curriculum, little or no evidence of computer usage existed at the end of the first year.

An overview of the project and integration of critical reflection

Forced by the inclimate weather of the winters in the northwest, a team of professors and graduate students developed the idea for online training. Part I of the venture had been offered in a traditional format and had given the faculty at the Native American school the opportunity to become computer literate. Although the technology was readily available and they had the basic knowledge, none were using computers in their classrooms. Part II was, therefore, developed to maximize the synthesis of technology with the current curriculum. Nineteen teachers and three administrators participated in *Excellence thru Linkages*. The material presented was divided into three modules:

* integrated software
* research and,
* presentation.

In the first module, integrated software, teachers were instructed on how to utilize word processing, database and spreadsheet as classroom tools. Activities, applicable to numerous subject areas and grade levels were suggested as were Internet sites for lesson plans using integrated software. Teachers were given three weeks to review the online material and to try one of the activities with their students, and to reflect on the results through the use of an online journal. The online journal was a critical component in this project, as the process of reflection and writing created a stimulus for teachers to better understand their own fears and motivations for teaching with technology. When attempted lessons did not result in the expected outcome, the journal again allowed for reflection. At the end of the three weeks, a required chat encouraged teachers to share their successes and failures and to communicate ideas of how this software package could be utilized in the classroom. Teachers were also required to submit no less than two ideas for using integrated software at their grade level.

The second module, research, provided information for use of the Internet as a classroom tool. Again, teachers were given three weeks to visit the sites offered in the online professional development and evaluate the activities with their students. The chat again encouraged sharing of ideas. Mandatory activities and lesson plans were not required by the administration during the research module, as teachers were becoming more self-motivated and willingly posted ideas to the listserv.

The third and final module, presentation, reviewed the use of PowerPoint, Hyperstudio and Digital Chisel as classroom presentation tools. The same time line and format was again used. This time teachers and their students posted the results of their integration of the software. PowerPoint and Hyperstudio presentations were uploaded to the webpage that hosted the online professional development.

Summary

While the project had many positive outcomes, the world of online professional development still has numerous hills and valleys to traverse before becoming the ultimate answer for continued teacher training. This project allowed for the reconstruction of teacher training and the launch of that training into the Information Age. *Excellence thru Linkages* has only touched on the possibilities of what is to come as the Internet and modern technology combine in the world of education.

Interactive Net Learning – a Matter of Facilitation

Ulric Björck

Henrik Hansson

The Viktoria Institute, Göteborg, Sweden
ulric.bjorck@ped.gu.se & hh@handels.gu.se

Background

At the University of Gothenburg we have for two years been working with a particular course curriculum as a "stomping ground" for developing net related pedagogics. The courses in Social economy have Problem Based Learning (PBL) as a pedagogical approach and the courses are built upon the use of computer mediated communication in distance education. The PBL approach is described by the CLEA[1] management as a structured model in which a number of necessary steps will be used. A number of cases are the starting point for the PBL process. The case is presented through a vignette that might be presented as a picture, a saying or a description of a situation and it will be of relevance to the aim of the course. The students in the course will then build the case around the starting point depending upon what they have found to be interesting in the presentation. In addition to the introductory presentation, a number of relevant terms will be supplied, which will mark out and enforce the character of the particular case. The idea is that the students, working in dedicated groups, will seek knowledge on their own from different sources.

The evolution of the course has led to a new entirely net-based application called Workspace, we will return to the thoughts behind the creation of this below.

Method

In all and together we have covered most aspects of this course, enabling us to give "thick descriptions" of the processes at hand. This paper merely presents an overview of the rich material that has not yet been fully analyzed. The students answered an electronic questionnaire on the web. The questionnaire dealt with questions about the students' background as well as how the start of the course turned out and what problems the course had at that moment. Both individual interviews of students and a group interview of the supervisors have been carried out. The individual interviews have been structured out of a questionnaire to the respondent. In the interview situation the questionnaire has been used as a support for the interviewer, not as a fixed agenda. The overall aim has been to let the respondent talk freely as much as possible. Almost all of the supervisors were present at the group interview as well as the system administrator. Kvale (1996) finds that the interaction among interview subjects in a group interview often leads to spontaneous statements about the topic being discussed, but that group interviews "generally require that the interviewer has a good grasp of the interview topic" (p. 101).

The interviews have been carried out from May 1997 to May 1998. So far, this work has resulted in 31 interviews with students (out of 50 students), and the additional interview with the supervisors. Most of the interviews have been written down in order to improve the quality of the analysis (compare Palmer, 1969).

Results

Results from the questionnaire showed that the students experienced the course as time consuming and the students had also problems in finding literature to solve the tasks/cases given to them. The

[1] CLEA was the name of the European Union project that produced the original courses.

questionnaire also showed that some students had left the course. The teachers each had a different approach to working with the students on the net. However, the main common role for the teachers is that of facilitation. This enhanced the learning process of the students as the teacher, who became the "facilitator", acted merely with a supporting role based on what he knew about the learning process - this rather than taking part of the specific learning process discussing subject matters. In participating in the course the teacher learnt a lot as well as the students, something that we find to have a lot in common to the discussion about symbolic interactions (Blumer, 1962).

One of the facilitators chose to further his experiences from this course together with the technician of the course and developed a new computer application called Workspace. The advantages of this can be summarized in the sense that Workspace does not reproduce the classroom in the way that the used software WEST did. It also has many more possibilities to create discussion groups and to search for information in these through an engine for statistics as well as content. Workspace is built with PBL in mind and is therefore fully developed for the encounters that PBL can create.

Discussion

A description of the development process, from the perspective of how the students experience their learning situation connected to the learning of the teacher, is the primary target of this section. This perspective is imperative to the continuous process of building and maintaining the group of students that emanates (Husserl, 1960) out of the understructure of the student body. This understructure is enhanced by the process of role taking (Mead, 1934) over the net, which has somewhat different preconditions to the role taking or socialization (Berger, 1967) of a student in an ordinary course. The mere knowledge of these mechanisms is a precondition to facilitate this process. For indeed it is facilitation rather than teaching or supervising. The "facilitator" rather than the teacher has not restricted the students' learning process and therefore both the learning process and the subject matter is developed more intensively than among the students of a teacher. One of the large advantages with a course like this is that the student is no more and most important no less, than their identity on the net. You are not intimidated by "normal" social handicaps like shyness, looks, speaking problems etc. The preconditions seem to be others, like primarily ability to express yourself through writing.

Time being the foremost variable of human interaction, rather than space due to the psychological permeation of that dimension (Bergson, 1912) This is obvious in that the space dimension is almost evidable and has a mere representation (Chaib, 1996) in the virtual room created for the Workspace. Time being the factor expressed as synchronous or asynchronous representation in the process of the student discussion. Being asynchronous in the beginning of the learning process and as it becomes closer to the deadline of the task the process becomes more synchronous. This process also accounts for the student's experience that the course was time consuming. This is due to the experience that synchronous interaction on the net with instant feedback is more effective towards the end of a task since the result needs to be summarized and systemized. This whereas the process of brainstorming of presentation of new ideas or thoughts is better presented in an asynchronous environment since it gives more liberty of thought for the particular student, since it is not met by a direct argument.

Factors for Successful Telementoring of Preservice Teachers

Barbara Brehm, Ph.D., Curriculum & Instruction, Illinois State University, USA, bbrehm@ilstu.edu

Abstract: This research examines how telementoring can provide introductory field experiences for preservice teachers through Internet links with classroom teachers as well as improve student telecommunication skills. It contains a discussion of factors impacting successful mentoring derived from three semesters of data collection.

NCATE/ISTE standards (ISTE, 1998) require that students have a working knowledge of telecommunications and its use in the classroom. The State of Illinois and NCATE standards recommend more field based training such as Professional Development Schools (PDS) for preservice teachers. Although Illinois State University continues to increase the number of PDS sites, increased field placement is difficult given the numbers of students enrolled in elementary education (more than 2,000). This research examines how telementoring can provide introductory contact with classroom teachers as well as improve student telecommunication skills.

Campbell and Yong (1996) had preservice teachers at two universities participate in a collaborative Internet project to examine classroom issues from multiple perspectives. Additional objectives were for the preservice teachers to acquire skills with networking technology and to develop a positive attitude toward CMC. Data collected from assignments submitted through e-mail, e-mail messages, e-mail process journals, and interviews. Participants' use of e-mail and trouble shooting of technical problems improved during the semester. They also found that technology was more effectively learned when it was embedded in content-base projects.

Norton and Sprague (1997) studied on-line collaborative lesson-writing between pairs of inservice teachers and preservice teachers. They found that preservice teacher's attitudes about telecommunications improved both for personal use and use with students. They suggest that on-line collaboration between preservice and inservice teachers may be used to enhance preservice field supervision.

This research examined how telementoring of preservice teachers (students) by practicing teachers can be an effective extension of classroom experience and identifies factors which promote successful mentoring. A pilot study was conducted, fall 1997 (Brehm, 1998). During that semester and the two following semesters, data were collected using questionnaires, journals, interviews, e-mail exchanges, and Web discussion forum interactions.

All students and mentor teachers had access to Internet e-mail and the Web from their school computer, home computer, or university computer labs. Students received two hours of Internet training. All teachers were experienced Internet users.

A discussion of factors impacting successful telementoring follows a brief summary of each semester's research. Resulting suggestions are divided into mentor recruitment, type and structure of the interaction, and the process of the interaction.

The first two semesters, undergraduate students were enrolled in language arts methods classes taught by the author. The third semester students were enrolled in an introductory methods class, Curriculum, Management, and Assessment. During Fall 1997 (Sem I), mentor teachers were enrolled in a Language Arts & Technology class delivered on-site in a school district. The groups discussed language arts related topics on netWorkPlace, a Web discussion space. During Spring 1998 (Sem II) and Fall 1998 (Sem III), individual e-mail between mentors and students was added to project. Mentors were assigned to individual students to personalize the interaction and create community (Brehm, 1999). Figure 1 illustrates the project participants by semester.

	Fall 1997 (Sem I)	Spring 1998 (Sem II)	Fall 1998 (Sem III)
Students	24 language arts class	23 language arts class	65 intro education class
Teachers	34 single district class	13 many districts	37 many districts

Figure 1 Telementoring Project participation by semester.

Based on suggestions from the Fall semester 1997, modifications were made in the recruitment of mentors, building community, and the types of mentoring activities planned for Spring semester 1998. Community between preservice teachers and mentors was built through pairing of a teacher with two students, an introductory e-mail exchange, the development of a collaborative project, and a campus visit by the mentors.

After the initial introductory e-mail exchange, pairs identified a topic for a thematic unit that the classroom teacher was currently teaching or developing for the future. The preservice teachers developed a lesson plan for the unit and the teachers gave feedback on the lesson plan.

Students reported pleasure in creating a lesson plan for a real classroom. Students had some difficulty creating lessons that were appropriate for the developmental level of the students and lasted the length of time that they were designed to cover. An unanticipated finding was that all of the teachers appreciated the new ideas in the preservice teacher's lesson plans and taught part or all of the lesson plan in their classrooms or planned to do so during the 1998-99 school year.

A frustration of the researcher was that some teachers were reluctant to send negative feedback to the students resulting in a few lesson plans that lacked quality even after revision. As a result, the role of the researcher for fall 1998 was changed from a teacher responsible for grading to a moderator responsible for student and mentor support. Responsibilities of the moderator included solving technical problems, posting bulletins and information, encouraging participation, and solving communication problems between mentors and students.

During Sem III students discussed course content (curriculum, classroom management, and assessment) with mentors through e-mail and on a NetForum. At the end of Sem III, 65 students and 25 mentors completed open-ended questionnaires about the class. When students were asked what they learned from the mentoring project, they reported the following: ideas for teaching from real teachers (28%), content (27%), Technology (13%), and very little or nothing (13%). Teachers reported the benefits of participating as reflective thinking (45%), helping future teachers (25%), and fresh ideas (15%).

Students reported that mentors rated as outstanding or good (66%) responded quickly, answered questions in detail were knowledgeable, and enthusiastic. Mentors rated as fair or poor (19%) mentors who responded infrequently. During the three semesters, mentors were recruited through required participation in classes, volunteer participation in classes, volunteers, and paid mentors. Mentors who volunteered were the most involved and enthusiastic. Mentors must also have convenient access to Internet to fully participate.

This researcher suggests that on-line discussion be integrated into classroom discussion for the most benefit. The mentoring should continue for at least two semesters for maximum effectiveness. Initial time is consumed with community building, overcoming technical problems, and learning the software. Technical problems were reported by 25% of the students and 20% of the mentors during Sem III.

Explicit structure is a requirement for telecommunications projects. Across all semesters, the most frequent suggestions from both groups for future mentoring projects was a rubric for evaluating the participation and a clear timeline of when electronic exchanges were due.

The researcher suggests that WebCT or similar groupware be used for mentoring. Such software allows e-mail, discussion participation, and chat with one sign-on. It also allows student work or presentations to be posted for student and mentor review. Pictures of mentors and students can be posted, Web pages can be downloaded or linked, and FAQs can be posted to save the moderator and participant's time.

Introduction

This paper presents the research project called A PONTE. The overall objective of the project is to design the appropriate setting and perform a range of "pedagogical experiments" integrating the use of Information and Communication Technologies (ICT) in rural secondary education centers. The main goal is to observe the inference, identify solutions and establish clear guidelines for similar cases in other regions with a considerable rural population, not only in Europe, but also in farther regions.

The research within A PONTE is carried out in the areas of Galicia (Northwest Spain) and Northern Portugal. Although part of two different member states, both regions show a similar model, human townships as well as correspondences in terms of socio-cultural and geographic features.

Setting the context

Two fields of study have been considered to constitute the research framework of the project: the use of ICT in education and the rural areas' idiosyncrasy. A third underlying field of interest is the issue concerning the gap between secondary education and university studies.

It is of common sense that the introduction of new technologies into educational contexts requires a transition from traditional learning methods to innovative ones. It is also widely accepted that distance education is one of the educational contexts which takes most advantage of the use of ICT.

Besides, rural areas, defined as such as they have to cope with specific problems as large distances and lack of appropriated physical means of communication, are conditioned by a hostile geographic environment making access to information resources difficult. For example, the information available for pupils when deciding on the type of studies they want to take up seems to be insufficient in many cases. Consequently the passage from secondary education to university is much more complex than the transition between the different levels of education. Both studied regions, Galicia and Northern Portugal, are aware that the use of remote applications using ICT is the best way to overcome the large existing differences between rural and urban population, or at least to reduce them.

Concerning the pedagogical framework underlying the setting and performance of the experiments, the following demonstration actions have been identified:

1. Many studies have highlighted that there is still widespread lack of awareness about the implications of using new ICT in education and training, and skepticism about the benefits. There is a need for broader dissemination activities to encourage the education communities to become involved.
2. In Galicia, surveys have shown that there is an important gap between secondary studies and university studies. The problem is that the only information given to the students finishing secondary schools on the possibilities to continue their studies is presented during a single day session and is far from being complete. A growing amount of web-based data readily available is provided by the Universities and

constitutes a valuable source of information that can be presented adequately to the students.

3. The consequence of low density and dispersion of population in rural areas is that classrooms are made up of small numbers of pupils. Due to this fact and to the diversity of the curricula in secondary education, many subjects are chosen only by a few students in each school. This means that maintaining teachers in each center for all possible subjects is not affordable and seldom-demanded subjects are merely not on offer in many institutions. ICT applications can help to overcome this situation, as a wide range of tools to support distance education is available on the market. Besides, participation in multicultural projects involving the use of the Internet under European ongoing initiatives will be encouraged and supported.

Project development

The methodology applied in this project is based on the following approach: educational needs analysis, demonstration and evaluation plan design, experiment setting implementation, results analysis and best-practice reports dissemination.

The report on educational needs is centered on the description and analysis of aspects susceptible to influence the pedagogical experiment's design. These considerations allow establishing the selection of schools in which the experiments will take place and describe the actual state of rural secondary education in Galicia and Portugal with special focus on issues related to the use of ICT. The crucial issue within A PONTE will be to define the evaluation parameters in order to carry out the experiments and assess the results. The objective is to identify and analyze the project evolution, from complete successes to deep failures. Evaluation actions and reports will focus on issues as the response to the regions special needs, the pedagogical value of the experiments, the technical value of the ICT applications implied, the socio-economic impact and the consequences for educational institutions. The intermediate analyses and the final results will be presented through public workshops involving teachers, students and parents. The interactive character of these workshops should allow the transfer of knowledge between the different actors, the confrontation between designers and end-users, and will give to the organizers the opportunity to collect feedback data.

As research on the impact of the use of distance learning facilities in rural areas for pupils to access less taught subjects will be one aspect of the demonstration, a web-based environment (called Aula da Ponte) will be integrated according to the specific needs of rural schools. This tool will provide an environment enabling instructional designers, monitors and students located in different rural areas to communicate and study in an interactive way. The idea is to integrate already developed components, as a preliminary study demonstrated that a valuable quantity of existing tools is available on the market.

Expected outcomes

At local level, the expected outcomes of the pedagogical experiments should be an increase in the awareness of ICT applied to education in Galician and Portuguese Secondary Centers, as well as the schools' access to learning communities, international ICT services and educational programs. On a wider scale, experience gained within A PONTE, guidelines and best-practice reports on how to use ICT for pedagogical purposes in rural areas should be made available to the international educational community.

Acknowledgements

The project A PONTE is an European funded demonstration action developed in collaboration with CESGA (Centro de Supercomputación de Galicia), AURN (Associaç o das Universidades da Região Norte), CEEL (Context European Educational Ltd) and SBLN (formerly the South Bristol Learning Network Ltd).

Hybrid Online Courses & Strategies for Collaboration

Marshall Soules, Ph.D.
Coordinator Media Studies,
Malaspina University-College,
Nanaimo, British Columbia, Canada
soules@mala.bc.ca

Hybrid web-based courses combine technologies of distance delivery with face-to-facc interaction. This combination of modes poses special challenges for instructors who hope to foster collaborative learning environments based on (inter)dependencies (Bourdeau & Wasson 1998). This discussion is based on the delivery of a number of online courses since 1996, mainly in the fields of Media Studies and Computer-Mediated Communication (English). (Websites for these courses can be viewed at http://mala.bc.ca/~soules/.)

The theoretical contexts for this discussion have been explored in previous papers (Soules 1997; Soules 1998) which explore how online learning takes place in a distinct performance medium, and how it is important for instructors to reflect on the new expectations, demands, and social dynamics resulting from the new medium. Research on video-conferenced courses offered in 1996 (Soules 1996) revealed that "student satisfaction and success are highly dependent on [a] sense of membership, or engagement by the learner in the educational process. Our research found, for example, that unlike the membership construct, the technology itself does not lead to high satisfaction rates: once the purpose of establishing clear and reliable communication has been met, further efforts to develop more sophisticated systems are not likely to result in more student satisfaction. Similarly, once basic student support services have been provided, more elaborate administrative functions do not significantly increase student satisfaction or success" (Dolan 1996; Soules 1998).

What we discovered in our attempts to create collaborative interdependencies was the need to supplement classroom lectures and discussions with web-based learning resources. Students at the remote video-conferencing site felt they were missing something that those in the host classroom were experiencing, and asked that lecture notes and resources be available to them through other means. For this video-conferenced course, we evolved a hybrid mode which combined synchronous delivery technologies with supplementary, often redundant, web-based technologies designed to foster greater course participation and involvement for an "ensemble" of learners.

Since 1996, I have delivered a number of courses which combine elements of face-to-face with online, web-based delivery techniques. In some cases, all course participants were expected to attend classroom discussions, and then accomplish certain online learning tasks in lab sessions. In other course configurations, there have been two sections of the same course: one section met in the classroom, the other was solely for online students studying from a distance. All course materials were provided on websites, and assignments for both sections were submitted electronically. In still another version of the hybrid online course, I accepted students who wanted to take a course completely online which had been scheduled as a traditional classroom session. Finally, I have delivered courses with no scheduled classroom meetings. In all of these instructional scenarios, the hybrid nature of delivery posed specific problems, and revealed important insights into the dynamics of online learning.

As one might expect, online students often express the suspicion that they are missing something. Not only are they missing what they might learn from any material presented in class not included in the resource materials, they are also missing the learning that comes from discussion and interaction. Additionally, some people do not find it easy to ask questions online. These concerns are valid in my experience: students do benefit from classroom discussions, from the clarification of difficult material, and from interaction with an instructor and each other. Online students do not participate as easily in the process that a group goes through in the construction of a commonly-held understanding of material--not that everyone has to have the same understanding, only that the group has collaborated on an exploration of the material from which they take their own conclusions. This collaboration defines, in effect, the condition of interdependency.

These impressions that something is missing in the educational experience is most keenly felt by students who take a course completely online and know that there is a group of students who meet regularly in the classroom. If all the students are online, the feeling that something is missing is less urgent.

Self-motivated online students are able to compensate for their distance from the classroom by making use of email and newsgroups to communicate with both instructor and other course participants. However, for students who are less sure of themselves or their abilities, I am discovering that there are a variety of strategies that can be used to foster membership in the course and its activities:

1. One obvious strategy for promoting a learning synergy in hybrid courses is to ensure that the online learning resources available from the website are up-to-date and as engaging as possible.

2. Similarly, it is important that instructions for assignments are clear, and do not require further in-class explanations to give fuller direction. For most of my online assignments, I specify the form and goals of the assignment in detail, and allow course participants considerable latitude in their choice of approach to the content.

3. I grade the assignments of online students first, and respond to all email queries as quickly as possible to demonstrate that someone is responsive to their needs.

4. After the earlier video-conferencing experience, I have used mainly asynchronous technologies for online courses--email and distribution lists, newsgroups, and websites. My use of newsgroups has evolved considerably, and become more structured. Where previously I asked students to participate in a newsgroup discussion over a period of time and graded them on their level of participation, now I assign short weekly assignments which are posted to the course newsgroup. These short assignments reflect on the course material, provide writing practice, and generate focused discussion. These weekly assignments allow me to monitor who is actively participating in the course. Collectively, all course participants are building a tangible dialogue related to the course content.

5. Since most of the courses I deliver emphasize writing skills, I ask participants to collaborate on the production of an electronic journal which provides tangible evidence that all course participants can contribute equally to the learning experience. It is not altogether surprising that those who volunteer for the production and design of these journals are often online students who want to participate more fully.

Strategies for creating membership in hybrid online courses should acknowledge that we are operating in a unique performance medium with its own protocols for effective interaction. The use of structured newsgroup discussions related to course material, and the production of electronic journals of participants' writing offer tangible evidence of interaction and collaboration. Participants are able to build dynamic documents testifying to their participation, and thus their rightful membership in the course.

A new concept for designing distance education courses for students of electrical engineering

Dirk Thißen
Automaton Technology Group
Hagen University
Germany
dirk.thissen@fernuni-hagen.de

Dr. Birgit Scherff
ATR-Industrie-Elektronik GmbH & Co.KG
Viersen
Germany
b.scherff@atrie.de

It is one of the concept's inherent objectives to be applicable to many of those subjects concerned with electrical engineering's curricula. To meet these special requirement, a structure was chosen, that consists of eight different modules and six tools.

The modules could be derived from investigations of the general demands of professional life nowadays and an analysis of the curriculum's single subjects' contents. They have two things in common, first of all, each of them is in a way related to a special subject's contents and second, they try to combine computer based learning with traditional methods in learning, e.g. solving exercises by writing on a piece of paper. But the modules differ with regard to the learning objectives, didactic approach, and the use of media elements.

name	description	learning objective
course	offers the contents of special subjects as it is done in specialist books, here however in multimedia form	gaining knowledge by instruction
exercise book	offers a number of exercises, derived from a typology of exercises, especially elaborated for engineering subjects	using knowledge to solve problems
media corner	presents strategies, hints, and tools for autonomous information acquisition	knowledge acquisition and knowledge processing
base knowledge	gives a brief summary of other subjects' contents necessary to comprehend the special subject	gaining basic knowledge
real life	points out the actual use of special subjects' contents in reality and professional life	making knowledge transfer-able
laboratory	offers simulation environments for special subjects' contents	gaining knowledge by autonomous exploration
formulary	present a combination of single subjects' formulas	gaining basic knowledge
cup of coffee	offers opportunities for recovering	learning by entertainment

Table 1: Modules recommended by the new concept. The table gives the name, a short description and the learning objective for each of the eight modules.

In dependence of the typical demands of a single subject, the developer can decide for his current distance education course, whether to stress one or a few of the eight modules, perhaps leaving out one and so on. In addition to that, it is still left in the hands of the special subject's expert to determine the composition of a certain animation, figure, video, etc.. The concept's intention is to provide a didactic framework. This framework is enriched by a detailed description of functions for each module. Thus, it serves as a guideline for the developer to facilitate an implementation of the modules in the concept's sense.

Each module should be divided into smaller information units, each of which can be visualized on a screen of its own(using scrolling if the information unit's size exceeds screen possibilities for visualization). For accessing the modules' information units, the concept recommends a linear navigation structure for each module, enlarged by a hypertext/media structure connecting all modules. This allows guided as well as self-determined exploration of the single information units.

In addition to the modules, the new concept recommends six tools for coordinating and supporting the student's learning sessions to become more efficient ("to do things in the right way") and effective ("to do the

name of the tool	description
learning optimizer	offers adaptability to different strategies in learning, which have been detected by empirical research
flipchart	gives an overview of the user's navigation schemes, comments, times for learning, test ratings, etc.
calendar	offers to plan a single learning session and to elaborate learning schedules
plant	motivates the student using the Tamagotchi-effect[1]
search engine	offers quick access to special information units or parts of them
calculator	offers a scientific, interactive calculator

Table 2: Tools for supporting students' learning sessions. The table gives the name and a short description for each of the six tools.

As the tools *search engine* and *calculator* are standard in highly sophisticated computer based learning, the other four tools are new. They could be derived from reflecting the concept's authors' experiences during their studies of electrical engineering. They are all intended to take advantage of the medium computer, that is the general possibility of recording learner's activities data.

Following the new concept when developing a special distance education course, has three great advantages:

- With its modular structure the human learning process (adopting knowledge up to using it) is not only supported on the whole, but due to the clear separation, it is in the student's hands to choose his own aspiration level at any time of his learning session.
- With the integration of traditional methods in learning and computer based learning in a didactic concept an pedagogical surplus value could be achieved.
- Assimilating the tools *learning optimizer*, *flipchart*, *calendar*, *plant* further contributes to the student's ability to learn.

Up to now, the concept has exemplarily been realized in form of an HTML-based distance education course for the contents of *mechanical engineering basics in automation technology*.

The Effectiveness of Metasearch Tools in Web-Based Information Retrieval

Judi Repman
Randal D. Carlson
Department of Leadership, Technology and Human Development
College of Education
Georgia Southern University
Statesboro, GA 30460-8131
jrepman@gasou.edu
rcarlson@gasou.edu

Basch (1998) refers to metasearch tools as "umbrella" sites, where the user enters a query once. The meta-engine then translates it and sends the query to several search engines and/or directories simultaneously. Notess (1998) calls these tools megasearch engines or parallel or multiple search engines. In looking at the features of tools that have been labeled metasearch engines, one characteristic differentiates "true" metasearch tools: following a simultaneous search of multiple search engines or directories, the end user is given a single integrated set of results. In the technical terms used by Dreilinger and Howe (1997) a metasearch tool must contain three components: a dispatch mechanism, interface agents, and a display mechanism. Choice of search engines for a specific query is the function of the dispatch component, while interface agents "translate" the user's search query into the format required by a specific search engine or directory. When the results have been obtained from the different search tools, the display mechanism merges them. Sometimes the results list can be sorted or ordered as the user specifies. Most metasearch engines also claim to have display mechanisms that eliminate or reduce duplicate links and which may check whether or not links are active.

True metasearch tools also fall into several categories. The largest group is web-based and free to anyone using a web browser. Next is a group of desktop applications. Some can be downloaded from the web for free and are used as an add-on to a single search engine. InfoSeek Express < http://express.infoseek.com/> is one example in this group, as is Sherlock, which is integrated into the new Mac O/S 8.5 and is the only desktop tool that can be used on a Mac. The final category also consists of desktop applications, but these metasearch tools are shareware or licensed software. Some sort of registration fee or purchase price must be paid either at the time of download or following a trial period. Sherman (1998) labels these as search software utilities or agents since they reside on the user's computer.

Unfortunately, there are some fairly significant limitations to metasearch tools. Basch (1998) likens the approach of many of these tools to the lowest-common-denominator effect. Interface agents may not be sophisticated enough to translate a Boolean query into the syntax required by a specific search engine. Advanced searching features may only be available as part of a registration/customization process. This approach is only practical in single user computer settings, a luxury few public, school, or university libraries would find affordable. The speed of metasearch tools also means that they retrieve only the few highest ranked hits from individual search tools. Most metasearch tools will time-out search engines or directories that take too long to respond to queries. (Notess, 1999) The cost of this emphasis on speed means that most metasearch tools sacrifice comprehensiveness, returning from 20-50 results per query.

The comparison and evaluation process began by identifying metasearch tools. Lists of metasearch tools were identified at the Open Directory Project <http://dmoz.org/>, Yahoo! < http://www.yahoo.com/>, and Beaucoup! <http://beaucoup.com/>. An initial examination of the tools indicated that while many were called metasearch engines, the majority did not fit our definition. After eliminating some tools that didn't seem to be functional, we were left with a set of 16 "true" metasearch tools. We examined each of these in depth, reading any background information, FAQ's or descriptions of features that were available and tested each with several sample queries.

Developing criteria for identifying top performing metasearch engines was an interesting task. Since successful searching is closely related to relevance this becomes a qualitative assessment. None of the metasearch tools examined provided anything beyond a general statement of how relevance was determined, since this information may be viewed as proprietary. A metasearch tool met our initial criteria for success if a result matching our information need was listed on the first page of the results display. The number of search engines/directories available, the look and functionality of the interface, and the results display were also important factors in arriving at any final judgments. Some results displays were so cluttered with advertising that the user has to scroll down almost a full screen before any results were visible. Metasearch tools that made it easy for users to customize their search by selecting which search engines to use or specifying how results should be presented were also viewed more favorably. Another convenient addition was a window that followed you on your desktop so that you could search immediately. Finally, metasearch engines using frames when results are linked were identified. When this happens end users don't see the URL for the site they have linked to in the location bar, which means that writing down or bookmarking a URL is problematic. This feature can be toggled off, but that is an unnecessary, and confusing step.

On the whole, most of the 16 metasearch tools examined performed adequately. None failed to answer any of our queries, but in some cases an acceptable hit was well down on the results list. Duplicate links were usually eliminated. In the end, we agreed that five metasearch tools (byteSearch <www.bytesearch.com>, Mamma <www.mamma.com>, Metacrawler <www.go2net.com/search.html>, ProFusion <www.profusion.com>, and SavvySearch <www.savvysearch.com>) were superior performers but did not attempt to rank them. Metasearch tools offer an excellent alternative for end user searching. All five of our top group did an above average job of translating a search into the syntax required by different search engines and directories. They provide a quick way for the end user to have some sense of the quantity of web resources available on a topic. If users pay attention to the attribution of results to search engines, it is also possible to determine which individual search engine might be the most promising search for more advanced or in-depth searching. The breadth of SavvySearch and the options available with ProFusion make them stand out from other metasearch tools currently available, but as with most discussions of web resources these features can and will change. Try to forget some of the negative comments you've heard about metasearch tools in the past (that is, two months ago). Their capabilities continue to improve and our experience has shown us that they have an important place in the information searching process.

Classroom Integration of Digital Humanities Materials

Edward John Kazlauskas
Instructional and Human Performance Technology
School of Education
University of Southern California
United States
kazlausk@mizar.usc.edu

Introduction

ISLA (Information System for Los Angeles) is a digital research resource of Los Angeles materials held in a very large, University-based archive. These resources are in multiple information formats and are used for teaching, research, and public access. The scope of resources includes the widest variety of information from all historical periods, linked by spatial and temporal coordinates. The primary, long-term goal is to create a system that will enable all kinds of users, including students, to search and access, via the WWW, a rich and diverse range of research materials about a specific geographic location. The ISLA project has been supported by many organizations, including the U. S. National Endowment for the Humanities (NEH), the City of Los Angeles, and the Thomas Brothers Map Company. It is envisioned that the software system will be transportable and other cities/locations can acquire the software to provide access to their own digital resources

The first version of the system was released in September 1998. This is Version 1.0, the proof-of-concept. This version contains a library of multidisciplinary digital materials (texts, photographs) and provides components of the sophisticated search and retrieval method.

This paper provides: 1) an overview of the current system; and 2) a description of ISLA training and development of K-12 curriculum integration plans

Overview of Current System

The ISLA interface provides space/time/fulltext/format indexing to allow for searching and retrieval of materials. This interface allows access by the conventional indices of author, title, subject, and other cataloging fields, but in addition the attributes of Geographic Information System (GIS) vector layers, and timeframes. A user, a student for example, can take a "core sample" of a geographic area, such as a neighborhood, street, or census area and examine this through layers of time.

The current materials/resources in ISLA include photographs, newspaper texts, aerial and satellite images, digital spatial data made available from Thomas Bros. Map Company and the Bureau of Engineering of the City of Los Angeles, data from the 1939 WPA (U.S. Work Project Administration), and land use maps. Additional items are being added to the growing ISLA digital archive. Other material formats, such as audio-visual media (audio, video, film) and demographic data, will be added in the future.

Education Applications/Curriculum Integration

A view of this project is that one of the keys to its success is the integration of ISLA into the classroom. We believe that ISLA is particularly suited to assist in the fostering of participation and critical thinking skills, and in the development of information literacy skills. At present, graduate students in education (teaching and learning) and in instructional technology are being trained, using the training-of-trainers model, in the use of ISLA. They, in turn, are providing training sessions for school administrators and teachers, and to a group of local teachers involved in an in-service program in computer competency and curriculum integration

Individuals and groups are developing humanities and social science focused lesson plans for their specific K-12 curriculum interest level. ISLA-based curriculum planning can also include integration of other content areas, such as mathematics, inclusion of other supporting instructional resources, and connection to standard curriculum guides, such as the California History-Social Science Framework. Most planning includes a description of the learning objectives, required tasks, and specific learning activities associated with ISLA, as well as a description of methods for learner evaluation. The following are two possible examples of ISLA curriculum scenarios.

Geography (Reading Maps); Social Science (Demographics); and History

The general learning objectives associated with this curriculum scenario include the following. Learners will understand and work with cardinal orientation, scale, and proximity; interpret map symbols; work with concepts of social categorization and elementary comparative statistics; understand the settlement patterns of different ethnic groups during different historical periods; and understand the modes of livelihood practiced by ethnic groups in various historical periods.

The tasks required of the students include: orientation of unmarked aerial photos, correlation of topography with cartography, comparisons in space, time, and by category; searching selected neighborhoods for evidence of ethnic settlement and ways of life.

The activities include the following. Students choose or are assigned different regions of the city and each is asked to construct a changing demographic profile of that neighborhood at three different points in time: 1939, 1960, and 1990, on three variables: occupation, race-ethnicity, and average income. After viewing and extracting data from ISLA, students perform simple summary proportion statistics and charts using typical spreadsheet programs. Students share results and then write reports about the nature of the changes within regions over time, and across regions, offering hypothetical explanations for those differences.

Art and Architecture

The general learning objective includes developing an understanding of historical architectural styles and their creator's intended meanings.

Tasks include identifying a style in different types of construction and then "reading" unidentified constructions to determine date of construction.

Activities include the following. Students search ISLA to discover buildings built during the 1920s, using dates in photographs and using "year built" data in the 1939 WPA Household Survey. They search for photographs and identify Art Deco styles in both downtown office buildings and residential structures. Students form teams and each team assembles a collection of residential and commercial buildings from the period 1910 through 1940. Each team attempts to identify the buildings constructed based on the styles of the sample chosen by the other team. As appropriate and if possible, teams will visit these buildings.

Conclusion

The ISLA archive continues to grow and the interface is still undergoing development. But in the meantime teams of education students and local teachers will continue to evaluate ISLA in terms of its curriculum integration capabilities and will develop additional ISLA-based lessons for eventual classroom use.

Information on the World Wide Web: Is It Fact, Fiction, or Scam?

Judy E. Mahoney
Cerner Virtual University
Cerner Corporation, United States
jmahoney@cerner.com

Now available on the World Wide Web (WWW), information on any subject, by anyone! There exists, for the first time in history, a channel that spans the globe where freedom of expression is open to anyone. It is this openness that signals a note of caution. Little of the information on the Internet is filtered as it is in the more conventional channels such as in libraries, newspapers, magazines, books, or television. What is accurate? Evaluating information available on the Internet is crucial if the information is used as teaching material, learning resources, or research reports.

Critical literacy is a prerequisite skill that must be fostered when using information from the Internet. This invaluable skill will carry over into a real world that contains ever more sources and quantities of information. On the Internet, where anyone may publish anything relatively easy, the huge quantity of extant information makes the use of search engines commonplace. However, search engines cannot rank the returned documents for credibility. This is left to the student, teacher, or researcher, who is faced, with a potential mountain of chaff mixed in the kernals of knowledge. As such, the source is not always easy to evaluate, especially according to reputation, because of the vast number of, often anonymous, authors involved. In the end, it is usually left to the document to speak for itself in terms of its content validity, and ultimate credibility lies in the critical literacy of the reader. (Farah, 1995).

An Example: The staff at Bishops High School, Newfoundland, Canada began to question the validity of information included in recent student term papers. Students were accepting almost all home pages as accurate regardless of content because they were "in print." Print materials commonly used for student research have usually passed through either peer research or editorial boards before publication. However, no such validation exists for Internet materials, which may be posted by both genuine authorities and those with questionable credentials. In response to problem, the Memorial University Faculty of Education Action Research began a project to develop a set of guidelines for students and teachers who want to use the Internet as a source of information for research papers. (Doug F. etal. 1996), As a basis for their guidelines they define validity as: The quality, fact or condition of being supported by commonly accepted facts or recognized authorities. Additionally they suggest using two types of validity with respect to home pages. The first, "concrete validity" is based upon a page being well referenced to known authorities. The second, "context validity" is based upon the content of a page being confirmable with accepted facts. In his presentation at the Association for Educational Communications and Technology, Dr. Don Descy of Makato State University in Minnesota defined information accuracy in using a two part definition containing these same basic points. (Descy, 1997).

Using above definitions as a basis, the following is a list of pertinent questions developed as a guideline for determining the accuracy of information gleaned from the Internet.
With respect to "concrete validity" the reader should be able determine the answer to the majority of the following questions.

- What is the source of the information?
- Does an individual, group, or organization sponsor this site?
- Can the location of the site be determined by the URL? (*See information on Uniform Resource Locator)
- Is the author/publisher a recognizable authority?
- Is the author the creator of the information or a compiler of other information resources?
- Does the author/publisher provide his/her e-mail address?
- Is there a common link to the page from recognized authority?
- Does the page provide other sources that could be contacted for confirmation or further information?
- Does the page cite a bibliography or provide references to confirm the accuracy of the information?

- Has the site been reviewed by a "content" reviewing agency?

Some pages/sites contain information that appears valid but does not meet the majority of the criteria for "concrete validity." To deal with these pages or further confirm the accuracy of the given information, which appears valid in comparison to other pages, "valid in context," the reader should be able to answer all of the following questions.

- Who is the intended audience for this site.
- What is the intent of this information?
- Why was it put there - entertainment, educational?
- Is the information presented in a well-reasoned manner?
- Can you detect any evidence of bias from reading the page?
- Is supportive information available in print?
- Does the information contradict or confirm the information from other sources?
- Does the site have links to other sources on the same topic?

Developing skills in determining the accuracy of information gleaned from the WWW has far reaching potential for lifelong learning. The Internet provides a virtual classroom for hands on learning of critical thinking skills needed in the real world to avoid the pitfalls of false advertising, pseudo-science, narrowed reality (gangs, cults), get-rich-quick schemes (scams, pyramid schemes, mail frauds), political rhetoric, indoctrination, media bias, twisted statistics, and other ills that prey on the unsuspecting in this information society we live in.

*URL information example: http:// www.mannlib.cornell.edu.reference/workshops/surf/url.html

The Protocol: This tells the Web browser how to load and interpret the document. For example, http:// tells the browser that the file is a hypertext document. Other protocols include gopher, ftp, and news.

The Server: The second part, www.mannlib.cornell.edu is the name of the machine on which the Web page is located. The following domain names provide information about the type of organization using or maintaining the server.

".com" names are used by commercial (for profit) organization.
".org" names are usually used by non-profit organizations or groups.
".edu" is for 4-year, degree granting colleges/universities.
".net" is for network infrastructure machines and organizations.
".gov" is for US Federal Government agencies.

The Path: The last portion of the URL, reference/workshops/surf/url.html, gives the path or directory of the document plus the name of the file itself. When the symbol "~" is included in the path it often denotes a private directory or file. To determine more information about the files located on a particular server, in the location window, try deleting the file and folders - one at a time from right to left. (First delete the file and press enter to logon to the site, then delete each of the folders in turn from right to left, trying to logon after each deletion. Many times this will open up other directories and files also housed on the site) Suggested sites for additional information Truth, Lies and the Internet http://www.cnet.com/Content/Features/Dlife/Truth/ss01.html; Kathy Schrock's Guide for Educators http://www.capecod.net/schrockguide/eval.htm The Six Quests-- WWW repair - Evaluative approaches http://www.ciolek.com/PAPERS/QUEST/Quest6.html Information Quality WWW Virtual Library http://www.ciolek.com/WWWVL-InfoQuality.html.

Applying Theories used in Drama to the Design of Educational Multimedia

Kevin A. Harrigan
University of Waterloo and TeleLearning Network of Centres of Excellence
Department of Computer Science, University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1
Email: kevinh@uwaterloo.ca

Introduction

Over the past ten years we have been involved in the design and implementation of many Educational Multimedia applications. We have found that the selection of media has often been a difficult decision as we try to balance the "best' media to meet the instructional objective with practical considerations such as cost and availability of appropriate designers.

Since 1993, we have applied several theories used in Drama to the design of six Educational Multimedia applications as an additional design tool to aid us in the selection of media in the interface. These theories have proven useful as design aids as well as a documentation tool for the design process.

Background

In her book "Computers as Theatre", Laurel (1991) argues that dramatic theory, which is centuries old, can be applied directly to the contemporary field of Human-Computer Interaction. She suggests that using dramatic theory provides "a new place to stand" for interface designers. She explains that Aristotle's theory of drama provides six points which are to be considered when creating a play or analyzing a play which has already been completed. A successful play should contain all six points. The six elements are: action, character, thought, language, melody or pattern, and spectacle or enactment.

The ideas put forth by Laurel have received considerable attention (see for example, Frenkel 1994) but we have struggled with applying these elements to the interface design of our Educational Multimedia applications because Laurel does not provide practical examples. Within the overall spirit of Laurel's argument, we have been using three dramatic theories which provide practical techniques that we can use in the design of our interfaces. In the following section we will describe these dramatic theories.

Dramatic Theories

A) Laban's Mastery of Movement System

Laban (1975) collected information about human movement and in fact the terminology used in the field evolved on the basis of his work. His book "The Mastery of Movement on the Stage" referred to movement on the stage in the theatre but Laban also used his ideas of movement in relation to the stage of human life. According to Laban, humans move in order to satisfy a need. For example, Eve had to move to pick the apple from the tree of knowledge. An actress representing Eve must attempt to pick the apple from the tree in an appropriate manner so that an audience member who is not familiar with the biblical story would be made aware of both her aims, the tangible and the intangible. The movement is all that the audience member has to interpret this moment. It should be noted that, according to Laban's definition, movement includes sound.

Laban determined that there are four motion factors: time, weight, space, and flow. Each motion factor may have one of two measurable and classifiable effort element states: fighting and yielding. Categorizing movement in this manner allows either for the analysis of any given movement or for guidance in creating effective movement. Thus, for example, a director should be able to consider any actor in any given scene and categorize the actor's movements in one of the potential states. Also, any given actor should be able to use these motion factors as a guideline in rehearsal.

B) Stanislavski's Source of Physical Actions and Intentions

Stanislavski's (1976) book "Creating a Role" changed the way many actors and acting schools approached acting. Stanislavski's main thesis was that the action performed by the actor is the most important part of acting and that feeling is not important:

> " Let each actor give an honest reply to the question of what physical action he would undertake, how he would act (Not feel, there should for heaven's sake be no question of feeling at this point) in the circumstances given by the playwright.... When these physical actions have been clearly defined, all that remains for the actor to do is to execute them... Note that I say show physical actions, not feel them, because if they are properly carried out the feelings will be generated spontaneously. If you work the other way and begin by thinking about your feelings and try to squeeze them out of yourself, the result will be distortion and force.... "

Stanislavski makes many points such as for every action there should be a beginning, a middle and an end and each of these structural elements should be played clearly and precisely. He also says that the context (or moment) of the movements are very important. He explores the purpose of the moment as follows:

> " To have any meaning, whatever happens on stage must have a purpose. It must serve some end beyond some accomplishment of the action itself. The meaning, both for the actor and the audience, rarely lies in the action but in the purpose for which it is done. Even loading a gun or mixing poison is not itself dramatic. We must know why, toward whom the lethal effort is directed (McGaw 1975, p. 23)."

C) Perceptual Mode Dominance Theory

The psychotherapists Bandler and Grinder (1975-1976) have a very simple yet powerful theory called Perceptual Mode Dominance. The theory says that of the five senses - hearing, seeing, touching (body sensations in general which are called kin aesthetic), tasting and smelling - the first three are the most important. Interpersonal communications are almost totally governed by these three modes. Human beings tend to favor one of the three modes. They tend to perceive life dominantly either through what they see, what they hear, or what they touch (or kinaesthetically feel). They learn or understand best if the information is communicated either visually, auditorially, or through physical-spatial means.

Conclusion

The three dramatic theories introduced in this paper do appear to be a useful tools for aiding the design and development of Educational Multimedia applications. Our current interest is to (a) continue performing experiments to empirically evaluate the usefulness of the theories and (b) get actual Instructional Designers to use these theories as a tool in the Instructional Design process so that we can get their feedback. Our long-term interest is in the possibility of incorporating these tools into an on-line Instructional Design toolkit that we have developed.

Providing Advising and Support Services to Distance Learners: Helping Distance Learners Connect with the University

Joanna C. Dunlap
School of Education
University of Colorado at Denver
U. S. A.
Joni_Dunlap@ceo.cudenver.edu

[**Note:** A full version of this paper, with bibliography, is available at http://www.cudenver.edu/~jdunlap]

Generally, most definitions of the term distance learning include the concept of time- and space-independent teaching and learning. Lately, definitions also include the notion of employing information and communications technology, interactive video, and computer networks to enable asynchronous and synchronous learner-instructor, learner-learner, and learner-advisor interaction. Simply stated, distance learning provides learners with educational opportunities offered outside of a formal classroom setting, combining independent study with guided instruction that is coordinated by a central facility providing a network of educational services. Applying this definition, instructors, support personnel such as academic advisors, and technology combine to provide an instructional delivery system that fulfills high academic standards while being flexible and considerate of distance learners' constraints.

Learners who choose distance education often face a number of obstacles:

- They live in remote geographic areas.
- They have limited program options at conveniently located institutions.
- They have work schedules that conflict with campus-bound course schedules. This includes people who work shifts, travel frequently on business, work long hours, and/or are in the armed forces.
- They have personal and family commitments that conflict with campus-bound course schedules. This includes having children at home and taking care of aging parents.

The obstacles to fulfilling their educational goals and objectives give rise to special needs which must be met if distance learners, and the programs that serve them, are to be successful. The special needs that impact distance learners' success fall into two main categories: instructional/resource access and communication needs, and advising and learner support service needs.

Needs of the Distance Learner

The needs of the distance learner provide a starting place for determine what a distance learner support services program (DLSSP) must effectively respond to in order to ensure that learner satisfaction and success in meeting learning plans are maximized. The following list includes some of the more obvious needs of distance learners that should contribute to the shape of a distance instructional as well as learner support services program:

- To learn and accomplish learning plans. This is the primary need for the learner. All instructional and service program components should ultimately support this endeavor.
- To have access to what the learner chooses to learn at the time and in the delivery mode preferred by the learner.
- To receive accurate and timely information inclusive of the following:
  - Program offering requirements (i.e., degrees, certificates, and credentials).
  - Educational provider, policies and procedures (e.g., registration, payment of account, drop/add/withdrawal).
  - Course offerings and content descriptions as well as prerequisite/corequisite information.
  - Self-assessment tools available to assist the learner in evaluating eligibility and preparedness for courses and programs of interest.

- How courses/credits/competencies apply to programs or transfer.
  - Learning outcomes expected for courses and programs and their relationship to personal/professional goals.
  - Technical support assistance with required software and hardware for selected instructional delivery method.
  - Learner support service availability.
- To ensure individual attention from the educational provider. The learner wants to have one point of contact to the organization and have the DLSSP network internally to meet learner needs. The learner wants the educational provider to respond to learner needs rather than the learner adjust to the organization's structure.
- To have a relationship of support with educational provider staff. The distance learner wants acknowledgment, positive feedback and encouragement (as appropriate), an early warning system for unnoted obstacles or potential problems, assistance in clarifying and validating learning plans, and a responsive problem-solver/trouble-shooter to assist when any academic or administrative issue arises.
- To be referred appropriately when the point of contact is not able to address the learners concern.
- To have a sense of connection and community with the educational provider and other learners with similar learning plans.
- To have special learner needs (e.g., accommodation of disabilities) addressed effectively both in the instructional and service arenas.

Roles and Responsibilities of the Distance Learner Support Services Provider

The general roles and responsibilities of the Distance Learner Support Services Provider (DLSSP) that respond to the distance learner needs are summarized into three primary categories.

- Communication -- There must be a variety of means for the learner to connect with the educational provider to gain learner support services. Because the DLSSP is working with distance students, personnel must not only have excellent interpersonal communication and instructional skills to be able to concisely and clearly explain policies, procedures, and requirements, but be able to effectively utilize those skills in a telephone- or computer-mediated communication environment.
- Information -- Information should be made available to learners in hard copy and Internet form. In order to accomplish this, a DLSSP need to be able to plan for learners' informational needs and organize materials and resources to meet those needs, develop and write supporting materials, and present information verbally and in written format in a clear and concise manner.
- Learner Advocacy and Liaison -- Addressing all learner issues with a customer service orientation, the DLSSP serves as the interface with the learner and the educational provider. The most critical aspect of being an advocate and liaison for distance learners is advising and counseling, which includes:
  - Understand learners' unique characteristics and ability to adjust advising and learner support style appropriately
  - Develop learners' personal learning plans
  - Clarify learners' career and learning goals
  - Select of appropriate courses and other educational experiences
  - Increase learner awareness of resources available
  - Evaluate learner progress toward established goals and provide appropriate response

Web and Computer-mediated Communication Support and Structure for Distance Learner Support Activities

Examples of online learner support services for distance learners that utilize the Web and other computer-mediated communications technologies can be found at http://ceo.cudenver.edu/~Joni_Dunlap/lssexamples.html

Characterizing Forms of On-line Participation in a Teacher Professional Development Setting

Beth Rosenstein Cole, National Center for Improving Student Learning and Achievement in Mathematics and Science, University of Wisconsin – Madison, USA, brcole@facstaff.wisc.edu

Electronic communication is a new and expanding medium for the professional development of teachers. This paper reports on some work conducted to begin to develop a framework for discussing the forms of participation that take place in the context of professional development on-line. (Cole, 1998)

As the use of email or other forms of electronic communication grows as a method of professional development research has been conducted in a variety of areas. Existing research on teacher-to-teacher electronic communication has focused on diverse topics including the reasons teachers used the network at particular times (West et al., 1989); the professional ties fostered by the network (Broholm and Aust, 1994; Stahlhut & Hawkes, 1994); the number, content, and writing style of messages posted by individuals (Weir, 1992; West et al., 1989); and the impact of participation on the professional lives of both active and passive participants (DiMauro and Jacobs, 1995; Jacobs and DiMauro, 1995). No matter what the focus of the research all work points out that individual teachers participated in different ways. However, these differing forms of participation are rarely described systematically. The goal of the work reported here was to begin to develop a means of carefully describing on-line participation in a professional development setting.

The work focused on the Elementary School Mathematics Project (ESMP), part of MATHLINE, a project of the Public Broadcasting System (PBS). ESMP has two components: a set of lessons presented on paper and video, and a system to link the participants electronically in a small group, a learning community, and throughout the country. This work was concerned only with the learning community on-line component.

To investigate forms of participation four representative learning communities were selected. All of the messages posted on each of the learning communities' electronic bulletin boards were collected for each of four weeks spread through the 1996-97 school year.

Close examination of the messages reveled three distinct types of messages, statements, inquires, and replies. A statement was defined as a message that makes a statement or tells a story. In a statement the author may present an opinion or may simply state facts. A message was classified as an inquiry if the purpose of the message was to seek information or to elicit a response. Replies were defined as messages in which it was clear that the message was prompted by another message. These message types were used as the basis for the development of categories of participation.

All of the messages collected were coded as one of the three message types or as a combination of two types. There were a total of 271 messages collected of which 24% were classified only as statements, 13% only as inquiries, 42% only as replies, 6% as both statements and inquiries, 10% as both statements and replies, and 5% as inquiries and replies. Once the messages were classified, they were sorted by participant in order to investigate the possibility of trends in participation. Some possible trends appeared and were used to identify seemingly different forms of participation or participation profiles. Previous work in the field (DiMauro and Jacobs, 1995; Jacobs and DiMauro, 1995; West et al., 1989) predicted two broad categories, active participation and passive participation. Jacobs and DiMauro (1995) had named one of the types of passive participation "active readers." These were participants who read almost all of the on-line communication but rarely, if ever, posted messages. These ideas of active and passive participation and active readers influenced the formation of the profiles in this work.

Once messages were sorted by participant, careful examination of each participant's messages took place in order to identify similarities and differences among participants. This examination suggested the existence of five distinct forms of participation, three passive and two active.

The first, and most easily identifiable form of participation was non-participant. These were participants who, while enrolled in the project, did not participate on-line. The second form of passive participation was the limited participants, these teachers read and posted messages infrequently. The exact definition of infrequent is difficult because in this data set there was no clear gap in terms of percentage of messages read or posted. The final form of passive participation was the form described in previous literature, the active reader. These participants read all or most of the messages posted to the network, but never posted their own messages or did so very infrequently.

There were two forms of active participation identified, informers and active participants. The informers were perhaps the most unexpected profile. These participants read and posted actively, but all of the messages they posted were either statements or replies. This group never posed inquiries always dispensing rather than seeking information. This was surprising since previous literature suggested that teachers participate in on-line communities in order to get answers to their questions (Broholm and Aust, 1994; West et al., 1989), clearly these teachers participated for other reasons.

The final form of active participation was named the active participants. These teachers read all or almost all of the messages posted and contributed regularly to the on-line conversation using all three message types. These were the people who kept the network going. In the data examined all of the people identified as on-line facilitators fell into this category as did others.

While it is difficult to develop exact definitions in this preliminary work with a limited data set, some reasoned decisions were made about cut-off points in order to classify each participant into one of the five styles of participation. When this was complete for the particular data set from MATHLINE, 12% of the participants fell into the non-participant category, 24% in the limited participant category, 29% active readers, 12% informers, and 23% active participants.

While it is clear that further work is required to verify and further refine the profiles identified, the participants in each profile were examined to investigate possible connections between the profiles and other factors. It was found that the most active participants were also the most experienced teachers with the active participants having a mean of 24.6 years of teaching experience while the next most experienced group were the active readers with a mean of 17.3 years. Almost all of the participants listed highlights of participating in ESMP, but the highlights varied with the level of participation. Those with limited on-line participation named the lessons as highlights while the highlights for those who were more active were mixed. There was no connection between the level of on-line participation and the grade taught or the amount of professional development in the year prior to the ESMP project. Finally, active participants tended to have access to the system at home (44.4%) or both at home and at school (44.4%) rather than only at school (11.2%).

The results of the study provide a beginning in developing a means of describing what happens in on-line professional development projects for teachers. The profiles should be verified and then further explored. While this study is preliminary, there are some recommendations or considerations possible from the results.

First, organizers should expect differing forms of on-line participation. Providing lessons, as MATHLINE did, or other materials may be important in keeping those with differing on-line participation engaged in the process. In addition, if possible, efforts should be made to make the on-line component accessible to teachers in their homes. While this does not guarantee participation, it appears to contribute. Finally, effort should be made to include teachers with a variety of levels of experience and not to exclude interested, experienced teachers who in this case were the majority of the active participants.

martinez@comp.uark.edu

Introduction

We are living in the emergence of the Information Age. Telecommunications and networked systems are becoming bigger and more functional. The Internet is considered the world's largest computer network and community of computer users. The Web, as the Internet is commonly known, provides cheap and simple access to a fast-growing, global information service, for both providers and consumers of information (Ford, 1995).

Most of the recent literature published about technology in the classroom refers to the highest profile element of the Internet, the World Wide Web. Faculties are involved in practices using the Web as an information resource or as a way to communicate with others. The use of e-mail and the World Wide Web in education is part of the daily activity in most of the colleges and universities. Educators have developed special classroom activities and collaborative projects using electronic media. Electronic information access and retrieval, e-mail, Bulletin Boards (BBSs), and Computer Conferencing are some of the possibilities of Computer Mediated Communication (CMC) that are effecting education daily.

Certainly, colleges and universities are particularly conducive to computer network use. Professors are invited to use or re-invent the use of the medium as they wish. However there has been resistance to many educational innovations introduced in the higher education over the years. Some educators possibly view CMC as another innovation that will come and go (Cuban, 1986). Nevertheless, the diffusion of an innovation and its use will depend on its acceptance among innovators and early adopters (Rogers, 1995).

Computer Mediated Communication is being implemented in the College of Education and Health Professions at the University of Arkansas. Most of the professors search the web daily and are using e-mail as a way to communicate with their students. However, little or no research regarding the concerns of faculties related to the utilization of CMC have been done.

Research Design

The purpose of this study is to determine the level of concerns among professors who use or do not use CMC for instruction in the College of Education and Health Professions at the University of Arkansas. Survey methodology was selected as the method of investigation. A questionnaire, Stages of Concern ©(SoCQ), developed by Hall G. E., and Hord, S.M in Texas Research and Development Center, was selected to gather data on demographics and levels of concerns among the teaching faculty at the College of Education and Health Professions at the University of Arkansas in Fayetteville, AR. The College of Education and Health Professions at the University of Arkansas was founded in 1934. It is located in the northwest part of Arkansas in Fayetteville. The target population for the study will be the entire teaching faculty at the College of Education and Health Professions at the University of Arkansas. The research questions are:

1. What are the stages of concern among professors who are using or not using CMC on instruction?
2. To what extent do stages of concern among the professors vary according to age, rank and by departments?

Instrumentation

The instrument will be sent through the campus mail to the entire teaching faculty during the Spring Semester 1999. Descriptive statistics will be used for all variables. The resulting descriptive statistics will include frequency distributions and percentages. For the SoC questionnaire, raw scores for each of the seven sub-scales will be tallied and converted to norm percentiles for each of those seven categories. Also, stages of concerns will be combined and analyzed by departments, age, and academic rank. The chi square test of association will be used to determine the significant difference among independent groups.

Results

This is an ongoing research project. Data will be collected during Spring Semester. In June, all the data will be collected and analysis will be completed.

Implications and Conclusion

As a result of the information age tool (i.e., the Internet) in school, innovative educational activities are growing. Opportune questions regarding the cognitive and social benefits of new interactions must be raised. Also questions about how educators concern about technology in school. This research suggests that change in teaching practice is based on the teachers' practices and believes (Richardson, 1990). It is important to consider the control that teachers have over change. Studies that are more comprehensive might take into consideration the nature of CMC, the way it has been used, the instructional context, and so on. Further research might look for the variability of these findings across other colleges of education.

Introduction

Aging is a natural phenomenon that refers to "changes that occur during the lifespan and result in differences in structure and function between the youthful generation and the elder generation, but these processes do not occur at a given age or set time in all individuals" (Kennedy, 1992 p. 10). The ability to learn and acquire knowledge does not end at the onset of old age. Rather, the focus of learning in adults changes from curiosity to a need to learn to function in society, solve problems, and to grow as an individual.

As we approach the twenty-first century, there is a need for the older adult population to acquire knowledge and compete with the younger generations. With the onset of new technologies, millions of older adults are learning to use the Internet (World Wide Web). Older adults are gaining Internet skills that are becoming a common aspect of life, yet few of these older adults have had formal instruction on how to navigate the web. The majority of them rely on self-directed learning and informal knowledge (Cahoon, 1998). According to Knowles (1980), self-directed learning is only one facet of adult learning. Knowles states that adults are: (a) motivated to learn, (b) pragmatic learners, (c) self-directed learners, and (d) they struggle to balance learning projects against the constraints of time, space, economic resources, and personal relationship. In fact, self-direction is a familiar characteristic of adult learning that is important for the acquisition of basic Internet skills and for successful participation in Internet-based distance learning (Cahoon, 1998).

Older adults are drawn to the new communicative channels of e-mail, on-line conferencing, and Web publishing because of its convenience. However, frustration and isolation can be found by the lack of familiar social cues when working in on-line environments. Older adults are facing the need to learn and at the same time, they have to deal with the demands of adult life. The Internet is becoming a demanding instructional tool among older adults because of the availability and flexibility of Internet resources. According to Grodsky and Gilbert (1998), "older adults are not moving slowly and cautiously, but are racing into the computer age" (p. 70).

In the past, combining older adults and computers seemed impossible. Now, with seniors returning to the workforce, contacting family and friends via e-mail, exploring new worlds through the Internet, or just the seniors increased ability to expand and gain new knowledge are defining new boundaries for the older adult learning environment (Spiezle, 1999). According to Kennedy (1992), "humans maintain an intellectual curiosity about the natural world throughout the lifespan" (p. 11). Therefore, it is important to encourage older adults to explore the avenues of new technology and to have access to the world of the Internet.

Many older adults are experiencing the Internet through a national non-profit organization called SeniorNet. SeniorNet is dedicated to "making sure that seniors are not left by the side of the road on the Information Superhighway"(Grodsky & Gilbert, 1998 p.72). SeniorNet has been enhancing older adults' knowledge about computer technology since 1986. SeniorNet not only has a Web page dedicated to older adult learning, but also the organization has established 128 learning centers in 35 states where adults over 50 years old can participate in classes ranging from introduction to computers to developing their own Web page. Amazingly enough, the key to the success of the SeniorNet classes is that the classes are peer taught (Grodsky & Gilbert, 1998).

Methodology

A survey was developed by the researchers to collect information pertaining to how and why adults 50 and older are learning on the Internet. A Web page was then developed containing the survey (see Appendix A). The URL address (http://www.infopoll.com/infopoll/surveys/s3253.htm) of the survey and a short description of the purpose of the survey was then sent to Marcie Schwarz, SeniorNet Director of Education. She added a link to access the survey from the SeniorNet Web page in March, 1999. This is an ongoing research project. Data will be collected once a month to ensure that people are still accessing the survey. The SeniorNet population will have access to the survey for an entire year. In March, 2000, all the data will be collected, and analysis will be completed.

Implications and Conclusion

Knowing how and why adults 50 years and older are accessing the Internet to learn can be beneficial in several ways. First of all, knowing this information allows higher education and senior organizations to participate in the changing environment of the Internet users and provide methods of lifelong learning opportunities to the aging population. This will in turn provide a chance "to deliver services that will upgrade the social, economic, educational, and personal conditions of the older adult population" (Swift, 1986 p. 19).

Imagining the future, there will be more access to on-line learning in the form of courses, distance learning, computer-based learning, and Web-based learning environments. Educators can take this information gained from this survey and incorporate it into curriculum for older adults learning in both informal and formal situations. Since the next century will be shaped by technology, it is important to understand learning on the Internet of all users (Cahoon, 1998).

Looking into the future, there is one thing for certain; the Internet will only continue to evolve, and that technology will continue to create learning opportunities for the older adult. The number of older adults using the Internet will continue to grow as access to personal computers becomes easier and programs become more user friendly. Society should not underestimate the abilities of the older adult population and how important it is to the older adult population to keep up with societal and technological changes.

Uncoupling Content in a Team Approach to Educational Multimedia Development

Trevor Doerksen
University of Calgary
Canada
doerksen@ucalgary.ca

Introduction

Due to the relatively easy use of the tools involved in developing educational multimedia, an individual could be Subject Matter Expert, graphic artist, computer programmer, and Instructional Designer on a project that they manage and distribute themselves. This method has been referred to as the "Lone Ranger and Tonto" approach by Tony Bates of the University of British Columbia (Bates, 1995). According to Bates this system, with the "Lone Ranger" as faculty member and "Tonto" as graduate student is not sustainable over time. An uncoupled content and team approach to educational multimedia development may lead to more applicable, more cost-effective, and more re-usable educational multimedia.

Team Approach

The team approach requires collaborative authoring of educational multimedia. The methods, approaches, and tools in collaborative authoring vary (Dobson, 1993). At the University of Calgary, collaborative authoring involves Instructional Designers, professors, multimedia professionals, students, and other Subject Matter Experts. The initial collaboration is often between Subject Matter Experts (SME) and Instructional Designer.

What is the best way that Subject Matter Experts can contribute to authoring the educational multimedia, recognizing that in many settings the best way is a balance between efficiency, cost effectiveness, and simplicity and accurate, innovative, and effective educational multimedia? This paper will suggest a process of collaborative authoring in educational multimedia development. The author is currently conducting research attempting to find out how best Subject Matter Experts contribute in the educational multimedia development process, in order to understand how to build sustainable, flexible, and applicable media.

Consider the following methods for dealing with content in educational multimedia:

1. *Teach* Subject Matter Experts multimedia and instructional design
2. *Teach* subject matter to Instructional Designer.
3. ***Team*** Subject Matter Experts with Instructional Designers

The first two methods listed above have had various levels of success, but importantly they can be considered less sustainable and applicable overall (Bates, 1995). As we develop skills, methods, and processes as specialists in the various disciplines in educational multimedia development we move towards a sustainable, cost effective, and innovative production system. The final approach from above when combined with uncoupled content holds promise for developing more high quality educational multimedia better and faster.

Uncoupling the Content

Recently, the University of Calgary's Advanced Media for Learning, has implemented a design process that separates the content from the engine that drives the educational media (Figure 1). By taking the content out of the programming environment we achieved shortened development cycles; and sustainable, versionable, reusable, and applicable educational multimedia and multimedia components. Importantly, the model also gives the authorship of multimedia to Subject Matter Experts and lends to collaborative authoring.

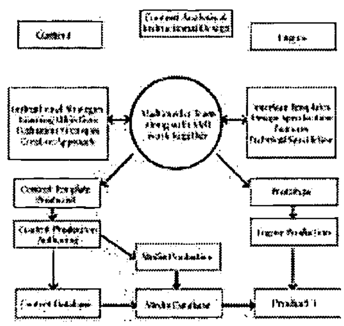

Figure 1. Uncoupled Content Model. The model demonstrates the separation of content from the engine, concurrent development, collaborative content authorship, and integration of content and media at run-time.

A team approach combined with uncoupling the content from the programming environment allows authors of multimedia to be Subject Matter Experts, the graphic artists to produce graphics, the computer programmer to focus on the programming, etc. And if the uncoupled content is stored in a consistent manner, e.g. a database, the assembly of educational multimedia is executed at run-time by drawing the appropriate information from content and media databases. With the content separated from the engine, changing the content does not require changes to the programming, only to the content data store. To change the delivery platform of the content, one may only have to program a new engine; one does not have to re-write the content.

This approach basically eliminates the need for an individual to integrate and assemble the production. The uncoupled content model, as pictured in Figure 1, demonstrates the simultaneous processes that can occur, namely content production, engine production, and media production. These simultaneous events shorten development cycles and, importantly, lead to a more predictable development cycle. The process also enables Subject Matter Experts and Instructional Designers to collaborate effectively to structure and author content using a standard word processor. Making it possible for multiple authors, using the authoring templates, to provide content. This can help increase the *buy-in factor* among potential users increasing applicability and validity of the end product.

The real "authoring tool" of educational multimedia then becomes a word processor not Director®, or Authorware®. Subject Matter Experts don't have to learn new tools, and software to produce educational multimedia for their classroom. Of course, they can if they want and there is plenty of software and support available. But on larger projects that could apply to multiple situations, a team approach that uncouples the content from the multimedia engine is beneficial.

Conclusion

Decreasing development times, increasing applicability, reusability and versionability have been realized through an uncoupled and team approach to multimedia development. This paper partially describes a process that is currently undergoing further study. The lack of metrics available to measure outputs will likely force the research to take the form of a case study. Some of the preliminary observations of the case study, following the production of a 4 CD-ROM set titled, "A Practical Guide to Communication Skills in Clinical Practice" will be presented at ED-Media '99.

The Effectiveness of an Electronically-Based Curriculum to Enhance Student Learning in a University Level Introductory Kinesiology Course

Nancy Knop, Ph.D.
Dept. of Exercise & Nutritional Sciences
San Diego State University, USA
knop@mail.sdsu.edu

Kathryn LaMaster, Ph.D.
Dept. of Exercise & Nutritional Sciences
San Diego State University, USA
lamaster@mail.sdsu.edu

Introduction

With the development of technology capable of enhancing communication through electronic media, universities and schools are rapidly being encouraged to take advantage of these advances to both enhance instruction and to provide educative opportunities to people previously prohibited from instruction because of spatial, financial, or time constraints (Gordon, H., 1996). Consistent with these national and international trends, San Diego State University has a recent history of encouraging faculty to re-envision what post-secondary education looks like through the use of the multiple technologies available on campus. For the first time last year one Exercise and Nutrition Sciences introductory class was offered completely on-line. The questions that this raises, particularly in a content area based on physical performances of various sorts and geared toward human interaction (like most health professions), are what are students learning and how is the learning enhanced or limited by the electronic media. The purpose, then of this study was to document the interactions students had with the introductory kinesiology course content generated by the instructor via electronic media. A further purpose was to document the interactive changes the instructor made in response to student feedback in an effort to make the class engaging and challenging for all learners.

Methods

All of the approximate 150 students enrolled in the introductory course were invited to be participants in the study. Qualitative methods (Bogdan & Biklen, 1992) were used to document learning and describe the learning processes of students throughout the study. Data sources included student work, teacher response to student interaction, and unstructured interviews of the current course instructor, graduate assistant, and students.

Student work was documented using student assignments, electronic journals in response to queries by the instructor about perceived problem issues, and grades. The timeliness, completeness, and depth of student work was used to document on-going student learning. Teacher response to student interaction was documented through e-mail interaction, in-class interaction, and phone calls. E-mail interaction was documented by archiving e-mails by the date they arrived. In-class interaction and phone calls were documented by a weekly log of interactions kept by the instructor that include the content or technological issue at the heart of the interaction. Teacher response to student interaction documented by any change the teacher makes with the class in response to students was documented by additional information posted on WWW and additional e-mail information or queries.

Student interviews occurred based on their technology and course content interest. After the first test, students were grouped by their performance on the content knowledge. Students who fell into the A, B, C, D, and failure assessment regions were provided the opportunity to participate in the study. One or two students participating in the study and randomly selected from each grade level served as the interview respondents after the midterm and final. Toward the end of the semester, several students representing the five grade assessments were assembled for a focus group interview (Fontana and Frey, 1994) to determine critical issues important to learning in the class.

Data Analysis

Student work, teacher generated documents, transcribed interviews, and teacher notes were analyzed using document analysis (Marshall & Rossman, 1995). To organize analysis of these documents, the theoretical perspectives and methodological approaches of structuralism were enlisted. Structuralism views "documents" as "texts" (Manning & Cullum-Swan, 1994, p. 467). As such, once the data is accumulated in written form, it was read through several times. With each reading a set of tentative themes was developed and refined. The emerging themes and issues arising from the readings created the codes or interpretive frames that guided and structured the analysis. Trends and commonalties informed researcher understandings of students' perceptions of the internet based course.

Data was organized chronologically to observe for trends. Within the chronological patterns that emerged, data was further organized into similar themes and categories. Rossman and Rallis (1998) suggest that once data has been coded into categories, themes, and patterns researchers have to "challenge the very pattern that seemed so apparent" (p. 181). To do this, once themes emerged within the chronology, negative cases or cases that did not fit the emerging trends were sought. Further, the trends across the chronology were compared to document how the context impacted the data. For instance, if some pedagogical decision were followed by trends in student response, this chronological trend was tracked across the chronology of the semester to see if similar trends existed. The credibility of data generated under qualitative research is determined by a network of methodological and analytical issues that focused on "establishing the match between the constructed realities of stakeholders and those realities as represented by the evaluator and attributed to various stakeholders" (Guba & Lincoln, 1989, p. 237). Three methodological issues that added to the study credibility are the length of engagement, the persistence of observation, and triangulation of data from multiple sources.

The results of this study add to the collective knowledge of distance learning and to what we know about student socialization into fitness, nutrition, and education disciplines. In addition, the efficacy of learning based on teacher/course expectations and actual learning were documented. It is further intended to support changes in on-line course design and presentation by describing the process students engage in to learn the necessary content. Data documented both the process of learning, the complexities of technologically based resources and how the process of accessing information enhances or limits student content learning and discovery.

The Integration of Classroom and Web-based Teaching: Utilizing technology to provide the best of both worlds for adult learners

Frances Dolloph
Shepherd College
United States
fdolloph@shepherd.wvnet.edu

The purpose of this paper is to describe the development of a college course for rural adults in principles of marketing that utilized both distance education and class meetings.

Faculty Support

Many adults know they need to upgrade their skills, but need encouragement and personal recognition to do so. In the past, regular class meetings have provided the opportunity for the teacher to provide this support and encouragement. In many rural settings, students and families are new owners of computers and neophytes at using the Internet. They often need assistance with using the Internet as a means of course work and resource while at the same time learning the subject matter.

Utilization of Student Time

Adult learners who are employed full-time often cannot attend classes on a daily or even weekly basis. When the instructor posts course work including assignments, readings, notes, and web sites on the Internet, students can access these materials at their convenience. By utilizing e-mail for the transmission of homework and questions to the teacher, the teacher can respond in a timely manner without having to wait for the class to meet. In addition, regular postings of homework assignments help to keep each student focused and moving forward. Using the Internet as a means of communication between groups and partners avoids extra travel or time off from work.

Utilization of Class Time

While some people may be able to work alone at home at the computer, most careers today involve personal interaction with others. In addition, not all courses or teaching styles lend themselves to total web presentation. Scheduling class time for teacher presentations, group discussions, student presentations, and exams provides face-to-face opportunities for learning and interaction. Utilizing technology to communicate with students saves valuable class time for subject matter discussions and the presentation of original materials not available in the text. Students come to class prepared having sent homework assignments via e-mail several days prior to the scheduled class meeting. By utilizing the Internet students receive individual attention and acquire group skills.

Class Description

During the fall 1998 semester, a totally web-based course was changed to include several class meetings. None of the students were proficient in the use of the Internet and e-mail, therefore time was allowed for orientation to the Internet as a resource and as a medium for learning. This is a very small rural branch of a small college where the only technical assistance available is from the instructor. Class time was used for exams, instruction in presentation skills, and class discussions of readings and assignments. Individual and group presentations of projects were completed in person.

Teaching Goals and Objectives

This course was developed for the rural adult learner, degree or non-degree seeking student. Behavioral goals included helping adults to achieve a positive attitude toward life-long learning and technology, and increased self-identity through the development of individual potential. Instructional goals included knowledge about the Internet and its application to marketing, the preparation and presentation of marketing plans, and the understanding of the specific objectives associated with marketing concepts.

Summary

By the midpoint of the course students were regularly sending assignments to the instructor via e-mail without difficulty. Assignments that included searching the Internet were well done and thoughtfully completed. Utilization of class time was very focused. Students expressed concern that the course took a lot of work and were reminded of the time saved by not driving to and attending some classes. Presentations and projects were completed in a professional manner. Responses to the students by the instructor needed to be better planned. This format was a good alternative to totally web-based courses, it allowed for personal interaction among students and teacher while encouraging students to use new technology.

Since Schon's (1983) work on the reflective practitioner, the teacher education literature has featured numerous calls for teachers (both pre- and inservice) to reflect upon their teaching as a way to take control of their personal professional development and their teaching success (Vogt & Au, 1995). Educators believe reflection should be encouraged, however, there is less clarity regarding how that process best occurs. This is especially true when it comes to the use of technology in encouraging personal reflection.

While the use of technology has been discussed as a supplement to instruction (Poling, 1994), a unique form of communication (Eiser, 1990), and a provider of new information sources (e.g., web sites), (Chandler & Maddux, 1998), these concepts are not without their drawbacks. Providing computer access for students is frequently cited as a major cause of frustration with students participating in e-mail oriented projects (Tannehill, Berkowitz & LaMaster, 1997). Helping students gain ease and familiarity with the technology is another challenge in implementing technology-based education procedures, requiring time for students to gain confidence in their computer skills (Delcourt & Kinzie, 1993).

A recent pilot study (Bayles Martin & LaMaster, in process) confirmed the roadblocks of technology access and familiarity in a graduate education course. Based upon findings of a pilot study conducted in 1997-98, the following research question was used to guide this study: How can a selected group of reading graduate students most ably use technology to support and enhance their reflection about teaching? It is the thesis of this project that students must be given time and support to develop the facility to reflect on their practice in various contexts and that this support can and should extend to use of technology in the reflection process.

Methodology

This study involves a semester of graduate student preparation in technology. During the previous study, it was determined that students' overt expression of reflection rarely surfaced without specific and explicit interaction by the course instructors. In other words, when asked simply to "reflect" about their teaching on email, students rarely did so. It was difficult to determine whether students were less reflective than expected, or whether technology challenges artificially truncated student responses.

To address issues of technology access and familiarity, graduate students in an education reading assessment course were introduced to email and listserv communication through weekly case study analysis. Students' ability to express their personal reflections and consider reflexive issues (beyond their classrooms) were also supported through the use of personal dialogue journals and weekly professional article response papers. Both of these activities involved more traditional communication means (paper and pencil; word processing) so that students' learning about reflection was not confounded with their familiarity with electronic communication.

The subjects for this study were 22 graduate students enrolled in a Reading/Language Arts Master's program and participating in a clinical reading experience. During clinics graduate students worked in small groups and individually with learners experiencing difficulty with reading. All subjects had campus access to e-mail accounts and computers through the university or their professional sites. Participants were assigned to the same listserv. The primary researchers and a graduate assistant were also included on the lists to monitor and provide guided reflection. At least once a week, participants posted to their class lists reflections to the case studies posted by the instructor. Peers read and responded to each others postings. All participants were urged to maintain communication with their peers through the e-mail class lists.

Analysis

Two goals directed the data analysis: 1) to identify the kinds of reflection graduate students engage in throughout the study; and 2) to determine whether graduate student reflections change throughout the semester;. A grounded theory approach was used for data analysis of electronic forum entries and other related artifacts (Strauss & Corbin, 1990). Forum entries were read and reread by researchers and categorized by themes. Because this study will span 16 weeks, opportunities for triangulation (Lincoln & Guba, 1985) will occur naturally and vary over time. For example, as students articulate concerns and reflections in email addresses, their actual clinical teaching can be observed for congruence with their comments. On-line member-checking will occur whenever instructors provide electronic (or verbal) feedback to students.

Implications from this study are best articulated as potential benefits to the profession. First among these is the opportunity to gain further insight into the reflective processes of teacher educators during an intensive and supervised course and field experience. A second benefit involves the exploration of the role of technology in facilitating (or impeding) attempts first at reflection, and second at guided reflection. A third benefit accrues from the opportunity to observe participants' actual instruction at the Reading Center to see whether (or how) various reflections and guided reflections are enacted with Center clients.

Courses delivered on the Internet provide "convenience to learners both in terms of time and freedom of space" (Schlough & Bhuripanyo, 1998). In their study of a course delivered on the Internet students were surveyed in an effort to identify advantages, disadvantages, and suggestions concerning asynchronous course delivery. Beyond convenience, advantages included learners accessing and reading course materials at their own pace and richness of materials through linkages to other sites. Weaknesses of this style of instructional delivery included students having to be self-disciplined, the instructional style was not appropriate for all learners, and some course sections were confusing to use. Suggestions included establishing a chat room for learner support, improvements in the site, provide a printed version of the text, and more in-depth orientation to the course.

As the use of Internet based instruction continues to develop it will be important to examine the issues associated with this style of learning. Studies concerning instruction on the Internet have examined the student's perspective (Mory, Gambill, & Browning, 1998), provided suggestions concerning course development, technical issues (Schuttloffel, 1998), and interaction guidelines. However, studies that examine and question pedagogical concerns are not as evident.

San Diego State University has encouraged faculty to re-envision what post-secondary education looks like through the use of the multiple technologies. In response to the campus wide interests, the Department of Exercise and Nutritional Sciences changed their introductory kinesiology course from traditional learning to asynchronous learning, using the Internet. The purpose of this study was to examine and explore various pedagogical concerns from the perspective of the introductory course instructor. The results of this study will add to the collective knowledge of Web based instruction methods. It is further intended to support changes in on-line course design and presentation by describing the pedagogical issues of concern to the instructor.

Methodology

This research study was designed to examine pedagogical issues associated with a Web based course. Introduction to Kinesiology is a required course taken by all students entering the department. Course information is designed to expose students to the department, faculty, campus, and potential careers through a series of lectures, assignments, and projects. Information for the course (syllabus, lecture notes, assignments, announcements, etc.) were organized through designed web links to individual parts of the course. There were two weekly course meeting times where the instructor was available, but no on-campus student attendance was required. Communication between students and instructor could occur through class session, e-mail, telephone, and office hours.

The subject for this study was the instructor for the Web based course taught to approximate 200 undergraduate students. This instructor was very familiar with pedagogical strategies, but had not designed the Internet course. It was the first semester that the subject had taught the course. Throughout the first several weeks of the semester the subject kept notes of pedagogical concerns and reflections. After the first few weeks the subject engaged in several informal interviews with the researcher. Both the subject and researcher kept notes, journals, and created further questions aimed at probing certain pedagogical topics identified by the subject.

Data Analysis

Qualitative methods (Bogdan & Biklen, 1992) were used to document and describe the process of identifying pedagogical concerns. Data sources included subject and researcher notes, journals, and reflections. Researcher and teacher generated documents and interviews were analyzed using document analysis. To organize analysis of these documents, the theoretical perspectives and methodological approaches of structuralism were enlisted. Structuralism views "documents" as "texts" (Manning & Cullum-Swan, 1994, p. 467). As such, once the data was accumulated in written form, it was read through several times. With each reading a set of tentative themes was developed and refined. The emerging themes and issues arising from the readings created the codes or interpretive frames that guided and structured the analysis.

Results

Several pedagogical issues emerged throughout this investigation including course content, testing, and communication. The subject identified concerns with the depth and breadth of lecture notes on the web sites. The question arose, how to provide focus and content emphasis for students. Many of the instructor reflections were directly impacted by feedback from the students. Student feedback was obtained through anonymous comment mailforms, e-mail message questions, questions asked during class sessions, and phone messages.

Developing an environment conducive to testing was another great concern for this instructor. Issues of honesty and integrity were an important concern, but was not overshadowed by location and proctoring problems. All of the exams were to be taken using a computer. In past semesters students were able to attend an open lab, show identification and take the exam at their convenience. This previous arrangement was not available during the semester that the study took place and resulted in several time management issues for the instructor and students.

Providing quality communication with students was another theme which emerged throughout the study. The course used e-mail, provided two weekly one hours sessions where the instructor was available, and instructor office hours. These strategies seemed to be sufficient, yet students were constantly phoning and visiting the instructor outside of these prescribed times. Previously identified suggestions for instructors of Internet courses include "don't be available to your students all the time" (Boettcher, 1997). Results from this study indicated that further examination of this web based course should occur.

WEB ASSISTED LANGUAGE LEARNING

Beverley J. Clinch
Department of Education
Edith Cowan University, Perth, Western Australia
bev1@concentric.net

Abstract: The purpose of this paper is to illustrate the incorporation of the World Wide Web into Spanish pedagogy at a local high school in South Carolina. This on-going project fits within the communicative emphasis on language learning. The open-ended nature of hypertext imposes an active role in the learning process which motivates the individual, crosses curriculum boundaries, and improves basic skills. Such an environment provides students an ability to "learn language, learn about language and through language". (Warschauer, 1997). However, what level or quality of *learning* actually occurs as a result? In examination, this paper provides preliminary findings and theoretical support.

WALL

"For every hour of instruction, there are 34 hours spent in the wilderness".

(McCarthy, 1992).

As a teacher in rural South Carolina, I facilitate the learning-process of my high school students through the implementation of a web page project in their Spanish class. Assigned cultural topics, these students become so absorbed in the work, that they are unaware of the skills being utilized, the cognitive thinking levels used to complete the task, or the hours of time given outside regular class meetings. This paper examines Web Assisted Language Learning (WALL) in the context of these on-going student projects with the primary foci being the effectiveness of the learning that takes place.

Based on theoretical principles laid out by cognitive researchers there is support for effective student learning facilitated by these projects. "Effective learning involves a desire on the part of the learner to grapple with and understand material in order to carry out higher cognitive functions."(Koppi, 1997). In other words the enticement of the learner to take a deeper, more internalized approach to his/her learning.

Traditionally, language learning has been viewed as a process of acquiring language skills, and evaluation has been seen in terms of achievement. "On-line language learning, however, is a different process. The educational objectives should not be defined behaviorally. Language learning on the Internet is more similar to painting, singing a chorus, or playing a ball game." (Kojiro, 1997) WALL therefore is more in keeping with John Dewey who recognized the need for more "cultural" education, one that combines theory and practice, to help create more well rounded, intelligent, and adaptable citizens. (Dewey, 1964).

Like a word processor a student engages his/her mind to comply with active learning. Engaged are his/her thoughts, imagination, emotions, and preconceptions as he/she formulates understanding of new information. (Caine, 1994). To examine the vast array of information the student encounters WALL requires this processor to operate at a higher cognitive level. As a tool, WALL has potential to implement student reflection, evaluation, organization, analyzation, creativity, comparative thinking, and information discovery which combine to encourage students to learn and to construct their own meanings regarding the assigned topic. This multiplicity of higher order thinking skills are automatically used as the processor sifts new information. In the words of "Plato and Aristotle, truth does not seep into the mind, but rather is discovered through thought and inquiry."(Harlow & Johnson, 1998). These web pages "enable students to create different maps or models, and to explore multiple answers". (Ervin & Baldwin, 1997).

If one changes the tools of thinking available to a child, his mind will have a radically different structure.

(Vygotsky, 1978)

Vygotsky lends credence to WALL and these hypertext projects, particularly in the development of holistic theories of language learning. Vygotsky places language learning as a forerunner to thought, asserting that only language use will cause the higher mental processes to become operational. (Zepp, 1989). Language is viewed as a tool used by the learner in social interaction resulting in the achievement of higher cognitive processes. Vygotsky's *zone of proximal development* encompasses "the distance between actual developmental level ... and the potential development as determined through problem solving under adult guidance or in collaboration with more capable peers." (Vygotsky, 1978). During these projects the Web is used as the tool of social interaction between student and learning, and, at the same time, encourages students to go beyond their current skill and knowledge levels. Given specific topics, students explore the Web in search of data. This requires them to read for a specific purpose, evaluate the authenticity of data, compare different view points, analyze and synthesize diverse sources of information, and construct their own understanding of the topic by creating their own web pages. Bruner explores the implications of tutoring and guided learning through his notion of "scaffolding"—step-by-step assisted learning until gradually gaining independence (Bruner, 1986). The active-learner goes beyond the information provided by internalizing the information, and constructing new ideas and concepts. The learning that takes place with these projects is student-directed. Each student makes choices and takes the responsibility for those choices thereby resulting in more meaningful learning (Dunlap, 1998) "In general, material that is organized in terms of a person's own interests and cognitive structures is material that has the best chance of being accessible in memory."(Bruner, 1961) Likewise Summers (1995) points out that when students are acquiring and evaluating on-line information found on the web, students gain extensive reading practice and make use of complex comprehension and analysis skills. Students employ strategies such as scanning to retrieve information. Despite unknown vocabulary structures students are motivated to decode text in the target language thereby extending their knowledge. Additionally, the Web offers language students multiple modalities through combined text, sound and visuals. "Visual stimuli can become memory-assisting devices" (Stickels & Schwartz, 1987).

The hypertext documents created by my students exemplify cognitive learning and use of critical thinking. Located at http://members.tripod.com/~clinch1, these web pages demonstrate the comprehension of information, organization of ideas, analysis of data, application of knowledge, synthesis into their written document and evaluation of ideas. Within the cognitive domain identified by Bloom (knowledge, comprehension, application, analysis, synthesis, evaluation) this project provides the opportunity for students to develop and to effectively use these skills.

The student produced web page project is an embodiment of teaching students how to learn.... Not what to think or how to regurgitate facts. But how do we assess this learning?

Literature is lacking in viable instruments for measuring hypertext learning, (Ryser, 1996), particularly in foreign language acquisition. "When students exchange e-mail with their peers from different cultures and create web pages, their interest is directed to the content" (Ervin, 1997) rather than the grammatical structures of the traditional classroom experience. WALL enables the language learner to learn in actual context as well as from each other. (Kojiro, 1997). My students are observed to ask questions of each other, aid each other, and collaborate together as they seek to achieve success in their projects. Instructional and educational activities assume new meaning. No longer is a paper written just as a course requirement, read just for a grade, but rather in the context of authentic communication read by "real" readers.

Bearing this in mind, there are a number of research studies assessing the effects of computer technology in the classroom. According to a study by McKinnon, Nolan and Sinclair (1996) in New Zealand, computer usage enabled students to not just become technologically literate, but also to become producers of knowledge as they analyzed data and information. (McKinnon, 1996). The study noted that within a given learning activity there was a broader cooperation among individuals, more spontaneous interest, an expansion of time and attention devoted to the activity, and a stimulus for developing the research spirit. Like examples have been observed in my classroom. These high school students willingly assist each other in the process of the web page creation, from simple data retrieval, cut and paste activities to HTML writing. Hours of extra time are dedicated to the activity, during lunch and after school. They even get-together at the homes of friends connected to the Internet to continue working. The search for more extensive information was exemplified by a student researching human rights issues in various South American countries----"How can these things happen? Why?....This is just so interesting, I'll just read a bit more, I'm almost through"-----an hour passed without noticing that lunch was missed.

Another study by Liu and Rutledge (1997) in Texas ascertain the same quality learning, motivation, and time on task. "Students began to exert pressure on those who tended to neglect the project.... students reminded each other not the teacher". Results of this study suggest that web page design is a motivation to learn, and program development for "real" audiences provide its impetus. Their research also revealed student exercise of higher order thinking skills such as project management, research, organization and presentation.

Further credibility to student independence, motivation, critical thinking was made in a 1997 comparative study in 7 urban school districts within the United States. (Follansbee). "Students who had access to on-line use not only were able to identify and articulate a problem more clearly, but also were more informed and had projects that were more compelling." (Chavez, 1998). This study concluded that the Internet can increase learning.

Personal web pages can be expressions of a students own ideas, thereby promoting ownership of the learning environment according to Kapur & Stillman (1997). Their study provides evidence of improved quality learning as well as enhanced levels of student satisfaction. Case studies indicate that Web supported learning causes a significant learning curve according to Gillham, Buckner & Butt (1998). Favorable student attitudes and motivational benefits are also provided by Keeler, 1996; Hill & Smith 1998; Forrester, 1995 to name a few.

All of these studies lend support to the observed behavior and learning outcomes of my students.

Learning in the hypermedia environment of the Web is a complex and dynamic interacting process, yet research provides no definitive answers to the "learning" that actually takes place with each student. I can only attest to the learning that I have observed in my classroom. My students thrive and interact with the Web as they embrace their Spanish projects. It is a key to improved learning in my language classroom. Within a structured activity, WALL is a tool to be capitalized upon by language instructors to improve learning. These activities are not just "cool" and "fun" but provide for "real learning" in a "real" world. Linguistic skills are strengthened, peer interaction-collaboration is established, while at the same time learning about contemporary culture and everyday life in the target country is maintained. (Standards, 1996; SC Frameworks, 1994). My analysis of WALL and stimulated "learning" continues as further activities are implemented and a qualitative study is undertaken.

Technology and Urban, Elementary School Reform

James M. Laffey
Linda Espinosa
Dale Musser
Center for Technology Innovations in Education
University of Missouri-Columbia
jim@coe.missouri.edu

The Panel on Educational Technology of the President's Committee of Advisors on Science and Technology (PCAST) summarized its findings about the state of technology in K-12 education as follows: "During a period in which technology has fundamentally transformed America's offices, factories, and retail establishments, however, its impact within our nation's classrooms has generally been quite modest." (PCAST, 1997 p. 6) When measured against the promise of educational technology the use and impact of technology in schools is small, and even less so in elementary schools. PCAST recognized the potential of technology to support fundamental changes in pedagogic models moving toward a more "contructivist" paradigm. In reality, however, computers are used primarily for learning about computers (keyboarding) and software applications (word processing, databases, and spreadsheets). In elementary schools computers are primarily used for practicing isolated basic skills and for playing educational games.

The Jefferson School Project focuses on implementing technology to bring about school improvement in an elementary school in an impoverished urban community. The framework for the project starts with a model of education that can be improved through the use of technology. The goal of the project is to (1) transform the school facility and culture from a factory model of isolated, and sequenced production units to a networked knowledge center of an involved community, (2) build instructional practices that embody a concept of the child as a constructor of knowledge, (3) improve the learning outcomes of children, and (4) understand the potential of technology and appropriate development methods for achieving goals 1, 2 & 3.

The Jefferson School Project is a collaboration among the Center for Technology Innovations in Education of the University of Missouri (CTIE); McCormack, Baron & Associates, a nationally recognized leader in community and housing development, Southwestern Bell, the Danforth Foundation, and the St. Louis Public School Board. The children of Jefferson School are in need of significantly improved educational opportunities. They live in an impoverished community and attend a school with low achievement test scores. The climate of the school is characterized by a high emphasis on control (e.g., silence during lunchtime); whole class instruction, drill and practice of isolated skills, and a faculty who felt left behind as the school district invested its few resources in magnet schools at other locations.

Rapid and dramatic changes are planned for the Jefferson School and community. A new principal was hired to lead the staff. The Danforth Foundation has committed $200,000 for professional development over a two-year period. Southwestern Bell has committed approximately $ .75 million to create an exceptional networking capacity for the school and has provided support for CTIE to assist the principal and community in planning reform efforts for the school in ways that take advantage of technology. McCormack, Baron & Associates is developing new low-cost housing for the community and is providing leadership and initiative to reform the school to serve the community, including efforts to fund the purchase of new computers for school and adult-learning objectives. In effect, the project is an emergence of an elementary school that will have great technological capacity and serve at-risk minority children and their community.

Most efforts to use technology in elementary education use technology to deliver computer assisted instruction. We agree that elementary education is a process of helping children develop the knowledge and skills that are the foundation of citizenry and competency in our society. In addition, however, during their pre-kindergarten and elementary school years children form important self-concepts and build habits of mind that lead to a social, intellectual, and economic destiny. Development of the young child is shaped by the social relationships formed with parents, other children, and teachers. The knowledge and skills that children develop are constructed in the context of these important social relations. The role of technology is not to replace these relationships as it builds skills, but rather to support, extend, and amplify the social relationships and levers they provide for early education. New and advancing technology can play this role through augmenting educational processes that are fundamental to early education and that have potential for significant improvement.

Technology can play this role by:
- Enriching experiences though visualization, simulation and other forms of mediation,
- Supporting active learning and individualization in the classroom,
- Making all members of the process more resourceful, and
- Implementing new and powerful forms of communication, sharing, and coordination for the children, teachers, parents, and extended members of the community (school board and administration, university partners, employers, etc.).

During the Summer of 1998 a new principal was hired, an advanced network installation and other facilities improvements were undertaken, a professional development plan was created for the faculty, and an initial workshop was held to develop a vision statement and build awareness about the use of active learning and technology in instruction. The key form of professional development is to get the faculty engaged in active learning with technology, and providing opportunities and support for reflection on those practices, so as to drive new models of instruction with their children.

During the school year of '98-'99 the following activities are underway:
(a) workshops for teachers focused on technology, project based learning, and safe schools (Nine day long sessions to be held on Saturdays as per the request of the teachers),
(b) placing two computers in each classroom with a goal of having at least 6 per class.
(c) having network services come on-line (including email and web servers)
(d) grade-level teacher teams that will implement interdisciplinary, technology-rich projects, on the theme of "community",
(e) teacher teams becoming engaged in the decision-making of the school improvement efforts, and
(f) individual support for teachers as they try new teaching approaches and use new technology in their classrooms.

Along with these work efforts to implement a technology infrastructure for the school, change instructional practices, and improve learning, we are documenting and studying the processes of implementation and socialization. Research methods include multiple interviews with all teachers and other key participants, systematic classroom observations of teaching and learning practices, records of learning outcomes, patterns of technology usage, and analysis of artifacts from teacher and student use of technology.

Early findings suggest several key themes:
(a) Irresistible technology meets immovable bureaucracy - the realities of large school districts often mitigate against rapid innovation.
(b) Through learning about technology, teachers can begin to feel and understand the power of hands-on, individualization and support, and then contrast this approach with traditional teacher telling and classroom seatwork.
(c) Through learning with technology, teachers can begin to feel the power of multi-media representation, networked resources and learner initiation.
(d) Network and media technologies are engaging for children and adults.
(e) True curriculum change will be a long process.

PCAST (1997) Report to the President on the Use of Technology to Strengthen K-12 Education in the United States. President's Committee of Advisors on Science and Technology.

MOVING TO THE WEB USING ELF POWER

Don Sheridan
Director, Business Education On-Line
School of Business and Economics
The University of Auckland
Private Bag 92019
Auckland, New Zealand
Email: d.sheridan@auckland.ac.nz

1. Introduction

The University of Auckland with an enrolment of 26 000 students shares with other tertiary educational institutions the vision of providing life-long learning for its students while attempting to deal with the current restraints on budget and a lack of progress toward optimal use of technology in teaching and learning.

The School of Business and Economics at the University of Auckland has developed a computer-supported learning system (CSL *aka* Cecil) that is now in its fourth year of operation and delivers browser-based assessments and other learning materials to tens of thousands of students in business and the sciences. On a weekly basis Cecil generates many thousand unique practice sessions and quizzes, sends out hundreds of diagnostic email messages and at times is processing more than 300 transactions per second. The work of developing Cecil and designing it for life long learning has been reported earlier at EdMedia conferences (Sheridan, 1997 & 1998)

In this paper we report on our efforts to move the curriculum content of a large business school onto the web-environment, as provided by Cecil, using as a guide the model provided by the University of Tennessee (Little & Derco, 1998). The principle actors in this success were Extroverted Learning Facilitators (ELFs) an idea derived from (Holt, 1997). This paper will outline the process, achievements, problems and current state of play.

2. The ITC Model

The Innovative Technologies Center, University of Tennessee provides a practical model for moving an institution toward broadly based web courses (Little & Derco, 1998). The four phases include: general information, augmentation, stand alone instructional pieces, and totally on-line.

Phase I: General Information
syllabus, course calendar, bibliography, communications (email), last date updated
Phase II: Augmentation
expanded course calendar, expanded bibliography, announcements, lecture notes, grades, glossary, communications
Phase III: Stand Alone Instructional Pieces
All of the earlier phases plus, tutorials, self-assessments, skills survey, communications (threaded discussions, chat, MOO/MUD)
Phase IV: Totally Online
All of the earlier phases and no face to face, student biographies and introductions, class photos, course authentication, online testing

This model does not prevent individuals from forging ahead, but it does give managers and administrators some achievable targets at the early stages of online development. Given the inevitable fiscal constraints then the question arises: How to get the existing materials converted and online.

3. The ELF

Course development for web based delivery poses a significant problem if the only people available are fully tasked academics. It seemed reasonable to adopt a model implemented at Athabasca University where students worked on course conversion, design and development with positive results. (Holt, 1997) It was noted that students often have a clear vision of what their peers would want in a learner centered environment and they also see the possibilities of the technology in achieving it.

In our instance we employed nine summer students across seven departments. We sought out students to become Extroverted Learning Facilitators (ELFs). The characteristics we needed were principally students who were in the honours or masters program of each department, and at the same time, enthusiastic about their discipline and technology in general. Their infectious enthusiasm would carry the day and allow us to pull the necessary information and knowledge from academics to ensure we could push the school to Phase II within three months.

The ELF worked principally in a designated department. Training was provided on the Cecil interface, Microsoft Office 97 to HTML conversion, simple HTML authoring and editing skills, document conversion to Adobe Acrobat, Lotus ScreenCam production, and document scanning and editing using Adobe Photoshop.

4. The Results

Over the summer recess, the ELFs exceeded our expectations by persuading even the most reluctant academics to participate. In meeting the Phase I and II objectives we now have 871 papers on line with total enrolment of 27,000+ students. More than 240 staff are using the Cecil Explorer (interface). Staff training was designed and carried out by the ELFs. A CD was also produced with learning materials better suited to off-line access. These included HTML documents, Office 97 and Acrobat files, software applications, browser updates, and a video and audio segment. The Dean and department heads were so impressed with the results they decided to extend part-time employment to the ELFs for the next academic year. ELFs are now providing individualised assistance to their staff as well as working the Cecil help desk for the benefit of all the academic community.

Cecil system provides a central focus for the integrity of course content by storing learning resources within its database. Cecil is a multi-tiered computer architecture. The database, SQL7.0, located on a multiprocessor Sequent NT has grown to 8GB in only a few months. The dual, fault tolerant, front-end computers are the internet servers and process approximately 3M hits per week. It has become a 7 day 24 hour operation. (www.cecil.edu)

While Cecil is being used a repository for learning materials, it is really an instructional management and assessment system. At this point, only a few academics have created personal bodies of knowledge (BoK) on their desktops and replicated portions of the BoKs across to the major Cecil site. More progress is expected on this front as the academics come to understand the significance of this feature since the goal is to provide a shared BoK that resides, in part, on the academic's desktop, the university's Cecil system, and a student's laptop. Collaboration among peers whether they be academics or students will result in dramatic changes in the way knowledge is created, shared, and managed.

This an on-going project. Phase I & II was for many academics a hint of the new frontier. An update will be provided at the EdMedia 99 conference.

The Learning Web: A Technical Evaluation of WebCT in Concurrent Classroom and Distance Education Sections of a Software Engineering Graduate Course

Niek J.E. Wijngaards, D. Michele Jacobsen, Rob Kremer, & Mildred L.G. Shaw
Department of Computer Science, University of Calgary
{niek, jacobsen, kremer, mildred} @cpsc.ucalgary.ca
http://sern.ucalgary.ca/

Introduction

The Software Engineering Research Network (SERN) is funded by industry and administered by the Industrial Software Engineering Chair at the University of Calgary to support the dissemination of good practice in software engineering. One component of SERN's activities is a thesis-based masters program with a specialization in software engineering targeted at students with industrial experience in full-time employment (Shaw & Gaines, 1998). This program has dual objectives: to develop highly qualified personnel, and to encourage industry-based software engineering research with a focus on good practice. Coursework includes requirements that have been developed in consultation with the industry partners. The learning environment is unconventional and reflects the industrial experience of the students. After the first lecture in a required course, students take on much of the responsibility for presentations on the various topics that draw upon their experience and that of their colleagues. The instructors' role is that of facilitator, "guide on the side", managing a process of debate and exploration rather than attempting to be the "sage on the stage" authority in the domain.

The overall aim of the masters program is to provide a supportive and nurturing learning environment in which experience and knowledge can be shared and created, and errors and omissions made without censure but with ready access to diagnostic help. Student assignments are submitted on the World Wide Web making them accessible to others. A list server is used for continuing discussion of the course topics outside the class environment. These two features have made it possible for students whose companies allocate them to work in other locations, or who change jobs to companies in other locations world-wide, to continue to participate in the courses. Remote students who have already come to know their colleagues can continue to present and share material through the web and participate in discussion through the list server. It becomes clear to students as they progress through the program that, while there are no easy answers to the core questions of industrial practice in software engineering, there are many useful perspectives and that simplistic answers generally have very limited applicability.

We are currently addressing the challenge of making our graduate program formally available and accessible to students who want to participate from a distance. A first step has been to develop and offer parallel sections of SENG 611, a six-week graduate course in Requirements Engineering. One section of SENG 611 was delivered on campus, and the other delivered at a distance using facilities provided by WebCT. Of the 21 students in the course, 7 chose to participate in the distance section, and 14 on campus in a conventional face-to-face learning environment. In addition to individual assignments, all students completed a major group project that was presented during the final lecture. The on-campus students recorded and summarized classroom discussions that were posted on the Web for the distance students.

WebCT and Technical Support for SENG 611

The technical support requirements for SENG 611 were concerned with two main issues: 1) supporting the organization and delivery of the course, and 2) minimizing the differences in student engagement. Although the course material already existed as web pages, WebCT was chosen as the web-based software tool to support the dissemination of course related information in this experiment (see Goldberg, Salari, & Swoboda, 1996). WebCT offered encapsulation and paths through the existing course content, student presentation areas for groups of students, individual student tools for note-taking, and a chat facility for synchronous, online discussions. It was the preferred choice for a number of reasons, including free testing of WebCT with full functionality at the University of Calgary, inexpensive licenses, a large customer base, proximity of developers, ease of access via common web-browsers, and ease of customization (if needed).

In Spring 1998, WebCT was installed on a local server so we could experiment with many of its features. This led to enough confidence in WebCT for its use with the graduate course in Fall 1998. The technical support person and a course instructor were well versed in HTML, scripting, and other computer-related activities which influenced the evaluation and usage of WebCT. Based on the current experiment using WebCT, we have made the following observations:

1. Support from developers of WebCT is very good. Queries and requests were dealt with quickly and to our satisfaction.
2. It is easy to (a) install WebCT (beta 1.3 on Windows NT took slightly more time than 1.2 on Unix), (b) create courses as an administrator, and (c) encapsulate existing course material.
3. It is moderately difficult to get used to all of the WebCT concepts and to develop a mental map of the course structures, and to keep information up-to-date in a course, because the tool imposes a certain approach to structuring on-line course materials. One must become familiar with the affordances and constraints inherent in WebCT's design in order to construct well-organized course materials.
4. It was difficult to customize WebCT to add connections to the external list server; Perl scripts had to be modified to add a mailto: hyperlink (referring to the list server) to WebCT's common button bar.

WebCT is geared to non-technical course designers; faculty with little or no prior experience with HTML will find the inherent structure and design of WebCT to be useful starting points. However, it was our experience that the WebCT designer interface often hampered the HTML-knowledgeable instructor's efficiency in building and maintaining the course material. For example, sequencing course materials requires the designer to set up a "path", which involves a number of intermediate steps that would not be required if the designer was using only HTML. However, for an instructor who is new to creating web-based documents, the structure and tool set offered by WebCT provide valuable entry-level supports and templates as they construct course materials.

We found that WebCT was not completely applicable to the current offering of the SENG 611 course. However, based upon research that compared WebCT to other web-based course tools (e.g., Kristapiazzi, 1998), we expect that other web-based course tools are also not completely applicable and would require customization for SENG courses. Courses in the research-based M.Sc. program have been developed within an open architecture philosophy and the belief that there should be public access to past and present SENG course materials and student work. Inherent to the design of WebCT is a closed architecture philosophy -- courses are password protected, and information in courses is not easily accessible to the general public.

WebCT's student tools, in particular note making and group presentation areas, offer useful tools for online courses. The e-mail and chat facilities in WebCT were not used for the current experiment; an external, publicly accessible list server remained in use. WebCT's quizzes, which employ selected response and open-ended questions, and so on, were not useful for this graduate-level course. However, we did employ these features in the service of a midterm examination for a large undergraduate course (CPSC 533) in Artificial Intelligence. We have found the online testing features of WebCT offer a reliable and useful environment for exams. In order to provide some practice with the WebCT exam environment prior to the midterm, we required students to login, change their password, and complete a short, pre-exam survey. In this way, those students who experienced difficulties had an opportunity to seek assistance before attempting the online midterm exam. Our findings, in brief: students were frustrated with a) the time clock feature, which only updates when an answer is submitted, thus giving a false impression about time left to complete, and b) having to submit each answer individually rather than the entire completed exam.

Using Technology in the Delivery of Teacher Education Courses

Dr. Teresa Yohon, School of Education, Colorado State University, USA Email: **yohon@cahs.colostate.edu**

Problem

Colorado business and marketing education programs face a state of emergency due to the shortage of qualified teachers. A qualified teacher is one who has completed a teacher licensure program and vocational credentialing courses in business or marketing. According to personnel at Colorado's Department of Education, approximately 60 positions will be opened next year in business and marketing, while only 20 to 25 new teachers will be licensed and credentialed in business and marketing education for the 1999-2000 school year.

Because of the shortage of qualified business and marketing teachers, secondary schools are requesting--in record numbers--emergency credentials for instructors so they will be able to teach in a business or marketing classroom while they go back to school for needed coursework. The majority of teachers on emergency credentials are licensed teachers from other disciplines, teachers from other states, or business people who have become teachers. Currently 44 business and marketing teachers across Colorado need between four to ten credit hours to be certified in business and/or marketing education. With the number of retiring business teachers increasing and the small number of new teachers being licensed and credentialed, emergency credentialing of teachers soon will become the norm instead of the exception.

One barrier in Colorado to the credentialing of marketing and business teachers is the availability of credentialing courses. Only Colorado State University (CSU) can offer these required credentialing courses. Some courses are offered only once or twice a year. In most cases, students must attend classes at CSU's main campus, a hardship on the students because of long driving distances in Colorado

The shortage of business and marketing teachers is further acerbated by the current delivery structure of teacher licensure courses. Most students wishing to become a business or marketing teacher already have completed their bachelors' degree in business. These preservice teachers need about 34 credits in education coursework to obtain a teacher license, plus eight to twelve credits in vocational education to obtain a vocational credential. The current arrangement of courses at CSU dictates an investment by the preservice teachers of at least a year and a half of full-time study, during which time it is difficult to maintain a job to support themselves and their families.

Project in Progress

To meet this need, Colorado State University has begun to turn to technology in the delivery of vocational credentialing and teacher education courses. A combination of face-to-face interaction (through the use of seminar-like sessions) and online learning will be used. For the online learning piece, CSU's School of Education will use WebCT for learning module coordination, online testing, threaded discussions, chat rooms, email, and bulletin boards. The inclusion of distance learning via digital satellite will be available as a teaching methodology sometime during Fall 1999 through CSU's partnering with the Agricultural Distance Extension Consortium.

The first phase of this project will be to bring online the graduate-level methods courses in business and marketing education which are used in credentialing. During Fall 1999, the undergraduate methods courses in business and marketing, and the other credentialing courses will be placed online. During 2000, approximately four teacher licensure courses (still to be finalized by the teacher licensure committee) will be coverted to include heavy (but appropriate) levels of online activity. Possible teacher licensure courses to go online are Schooling in the United States, Educational Psychology, and parts of Classroom Management and Classroom Technology.

This project allows new teachers, especially those entering the educational field from industry or from another teaching area, to gain the knowledge and skills necessary for success in the classroom in a timely, but quality-based manner. In addition, the potential teacher could remain employed for a longer period of time while acquiring the skills and content needed to teach.

Data Available at the Time of Publication

Several areas already have been researched: (1) the technological capabilities that are available and which ones will be used (described briefly in the section above), (2) standard format for online credentialing courses, (3) the topics that should be covered in credentialing courses, and (4) what linkages should be made between the Colorado Department of Education (CDE), Colorado Community College and Occupational Educational System (CCCOES), "expert" teachers, and business people.

Online credentialing courses will assume one of two formats. Format 1 uses ten to fifteen hours of face-to-face time at the beginning of the course, with the remainder of the course to be completely online. Format 2 also has the majority of educational time online, but will utilize face-to-face seminars once a month, to cover the more delicate educational issues. With both formats, guest speakers will either be present during the face-to-face meetings or available during assigned chat times. Students will share projects, either during the seminars or online. Collaborative learning environments will be developed, utilizing WebCT's ability to aid inquiry-based learning through bulletin broads, email, and web site posting. Philosophically, the educational theory that will underpin the building of these courses is pragmatism and constuctivism (Miller 1996).

In preparation for online delivery of credentialing courses, research was conducted to determine the salient topics that should be included. According to (Lynch, Smith, & Rojewski 1994), the major educational reform themes that should be addressed in secondary vocational education include secondary/postsecondary institution linkages, equal access and opportunity for all students, flexible/alternative delivery systems, support services and funding, curriculum redesign, business-education partnerships, alternative assessment techniques, world class standards and assessment, and on-the-job training models. According to a 1999 survey conducted by myself with Colorado business and marketing teachers who have taught three years or less, the areas where additional training is needed are: the integration of vocational student organizations into the curriculum, funding sources for student and school projects, recruitment of students, marketing of their vocational program, and classroom management. Obviously, a marriage will need to be made between reform themes, which may not be first on a new teacher's "need to know" list, and the practical needs identified in the 1999 survey.

Four graduate courses have been converted to an online format and will be offered during the 1999 summer session. These courses are: Methods in Vocational Marketing Education, Programs in Vocational Marketing Education, Management of Business and Office Departments, and Organization of Business and Office Education. The topics identified above have been integrated into these courses, along with the areas of technology in the classroom, Colorado Standards, and career preparation and development.

Linkages have been established with CDE and CCCOES. Representatives from both agencies have reviewed the content for the graduate-level methods of business and marketing education courses (phase one). Suggested topics for inclusion were: integration of academic and vocational education; evaluation tools for employers, students, and follow-up; program approval; professional organizations; and support systems for new instructors. Staff from both agencies will participate as guest speakers. A survey is out now in regard to linkages that could be established with expert teachers. Business linkages will be established through expert teachers.

Additional Data to be Available at the Conference

At the time of the conference, module outlines for business and marketing education and other credentialing courses will be available. Specific issues as orientation to an online course, building collaboration online, using threaded discussion and chat, and evaluation of online courses will be discussed. Field test comments on two or three courses will be available. Expert teachers' participation level will be identified.

Web Instruction to Promote Successful Inclusion of Limited English Proficient Learning Disabled Students

Lanna Andrews, Ed.D.
School of Education
University of San Francisco
USA
Andrews@usfca.edu

Two growing factors in today's classrooms, diversity and technology, are impacting teachers' ability to influence student growth (Grossman, 1995; Male, 1994). Even for prepared teachers, today's heterogeneous classrooms, with bilingual and disabled children, are a constant challenge. The information highway can benefit both students and teachers if the proper structures are in place (Male, 1994).

In California's urban schools, the challenge is paramount. The overwhelming majority of the students are from culturally and linguistically diverse backgrounds, and over ten percent of the students qualify for special education (Grossman, 1995). A typical classroom has several students for whom English is a second language and who have either learning disabilities or language disorders. It is difficult for a teacher to prepare interesting, appropriately adapted lessons for every child in her class six hours a day, 180 days a year.

Given the mandate to include all students in the general education classroom and to create a classroom climate that is an arena for goal-oriented, reflective problem solving (Laboratory of Comparative Human Cognition, 1989), schools need new technologies. An integrated curriculum is key to including all students (Sheppo et al, 1995). Multimedia technologies have significant potential for supporting an integrated and adaptive curriculum (Willis, 1992). Gardner (1993) argues that individual children need to be taught differently, because individuals understand the world in different ways. Gardner recommends that schools be filled with "apprenticeships, projects, and technologies" so that every kind of learner can be accommodated.

Telecommunications can open up vistas of new learning for students and expand collaboration between colleagues (Reinhardt, 1995). Teachers can interact and share ideas with colleagues and the interaction need not occur in "real time". The benefits, however, go far beyond simple communication. Databases can be developed which will be a resource for trying various methods and collaborate about their effectiveness.

The present project was created to: (1) use web instruction in a University teacher preparation program; (2) prepare student teachers to transfer learning from University classroom to school district classroom; and (3) provide a structure for student teachers and classroom teachers of mainstreamed learning disabled, limited English proficient students to collaborate about adapted lessons.

The ongoing project begins with student teachers in an urban general education teacher-training program by providing training during a required course, Teaching Exceptional Students. The instructor uses Web-CT software to develop a course website and place course components on the internet (agendas, requirements, activities, quizzes, discussion forums, and teaching cases). Students all have internet accounts provided by the University.

The on-line curriculum adaptation project requires a training phase. The training covers teaching students with learning disabilities, understanding stages of language acquisition with implication for instruction, strategies for adapting integrated lessons for disabled and limited English proficient students, and instruction regarding web site navigation. A long-term goal of the project is to develop an adapted curriculum database on the internet. In order to do this, student teachers are also given training regarding inputting lessons on a curriculum development tool placed on Web-CT. Once this training is complete, the student teachers form cooperative learning groups to begin applying their learning.

After the training phase, groups are given teaching cases that include written descriptions and the Individual Education Programs of actual special education limited English proficient students mainstreamed into an actual neighboring inner-city classroom (names are changed to provide confidentiality). Students then work together to examine previously written lessons designed for "typical" general education students and develop ideas for adapting lessons for these students using strategies for working with their learning disabilities and language comprehension needs. The cooperative learning groups then input adapted lessons in the web.

The project then goes one step further by conveniently putting the student teachers in touch with the actual classroom teacher of the students that have been studied. This is an advantage of using the internet far beyond the collection of a database. At her convenience, often at home late in the evening, the classroom teacher is able to access the curriculum development tool on the web and comment on the lesson and adaptations. The student teachers are then able to reflect on their adaptations and comment back to the classroom teachers, again on the internet. This dialogue provides real-life feedback and two-way communication.

The college instructor also accesses the lessons on the web and comments on the groups' work, giving immediate feedback. While this feedback is an effective teaching tool for the course, the responses from the classroom teacher prove to be the most helpful. Finally, the students revise their curriculum adaptations, based on the feedback.

The project is evaluated in three ways. Students complete course evaluations. In addition to this, they also respond to a survey instrument regarding attitudes about adapting curriculum and online instruction. But perhaps the most important evaluation is careful observation of the process from beginning to end, with special attention paid to the two-way feedback process.

Course evaluations regarding use of the curriculum development tool have been extremely positive, indicating that success relates to the structure of the tool itself, the teamwork involved, and the on-line feedback component. Additionally, student teachers self-report that they are using other students' adapted lessons, which are available on the internet.

Survey responses from participants in the first semester of the project were categorized into two general areas. There was a mean score of 4.4, somewhere between "agree" and "strongly agree," for all participants on the items focusing on perceived ability to adapt instruction, indicating that the project increased their ability to make curricular and instructional adaptations for differing student needs. The mean score for all participants on the items regarding the perceived effect of on-line collaboration and feedback with the classroom teacher was 4.0. This indicates agreement with the notion that the collaborative aspect of the project was a positive factor.

The results of the two-way feedback between the student teachers and the classroom teacher continually go beyond the project's original expectations. Each time groups receive feedback from the classroom teacher, usually in the form of questions, group members brainstorm and respond back in a more sophisticated manner. The case responses are not quantified, however, it is apparent to both the professor and the 5th grade teacher that the group responses to the on-line feedback demonstrate expanded reflection and adaptation ideas.

The implications for web instructional activities are far-reaching. This project shows that the convenience and speed of communication and collaboration on the web can enhance traditional teacher training. The skills that student teachers continue to develop during this ongoing project will contribute to the success of special education limited English proficient students in the mainstream.

1. Introduction

Recently, there are a lot of researches on real time online teaching. Until now, online teaching focused mainly on communicating from teachers to learners, that is to say, in one direction only. However, learners would deepen their understanding by performing themselves experiments in the field of science. Therefore, we proposed a scientific experiments system in which learners could operate experimental apparatus through the Web (Saisho et al. 1998). Moreover, we discussed issues in the development of WWLab (World Wide Laboratory) for scientific experiments. We classified scientific experiments in the following three groups, 1) Live experiments, 2) Web-based experiments, 3) Experiments by computer simulation.

This paper describes the classification of scientific experiments and what kinds of experiments were suitable for the system. We have a plan to apply the system for K4-K8 learners.

2. Outline of WWLab

WWLab, shown in Fig.1, consists of a web server machine, a video camera and experimental apparatus including a computer-controlled robot arm. A learner can see our Web page using an Internet Browser, such as Netscape Navigator and Internet Explorer. On the page, the learner can operate the experimental apparatus using controlling a robot arm. At the same time, the learner can see the state of the experiment by the video camera. The learner can also control the video camera on our Web page. Real time computer display of the experiment is observed simultaneously by other learners. And, the experimental process is recorded by means of the MPEG method on the server computer. And then, learners can replay the MPEG movie file on the Web.

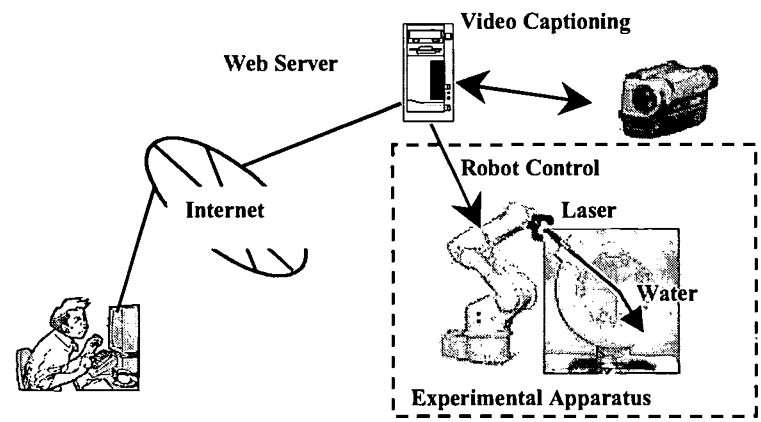

Fig.1 WWLab System

3. Advantages and aspects of WWLab

We will discuss advantages and aspects of WWLab that we have proposed. The advantages of the system are :

1. The result of the web-based experiment is not predictable because learners operate an experimental

apparatus by themselves although its operation is indirect.
2. Expensive experimental apparatus is made commonly available.
3. Even if an experiment may not go well, learners can have insight into a subject through failure.
4. Learners can collaborate with other on an experiment through the Web.
5. The system records experimental status in an MPEG file. Consequently, learners can repeatedly review the experiment.

There are a few problems of the system outlined below.
1. Learners do not have real experience because they can only operate experimental apparatus through the Web.
2. A robot arm carries out a learner's instructions. Therefore, this system is not suitable for precise experiments because the arm is not able to move with precision.
3. Though there are various methods for an experiment, this system is restricted to the experimental method which we have prepared.
4. A response to a learner's instruction is delayed when the network traffic is crowded.

4. Classification of experiments in online teaching

We classified experiments under the following three groups in order to discuss what kinds of experiments are suitable for WWLab.

1. Live experiments
   This group includes experiments in which learners are easily able to find necessary experimental apparatus in their own environment. Also, it includes experiments that are not suitable via the Web such as those concerning smell, taste and tactile sensation, as well as experiments that are influenced by the surroundings circumstances, e.g. temperature and humidity.
2. Web-based experiments
   This group includes experiments in which learners are not easily able to get experimental apparatus because it may be very expensive and specialized. Moreover, it includes experiments that are not influenced by the surroundings, e.g. time, place, temperature and humidity, as well as experiments which are limited by the requirement of a place such as a photographic darkroom and so on.
   There are two kinds of web-based experiment. These are experiments in which the parameters are fixed and experiments in which the parameters are freely set. The former has the advantage that learners can easily conduct experiments. The latter has the advantage that learners conduct experiments with their own ideas. However, in this case there is the possibility of having different results according to whoever conducted the experiment.
3. Experiments by computer simulation
   Suitable experiments in this group are those which would normally require much time to conduct. Computer simulation would decrease the experimental time. Also, it would be suitable for experiments where equipment is normally destroyed and costs would be very high. Moreover, there are other groups of experiments apart from 1 and 2, in which learners may wish to review 1 and 2.

5. Conclusion

In this paper, we discussed issues in the development of WWLab. We concluded experiments that require high accuracy and/or quick response are not suitable for WWLab. On the other hand, suitable are experiments that learners can not prepare experimental apparatus around them because of too expensive or special ones. We expect learners to develop positive creativeness and collaboration because they can conduct experiments and have communication with each other through the Web. In the future, we plan to develop other kinds of scientific experiments system and discuss problems of implementation in the system.

Virtual Lectures Free Students to Think Critically

Harry R. Matthews
University of California,
Davis, CA 95616
hrmatthews@ucdavis.edu

Introduction

This paper is based on results from a pilot project now offered twice. The method depends on reconstructing lectures on the World Wide Web, to free up time for associated small group discussions. The distinguishing features of this approach include the use of virtual lectures to free the small groups from responsibility for content and the use of a comprehensive database that addresses all aspects of offering a course, with a focus on content organization and delivery (Matthews 1997a, 1991b, 1998).

Some university teachers espouse the lecture approach and some prefer the group discussion approach, of which problem-based learning is a subset. The strengths of lectures include an organized approach to the subject matter and a comprehensive coverage of topics deemed appropriate by the instructor. The strengths of discussions include better context and more active student involvement. Virtual lectures, now evolving into a virtual course, aim to combine the advantages of both approaches, to improve higher education.

The prototype course comprises twenty-three 50-minute lectures on Molecular & Cell Biology. The students, about 95 per class, are at the beginning of their first year in Medical School and come with a very wide range of backgrounds. They are intelligent and motivated to learn medicine but are not necessarily interested in molecular biology. The new approach was evaluated by comparing examination results with historical performance and by a detailed anonymous student questionnaire. The results show that factual and conceptual learning was at least as effective as with the traditional methods and that student acceptance was very high. Students believed their intellectual skills improved but this needs to be evaluated objectively and historically.

Ideas Behind the Course Design

Our students do well on our examinations and on those set by the National Board of Medical Examiners. Nevertheless, when they have completed their two years of basic science and move to the clinical environment they often feel that their basic science knowledge is irrelevant to clinical medicine and clinical instructors complain that the students lack basic science knowledge. More likely is that the students lack the ability to take material learned in one context and apply it in another and to take a general principle and apply it to a specific situation.

Many of our students learn very well visually and aurally. The computer has some advantages for this. First, students choose their own pace through the material as well as their own time and place for studying. Second, once the transformation to the computer was complete my time was freed up to focus on the development of the intellectual skills that I feel our students need badly.

Computer Techniques

The complete course content is now accessed exclusively through a web browser running on a personal computer. I have in-person office hours but students rarely use them. Students voluntarily attend the small-group discussions but these are oriented towards specific clinical cases that may or may not be germane to the topics in the virtual lectures.

The database integrates all aspects of a course, including course content, assignments, examinations and other components. The structure allows an instructor to select the parts (s)he wants to use and ignore the rest, which is then hidden from both instructor and student, until the instructor wants to extend the application. The course content is both structured and flexible accommodating many different types of multimedia. The multimedia files are distributed over additional Web servers and local CD-ROM drives while their display remains under the control of the central database. This architecture provides good performance under heavy load and over standard telephone lines.

The virtual lectures include animated graphics, sound and text. The format is flexible and modularized into the short topics so that each lecture can be easily edited and reorganized. The text is hyperlinked to a glossary and the lectures are linked to a bank of self-test questions also hyperlinked to the glossary. Additional tutorials, including video modules, and advanced topics, as well as readings and interactive 3-dimensional molecular models are integrated into the virtual course. Students have a personal notes page and preformatted email for asking questions by email. The course is available at http://trc.ucdavis.edu/coursepages/bcm410a/.

The database tracks and records key features of each student's use of the material and records the time and IP number for each logon. The time and IP number permit detailed analysis of the server log files and correlation with individual logons. This information shows objectively which components of the virtual course are most used, and, by comparing individual outcomes, which components are most effective as learning tools.

Measured Results

Examination results from the virtual offerings of BCM410A were better than from the face-to-face offerings although the students spent slightly less than the allotted time on each lecture. There are good textbooks in this field including my own (Matthews, Freedland & Meisfeld, 1997), but the students had an overwhelming preference for the virtual lectures. Anonymous student evaluations showed strong acceptance of the virtual lectures. The full evaluation results are available at http://trc.ucdavis.edu/coursepages/bcm410a/evaluations/.

Further Development

Three steps are proposed to make the success of the Web-plus-small-groups approach more widely available. First, objective evaluation tools will be developed to exploit the rich data in the database in order to determine how students used the virtual materials and how that relates to their outcomes. Evaluation will also be extended to better assess development of students' critical thinking skills and to include focus groups as well as anonymous surveys and analysis of objective data. Evaluation will exploit the existence of a closely related course that has been taught—more or less unchanged—together with the present course to the same students for more than 6 years, providing a control for each individual class. Second, the system will become "instructor-friendly", by providing flexible Web-based forms for interacting with the database for adding and organizing content and other information such as quizzes, examinations, assignments and student data. Third, the program will be used with another course, probably at the undergraduate level.

Hypermedia Course Transformed: in-person to on-line Gains and Losses

Beva Eastman, Ph.D.
Educational Technology
New Jersey City University
beastman@njcu.edu

As the present culture becomes more and more graphic in information presentation, education now uses hypermedia to encourage students to acquire information and to construct knowledge. Teachers, trained in the traditional text methods, need to expand their teaching not only to include the new ways of presenting information using text, graphics, sound, and animation, but also to foster learning in a non-linear environment.

The Master of Arts in Educational Technology at New Jersey City University has as one of its required core courses: Hypermedia Across the Curriculum. This course up until Fall 1998 semester had always been taught in-person, because the many technological skills seemed too complicated to learn through an asynchronous course. However, in the Fall 1998 semester, the course was offered on-line. This paper will: a) discuss the differences between teaching/learning hypermedia in-person and on-line, b) preview the web site of the course to show how the hypermedia technological skills were transferred to the web medium, and c) assess the learning through specific examples created by the participants in the course.

BACKGROUND

Hypermedia is defined as multi-media technology controlled by and/or delivered through the computer. HyperStudio™ was the course software because of its non-linear capabilities, its availability on both platforms, and it is being used extensively in K-12 classrooms. The technical topics included manipulating graphics, sound, and text; cell and path animation; use of video, CD's, and Laserdiscs; scripting; and placing a stack on the web which required the use of the HyperStudio™ plug-in.

The students in the class were all educators: either teachers of a contained classroom or a particular curriculum area or computer coordinators who were responsible for more curriculum areas than just computer literacy. The course required that all technology be expressed within the participant's discipline which meant that all assignments were to be developed using the participant's curriculum.

All course materials were available on the web at the beginning of the course, so that more experienced participants could move around the course if they wished. All communication was done through private e-mail notes, public listserv notes, and through a public discussion forum. Participants, placed in groups of four, e-mailed their hypermedia assignments each week both to their group and to the instructor. The listserv became a place for technical help questions. The public discussion forum focused on different learning theories and/or the impact of a particular technological skill (such as cell animation) on learning.

DIFFERENCES IN ON-LINE AND IN-PERSON TEACHING/LEARNING

Because the on-line course was a first-time experiment, the differences discussed here are not the results of a formal study, but are anecdotal.

The first 20 minutes of an in-person class are always spent in a "show-and-tell" of the week's assignments with each stack being gently reviewed by everyone in the class. The on-line environment loses the class response to a stack and, what is extremely important, the class experience of the variety of stack design. However, the on-line environment, in which the instructor becomes a mentor to each individual participant through personal e-mail exchanges, does result in faster learning: more modification of stacks, more quickly.

On the other hand, non-hierarchical presentation of information was learned more slowly by participants in the on-line course. The simple use of a menu card to allow options needed to be addressed repeatedly in the on-line course, partly due to the fact that the web environment is not as flexible as a HyperStudio™ stack.

HYPERMEDIA WEB SITE

An on-line hypermedia course must demonstrate on its web site all of the technological capabilities that the software has. However, even simple transitions between cards are not possible yet on the web. Some of the graphic and text object manipulations could be done with static gifs, but all path and cell animation were translated to animated gifs. The section on sound and video used QuickTime movie format. But all of these examples are still presented linearly, which does not give a complete understanding of hypermedia. So, at some point in the course, everyone had to view completed stacks and hence use the HyperStudio™ plug-in.

The assignment which asked everyone to use the HyperStudio™ plug-in was designed as a "win-win" contest. The stack, to be viewed with the plug-in, was about a common plant with various clues. By identifying the correct name of the plant, every student could win, but only if they could view the stack! Although it was a course requirement to download, install, and use the HyperStudio™ plug-in, downloading the plug-in from a reputable commercial site was not something that everyone wanted to do because of past bad internet virus experiences. Installing and troubleshooting the installation added another level of technological frustration.

The most difficult technological assignment was the posting of a stack to the internet. This involved learning to "ftp" stacks to an anonymous ftp site, and creating a small HTML document. HyperStudio™ has a web page converter command to create the HTML code. However, since this code produced by the converter was not complete, a template code was placed on the web site that the participant could then copy, paste, and modify. But severe limitations exist with the HyperStudio™ plug-in. First, all techniques in HyperStudio™ stacks are not cross-platform, which leads to stacks crashing or simply not functioning correctly. Second, certain techniques are not possible to view with the plug-in. Last, size is essential!!! No compression is available for HyperStudio™. To view a stack larger than 500K real-time becomes an extremely time-consuming download!

ASSESSING THE LEARNING

Technological skills are easy to assess. A participant would send a stack with a path animation, and it could be easily seen whether or not the graphic did animate in a path. But, a course on hypermedia requires more than just a cluster of technological skills. The course offers the time to begin to look at presenting information in new ways. For example, HyperStudio™ has now added the dimension of direct links to the internet, which allows a stack to become the framework or context for viewing the variety of information on the internet.

One of the problems about an on-line course is that by not having the class conversation, an on-line student can move rapidly to fulfill the "tech" part of the course without participating fully in the discussions. How then, is such a student slowed down to begin to question and deepen his/her thinking beyond the technology? Not easily! The main way used in this course was through the instructor's e-mail exchange with each participant, by raising questions regarding the stack's information designed to focus the participant more fully on curriculum and methods of information presentation.

The final requirement for the course is to produce a curriculum-based extensive hypermedia project through which the participant's knowledge and understanding of hypermedia theory may be assessed. A comparative look at projects developed in an in-person course and in the on-line course will be briefly previewed in this presentation.

CONCLUSION

In comparing the on-line participants' portfolios to an in-person class's portfolios, the assignments and projects demonstrated quality similar to an in-person course. However, the level of frustration learning the technological skills at home alone seems to be higher than that in an in-person course. Also, the web site, which followed a previously designed syllabus for an in-person course, must be redesigned to incorporate more non-linear experience. The course focus, firmly grounded in the curriculum, gives the course its strong foundation, but a way to break the isolated learning of multiple technological skills in an on-line course must be found.

Integrating digital and classroom environments in the search for creative solutions to improve teaching/learning quality

Author: Garcia, Marilene (PhD) lena@anhembi.br
Affiliation: Universidade Anhembi-Morumbi - São Paulo - Brazil
Address: Rua Casa do Ator, 90 - ZIP CODE 04546-900
Phone numbers: 055 + 11+ 821 9020 / 055+11+280 8598 / 055+11+9112-7445

1. Introduction

This study main objective is to look for creative educational solutions to exploit Internet informational, communicative and research resources to improve classroom teaching quality. In order to do so, we had to invest in updating programs for our faculty and also in a program that guarantees the development of interactive and informational interfaces for classroom learning integrated with Internet/WWW. We are taking measures to improve the quality of educational strategies in our institution based on two projects:

Act-On-Line project, which, besides creating short-term on-line courses, develops interface and interactive design through Web-activities to integrate them in courses taught in the classroom.

PADO project, which develops programs (courses, workshops, didactic-technological counseling), aiming at updating university teachers on the use and exploitation of new technologies in higher education.

These two projects aim at the following goals:

- Invest in methodological research to create distant learning environments, emphasizing the exploitation of interactive tools for communication and information to give support to courses taught in the classroom.
- Stimulate faculty to create educational projects exploiting Internet resources: virtual experimental labs, expert systems of simulation, data banks of various formats (images, slides, graphics, etc.)
- Enable transference of different information through courses and interactive repositories available at WWW, in which the information being searched is driven by activities started in the classroom.
- Develop course methodologies and miscellaneous assessment processes, preferably exploiting Internet interactive tools.
- Practice formal and informal distant learning simultaneously.
- Assure participation and contribution of faculty members through their ideas to exploit Internet resources
- Research pedagogic effects related to WWW instructional interface

2. Internet/WWW environment solutions

For over a year, we created the Act-On-Line Project, which has two main objectives:

- Offer courses of recognized classroom acceptance in on-line format, aiming at reaching the public outside university campus in general. These are short-term courses, which last three months, in average, for continuous professional upgrading purposes. Presently we are on the Fourth Edition of these courses, working together with an interdisciplinary production team (Garcia, M & Maia, C. 1998).
- Create technological and didactic conditions to enable our professors to develop new routes between classroom classes and distant learning to get access to different contents and activities related to the subject taught within Internet/WWW environment.

Initially, we offered short-term courses aiming at researching environments and interfaces. We presently managed to implement two programs that combine classroom learning and distant learning through Internet. We use short-term courses and WWW activities of exercise and research.

Standards for developing mini-courses and Web-activities providing direct access interface and supporting tools for navigation and learning, which enable page reading, guided research to other pages outside the course/activity site, participation in discussion forums and chats, reposition of information in conjunction with other students, among others:

Interaction tools - direct access to permanent line e-mail, discussion forum opened to all participants, teacher's voice and help regarding interaction;

Learning tools: the course page itself, from which the content is accessed, external links for guided visit to sites of interest, suggestions for reading, glossary and help with the content;

Navigation tools: guide to the content and activities within the course;

Information tools: download, hot-links, bibliography and help on how to research in other sites of interest;

Educational contents shown in the program are basically of two natures:

- The ones that reflect course objectives;
- The ones that enable self-study
- The ones that enable deep discussion and exchange of ideas in the classroom.

Activities are prepared using multimedia elements, such as sound effects, animated images, besides text source. Another interesting aspect is the possibility offered to the students to discuss their difficulties with other participants in special forums, besides receiving answers via WWW page afterwards.The pedagogical goal is trying to assure a previous reflection and construction of arguments based on guided research to accomplish the activity.

3. Faculty updating program solution and steps

Universidade Anhembi Morumbi faculty-updating program has been created in order to assure that projects aiming at improving educational strategies quality through the use of new information and communication technologies would be implemented.

Initially, our goal was to get a teacher who had good performance in the classroom, take advantage of his/her motivation and didactic experience, and start the first attempts of technological and didactic updating.

Our goal is to check how faculty updating programs can be developed and implemented, aiming at general and specific goals and how to maintain and follow-up the teacher to help him/her achieve effective results in the classroom, creating conditions not only for technological updating but also for didactic and qualitative exploitation of WW/Internet for classroom work. This is an attempt to broaden the concept of distance education in WWW/Internet environment aimed at classroom work.

1. Program Phase:

At this phase we emphasized the use of Word to create handouts, exercises and tests, the use of Power Point to create presentations, as well as basic notions of hardware. Browser basic functions and fundamentals to surf and do research in Internet have also been explained. This step comprised 24 hours of classroom work.

2. Program Phase:

Deeper research notions, as well as exploitation of Internet communication resources. Basic principles to create html pages, which can be proposed in an educational site, have also been shown. This step comprised 24 hours of classroom work.

3. Program Phase:

How to create Web-activities and on-line courses. The course aims at preparing teachers to use Internet and produce classes, didactic contents, and activities for WWW environment. The course consists in three Workshops, each one of them working on a theme. First Workshop, theme: computer mediated teaching and learning

- Second Workshop, theme: course structure and on-line activities.
- Third Workshop, theme: tools to create on-line course

4. Conclusions

The goal of creating interactive and effective learning environments is the main purpose of these actions. Thus, it is our task to design educational products, within WWW context, involving data transmission interfaces and information that lead to the production of new knowledge from discussions and considerations made in the classroom.

The way of structuring data and information within WWW environment, aiming at knowledge, is directly related to the methodological organization that must comprise content transmission resources and create opportunity for interactions between learners and their facilitators.

Thus, our pedagogical model integrates educational interface development to the human potential that should exploit it. This potential is made of learners and facilitators of the process, who act both virtually, by accessing lists and discussion forums, and in the real world, when students are in the classroom.

The advantage of this pedagogical model can be noticed by the way through which teachers and learners effectively interact. We believe that the production of knowledge depends on people behind the interfaces developed.

Using Computer-based Visual Mapping Tools to Enhance Pedagogical Practice.

Ian Brown & Brian Ferry
University of Wollongong, NSW Australia
ian_brown@uow.edu.au

Rationale

Visual mapping tools are computer-based and are essentially two dimensional and /or three dimensional spatial arrangements of text and diagrams. They have shown to help pre-service teachers to efficiently link curriculum content to instructional plans in Science and language contexts (Ferry 1996a, Ferry, 1996b, 1997; Novak and Gavin 1984; White and Gunstone 1992). This project attempted to enhance these findings by extending the process to another subject discipline, Visual Arts education. It was the researchers' belief that visual mapping tools could be used with other subject areas but difficulties may be experienced due to the unique nature of the particular subject discipline. For example, the reliance on visual representation in Visual Arts education may affect the efficient use of the tool. It was predicted that existing mapping tools may have to be redesigned or modified to enable for efficient use to occur. As a result of this project a number of significant results and areas for further study have started to emerge.

Aims of the Project/ Areas of Investigation

The initial aims of the research project was to compare the use of the computer mapping tool Inspiration® by pre-service teachers as they plan instruction in Science and Visual Arts education. A number of broad areas for exploration were developed and investigated by the researchers. For the purpose of this paper, the following specific questions will be addressed: Do computer based visual mapping tools assist or hinder pre-service teachers to organise curriculum content and knowledge to be effective instructors? When using computer based visual mapping tools to construct knowledge, do differences exist when applying subject matter knowledge in Science and Visual Arts education? Can the creative process in Visual Arts education be represented and deconstructed as a cognitive framework in the form of a visual map?

Methodology and Data Collection

During the research study twenty four volunteer pre-service teachers in their final year of elementary school teacher training were invited to: i. compare the use of the visual mapping tool Inspiration® to plan instruction in Science and Visual Arts education ii. analyse and deconstruct the creative process with the use of the visual mapping tool Inspiration® Data was collected through three main sources, ongoing written personal reflections, analysis of the visual maps produced and interviews. Interview transcripts, reflections and visual maps were coded and analysed for trends and emerging themes.

Brief Description of Study

Students were given four specific tasks to perform over a eight week period which involved both Science and Visual Arts education. They were: i. to plan a short program of work for an elementary class, using the visual mapping tool package Inspiration®, to conceptualise ideas and discipline specific knowledge ii. to research/investigate an artist/artwork, gathering as much information as possible in relation to lifestyle, historical background, media used and possible influences. iii. Students were required to construct a visual map of the information/knowledge gathered in (ii) conceptually, using the visual mapping tool Inspiration®. iv. plan the development of a personal creative response (artwork), using the visual mapping tool Inspiration® to conceptualise thoughts, ideas, materials and processes. Students were required to analyse their actions and thoughts, both positive and negative, through personal written reflections and interviews.

Preliminary Results and Emerging Themes

As a result of the analysis of preliminary data relating the areas of investigation (relating specifically to this paper) the following can be reported: All students agreed that the visual mapping tool package Inspiration® clearly assisted them with their organisation of curriculum content and knowledge. The students felt comfortable in a very short period of time in visually representing their knowledge and conceptualising in both subject disciplines. They commented that it provided a clearer way of thinking, it was more efficient which allowed the students choice in changing thoughts, conceptualising and recording their ideas. The students unanimously agreed that they would use the package again to prepare and plan their work. They believed that the visual mapping tools would enhance their abilities to be more effective instructors. These results are congruent with earlier studies conducted by Ferry 1996, 1997 and White and Gunstone 1992. Note: a number of criticisms/annoyances were raised by the students about specific actions relating to navigation which occurred when using the package. These points will be discussed in detail later in the paper.

From the interviews it can be concluded that the students felt that some differences were evident between the two disciplines when using the visual mapping tool package Inspiration®. Students generally commented that initially few differences occurred when planning instruction between the two disciplines, but when conceptualising knowledge, greater differences were apparent. This could be attributed to the nature of the task. In the Science area students were given a topic or concept from which the knowledge was drawn to develop the visual maps. While in one activity in the Visual Arts area, the students had to work in reverse, the concept was provided (the artwork development), then categories were constructed and developed.

From the visual maps provided by the pre-service students in this study and the analysis of the results it appears that the creative process can be represented and deconstructed as a cognitive framework in the form of a visual map. It is the researchers' belief that deconstruction or analysis of an artwork is a common practice in art education, but deconstruction using a visual mapping tool is a particularly unique phenomena. It is interesting to note from the results of the analysis of the visual maps, both the deconstruction of the artwork/artist and the construction of the personal response (artwork), is that it appears that the concept clusters developed by the pre-service students align closely to the New South Wales Visual Arts Years 7-12 syllabus framework for conceptual organisation, (a document that the students used in this study would not be familiar with). The conceptual organisation evident in the syllabus, includes areas such as structural, subjective and cultural, which was developed from postmodernist and deconstructionist theories.

Conclusion and future directions

This paper has only addressed a small area of the total research project. Other areas presently under investigation and proposed for future research include: the relationship between learning styles and the selection of visual mapping formats; the difficulties experienced in navigation by the pre-service teachers when using the visual mapping package, such as, screen size and printing problems; the problems of visualisation and the need for a package which could import visual or photographic images to enhance the deconstruction process; and the issue of cross-cultural applications when using the packages. In conclusion a number of significant findings have been addressed in this research project. Students unanimously agreed that the visual mapping package has enabled them to plan more efficiently, conceptualise their knowledge and ideas more clearly and allowed them to use the process successfully in two subject disciplines. As one student commented when using the package... 'her learning was active because it made her thinking process more visible and more structured'.

The Problem of Transitions Between Discrete Multimedia Spaces

Jacqueline Bourdeau, Education, Université du Québec à Chicoutimi & Licef, Télé-université
jbourdea@uqac.uquebec.ca

In virtual learning environments, learners accomplish different actions in different media spaces, interacting with different tools and documents. However, they need to keep threads between their actions : logical, structural and functional threads. Based on what we know about actors, actions and situations in virtual learning environments (Bourdeau et al. 1998; Bourdeau et al., 1997), we recognize a problem in the transitions leaners make between different media spaces in three typical situations : individual, team and group. In an individual learning situation, actors interact with their tools and documents, with individual intentions, goals and objectives. The types of individual tasks can be: exploration, consultation, production, playing; the basic interface is a multimedia computer. In team-based situations (2-6 individuals), actors interact with each other and with tools and documents; they share intentions, goals, processes and tools. Their tasks can be: exploration, consultation, production, playing; tools can be shared applications and documents with video, audio or text conferencing. Group situations (6-30 or more) are different in many aspects: the media space consists of several sites equipped with videoconferencing rooms, with various types of computer-based facilities; actors may interact via a floor-taking protocol or via an animator; their tasks can vary from interactive presentation to discussion or collective decision-making.

In looking at actions rather than discourse, a central question is: how can learners keep track of their actions, processes and products? In various worlds that have different rules, how can learners find the threads they need in order to achieve their goals? What happens to the concept of seamlessness, considered as essential in human-computer interface design, when the media space is a room? How does the impact of tele-presence vary in the three different situations, from inter-individual text-based asynchronous communication to videoconferencing rooms for group interactions? If changing from one media space to another one presents obstacles to learning, or a loss of time and attention, should instructional designers recommend that, for each learning scenario, learners remain in the same virtual universe? Should designers search for new design principles in order to solve or to reduce this problem? How can pedagogical agents be designed to intelligently support the learning process, when learners going through these transitions?

Given three learning situations (I, T, G), a set of learning tasks, and a set of technologies, transition needs and problems can be identified, as well as potential solutions. As an example, it appears that Learner I1, when involved in the task of exploring, with a navigator, needs a transition process to Team T1 for referring, asking questions, displaying, reporting, or receiving feedback on his/her learning process or product. Transition problems can be the lack of transferring, of conversation, or of sharing facility. In another example, T1, when reporting to the group, wants to refer to interactions they have or had with T2, T1 may encounter transition problems such as lack of display or recording facilities; they can also face a problem of technological overload if they try to work with different media spaces at the same time.

Results from previous studies indicate transition problems when students move from one situation to another and change spaces at the same time. In the case of a Web-based business simulation, students shared information and tools for their teamwork within the simulation, but found themselves away from this space when meeting as a group. Coordination analysis pointed to critical interdependencies between actors and resources, where transition could be supported (Bourdeau & Wasson, 1998). In a videoconferencing-based group situation, students enjoyed a strong tele-presence through shared time and multimedia group space, but with no transition for individual or team situations once the videocommunication was cut off (Bourdeau et al., 1998). These problems can be anticipated and avoided in a design process that respected principles specific to these situations.

Coordination theory's framework, adapted to educational situations through analysis of interdependencies among actors and among resources (Wasson, 1999) provides a framework to identify potential coordination problems. Bates (Bourdeau & Bates, 1996) and Collins (1999) provide classifications for new media based on their attributes. These frameworks can be used in the design process in order to locate potential transition problems in the design. Among transition problems, some will soon find a solution through technological integration in network-based environments. In other cases, bridging processes (capturing, recording, scanning, reporting, projecting), or gateways can be built into the learning scenarios. Concepts such as seamless, transparent, and invisible, should guide the design for learning situations so that technology is not (too) intrusive.

In an attempt to find a solution to this problem, we suggest a design process in seven steps : 1) Analysis of the three situations, 2) Design of learning scenarios, 3) Modelling, 4) Virtual experimentation, 5) Field-testing, 6) Extraction of design principles, 7) Validation.

An analysis of the three basic situations (individual, team, group) is conducted while studying their components and their features : space (physical, virtual); channels (audio, video); time (synchronous, asynchronous, quasi-synchronous), duration and rhythm; interactivity; needs, potential and limits of each situation for transitions with the two others.

The design of learning scenarios involving the threefold situations (individual, team, group) gives specifications for the learning activities with their spatio-temporal dimensions.

Modelling is the activity by which the scenarios are dynamically represented with a modelling tool (Wasson & Bourdeau, 1998).

Virtual experimentation is conducted by manipulating variables in the scenarios and assessing the impact of the variations, using the modelling tool.

Field-testing represents a partial implementation of the scenario with a limited number of subjects and an observation protocol.

Extraction of design principles is oriented toward the design of: a) learning scenarios, b) technological environments, c) pedagogical agents.

Validation of these principles is done by a full implementation of a collection of scenarios with a data collecting protocol.

As a conclusion, a design problem has been identified and briefly described. A process in seven steps has been proposed in order to better understand the problem and its dimensions, and to propose directions for the design of learning scenarios, technological environments and pedagogical agents. The concepts of telepresence and of seamlesness receive special attention in this approach, as well as the consciousness of time and space by learners. This view underlines the necessity of analysis (using frameworks and modelling), and of observations (through virtual and real tryouts) when designing learning scenarios, in order to support the continuity needed in the learning process.

Increasing Retention in Computer-Based Courses

Carol Berrey
Executive Director of Government and Public Affairs
Weber State University
United States
cberrey@weber.edu

The Special Problems of Computer-Based Teaching

Academia, both in the U.S. and abroad, is increasingly adopting new instructional delivery methods. Limited experience to-date shows that attrition rates for computer-based courses often runs higher than for traditional courses. Adopting savvy strategies can offset this handicap and significantly enhance student satisfaction and retention. The secret of retention in this new world is to help students feel and be involvedB-with faculty, with classmates, and with the institution.

This year I taught three consecutive terms of an online introductory interpersonal communications class. I found maintaining high levels of student participation and retention difficult but important, especially in the mediated instructional setting.

Because distant students= primary concern is losing interactivity with the faculty or other students, the most important adaptations make the learning experience more personal and less Amediated.≅

1. *Start with a good foundation*

   Require new student orientation. If students can=t log onto the World Wide Web, use e-mail or post assignments, they will be handicapped throughout the course. A grounding in Internet basics assures all students have the minimum skills for success.

2. *Develop integrated course curriculum.*

   Build in redundancy. Not everyone follows the same Alogical≅ paths to information. With hyperlinks the Internet provides a powerful tool for building a non-linear, multi-stream logical structure. For example, hyperlink the grading scale to the syllabus page, the assignment page, and the grade page to increase the odds of students locating key information.

   Include detailed course information. Online syllabi should provide all the information usually given in a traditional syllabus plus everything you would have said in classroom instructions. Instructor expectations should be especially clear to foster better communication and higher performance.

   Schedule multiple assignments. Rather than a single large paper/project/exam due at term end, design multiple small assignments or phases of a larger assignment due periodically during the term. This keeps student involvement constant, and allows you to identify immediately when a student is falling behind.

   Hyperlink appropriate Internet resources. Use the immediacy and breadth of information available on the net to enrich your traditional course materials.

   Do a complete dry run. After designing your online course, go through *everything, personally*. Log on as a new student, access the syllabus, post assignments, take exams and enter the chat room -- *try everything*. Then ask another person, with no familiarity with the course to do the same. This naive subject, like a cold reader, can often identify otherwise invisible problems.

3. *Create a friendly environment*

   Help students feel comfortable. During the first week introduce yourself, and invite students to introduce themselves. You might also post your photo, and invite students to do so.

   Send personal e-mail. Show the students that you are there and care about them. Send answers to questions, comments on individual assignments, or just contact students who have been suspiciously quiet. Even if you can=t respond immediately, always acknowledge a message or assignment received. Many systems automatically generate a return response. AGot your message -- full response follows.≅ This lets students know their messages aren=t lost in cyberspace.

Be accessible. Log-on frequently. More frequent log-ons, even if shorter, give a greater sense of faculty presence than do less frequent, but longer, log-ons. In addition to regular e-mail contacts, identify real-time office hours so students can telephone or meet you online.

Include electronic participation in grading criteria. Both personal experience and literature reviews suggest that the more frequently and actively students participate, the better their retention and learning. Encourage student involvement by making it a part of their grade, or by requiring a certain number and quality of interactions per week.

4. Treat students as active learners

Facilitate learning. Most online students are working adults, use to taking responsibility for themselves. Take advantage of this maturity by involving students as much as the first shot at answering each other=s questions before you jump in as the Aexpert.≅ Structure assignments requiring student collaboration, assign students to create exam questions, or have them evaluate each other=s work, etc.

Give substantial feedback. Students need full, concrete feedback on how they=re doing, especially with initial assignments. Explicit examples of what they=ve done right and/or wrong are more helpful than general comments like AGood job!≅

>Unbundling= Instructional Tasks

Academia already Aunbundles≅some traditional instructional activities, shifting them from overworked and costly faculty to skilled helpers. Teaching assistants grade, academic advisors counsel, and departmental secretaries post grades. Online teaching is even more suited to unbundling.

Technological complexities and system glitches are constants in mediated teaching, and demand a Ahand holding≅ function. Students don=t see faculty in class, so they must find answers already posted, or contact someone to get the information. Even if you post and students are able to find a detailed syllabus, questions inherent in the technological medium will still arise. AIs that hyperlink dead?≅ AHow long will the system be down?≅ AWhy doesn=t my password work anymore?≅ require a personalized answer.

A few weeks into the quarter, I realized I had *de facto* unbundled the course. I continued the traditional instruction tasks, but my secretary became the class manager. Available by phone, fax or mail during regular business hours, she handled day-to-day class operations, answered procedural questions, walked students through processes, checked on system glitches, and posted grades online. She also monitored student log-on frequencies. If a student went inactive for a specified period, she alerted me so I could make special contact to identify problems and encourage reactivation.

Conclusion

The demand for higher education continues to grow exponentially throughout the world. Already, mega-universities in China and India enroll as many as 250,000 students, many taught via distance education. The rapidly changing face of education brings new opportunities but also the demand for innovative solutions. Teaching online presents additional challenges, but a creative, problem-solving attitude and artful strategies make it rewarding for both faculty and students.

DUKES: Creating Real-Time Variable-Speed Speech for use in Educational Multimedia

Kevin A. Harrigan
University of Waterloo and TeleLearning Network of Centres of Excellence
Department of Computer Science
University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1
Email: kevinh@uwaterloo.ca

Introduction

DUKES is a computer application that we have created to allow developers of educational multimedia to produce applications that include real-time variable-speed speech. Variable-speed speech is speech that is played back in more time (called time-expanded) or less time (called time-compressed) than it was originally recorded. For example, a one minute speech segment played back in 40 seconds is time-compressed by 33%. Research has shown that learners can listen to speech that has been time-compressed by up to 50% without any loss of comprehension or retention (Harrigan 1995; Harrigan & McLean 1995). People normally speak in the range of 125-175 words per minute (wpm) and silently read at 275-300 wpm. Thus, when listening to time-compressed speech which has been compressed by up to 50% learner's are listening at approximately the same rate at which they would silently read. Listening to time-compressed speech can produce a significant increase in learning efficiency (learning per unit of time) compared to listening at normal speed, without any known negative side effects.

Producing Variable-Speed Speech

There are various methods of producing variable-speed speech. Learners do not like the "Mickey Mouse" effect that is produced when speech is time-compressed by simply playing it fasterr, so researchers have create various other methods of time-compressing speech without a significant pitch change. Some of the most often cited methods are: (a) removing pauses in the speech, (b) removing small chunks of the speech at regular intervals in time, and (c) using the Synchronized Overlap and Add (SOLA) (Roucos & Wilgus 1985) technique. In the implementation of DUKES we have used the SOLA technique because it produces the best quality speech of all the methods (Arons 1994).

The SOLA method is a selective sampling method. With this method, the beginning of a speech segment is overlapped and averaged with the previous speech segment at the position of highest cross-correlation. The resulting time-compressed file is of very good quality, and there is no significant change in pitch. The SOLA method requires a large number of multiplications and additions in the calculation of the point of highest cross-correlation but our implementation has been optimized to run in real-time on a Pentium 90MHz or faster computer.

Before we developed DUKES, we used Wave for Windows (Turtle Beach Systems 1992) to create educational multimedia applications in which we included multiple versions of the same speech file which was time-compressed by various amounts such as 15%, 30%, and 45%. We then gave the learner the ability to change speech files at any time. This worked quite well (Harrigan 1995) but it was limited in two ways: (a) multiple speech files consume an enormous amount of disk space and (b) the learner could only select the time-compression percentages that we provided rather then being able to select their own. We developed DUKES so that we could give the learners more control by allowing them to control the speed of playback in real-time. To date we have only concentrated on speeded-up speech but our application has the ability to slow down speech as well.

The DUKES Software

Figure 1 shows screen images of the only two screens in DUKES (note that DUKES could be imbedded within an application and thus the learner may not see this interface). It shows that the input can be from a sound file or in real-time via a sound card. Our application determines the characteristics of the input signal. The user is given control over the default parameters that control the quality of the resulting signal. The resulting speech can be saved as a sound file or played on the sound card, whichever is appropriate. When the user selects "Do TSM" to do the conversion (known technically as Time Scale Modification) a second screen appears to give the user the ability to change the speed of the speech as the speech is playing.

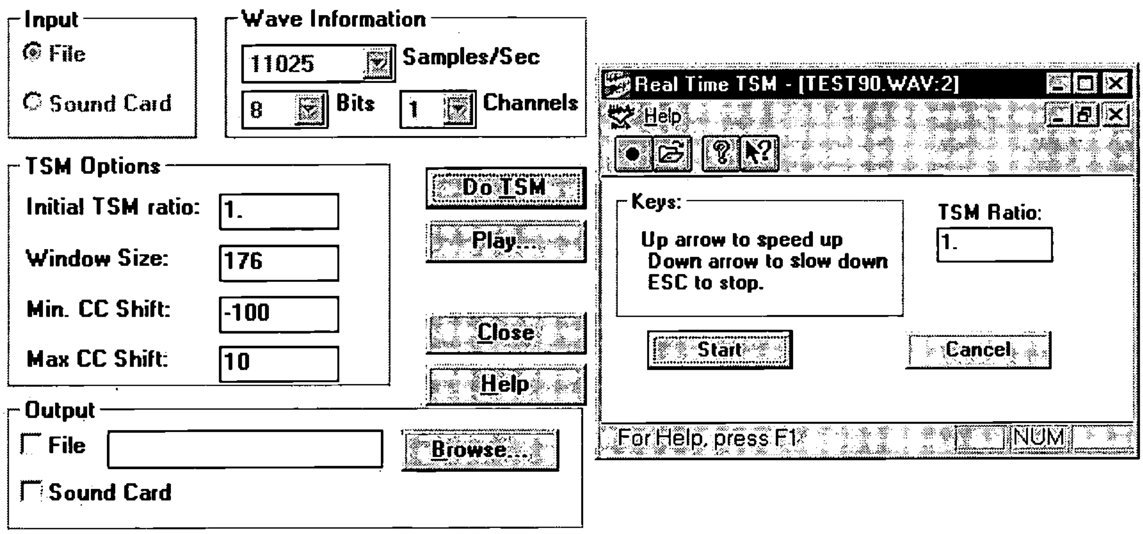

Figure 1. Screen shots of the only two screens in the DUKES software for creating variable-speed speech.

Conclusion

We have used time-compressed speech in several educational multimedia applications and have received no negative feedback from our learners. We feel that variable-speed speech is a feature that designers of educational multimedia applications should consider using in the products that they produce. Our software is available as freeware from the author.

On the Receiving End – Supporting Faculty and Students in a Distance Learning Environment

Gail S.M. Evans, J.D.
Executive Director and Dean, The University Center
North Harris Montgomery Community College District, U.S.A.
and Professor of Business Law, The University of Houston-Downtown, U.S.A.
gail.evans@nhmccd.edu

Key to the growth and success of distance education as an alternative delivery system for university courses is faculty confidence in the effectiveness of distance education systems for the delivery of curriculum, and student satisfaction with the learning experience in a distance education environment. Yet, too often, the planning process is managed by persons who have little or no experience in teaching in a distance environment. And the technology issues are often so daunting that they become the dominant concerns of all involved. Lost in the discussion are the needs of the faculty and the students. These needs have special relevance for the persons serving as the link between the students and faculty – the on-site administrators of remote site facilities.

The University Center of North Harris Montgomery Community College District (NHMCCD) is a collaborative partnership of the community college district with six publicly funded universities: Prairie View A&M University, Sam Houston State University, Texas A&M University, Texas Southern University, University of Houston and University of Houston-Downtown. NHMCCD covers the northern one-third of the Houston metropolitan area. Residing within the district's boundaries, which cover more than 1400 square miles, are 1.2 million people. No university is located within the district's boundaries. NHMCCD took the lead in developing The University Center (TUC) to improve access to higher education for its graduates, residents, and businesses. The six university partners deliver all required upper division and graduate courses to support 30 undergraduate and 23 masters level programs. In some instances, entire major programs are being delivered using compressed video interactive classes originating at the main campus location. Some programs are delivered using a combination of live-on site, compressed video, tape, and Internet.

Approximately 170 sections of upper level and graduate courses are offered each long semester at The University Center. Of these, approximately 40% utilize compressed video interactive technology for delivery to multiple sites. Four of the six partners utilize the compressed video technology. In most cases, TUC is the "receive" site. However each semester anywhere from 4 to 8 sections will originate on a regular basis from TUC. And in approximately half the remaining sections, the faculty member will travel to TUC at least once during the semester to broadcast the course from there. Thus, the primary focus of concern for The University Center is providing adequate support to facilitate delivery of compressed video interactive classes.

Because The University Center draws from several universities with different policies and processes, it provides an excellent laboratory for gathering information and testing support strategies to achieve a high level of student and faculty satisfaction with distance education. This paper presents the results of two surveys. The first was directed to faculty to identify their expectations related to types of support that they perceive necessary for their distance education courses to be successful. The second was directed at students to determine their level of satisfaction with the compressed video classes at The University Center. The surveys are part of an annual assessment process used to review current practices at The University Center and to initiate change as appropriate.

A brief summary of current classroom operation provides the framework for understanding the information gleaned from the surveys. In the typical "receive" classroom situation, a member of the student services office meets the class the first day prior to the beginning of class. She provides a brief explanation of using the push-to-talk microphones and describes to the students the process for calling for technical assistance using the telephone in the classroom to page a technician. She hands out the syllabus for the class and any other material the faculty member has sent. Additionally, she demonstrates to students the procedures for redialing a class in the event of disruption.

For daily class, a technician connects the class approximately 15 minutes prior to the start time and tests the audio as well as video transmission. Students arrive and take their seats just as for a live-onsite class. A student services staff person brings any handouts to the classroom and collects any papers which she has been notified by the faculty member to collect. Students are unattended during the class period. Exams are proctored by a contract proctor, if requested by the faculty member. When only a couple of students are at the "receive" site, the faculty member will often proctor using the connection. In those cases, a student services staff member distributes the exams at the beginning of the class period and then returns at the end of the period to collect the exams. Students who leave early place their exams on the desk if they do not want to remain until the staff person returns. If the course requires a class presentation, then the student services support staff provides broadcast training for the students, demonstrating to them the process of changing from camera to powerpoint to document camera. Students are allowed access to the classroom for practice. At this time, only one college from a partner university utilizes web-based classroom management software to support delivery of its courses.

Overall, the types of support that faculty perceived to be important for their compressed video courses to be successful were directly reflected in the students' level of satisfaction with the course. The two areas of greatest convergence centered on technology and getting information/assignments/tests to and from students. Faculty expected the technology to operate in a trouble-free manner, and for technical assistance to be quickly available. Students correspondingly, found interruptions in the broadcast, and inferior quality in such things as audio, to affect how they felt about the course. Where there were continual technical problems, students were less satisfied and expressed concern about taking another course delivered via compressed video. In response to this finding, The University Center technical staff instituted a room log to track connection problems. This procedure will help to quickly distinguish general problems from those that are specific to connecting with a particular institution. Additionally, to speed troubleshooting, the staff developed a "call a tech" procedure using the alphanumeric paging system through the computer to page the technical person on duty. By following the instructions taped to the desk by the computer keyboard (just in time instructions) the student can send a page with the room number and brief description of the problem. That information can help the technical staff determine quickly the magnitude of the problem and level of response necessary.

Faculty want and need to get information/assignments/tests to and from students in a timely manner to derive maximum pedagogical value from the activity. And students indicated on their surveys a high level of frustration at the amount of time it often took to receive back graded work. The highest level of dissatisfaction existed where the universities were using an informal courier system (i.e. whoever happened to be headed to the vicinity of TUC) to transport materials. In that case, faculty felt they were not being supported because it would sometimes take more than a week for materials to reach the students. And the students were dissatisfied because they didn't know how they were doing in the course or felt they were at a disadvantage when compared to the students who were physically with the professor at each class. In those cases where overnight express mail service was used to send materials both parties were somewhat more satisfied. The problem was significantly diminished in the case of the partner university using course management software to communicate the syllabus and transmit assignments. In response to this finding, whenever possible TUC now utilizes express mail to send to the faculty member all class materials collected. Additionally, the TUC staff is evaluating the feasibility of providing access to course management software through the TUC server for those faculty who do not have such access at their universities. The information gathered in this section of the survey demonstrates the value of systematic assessment in identifying needs and devising solutions. By pinpointing the relationship between high satisfaction and the efficient transporting of materials between students and faculty, TUC was able to justify the budget expenditures related to using express mail and to provide incentive to its partners to seriously consider mechanisms for web support for classes.

The U.S. Department of Education has reported that more than 50 percent of American colleges and universities offer or expect to launch distance-education programs in the near future. If distance education is to prove a successful system for bringing education to the people then we must move from our preoccupation with technology and address the nuts and bolts issues of support. The information derived from systematic surveying of the parties most affected by the technology - the faculty and the students - provides a basis for beginning to address this issue.

Early Experiences in Broadening the Use of Web-Based Learning to Mainstream Faculty

Wendy Freeman, Digital Media Projects Office, Ryerson Polytechnic University
Dr. William Brimley, Digital Media Projects Office, Ryerson Polytechnic University
Dr. Rheta Rosen, Learning and Teaching Office, Ryerson Polytechnic University.

The history of instructional technology is littered with discarded technological innovations that promised to revolutionize the way teaching and learning occurred. This paper will describe the efforts of the staff of the Digital Media Projects Office at Ryerson Polytechnic University in introducing an integrated web-based course delivery package called WebCT to Ryerson faculty and students. The goal was to provide and support a software package that would enable faculty considered to be non-technical to use the web for instruction, extending the reach of this instructional technology beyond that of the typical innovators and early adopters. In this paper we will report on our efforts to ensure that these web-based tools do not ultimately contribute to the list of discarded instructional technologies. Specifically we will reflect on the techniques used to promote and support WebCT, our experiences on the successes to-date and suggestions on how to continue to reach out to faculty not already using web-based tools for instruction

Ryerson Polytechnic University is an undergraduate university in the heart of downtown Toronto. Full-time and part-time student programs are divided into five faculties covering 37 program areas. Faculties include Applied Arts, Arts, Business, Community Services, and Engineering and Applied Science. In addition to 14,000 day students, there are 65,000 student enrollments in continuing education courses (both on campus and through distance education).

In 1996 the Digital Media Projects Office (DMP) was established to provide support for faculty with an interest in using multimedia for instruction. The DMP provides a range of services for faculty including, workshops, drop-in multimedia suites, and consultation. Faculty receive support in presentation technologies such as PowerPoint, web authoring, and advanced multimedia authoring (Brimley, 1998).

The orientation of the DMP is to provide support for faculty with the goal of helping them to develop the skills to create their own multimedia resources. This approach has been very successful for a small number of faculty that could be classified as innovators and early adopters according to criteria suggested by Moore (Moore, 1991). The DMP workshops are typically attended by faculty willing to learn to use technology that is rapidly changing, that may be in a beta or development phase, or that requires a significant time commitment.

In the summer and fall of 1998 the DMP introduced WebCT, an integrated web-based course delivery software package. WebCT is just one of many new like products becoming available to higher education institutions in the past few years. These integrated packages combine common internet-based tools such as threaded discussion groups, real-time chat, web page delivery, online quizzing and student management in one package. The instructor can mount and maintain a fully functioning web-based course with little or no technical knowledge of the intricacies of web servers, Javascript, or Perl, etc.

The software was introduced to provide an accessible set of tools for web-based instruction. The goal in introducing WebCT was to continue the efforts of the DMP to assist faculty in becoming self-sufficient when using technology. An effort was made to make web-based tools accessible to a group of faculty as yet reluctant to use the web for teaching. This group of faculty is classified as the early and late majority or the mainstream by Moore (Moore, 1991).

In his paper "What Ever Happened to Instructional Technology", Geoghagen (Geoghagen, 1994) suggests that mainstream facultydiffer from their innovator/early adopters colleagues in their reasons for adopting any new technology. Primary among these reasons is a general interest in the technology itself. While innovators and early adopters are "techies" willing to explore the potential of the technology, the mainstream is not. Faculty falling into the mainstream are interested in seeing tried and tested applications and do not want to use technology that is not congruent with the way they carry out their daily tasks.

As well, different methods are required to promote and support new technology for the different groups of adopters. The standard strategies of highlighting the technology itself and teaching people how to use the technology may be appropriate for faculty interested in technology, but this is not effective for mainstream faculty. The mainstream is more inclined to show interest in a new technology if it is easy to use and does not require a major change in the skills they already possess.

With these issues in mind, the DMP set out to select and implement a web-based course delivery package for mainstream faculty. Our primary assumptions in selecting WebCT were that the software should meet the instructional needs of faculty using the web for instruction and that little or no knowledge of HTML should be required.

As much as possible, faculty were involved in the selection and implementation process. A committee of faculty and support representatives was formed to assist in the final selection of the software package and to advise on the implementation plan. A short survey was circulated to provide the committee with feedback on the key features required by faculty.

All faculty were invited to participate in the pilot project. One training session was arranged and two more were added after the overwhelming initial response. During July and August 1998, 54 faculty were trained in how to use the basic features of WebCT and how to convert standard word processing files to HTML.

An effort was made to provide as much a support as possible. A student was hired to provide telephone and one-on-one support. In addition, a listserv, an e-mail address and a website were provided (http://www.ryerson.ca/dmp/courseware) to communicate with faculty participating in the pilot. At the start of the school year one more support person was added to assist faculty and when necessary, students in using WebCT.

In the first semester there were 25 faculty using WebCT to offer a total of 34 courses with approximately 3,500 students enrolled. WebCT is being used across the five faculties and for all four years of study. In its second semester WebCT was used to offer 44 courses by 32 faculty.

It would appear that WebCT has attracted some faculty that had not yet used web-based instructional technology. A small group of faculty who are interested in or are now using WebCT know nothing about HTML and had not used the World Wide Web for instruction prior to WebCT.

In an effort to assess the effects and effectiveness of the WebCT pilot, student and faculty surveys are being used to gather data. Faculty were asked about their previous experiences with this type of instructional technology, their reasons for choosing to use WebCT, how they are using WebCT, etc. Students were asked similar questions about their experience with the Internet and the computer along with the barriers and uses for WebCT.

It is perhaps too soon to reflect on the reasons for mainstream faculty adoption of the web as an instructional technology. However, it may be possible to make some general observations about the effectiveness of our decisions and process so far.

The decision to involve faculty in the selection and implementation process was a good one. Input provided DMP staff with insights into the day-to-day needs of faculty that would not have been considered otherwise. WebCT has proven to be a tool that is attractive to mainstream faculty because it is flexible, it meets some or most of their instructional needs, and because it is an aid in course administration.

Although support personnel were not always kept busy, faculty appreciated knowing that there was a high level of support should they need it. As faculty take small steps toward full course implementation and begin to push beyond their current WebCT skills the number of support calls has increased.

There are factors beyond our planning and procedures that contributed to the pilot's success. These factors include increased access for both faculty and students to networked computers, a growing understanding of the instructional applications for the Internet, and the availability of WebCT and integrated packages like it that are designed specifically for web-based instruction in higher education.

As we begin to plan to move out of the pilot stage we are refining our strategies and continuing to look for ways to make the web more accessible to mainstream faculty for instruction. We have initiated a "house call" service that provides one-on-one consulting for faculty using WebCT. Initial faculty and student feedback suggests that we must put more effort into supporting students to eliminate the support burden for the faculty. We will also continue to investigate better tools for creating web pages from word processing files. Finally, by focussing on the instructional applications of this technology we continue to explore the World Wide Web as a means for effective and innovative teaching.

The Venezuelan Universities and the Cyberspace

Rosa María
University of Zulia, Maracaibo
Venezuela

Increasingly, both the public and private sectors are demanding more efficiency from public Venezuelan universities. This pressure for efficiency in education has resulted in an increasing adoption of New Information Technologies in the educational, research and administrative areas of higher education. In fact, the use of NIT in Venezuelan universities is superior to averages elsewhere in the Latin America and in the world.

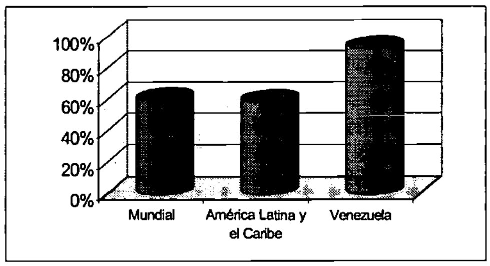

Figure 1: Universityes Web Sites

The above chart shows that while 60% of the universities in the world have a web site and 58,8% of the South American and the Caribbean universities have a presence on the web, almost all public Venezuelan universities (89%) and less than half of the private ones, have a web page that basically fulfills the institution's information needs.

However, in analyzing the possible uses of these technologies, it is clear that only a few universities have effectively incorporated the NIT into their systems.

For example, while some universities such as the Universidad Simon Bolivar, the Universidad Central de Venezuela and the Universidad Nacional Experimental Simón Rodríguez use NIT in the decision making process, only 40% of the public universities with on-line systems use them as a support for the research activities.

Mostly, the NIT are being used to display information on the web about the universities' programs and mission. However, without a clear picture of the total information system and its relationship to a communication policy statement, it remains unclear how NIT are being incorporated to the universities policies as a whole.

Despite the efforts made, only three universities (Universidad de los Andes, Universidad de Carabobo and Universidad Simón Bolivar) have an effective on-line library consultation service. The others struggle against the generalized financial crisis and poorly trained personnel to update their library collections.

E-mail services are not of common use: i.e. only 25% of the professors at the Universidad del Zulia (the second largest Venezuelan university) has and uses an e-mail address. It was during the second semester of 1998 when administrators of this university began using e-mail services to communicate with the faculty.

The use of NIT among each university has grown at a different rate and speed, thus displaying different modalities. This hinders both inter-operability between systems, as well as each system's uses. For example, private university students produce 100% of the "unofficial web sites"; students attending public institutions have made none.

Universities like Universidad del Zulia, Universidad de Carabobo and Universidad de Los Andes develop communication infrastructures that include not only web sites and e-mail and Internet services, but also Radio and Television Stations of public service. However, these services do not collaborate to foster and coordinate a common communication objective.

The architecture to build the different systems among Venezuelan universities varies. The Universidad Nacional Experimental del Táchira's project is based on a joint venture with IBM. The system will serve the administrative and academic sectors and coordinate the beginning and development of specific data pools of academic information (Regional Information Center, Research Lab, Libraries, Dean's Office and all units that require information services).

The UNELLEZ (Universidad de los Llanos Ezequiel Zamora) established an agreement with the Universidad de Carabobo for the development of specialized services of personalized consultation on the library. This will allow access to the university's databases as well as to on-line consultation by modem at all four of its campuses.

The Universidad de Carabobo could be considered the biggest virtual library of the central area of Venezuela. This institution is performs highly in the area of information management.

In 1987, the Universidad Simon Bolivar began an internal discussion on the differences between *information industry* and *knowledge industry* concepts. The discussion resulted in a small team of information and technology specialists who input data for the Information system of the institution. The system bases its performance on the matrix organization, an organizational structure that characterizes the Universidad Simon Bolivar. This team of specialists also manages the web sites of the university.

The Universidad Simon Rodriguez pursues a project considered the most advanced in Venezuela. It consists of the use of networked computers to enforce the curricula development model of the university, a model based on the Andragogy. The project also includes intercommunication with 27 satellite campuses of the university around the country.

While most of the Venezuelan universities claim that they use NIT, just a few have their entire library collections available for on-line consultation. Some others offer workstations with basic programs, such as word processors for at least half of their student body, but very few can guarantee workstations with internet access, e-mail service and on-line data search capabilities for research purposes.

Despite the evident delay in the full application of NIT, Venezuelan universities have made a great effort to update their technological infrastructure and to adjust their management methods to become more efficient through the uses of technology. Even so, the major challenge they face is to overcome the financial crisis that characterizes most underdeveloped countries. Such a barrier must be surmounted if Venezuelan universities are to offer the top quality education level opportunities necessary for students to gain a seat at the banquet with those who are educated in the wealthier, technology-rich countries of the world.

Remote Control of Hybrid Analog/Digital Video Networks in Distance Learning Environments

Anatoliy Gordonov: GORDONOV@POSTBOX.CSI.CUNY.EDU

Roberta Klibaner: KLIBANER@POSTBOX.CSI.CUNY.EDU

Computer Science Department, Staten Island College, City University of New York,
2800 Victory Blvd. 1N-215, SI, NY 10314, USA

Introduction

Hybrid Analog/Digital Video Networks (ADViNet) become more and more popular on the market. They are employed in the applications that require full-screen motion video transmission in the local area networks and, at the same time, cannot afford slowing down regular network activities. Among these applications are real-time control systems, electronic classrooms, and distance learning environments.

The typical physical architecture of ADViNet includes two communication media: digital and analog (Computer Video Web 1996). The digital medium is used by a regular digital network according to its type and topology. The analog medium combines a VGA bus with several additional control lines.

ADViNet allows users to send real-time full-screen motion images through an analog communication medium. Main video network operations--Broadcast, Multicast, and Monitoring-- cover basic instructors' activities such as lectures, tutorials, individual and group supervision. Recently developed logical level intelligent video network operations make teaching in the ADViNet environment more productive for the students and instructor (Gordonov A. 1997), (Gordonov, A., Kress, M. 1997). However, the architecture of ADViNet permits its use only within a limited area. A distance learning environment includes groups of network nodes dispersed far apart. ADViNet, being very useful in a local classroom, cannot automatically be used if several local classrooms participate in the same session. In this paper we present our current development of a distance learning environment that includes several classrooms equipped with ADViNet. We define distributed video network architecture, methods of video transmission between sites, and methods of the remote control of a remote site.

The Architecture of a Distributed Video Network

First of all, let us give several definitions:

Cluster - a set of computers connected to the same ADViNet video bus.

Primary Cluster - the main cluster in the distributed distance learning environment where the instructor is located.

Secondary Cluster - any remote cluster which participates in the distance learning session.

Primary Teacher station - the teacher station in the primary cluster.

Secondary Teacher station - the teacher station in a secondary cluster.

A general structure of the distributed ADViNet architecture is shown in Figure 1. Video information may be transmitted between nodes inside a cluster and between the clusters. Each node of a cluster can use ADViNet to transmit images from one member of a cluster to some others. Technically, digitized video

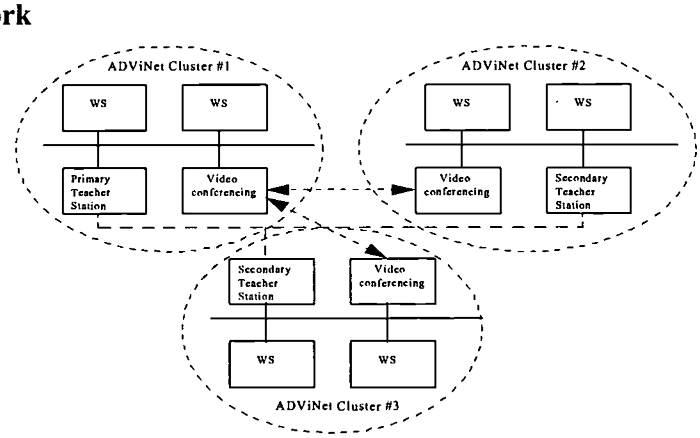

Figure 1: General Structure of Distributed ADViNet.

can be transmitted from one cluster to another. Virtually, any commercially available videoconferencing system (such as CU-SeeMe, Intel ProShare, Tenberg, etc.) may be used for this purpose. Some of them (such as CU-SeeMe, Intel ProShare) must be installed on the teacher stations in each cluster. In this case video information is distributed inside the Primary Cluster through the local ADViNet and may be transmitted to the Secondary Teacher stations over the videoconferencing system. In the Secondary Clusters local ADViNet sends video information to all the local nodes participating in a session. If the videoconferencing system is a separate device, it should be connected to a teacher station though a video card. It allows this station to provide exchange of video information through the videoconferencing hardware. The quality of video transmission depends on the characteristics of the digital channel between clusters and is very often limited by these characteristics, yet, it could be acceptable for many applications. Inside each cluster, ADViNet relieves the burden of video distribution. Using ADViNet in any cluster insures delivery of video information to any student station without interfering with other network users connected to the same local area segment. Although technically possible, this structure suffers the lack of remote control: a user in one cluster cannot control video equipment in others. In a distance learning environment the remote control is a vital necessity. It allows the instructor to implement many functions (such as remote control of video equipment, control of video distribution in a remote cluster or remote ADViNet configuration) without asking for assistance at the remote site.

For control and management purposes, in any cluster one station (control station) is chosen for remote communication with other clusters. By default, this is a Teacher station. For any session, one of the control stations is the primary control station, and the others are the secondary control stations. The primary station communicates with all secondary ones. Any secondary station may gain control over the entire video network (which includes several ADViNet clusters) only after it gets the permission from the primary control station. The primary station may set and monitor a time limit for the current session, may extend this time, or interrupt the current session. Any control station which is authorized to manage a video session may request from all other control stations the information about the current status of the ADViNet clusters and/or send the necessary commands to change the local mode in an ADViNet cluster. It may also issue special commands to control video equipment in a remote site such as video cameras or teleconferencing equipment. During a session, a cluster may drop the connection or connect to the current session. By default, the Primary Teacher station controls the distributed ADViNet. Any Secondary Teacher station may gain control over the distributed environment after getting permission from the Primary station.

All remote control commands as well as local ADViNet commands are included in the Remote ADViNet Management Protocol. This protocol allows the users to control video distribution in remote clusters in the same way as they do it in a local area network. Most local operations are implemented remotely. Among them are various types of broadcast, multicast and management operations.

The distributed ADViNet architecture and Remote ADViNet Management Protocol are supported by specially developed software. This software provides remote programming control in a number of ways. Recently we have developed three different variants of establishing communication between Primary and Secondary stations. They are:

- communication through a local area network. This situation may happen when all the clusters are located inside one campus. The supporting software works in the Windows NT environment and may use any available protocols for the communication;
- communication through TCP/IP protocol. The communication may be established between any nodes connected to the Internet or inside a local area network with appropriate protocols installed;
- transmission of the control information using special functions of the videoconferencing systems. This method is used if not all the clusters have the Internet connection. Intel ProShare videoconferencing system includes a special function that supports transmission of text or binary information concurrently with video. This function is used to establish communication between clusters and to transmit commands.

The proposed paper represents an ongoing project. The implementation of the proposed distributed video network architecture and methods of the control of a remote cluster allow us to incorporate ADViNet in the distance leaning environment and use all the benefits of ADViNet in any cluster.

"HISTOMANIA" A VIRTUAL ENVIRONMENT PROMOTING A COMMUNITY FOR HISTORY STUDY

Avigail Oren
Zvia Lotan
The Center for Educational Technology

While browsing the Internet we may find various types of educational sites, but not all of them could be addressed as an environment hosting a learning community. In this article we would deal with both terms in order to show their educational advantages, Likewise, describe Histomania as an environment hosting a virtual community of people interested in history.

Virtual communities and environments

A survey, that explore learning communities, defines two types of communities existing side by side, even in our time. One type refers to people basically sharing a common place and the other type is based on people sharing interests. Both types include members sharing culture (language and values) and communication means (Office of Learning Technologies, Canada, 1998). By that definition learners and teachers in school form a community of the first type and subscribers to theater or music programs form communities of the second type. Members of the first type do not choose their membership (the place and the subjects studied), but they share a place, use common culture and feel affiliated to the school. Members of the second type are volunteers who choose to be part of the community on a ground of common interests. But, in order to fulfill their membership they also have to share a specific place and time. The main feature of network technology is the communication capabilities which may free the community from being place and/or time bounded. The main question is how do we use these net capabilities as a place for developing a community which will promote the study of history.

When analyzing the term "virtual community" we find two phases in the community development: registration and ongoing existence. At the registration phase people check in voluntarily and look around to find out whether they may gain advantages or be satisfied socially. At the ongoing phase membership is significant if the member feels that he contributes to the community and that he is gaining advantages from his visits. Likewise, he has to develop a sense of identity and a feeling of affiliation. These will emerge only if social bonds will be established between members. We assumed that given a place where teachers may consult each other and hold a dialog with historians and history instruction experts will create conditions for a community. Likewise, offering students tips for learning history and game like activities might do the same. Moreover, the opportunity of a dialog between students and teachers, teachers and parents, students and parents, who will know each other only virtually, will help in crating a new trust between populations who seem to be in an ongoing conflict.

Virtual communities grow and function in virtual environments. The environment that hosts the community represents the logical framework as well as the virtual place for its existence. It is apparent that the communication layer of a web site is a main factor in establishing a virtual learning community by supplying the social factor needed in the learning process. Likewise, we propose the idea that conditions needed for a community to emerge and evolve are not only the technological capabilities of the net but also a meta outlook which produces not a site but an holistic wired environment. we define an "holistic learning environment" as a set of web sites who share the same meta subject (for instance, a discipline) and supply a place for various interested visitors (like, students, teachers, parents, specialists) etc., by means of CMC. We argue that the existence of a larger structure to which the discrete sites belong gives rise to a feeling of stability which creates an atmosphere of security and seriousness. We assume that this atmosphere helps the visitors in developing a sense of identity with the environment, similarity with other users and willingness to visit once more and participate in the activities proposed there.

Histomania

The environment is a tryout to implement the concepts described above.
It is based on a holistic approach in web based learning where the environment should be a combination of information handling and of communication tools. Developing a community is the main aim of the environment. Like in virtual places the membership is on a volunteer base. Any body might be a guest. In this position he may

look over the information sites available at the resources center. But it is expected that guests will find the place interesting enough to register as members.
The environment consists of five components:

Following Time
A resources center comprised of several sites, most of them build as data base including a search engine, and all are related to the to the Israeli history curriculum. We think that the focus of history instruction should be the primary sources - texts and visuals.. Therefore, primary sources as well as historical research are the main content of the resource center. The place is divided into four parts according to historical periods: The Classic World, The Middle Ages, Modern Western Society, Contemporary History. In each period Jewish History is dealt as well. The center is intended for students who wish to prepare papers or presentations as school projects and for teachers who look for primary resources for building their lessons.

A Disciplinarium
A center which serves history teachers according to needs defined by the members. Discussion groups enable teachers to discuss pedagogical questions related to the implementation of learning materials. Participants are requested to contribute ideas, tips, questions etc. to each other. Likewise, teachers are expected to send to the students' center tips for learning history or participate in students discussion groups. Members may also meet in a chat room where they may talk on any subject they like and develop social relations. Parents may participate in discussions groups of teachers, but have also a place of their own where they may discuss other subjects as they will define.

Tips from Clio
The students center. That is the place where students may share information with other students, discuss subjects in moderated groups, get tips for history learning from teachers, students, and from any body else who will be willing to help. At the same section where learning occurs a chat room called "Nirvana Pub" operates. That is the space where students may talk freely and develop social relations. Being members of the community, students may ask historians questions in subjects that they are interested in.

Time Machine
It is an effort to use edutainment concept for enhancing motivation towards historical issues.
Riddles, puzzles and crossword puzzles are organized in a curricular approach and are related to the Israeli Syllabus.

The "Seal Defenders" Club
The club will include members who proved themselves to be as active. They will be coaches of new members, guides to guests, participate in mingled discussion groups (students, teachers, parents, and historians) and talk over issues in history and in education as well. Club members will propose new ideas to be developed in the environment and evaluate ideas proposed by non-members.

In the recent months almost 700 teachers registered voluntarily and 400 students. 3 projects based on the resources embedded in the environment were held. Students from different schools used primary resources and participated in discussion groups. Some students send riddles and puzzles they solved. Teachers participated in discussions held in the the disciplinarium and some of them sent lesson plans and recommendations related to history sites on the the Internet.
Still, we are not satisfied with the activity done but feel that we are in the right direction.

Masters' Portfolio in Project Management Through Distance Education

Cecilia Hannigan
Lecturer

Mike Browne
Director

Centre for International Project Management
University of Ulster at Jordanstown
Northern Ireland
Email: cm.hannigan@ulst.ac.uk, ma.browne@ulst.ac.uk

1 Overview

The University of Ulster has approved the planning of a linked series of postgraduate awards by distance education that will focus upon various themes within the Project Management discipline. The international market for project management is extensive in both the developed and developing world. We have identified students in Asia who wish to undertake postgraduate courses at an overseas University but who cannot, for various reasons, leave their job or family to study abroad.

The Centre for International Project Management, based within the Faculty of Engineering has been established to deliver the Portfolio. It will draw upon the expertise of staff from the School of the Built Environment, the School of Electrical and Mechanical Engineering, the Faculty of Informatics and the Faculty of Business and Management. Critical factors involved in the success of this venture will be:

1. The formation of joint ventures and strategic alliances with other institutions and colleges based in each country where the courses are to be delivered and
2. World-wide commercial and professional organisations that can introduce state of the art practices into the curriculum.

Modern organisations are effectively introducing change through the use of business projects that will further their corporate objectives. We will meet the requirements of prospective part-time students, in their late twenties to early fifties, who have been chosen by their organisations to deliver such projects. Initially, it is anticipated that two streams or pathways will be available. These pathways are Construction and Engineering and will be followed by Informatics, Business and Leisure and Tourism, dependent upon demand.

University of Ulster (UU) academic staff will deliver the Portfolio via a series of residential courses at each international centre, supported by the staff of the local institution, independent study materials and dedicated UU administrative staff. The role of the International Partner Institutions is extremely important to the successful delivery of the Portfolio. We expect each institution to send a member of their staff on our existing Masters Programme to get a level of expertise in the discipline and form links with our staff, with a view to their being involved in the local co-ordination of the Portfolio on their return home. The use of advanced telecommunications facilities would be incorporated into the delivery and support aspects of the Portfolio. Teaching approaches will comprise a combination of conventional methods and tutoring via the Internet, using an integrated environment specifically for this purpose. In addition, supplementary resource material, in the form of CD ROMS, videos and paper-based materials will be distributed to the students.

As an open and distance learning programme, the duration may be varied dependent upon the requirements of each country. However the preferred model of delivery is that the taught modules will be completed over sixteen months and the Dissertation and accompanying Project should be completed in a further eight months.

2 Rationale

The rationale for developing the Portfolio is to

- Meet the increasing global demand for qualified project managers
- Develop further our existing Masters' programmes
- Provide a focused strategy for growth in teaching and research
- Enrich staff development via the direct experience of design and implementation of distance education programmes
- Further the achievement of the University's international objectives
- Indicate the University of Ulster's commitment to widening access to its courses
- Provide an opportunity for those people who are constrained by employment, by geographical location, or who are unable to attend conventional full time or part-time study programmes to get a University of Ulster Postgraduate award.

3 Issues

Currently the project team is evaluating various systems that support tutoring over the Internet. Based on evaluations carried out in similar projects, there are features that will be considered essential for inclusion in the selected computer managed instruction software.

3.1 Communication

Given that the Portfolio is being designed primarily for delivery overseas, we consider that in the first instance, asynchronous tutoring will be adequate. Taking into consideration time differences between students and tutors, it is unlikely that both groups will communicate synchronously, except in exceptional circumstances. However, asynchronous electronic communication tools such as electronic mail and discussion threads are perceived to be crucial to the success of the project. (Heywood and Cornelius 98) have identified that such communication tools promote a feeling of 'belonging' among students who are registered in a virtual class. (Paul and Brindley 96) also point out that the incorporation of good support mechanisms is crucial to the success of distance education courses.

Considering electronic mail, a useful feature would be the ability for the student to email a tutor or peer, *in context,* from every section of courseware while the system automatically includes the Uniform Resource Locator (URL) for that particular section within the body of the email message. The recipient is then in a position to click the URL and the section to which the sender referred in the email is launched - a great time saving feature.

One of the advantages of threaded discussion is that it can be used by tutors as a means of eliciting student response to various topics. Occasionally the material generated by these discussion threads may include aspects that the tutor had not considered while designing the course, and thus the material may be subsequently incorporated into future module revisions. In addition, this form of communication would require little effort on the part of the tutor, and could be a means of easily immersing students in the learning environment.

3.2 Access

Emphasis will be placed on course structure, and assessment, using text and graphics. (Heywood and Cornelius 98) have also identified that students' concerns include download times for course files, and actual duration of on-line study. Bearing this in mind, initially, the intention is to develop a course with small file sizes, thus facilitating access via low speed modems. Supplementary traditional material, such as video files, will be sent to the student. It is likely that such concerns will fade when the cost of technology and access to the Internet drop. However, in the meantime, the use of software such as Macromedia Director allows the development of animated interactive sequences that can provide an engaging stimulus while requiring considerably less download times than video files. (Riley and Hodgkinson 97), in early studies of students using an interactive multimedia package incorporating structured student guidance as part of their construction course, conclude that students consider such interactive systems to be a motivating and flexible means of self learning. They also state that such systems should be comprehensive in order to provide for the various learning styles exhibited by students.

3.3 Learning Environment

The learning environment created for the student will not only draw upon a state of the art computer managed instruction system, but will allow direct interaction between tutors and students by the use of short residential courses. The latter is seen not as an information transfer exercise, but one that promotes a 'deep approach' (Entwistle 95) to teaching and learning that can significantly 'add value' to the quality of the educational experience.

Considering the Internet aspect of the Portfolio, (King 98) makes several suggestions, based on evaluation of current applications, for enhancement of predominantly document orientated web based courseware. It is important that such courseware is not seen as simply an on-line page turning exercise. Students benefit from being engaged with the system. (Paul and Brindley 96) stress that one of the lessons to be learned from previous forays into distance learning is that students' individual differences should be taken into consideration when designing a course, in order not to produce an assembly line type of learning. To this end, we will include several self-assessment exercises, such as multiple choice, image map or list map exercises, which are automatically graded by the system. These will have the double advantage of incorporating interaction while providing students with instant feedback, along with direction to remedial or further tutorial material. Based on previous research into intelligent tutoring systems, carried out in the University of Ulster, (Hannigan et al. 97) significant effort will be expended on the provision of an *individualised* feedback feature. The software system chosen to 'host' the Portfolio, therefore, should be capable of supporting this.

4 Future Directions

This project is in its infancy, and our current goals are to develop course modules in a manner suitable for delivery over the Internet, to decide on suitable software for the delivery of such modules, and to positively deal with the issues we have discussed above. Although our first 'intake' of students is not due until March 2000, we anticipate that a good proportion of the Portfolio will be in place over the next six months.

An Analysis of CD-ROM and Print Storybook Reading by Parents and Preschoolers

James P. Van Haneghan, Dept. of Behavioral Studies and Educational Psychology, UCOM 3705, University of South Alabama, Mobile, AL 36688, USA, email: jvanhane@usamail.usouthal.edu

Abigail Baxter, Dept. of Special Education, UCOM 3800, University of South Alabama, Mobile, AL 36688, email: abaxter@usamail.usouthal.edu

Despite the proliferation of Multimedia CD-ROM software aimed at preschoolers, there is little data on how children and adults interact with such software. Nor is there data concerning educational significance of such software. Hence, studies of how children and parents interact with multimedia software are of great importance. The goal of this paper is to examine parent-child interaction with CD-ROM storybooks and traditional storybooks to determine whether the interactions between parents and children using CD-ROM's are different from interactions between parents and children in joint book reading. Joint book reading has been found to be an effective context for the development of pre-literacy skills (Bus, Van Ijzendoorn, & Pelligrini 1995). Hence, comparisons of book reading and CD-ROM storybooks could provide insight into how CD-ROM software may impact literacy development.

Most of the previous studies of CD-ROM storybook reading have focused on school-age readers working with CD-ROM or written versions of storybooks (e.g., Matthew, 1997; Okolo & Hayes, 1996). Findings have been mixed. Some studies found that CD-ROM versions led to better comprehension (Matthew, 1997). Matthew found that students' retellings of stories were better when they worked with the CD-ROM. Others (e.g., Okolo & Hayes, 1996) have found that comprehension could possibly be hurt. Okolo and Hayes found that students spent a great deal of time clicking on animations, rather than focusing on the story.

There is virtually no research examining preschoolers' interactions with CD-ROM storybooks, even though many CD-ROM developers target preschoolers. Research on joint storybook reading suggests that there are several benefits to such activity (Bus et al., 1995). Children whose parents read with them are more advanced in language and pre-reading skills (Bus et al., 1995). Interventions that have targeted joint reading of books in children at-risk (e.g., Whitehurst & Arnold, 1994) have found that joint book reading improves reading and language readiness. We were interested in whether CD-ROM storybook reading had the same potential. Our goal was to study joint (parent-child) CD-ROM storybook reading, much like investigators have looked at joint reading of storybooks with preschoolers. We use examples from our investigation to ask what potential benefits there might be to preschoolers and parents jointly reading CD-ROM storybooks versus traditional print storybooks.

We report here on six four-year-old girls and their mothers as they worked together on two storybooks. The books were part of the Living Books Series produced by Random House/Broderbund. The Living Books were ideal to study since print versions of the stories accompany the CD-ROM versions. Hence the CD-ROM and written versions of the stories were comparable except for minor variations. The children and their parents varied widely in their computer knowledge. Three children had a computer in the home, and all of the children had used a computer. The children and parents were randomly assigned to read one of two stories on CD-ROM and one in a print version. The order of reading was counterbalanced. We examined, the children's comprehension, the time on the task, and examined differences in interaction.

We found that children and parents spent more time interacting with the CD-ROM than the book versions of the stories. However, the activities afforded by the CD-ROM did not seem to enhance comprehension or vocabulary. Children and parents simply did a great deal of clicking on each page of the CD-ROM to see the effects. For the most part, the effects were visual, unrelated to the story, and were done to for the "fun" of clicking. One child spent over an hour clicking on every single thing she could find on a page. The typical pattern of interaction involved the playing of the narration of the text on a page, and then, clicking on things until either the mother or child were ready to move the next page. Reading pages of the books involved the typical processes of book reading. The mother would read the page and sometimes elaborate on the story or vocabulary relating to the child's previous experience. Typically, the book reading took approximately 10 minutes, whereas the CD-ROM interaction lasted a minimum of 30 minutes.

Although based on a small sample, these findings raise some important issues about the role of CD-ROM storybooks in promoting emergent literacy. One element of the interactions with the CD-ROM's was the propensity for dyads to focus on clicking to see "effects". To the extent that clicking might introduce the child to new words, help facilitate comprehension of the story, or simply create a positive shared interaction with a parent, there would seem to be clear benefits to enhancing interest in stories and reading. Alternately, there were times that the clicking became the primary purpose of the interaction. While all of the four year olds in the study could correctly remember the story events, younger children who have not had much experience with storybook reading may comprehend less because of the change in task focus. Additionally, to the extent that clicking on something does not provide anything but a visual effect, the potential for learning vocabulary is limited. Two examples from one book used in this study, The *Tortoise and the Hare* (Random House/Broderbund, 1993), illustrate this issue. On page two of the book, clicking on various animals leads them to play musical instruments or sing. The animals are unrelated to the story, and unless a parent works on naming of the different animals, there is little in the way of vocabulary learning. For example, a parent might point to the squirrel and say "let's click on the squirrel". Their use of the word is facilitative of vocabulary, but because it is not really relevant to the story context, it might not be as well learned. There is nothing to anchor the squirrel to in the story. Additionally, the animals singing and dancing have the potential to distract children from the story and hurt their comprehension. Page six contains a more functional click with references to the Hare's different "moves" as he runs the race. The page lists and illustrates, with a click, the various ways of moving (e.g., skipping, sprinting, etc.). The clicking affords links to vocabulary that are related to the story and thus seems more facilitative of interactions that could increase vocabulary and comprehension. Hence, our analysis suggests both potentially positive and negative effects of using CD-ROM animated storybooks.

An additional issue concerning CD-ROM storybooks is their potential effects on the motivation to read among children. Do CD-ROM storybooks increase or decrease motivation to read? Children and parents working together on a CD-ROM version of a story seem to spend more time working together than when a parent reads a story. The children spend more time on task, and therefore, the parents have a greater opportunity to enhance literacy development. The special effects and animation provide a joint context that can facilitate parental mediation of language and literacy development. However, the presence of animation and special effects may make text versions of stories less interesting for some children. The only evidence we have for addressing this issue is our analysis of our own daughters' work with CD-ROM storybooks starting at about age three years and continuing to the present (they are now six years of age). While they request the CD-ROM books from time to time, they are far more interested in print text. Print text still, as many have pointed out, is far more convenient and portable. However, our children may be the exception rather than the rule in the sense that both of their parents are well educated and began reading storybooks to them very early in their development. Younger children and children whose parents have put less emphasis on storybook reading may differ in their motivation to work with CD-ROMs or print storybooks. Also, the sample included only girls and their mothers. Hence, there may be some gender differences to consider.

Overall, the data suggest that although CD-ROM story books can be used like print storybooks as a tool for developing language and literacy by parents, there are some differences in how CD-ROM's are used and some drawbacks to CD-ROM storybooks as they are presently designed. We would like to see more functionally designed storybooks that take include more functional "clicks" that are linked to the story rather than clicks that are simply distract and entertain.

Introduction

The University of Alberta (U of A) Faculty of Education has undertaken a restructuring process with the goal of better preparing teachers to effectively integrate technology into their teaching. This paper describes the authors' participation in one project which is a component of this renewal process: the development of a teacher education course offering an introduction to educational media and instructional technology. This course emphasizes a constructionist approach to problem-solving with multimedia tools.

Although it is still important to understand how technology can be used to assist in the development and presentation of instructional material, one can also think about how students in grades K-12 can use technology themselves to construct a learning environment. The idea is simple, children construct their own multimedia material and in doing so "learn by doing." The children become multimedia developers and in the process they gain both content and process knowledge. This approach is only made possible by the continuous development of more powerful microcomputers and easy to use tools for constructing multimedia software. For this approach to work, teachers themselves must be familiar with the current technology that can be used to create multimedia material. Furthermore, teachers must also know how to obtain and organize content material, and how to design and develop a multimedia application.

Course Design

This course has two streams, both of which run concurrently. One stream emphasizes a survey of the existing technologies that can be used to create multimedia material. This is the pragmatic side, i.e., getting your hands dirty. For example, students learn simple things like how to: (a) scan a picture into the computer, (b) record audio and video into the computer, (c) use graphic tools, (d) use Computer Mediated Communication (CMC) tools, including the course website (http://www.quasar.ualberta.ca/edpy485dev), and (e) use a multimedia authoring system (HyperStudio). As byproducts of learning these tools they discover their potential for the development and presentation of instructional material. The second stream involves the student teacher acting the part of a K-12 student, representing knowledge by developing a series of small, theme-based multimedia projects.

Theoretical Course Design Considerations

Two important theoretical considerations concerning the role of computer technology in teacher education greatly influenced the course design. The first of these is the importance of early technology learning. Logan (1995) postulates that there are five languages presently being used to communicate and process information: speech, writing, mathematics, science, and computing. In the course of history, each language evolved from its predecessors due to the need to address more complex information processing problems that were associated with economic and cultural advancement. Currently, the first four levels of language are integrated from early education onward. However, Logan argues that most students do not have the opportunity to learn the fifth level properly or early enough.

The second theoretical consideration was that computer-based tools and learning environments (e.g. databases, spreadsheets, semantic networks, computer conferencing, hypermedia construction, or microworld environments) can serve as cognitive tools or extensions of the mind. With the use of such "Mindtools" (Jonassen, 1996), learners can enter an intellectual partnership with the computer, in order to access and interpret information, and organize personal knowledge. This moves in a very different direction from traditional computer use in education. In the past, the emphasis was on computer literacy (learning <u>about</u> computers) and computer assisted instruction (learning <u>from</u> computers). The application of "Mindtools" involves students learning <u>with</u> computers (Jonassen, 1996).

Conclusions

Multimedia projects can improve educational outcomes by enabling students to represent information using several different media, to link and organize information in many meaningful ways, to draw knowledge and experiences from a wide variety of sources, to practice problem-solving and decision-making, to achieve high self-esteem and to become more self-directed. Such projects include a wide variety of activities and skills which groups can work on effectively over an extended timeframe. They involve a substantial amount of work, open-ended assignments, theme-based activities and interdisciplinary activities. Multimedia projects require and reward good planning and execution skills and students are motivated to create a quality product because a wider audience may view it (Agnew et al., 1996).

As student feedback indicates, the constructive, collaborative, student-centred nature of this course has proved to be a very engaging learning environment. Most pre-service and in-service teachers indicate that they feel more confident about integrating technology into their teaching after completing this course. Course observations have produced support for the use of information technology as a cognitive tool in today's classrooms. Applications such as hypermedia projects or CMC appear to have the potential to more powerfully impact student learning than traditional uses such as drill-and-practice. "Mindtools" elevate educational computing from addressing only simpler skills such as memorization into the realm of complex reasoning processes such as synthesis and evaluation. Hopefully this course furthers the "mindtools" cause by providing teachers with a glimpse of how information technology can contribute to the creation of engaging and relevant learning environments.

Introduction

The scope of the definition of educational technology has changed along with the development of advanced technology over the years. Many educational technology centers at universities were only used to serve as warehouses for distribution of audio and video media in the old times. With the diversity of today's computer technology, a modern educational technology center at a university setting can offer services to cover ED-MEDIA and even ED-TELECOM, in addition to its traditional roles. The purpose of this paper is to reexamine the dimension of educational technology for the mission a university technology center can carry.

New Role of a University Technology Center

The rapid progress of the use of technology in education has made major changes in the ways that students learn and teachers teach. To create an enriched learning and teaching environment to meet the challenges resulting from the development of the advanced educational technology, a university technology center can not serve solely as a distribution center for teaching-aid materials but need to extend its mission to provide the necessary organizational infrastructure, hardware and software support for the integration of technology across the curriculum and to offer pedagogical and instructional training for faculty and staff members to use new technology to enhance their teaching or daily operations (Georgia Southwestern State University, Technology Committee, 1998). Furthermore, the center must also assist faculty and staff in developing positive attitudes towards new technology, add new strategic visions for technology to the campus strategic plan, and provide consultation and active involvement to support the movement as an active participant in the global electronic community.

Decentralization of Instructional Technology

Modern instructional technology involves a great deal of communication infrastructure, computer hardware and peripherals, communication and application software, and presentation equipment. As a result, the complexity of providing efficient and effective services to faculty and staff members has dramatically increased and, therefore, approaches to establishing a foundation and to building a technology infrastructure must be carefully studied. There are basically two approaches: a centralized approach and a decentralized one. In a centralized environment, there is normally a single unit in the university that manages the operations and controls the access to the resources. This approach works well in a traditional setting since it does not require a great deal of diversified expertise to provide the service and the demand of flexibility is not high. In a rapidly changing high-tech field such as the current instructional technology, however, the diversity of expertise and the demand for flexibility in providing the service have made the centralized approach less efficient. Due to the complexity of the existing and forthcoming new technology, we feel that decentralization of the basic technology is vital to the success of the operation. To achieve this goal, basic instructional technology stations consisting of VCR's, TV's, monitors and projectors should be distributed and put directly in the hands of faculty and staff to make the use of the technology on campus flexible. This decentralization can also be applied to include computers and networking equipment to allow for easy access to outside world via the Internet.

Use of Satellite Technology, TV Broadcasting and Distance Learning Programs

Satellite technology has found several important applications, including television distribution, long-distance telephone transmission and private data networks. Currently, there are many national and state educational programs and live teleconferences broadcast via satellites. The Public Broadcasting Service (PBS), for example, provides many episodes for "Technology in the Classroom", "Next Steps in Technology", "GED Classroom", "Classroom Contact", and "Real Science", just to name a few. It is, therefore, very desirable to have downlink capability to receive those programs over the air to enrich educational resources, to assist teaching in the classroom, and to enhance faculty and staff development. On the other hand, maintaining and operating a TV station on campus offers the ability for a university to provide broadcasting services, including educational and entertaining programs downlinked from the satellite system, to not only the students, staff, and faculty on and off campus, but also the neighboring communities. It can also be used to train students with mass communication major to gain experience in the production, programming, video and audio editing, and broadcasting of TV programs.

Made feasible by the availability of video conferencing networks and the Internet technology, distance learning has several advantages over traditional classroom learning, such as flexibility, convenience, and adaptability. It is flexible because learners can take lessons at the time they feel most comfortable. It is convenient because taking lessons is, to a great extent , geography-independent. It is adaptable because learners can adjust their learning speed and path based on their progress. These advantages are especially apparent if the learning takes place on the Internet using the WWW technology. Although there are still arguments on the definition of distance learning, distance learning has already had a impact on the way instruction is designed and delivered and will continue to affect the filed in a significant way (Reiser, Ely, 1997). Accordingly, it has become essential for an instructional technology center to establish distance learning programs using both video conferencing networks and the Internet. This involves not just establishing distance learning classrooms for the students, staff, and faculty to use, but providing the capability and environment for faculty members to develop their course material for distance learning and to conduct online examinations, online survey, and online enrollment (Tu, Babione, and Chen, 1998) over the Internet.

Conclusions

Judging from the rapid progress in the computer hardware, software, and applications, in the communications networking technologies, and in the development of WWW, it is not difficult to envision that educational technology will continue to grow and, very likely, lead us to an even newer world in the future. If we are the practitioners in this field, what we need to do is to open our eyes for the new trends as long as it opens some avenue for teaching and learning. There is no need for us to limit ourselves to just what are available today.

The Influence of Multimedia Lesson Structure & Learning Styles on Prewriting Skills and Composition

Gayle V. Davidson-Shivers, Dept. of Behavioral Studies & Educational Technology, University of South Alabama, Mobile, Alabama, gdavidso@jaguar1.usouthal.edu

Introduction

Most of the recent research investigating the effects of multimedia on student writing has converged on the computer's capability to process text (Hartley, 1993). And, to date, much of this research has centered on the use of word processors to transpose text or on the use of style checker applications such as *Editor's Assistant* (Dale, 1990). Although new programs continue to be developed, development and use of multimedia or computer applications have not kept pace with emerging cognitive theories about composition as a goal-directed, problem-solving activity (Flowers & Hayes, 1981, 1977; Scardamalia & Bereiter, 1986).

Most of these modern composition theories encourage the use of some version of prewriting activities such as planning, translating, and reviewing. Often to aid the students with these prewriting activities, heuristics are incorporated into the instruction. These strategic exercises ask students to envision solving specific communication problems (Flower & Hayes, 1981). However, little research using multimedia for teaching prewriting skills as a heuristic can be found in the literature. Therefore, these researchers speculated whether teaching such heuristics via a multimedia environment would be successful and for which type of learner.

These learners vary according to learning styles, which can be an important variable in cognitive processes and perceptions and use of heuristics (Rasmussen & Davidson-Shivers, 1998; Davidson, 1990; Kolb, 1984). Kolb's four learning styles are based on active or reflective processes and concrete or abstract perceptions when learning. *Divergers* tend to use concrete conceptualization and are reflective processors; *Accommodators* rely on the concrete concepts, but are active processors; *Assimilators* rely on abstract concepts and are reflective processors; and *Convergers* also use abstractions, but are active processors of information. In addition, recent studies using various structures within multimedia environments for various learners have yielded mixed results (Rasmussen & Davidson-Shivers; Lin & Davidson, 1996; Kinzie & Berdel, 1990). Rasmussen and Davidson-Shivers reported a significant difference in the interaction of structure that allowed various learner control and learning styles on performance as did Lin and Davidson in their study on structure and cognitive styles. However, other studies have not.

Therefore, using a multimedia lesson on prewriting heuristics, the purpose of this study was to investigate learning styles and multimedia structure (random and hierarchical) on writing performance of undergraduates. Of primary interest, the researchers asked does either structure affect composition quality and do learning styles influence writing performance? As a secondary focus, the researchers collected data on student demographics, writing and computer skills, attitudes as well as time spent on the lesson.

Methods

Subjects

Forty-seven students in an undergraduate composition course at a regional university in the Southeast participated. There were equal numbers of males and females with the majority of them being freshmen.

Materials

The researchers designed a multimedia lesson on the prewriting heuristics of brainstorming and outlining for developing a written composition. This lesson was developed using Authorware and Windows-based computers. The content and instructional strategies were the same for both treatments. However, the lesson had two versions based on how the lesson was structured. The hierarchical structure (HS) allowed students to move through the lesson in a sequenced manner while the random structure (RS) allowed students to choose any parts of the lesson they wished to see and in any order. Both versions of the lesson allowed the individual to spend as much time on any given section as they desired. The multimedia program was designed to collect data on the amount of time each individual spent on the lesson and its subsections for both RS and HS treatment versions as well as to indicate the order of the path chosen by those in the RS treatment version.

Procedures

Prior to the study, students completed a demographic survey and an attitudinal questionnaire about their computer and writing skills. They also completed the Kolb's (1981, 1984) Learning Style Inventory. Students were then randomly assigned to one of the two treatment lessons. At the beginning of the lesson, the researcher read written directions stating that three in-class assignments would be given: brainstorming a list of ideas for a composition, outlining based on the brainstorming, and composing an essay. Students were able to work at their own pace using the multimedia lesson during the regularly scheduled class periods for one week, and were told their compositions would be due at the end of the last class period and would be graded.

Results

Researchers, having been trained on a rubric for grading quality in writing, critiqued and scored the compositions (with an interrater reliability of .70). Results of the study indicated no significant differences in performance between the two treatments; however, the RS group completed the lesson faster than the HS group without a qualitative difference in their compositions.

Although not statistically significant, there was a trend toward the Divergers writing better compositions than the other three styles. In comparison, Accommodators did less well on performance; furthermore, their attitudes about the lesson and the writing assignment were less positive than the other styles; again this finding did not reach statistical significance.

Discussion of Results

Although the results of the study were not as anticipated by the researchers, they may be of importance with regard to using multimedia for teaching heuristics about writing. First, even though type of structure did not achieve significant difference, the RS subjects completed the heuristics lesson faster than the other group. This may suggest that students who select their pathway through the lesson may complete it more quickly without the loss of writing quality. Additional research is needed to support these findings as well as investigate the relationship between prior writing experience and prewriting skills instruction. Additional research is also needed to verify whether learning styles influence writing performance and attitudes toward writing.

Introduction

Southern Cross University offers a Bachelor of Multimedia program to provide students with comprehensive study in the field of multimedia, taking advantage of specialisations within teaching units to consolidate the multi-disciplinary nature of interactive multimedia. On completion of the course, students would be expected to have (a) developed comprehensive skills and knowledge in the foundations of interactive multimedia, (b) demonstrated skills in the design and development of multimedia applications incorporating digital media; and (c) undertaken a major study in one area of the multimedia field. The locations http://edmm.scu.edu.au/ and http://multimedia.scu.edu.au identify the teaching and marketing web-sites of the multimedia program. There were several reasons for moving towards on-line delivery of multimedia content, including an increased focus on international delivery of courses, a large cohort of mature and part-time students, changing socio-economic conditions and an overall commitment towards more flexible delivery within the teaching unit, the School of Multimedia and Information Technology.

With the overall goal of being able to offer the full undergraduate multimedia program in a flexible mode of study from 2000, a phased program of preparation for on-line delivery was commenced during Semester 1, 1998. The initial phase of this process involved introducing the on-campus students to on-line access of materials by providing the majority of unit resources and teaching materials on the web, even though classes continued to be delivered in the traditional internal (face-to-face) mode. Additional preparation for the task of adopting an on-line strategy consisted of informal interviews with students to discuss the structure that would be most beneficial to their learning, assessment of other similar implementations, a review of similar teaching sites already implemented and a review of the overall strategy of the multimedia program.

Design

A structure for the site was designed to include a news area, unit statements, staff contact details, the teaching timetable and links to each unit being taught. For the individual units, information included a semester outline, links to web-based readings and library resources, lecture notes and weekly exercises, on-line tutorial material and assessment specifications. One of the design parameters was to restrict access to those students enrolled in the program. The two main options available were to restrict access by network address or by username and password; initially the username and password option was ignored because of the potential administration problem of maintaining password lists. However, after determining that students could conceivably wish to access the site from anywhere in the world, making network address restrictions impractical, the second option was chosen. Fortunately the web server being used (Novell Web Server 3.1) allowed the securing of web sites using existing IntraNetware account information, which has to date worked well in practice.

The design of the web pages themselves was driven by several main goals, chiefly the desire to make a site that was easy to navigate and pages that were fast to download over a modem. The wide range of client machines, operating systems and web browsers that could be used to view the site meant that the HTML code had to be simple and straightforward, avoiding browser-specific tags and scripting languages. Many of the conclusions of Nielsen relating to site navigation and page design were found to be very useful in achieving these goals (Nielsen & Sano, 1994; Nielsen, nd). The resulting site features minimal use of graphics, with techniques such as table background colours being used instead. Pages are identified with the name of the author, the date first published and the date of the most recent modification to indicate to students when material has changed. An hierarchical navigation system at the top of each page indicates where in the site structure the student is currently browsing, with links on the left-hand-side to the top of each significant area of the site. Links to pages that are within the current site structure are marked with blue arrows, while links to other web sites are marked with red arrows; links to non-electronic resources are marked in black.

Development and Assessment

Initial production of the site was implemented using a template-based publishing system (Userland Frontier), which enabled rapid development of the structure of the site. Because the overall look of the pages is governed by these templates, and the content of the pages is stored separately, changes to the whole site can be implemented quickly and easily. The original web site incorporated most of the features of the original design, the major omission being the news area. As electronic mailing lists were already heavily used within the multimedia program to communicate with students and disseminate news, it was decided not to create yet another place for news to be published, and instead to use the web site to archive postings to the mailing lists. The archival feature is to be incorporated into the next major revision of the site.

Initial assessment of student feedback to the site revealed overall positive results. In a rating scale from 0-5, all major factors were rated favourably, with the possible exception of the *On-Time* factor. This highlights one of the major issues confronting the development of web-sites in general and on-line learning sites in particular, that of regular and up-to-date maintenance. Once the student cohort becomes entrenched in using on-line materials, any delay in access is noted almost immediately!

Overall, the Multimedia On-Line site has been used as the primary information resource for most of the twenty units taught during the first and seconds semesters of 1998. While there were some difficulties in producing and publishing the information in a timely fashion, many of these were related to a lack of suitable writing tools for on-line publishing. The traditional software packages used for writing have many problems when they are used to write material intended for on-line delivery, but as this is an area of significant change, it is anticipated that such tools will mature over time.

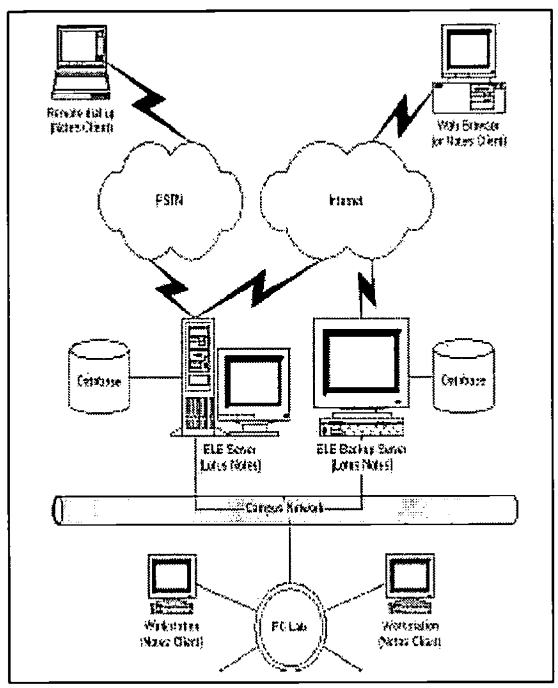
Abstract: This paper describes in detail how an IT-based course is designed and delivered using the latest information technology (IT) in Hong Kong. Based on Lotus Notes, an electronic learning environment called ELE is developed and used in an IT-based course as an alternative for delivering distance education. The ELE runs on both Windows and Macintosh, caters for communication, collaboration and course co-ordination purposes, and acts as a transportation vehicle for distributing course materials. Evaluations of the ELE are conducted throughout the course. Very encouraging results are obtained.

Introduction

The Open University of Hong Kong (OUHK), formerly the Open Learning Institute of Hong Kong (OLI), is the only distance learning university in Hong Kong. Currently, most OUHK courses are print-based. Communication between students and tutors is carried out through telephone and correspondence, and assignments are submitted and returned by mail. A number of initiatives along IT strategy in distance learning were started at the OUHK in the past years. This paper reports the first experience of online course teaching and learning in the OUHK.

The Aims of this Research

In 1997 an OUHK research project was initiated with the aim of designing, developing, delivering and evaluating an electronic delivery system for distance students in Hong Kong. It is expected that this system not only provides an alternative for the delivery of course material but also fosters a better environment of communication and collaboration between students, their tutors and their peers.



Research Methodology

An IT-based course is selected for pilot purposes. Students are first asked to opt for the '*electronic*' or '*print*' version of the course. Sixty (out of 120) students opted to take part in the pilot study and they are divided into two tutorial groups with 30 students each. During the course, they studied the course online and did not receive any printed materials. Three electronic questionnaires are sent to students on: (a) background and initial reaction to the electronic course delivery system, (b) usage characteristics and problems encountered, and (c) summative evaluation at the end of the course. Interviews are also conducted with a sample of students and tutors.

The IT-based Course

The course selected for the project is *B321 Advances in Information Technology*, which aims to develop students' knowledge and understanding of current and emerging IT, and their capability to identify, evaluate and apply these IT products to appropriate business situations. Topics include OA (Document Management and Groupware); DBMS; OO Visual Development Environments; Networking; Open Systems and C/S Computing; the Internet and Electronic Commerce; and Knowledge Work Support Systems.

The ELE Architecture

The electronic course delivery system developed (based on the Lotus Notes R4.5) for this project is called the Electronic Learning Environment (ELE). The server is a Pentium-based PC, featured with 64M RAM and 2GB hard-disk space (see the network infrastructure of the ELE). The backup server, also configured with Lotus Notes R4.5 and connected to the ELE server via a fast Ethernet, runs an agent program to replicate all the ELE databases every 30 minutes. In case of systems failure, the latest backup databases can be reloaded to recover the ELE server. The ELE has been further developed to allow Internet access with proper authentication. The ELE components include **Course Materials, Assignments, Discussion, Information, Evaluation**, and **Personal Folder**.

Major Findings

Student Background – of the 60 students, 46% are married. The majorities of the students have sub-degree qualifications, and are working in the technical (35%), administrative (18%), and business (18%) professions, with monthly salary of US$2,000 or above (68%). They have access to a desktop computer, with Pentium or higher processor running with MS Windows 95, more than 16 hours per week. All students are equipped with at least one telephone line at home and 30% of them have two. Overall, the students found the Lotus Notes and ELE installations easy and straightforward. Some minor problems were encountered initially but they were manageable.

Usage Characteristics and Problems Encountered – although the majority of students found it more effective to print out the course materials to study, a few students generally preferred to study on-screen. Interestingly, not many students posted but frequently read messages in the Discussion forum. The arrangement of the assignment submission electronically is frequently praised. Overall, students found the ELE system easy to use, and preferred ELE to the print-based mode.

Summative evaluation – the proportion of students who indicated that they enjoyed studying the course is 82% while another 18% of students indicated that they are neutral or of mixed option. The electronic course features that students liked most the electronic course are 'Email', 'Discussion forum', 'Electronic assignment submission', 'Search engine', and 'Advances in IT'. While the features that they liked least the electronic course are 'Computer dependence', 'On-screen study', and 'Printing course materials' respectively. There are 5 assignments and a final examination for this course. The electronic mode students performed as well as the printed mode students. In particular, they performed better in terms of the number of 'Pass 1' and 'Pass 3', and the overall passing rate in the course.

Discussion

The ELE offers better assignment submission process – it is validated that the ELE has helped a great deal in the assignment tracking, submission as well as the due date extension approval process. This shortens the assignment submission cycle from 2-3 weeks to a 1-2 hour.

The ELE acts as a transportation vehicle for distributing course materials – as an extension of the study materials, it provides learners with pointers (such as URLs), presentations, images, audio/video clips, animations, exercises/workshops, simulated laboratory environment, etc. which are almost impossible in traditional print-based materials. As an information delivery mechanism, it facilitates assessment, discussion, Q&A, etc. It has also enhanced offline communication on administrative and ad-hoc matters.

The ELE is used to enhance distance education – instead, the ELE should not be aimed at replacing the traditional print-based study materials in the sense that the current display technology and user interface do not seem to offer a better alternative to print-based study materials. Besides, the traditional mode of study is location-independent while an access to the computer (and occasionally the network) is required for the ELE. In addition, psychological barriers need to be overcome, as the ELE does not satisfy the sense of possession of the learned knowledge as everything exists in an intangible form.

Lotus Notes vs. WWW – Notes offers an '*offline*' communication. However, it is location-dependency as a user identification file (*user.id*) and the study materials, which are usually stored inside a predefined machine, are required. WWW which offers a '*real time online*' solution is also a good alternative platform. It is potentially more convenient as no set-up is required and students can access the ELE server from any location. According to our research, students are typically equipped with only one telephone line at home. They may need to resolve conflict regarding with other family members using the telephone line for a real time access.

The ELE training and supports are necessary – a tutor has to know more than the students on the use of the ELE as he or she is probably their first contact for problems. Training for tutors becomes mandatory. A well-organised technical support mechanism providing support at night time is critical as most problems occurred at night that is the peak time for students and tutors using the ELE system.

Conclusion

In general, we found that the objectives of the research project were achieved. An electronic course delivery system was designed, featured with six major components: Course Materials, Assignments, Discussion, Information, Evaluation and Personal Folder. An IT-based course was converted into Notes database document format and delivered to students electronically. Very encouraging results are obtained. Experiences gained in running the online course are useful in the subsequent offer of other electronic courses in the University.

The Intelligent Test Toolkit: Story/Concept Generator

Michael Yacci
Associate Professor
Information Technology
Rochester Institute of Technology, USA

Story/Concepts

A *story/concept* is a concept that involves a situation rather than an object. Many concepts in the social sciences involve more than the examination of a particular object--rather, they involve complex actions and events often involving human actors. These concepts are the basis of many social science principles. For example, the field of group dynamics uses the related concepts of *constructive conflict* and *destructive conflict* in the analysis of group interactions. In teaching story/concepts, many teachers will use "word problems" that explain a situation to a student and asks the student to classify the word problem.

Such a word problem might look like following:

> Bill and Jim are working on a project for the Chain Division of General Bicycle, Inc. Bill suggested that they use a titanium chain for the project, but Jim was against the idea. Their dialogue went like this:
>
> Bill: "I think the titanium will be more powerful--provide added strength."
>
> Jim: "No--a thousand times no! You have the worst ideas--always. Can't you think?"
>
> Is this an example of *constructive* or *destructive* conflict? Why?

Story/concept examples are time consuming to create; consequently a teacher may provide only limited examples. For some students, a few examples may be sufficient, but others may need additional practice in classifying the concept. Therefore, a tool that could help teachers create a large number of story/concepts, quickly, would be useful.

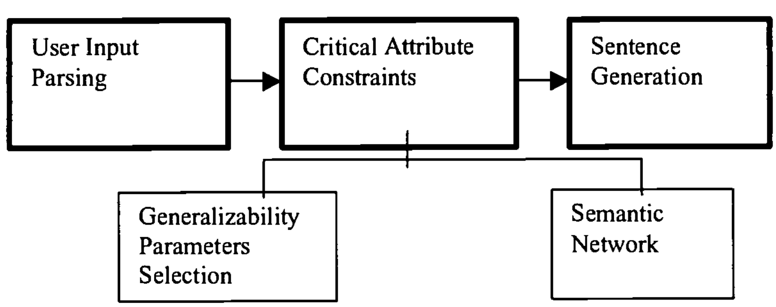


Figure 1. Components of the Story/Concept Generator

The Intelligent Test Toolkit Story/Concept Generator

The Intelligent Test Toolkit Story/Concept Generator (SCG) is a natural language text generation tool, designed to take a single story/concept example and to generate many parallel story/concept examples. Specifically, it (a) accepts user input, in the form of a paragraph, (b) prompts the user for the critical attributes of the story/concept and the degree of generalization and (c) creates as many parallel story/concept examples as possible, given its current knowledge base. These activities coordinate with three general components in the SCG as shown in Figure 1. There are four screens within the SCG that represent the functions described above.

1. Parser Screen for User Input

The user enters information into a Parser Screen that allows for free-text input. When the user has finished entering the story/concept example, the story is parsed in several different ways. First, the parser is seeks the verb in each sentence and also all *content words*. Harris (1985, pg 322) describes content words as nouns, verbs, adjectives, and adverbs. Verbs are used to recognize the *conceptual primitive* (see Schank & Abelson 1977) involved in the sentence. Each primitive in the story is added to a *discourse structure* list, that keeps track of the order of the sentences.

2. Generalizabilty Parameter Screen

The Genralizability Parameter Screen (GPS) is the first of two areas that are used to limit and understand the degree of generalizability of the story/concept. The GPS lists each content term in the story/concept. It then prompts the user to answer questions about the desired degree of generalization of each term.

All knowledge for the SCG is contained in a knowledge base using a semantic network representation. The knowledge base is initially searched for hierarchical data (links labeled "a-kind-of"). Because terms may be members of several categories (a car is a kind of vehicle, is also a kind of gift, and is also a kind of status symbol), users must clarify the "tangled" induction (Holland, Holyoak, Nisbett, & Thagard 1986).

3. Semantic Network Screen

Certain key elements in the story/concept have relationships that must be preserved while the hierarchical inference occurs. These relationships are then used throughout the new story/concept example. A semantic network tool allows users to create an ad hoc semantic net of the relationships that must be preserved as new story/concept examples are created. A search and match function attempts to find parallel structures in the knowledge base.

4. Sentence Generator Output Screen

The Sentence Generator screen uses the decisions that were made on previous screens to re-construct a series of parallel story/concept examples. The number of possible parallel story/concepts is limited to the data stored in the knowledge base. Ideas relating to discourse structure are relatively unexplored in this tool. It would be interesting to explore an "understanding component" to the SCG that could attempt to "understand" the story's goals with a richer internal representation. This could lead the system to create alternative discourse structures to convey that information.

Introduction

Currently many approaches are suggested to achieve CAI in a networked environment such as the Internet. They all try to enhance and make more efficient the physical components of the learning environment on campus by creating a digital infrastructure that has come to be known as the virtual university. UNU in collaboration with IIS has launched the "Virtual University" project to jointly develop new technologies for instructors/students on the Internet. In this paper, we focus on a sub-component of the project that attempts to provide support for the full cycle of organizing and developing education on the Internet, from registration to curricular development, and from learning to student evaluation.

The problems found in the past

Even though CAI software is fabricated very well these days, not all of them are based on the goal of improving the quality of the education nor on the methodologies specially studied for CAI software. Besides problems of quality, not all instructors are happy to use the software due to two reasons. One is a problem of teaching style and the other is a course material problem. CAI software does not always fit the instructors' needs nor his/her style of teaching. Usually the software is produced based on the teaching methods of one particular instructor. It works very well only when either the instructor is a programmer or the instructor has his/her own programmer to modify/update the program for his/her needs. This scenario rarely happens in the real world. Some software developers try to offer authoring tools to cope with this problem. However, most instructors do not have enough time to learn how to use the tools, and then collect or create multimedia contents. It is not cost-effective even for skillful instructors to create multimedia data by themselves, and multimedia data sources on CD-ROMs are limited in quantity. These are the reasons why CAI software is not becoming very popular among instructors.

Here, we have a proposal that leads to the solution of the problem above. The Internet is a treasure box of multimedia data sources. If we have an effective tool to find course materials in an intelligent manner, one of the problems is solved. If we expect the software to be a tool to help instructors teach rather than a substitution for conventional textbooks, we can see the solution for another problem. This is the role of SmartSearch in the Virtual University project.

CAI with SmartSearch

SmartSearch is a web-based search engine classified as "Meta-Search Engine." The well-known example of Meta-Search Engine is the Internet search feature of "Sherlock" of MacOS 8.5. The web-based example is "Metacrawler" which works very well. Meta-Search Engine is an intelligent state-of-the-art search engine (SE). Conventional SEs, web-directory service SEs and robot-driven SEs, have a lot of problems due to their structure. The main point is the relevancy of the result with users' input. The Meta-Search Engine focuses on the improvement of this relevancy rate, and uses these conventional SEs by sending queries to them in the background. This system eliminates the costs of building up a new SE while achieving a higher relevancy rate with less waiting time. The effective ranking/re-ordering techniques of the results are studied in Meta-Search Engines. The main point is the *relevancy of the output* and not the *size of the main database*. Therefore, the key to "Meta-Search Engine" is "re-ordering."

Our SmartSearch claims to perform better than these examples by featuring weight adjustment techniques. The following are the factors we count to retrieve relevant data:

- The number of keywords appearing in the title
- The number of keywords appearing in the main text
- The number of keywords appearing in the URL
- The relevancy information returned from conventional search engines
- The number of URLs which share the same web-server
- Whether or not the keywords are jargon which can specify the area the user is looking for
- The type of search engine which returned the link
- The host type (e.g. edu, com, net, etc.)
- The length of the URL

After SmartSearch retrieves the actual HTML from the site, it will calculate the relevancy score for each link. Ordered by this score, the new list of relevant links is shown to the users. This system works very well with ordinary keywords, and we are enhancing its features especially for CAI use of handling multimedia data.

As we proposed, SmartSearch will be able to solve one of the big problems of current CAI software. Instructors will have fewer troubles using CAI software and finding digitized data, as we all hoped for in the past. This idea can be applied in two ways. One of them is to prepare course materials: a sub-component for conventional CAI software is to help the instructor produce his/her own digital textbook. Another is to help instructors actually teach in class: SmartSearch can be used online as a dictionary or as an encyclopedia which has accumulated knowledge of everyone in the world. Also, students can take advantage of this system. In the past CAI software, all system components including the authoring tools are for instructors who are supposed to be the only people who create materials. Although the conventional hardcover textbooks are made by educators, the students of the next generation can edit their own references. This tool is also useful for students to find relevant information for self-studying.

Conclusion & Future Work

Again, collecting/building up course materials is not a simple task. If we want to automate this task, we need something intelligent. We can use SmartSearch to gather information in order to skip first stage. The collected data at the first stage may need modification for teaching use, but should help instructors considerably. The Digital Library of UNU, where the digital information of the world will be served by SmartSearch, will greatly facilitate inquiry-based learning. For digital libraries to be useful, SmartSearch will allow users to access quality information more efficiently, and to make such information easier to search for.

Increasingly many universities around the world are taking advantage of the wide accessibility of the Internet to deliver educational contents online. Mobile computing, building upon the global connectivity of the Internet, adds a new dimension to the learning process. In particular, it gives users the illusion that their computer-mediated learning environments are ubiquitous. Users can continue their learning applications irrespective of the users' physical location and the computer being used for the task at anytime, right down to the last mouse-click as when last accessed. Under this model, data and/or applications follow users wherever they go. However, the past approaches of virtual classroom, library, and laboratory do not take into account the mobility of the learner in most cases. In our Virtual University project, this ubiquitous learning environment is an important element.
SmartSearch will be enhanced by the feature for distant-learning. Wherever the user is, the software will download the last state of the search and user's interests/preferences.

Evaluating a Simple Realization of Combining Audio and Textual Data in Educational Material.

Making Sense of Nonsense

Robert Grimm
grimm@uni-paderborn.de

Markus Hoff-Holtmanns
frs@uni-paderborn.de
Computer Science and Society
Paderborn University
Germany

Introduction

In our workgroup of "Computer Science and Society" at the University of Paderborn lectures are usually presented with Powerpoint slides. Afterwards these slides are made available to the students of this lecture within our local Hyperwave-Server and Teaching Environment (Engbring, Schwolle 1997). The content of these presentations is highly condensed and the students are advised to make their own notes and comments during the lessons. Experience showed that most students lack the key qualification to follow the different branches of argumentation given by the professor and to write down their own notes, deciding online what makes sense and what is nonsense.

As we saw the problems of the students with grasping intention and contents of the lectures, we had to find a way to give them a second opportunity to understand the lecture and to support the learning process. This required a more differentiated form of course material. We decided to record the whole lecture, audio, video and slides, and to make it accessible for the students. We thought it useful for understanding the intention of a lesson to *"re-listen"* to the spoken word of the lecturer. But in our opinion it was not necessary to view the video because it is not very expressive in itself. The experience of "Authoring on the Fly" (Bacher, Ottmann 1996) showed that video did not improve the learning process, so we decided to use only audio. For fast access the audio-streams had to be compressed and linked to the slides of the original course material. So any student not quite understanding the contents of one slide could download the original spoken lecture by internet and replay it at home or at a workplace at the university.

We were convinced that this was useful because our professor gives the students many different examples during one lesson for better understanding. This approach to expand the amount of information available on a lecture had an advantage to writing down long text passages, because the recording of audio is done on the fly. The only work was to cut it up in usable pieces and connect these semantically as well as physically to the existing slides. Here it seemed reasonable to use short pieces of maximum 10 minutes for better motivation and precise navigation.

Development of an Effective Technical Realization

The actual recording of the lectures was done by using readily available tools. We used a standard 8mm Camcorder with an external microphone. For archiving purposes, we first transferred the recordings to VHS videotape. Afterwards the audio of the recordings was digitized by an audio connection to a standard sound device of a PC. After several revisions it proved to be most efficient to permanently install all the needed equipment in one transportable compartment. This way the recording, archiving and digitizing was all done "on the fly" during the lecture in one go. The resulting audio-files still had to be remastered. First it was necessary to erase the rather high noise level from the audio files. The students present at the lectures were not totally silent and noises like air conditioning and chairs and the like were not to be dismissed. After that the volume level had to be adjusted, because we could not place the microphone directly in front of the lecturer. And lastly we had to reduce the files in size. One hour of lecture resulted in about 160 MB of data. After some considerations about availability, reduction factor and performance we decided to use MPEG I Layer 3 (MP3), which allowed for data compression of about 1:14 (which left us with about 20 MB for one 90 minute lecture including slides and compressed audio). That way the audio files became possible to handle by internet. All this development was done during the course "Computer Science and Society".

Evaluation

After finding an easy way to record a lecture and producing the improved course materials, two different approaches to use these were developed. One was to apply the course materials to a distance learning course at Potsdam University. The other was to use the recording technique to accompany a second lecture course, "Softwareergonomie" at Paderborn University.

For the distance learning course at Potsdam University we used the audio files in addition to the lecture slides. The contents of the course where identical to those of the on campus course "Computer Science and Society", just that the attendants had to retrieve all their material by internet. Because of the big quantity of audio files we selected only parts of them which still amounted to about 150 MB. This may be the reason why an evaluation (Hoff-Holtmanns 1999) showed that from the 36 students only 30% where able to download and use the audio-files. Of these 72% made effective use of about half of the recordings. The other 28% actively used more than 60% of the recordings. This allows the conclusion that given an easier opportunity to access the files needed, most students would make use of them and a satisfying number would use them to support their learning process. One solution for this would be the production and distribution of a CD-ROM for the students with all the course material beforehand.

To evaluate the use of the audio annotations in the lecture "Softwareergonomie" we chose to interview the students after their colloquium. Unfortunately on writing this paper the evaluation still is in progress. For more information see (Grimm 1999). Nevertheless we have first results:

- The majority of the students used the CD we produced after the semester. Nobody listened to an annotation during the course period.
- To improve the usability we need to cut the lectures into smaller pieces than our maximum of 10 minutes and increase the audio quality.
- It seems the annotations are of great interest in the preparation for the exams.
- The students reviewed most of the slides, but they only listened to a small part of the audio annotations, mostly those in connection with graphics, diagrams and summaries.

Prospect

Despite the problems we had to face and will encounter in the future, this approach of enhancing course materials by audio recordings of the lecturer is promising. The process of creating these materials is easy and readily transferable to other courses and different lecture situations. It remains to be seen if the experiences described above are correlated to the form, content, and niveau of the lecture, the lecturer herself, or if they are specific to learning with audio annotations. Therefor we intend to record lectures in other disciplines such as e.g. business management.

Future work will also concern enhancements in quality and size of the materials as well as further functionality. This being especially solutions to questions like what about links *"inside"* the audio-files, or links and references from within documents to just parts of an audio annotation.

Video Conference and Distance Learning Scheduling System on WEB

Qinghui (Gretchen) Guo
Northwestern University
2129 North Campus Drive
Evanston IL 60091 USA
Gretchen-guo@nwu.edu

Using the advanced WEB and the Oracle Database technology, I created an interactive videoconference and distance learning management system. This system has been used for 3 years, and has saved a lot time and trouble for both the users and administrators of the videoconference rooms.

Powerful Features

1. Provides searchable and automatically updated Video Conference Schedule on the WEB

A user can view the up-to-date schedule on the WEB, and can search the schedule by date and by the conference organizer's name.

2. Enables users to make video conferencing reservations on the WEB

A user can send a request to reserve the video conference facility by filling out a form on the WEB. The inputted data will automatically be put into a database and a copy provided to the videoconference room administrator via e-mail. Remote site technical information is also inputted this way.

3. Generates Video Conference Room Usage Report

An additional feature generates useful reports to answer the questions such as who had videoconferences, how many times, and with what sites the conferences were held. This feature also provides information such as how many were classes, administrative meetings, or training workshops. It can provide reports on all the videoconferences or for a specified time period. For example, it can answer a question such as how many training workshops have been held from September 1 till December 31, 1998.

4. Complies the form of "Request for Off-NSHEC Network Calling Assistance"

To do an "off-net" videoconference, we need to send a special request form to a company called Tendberg. In the request form, we need to provide both the technical and contact information related to our sites and to the site with which we will hold the conference. The system can compile such forms automatically by pulling data from local user input and from the remote site administrator's input.

An Inside Look

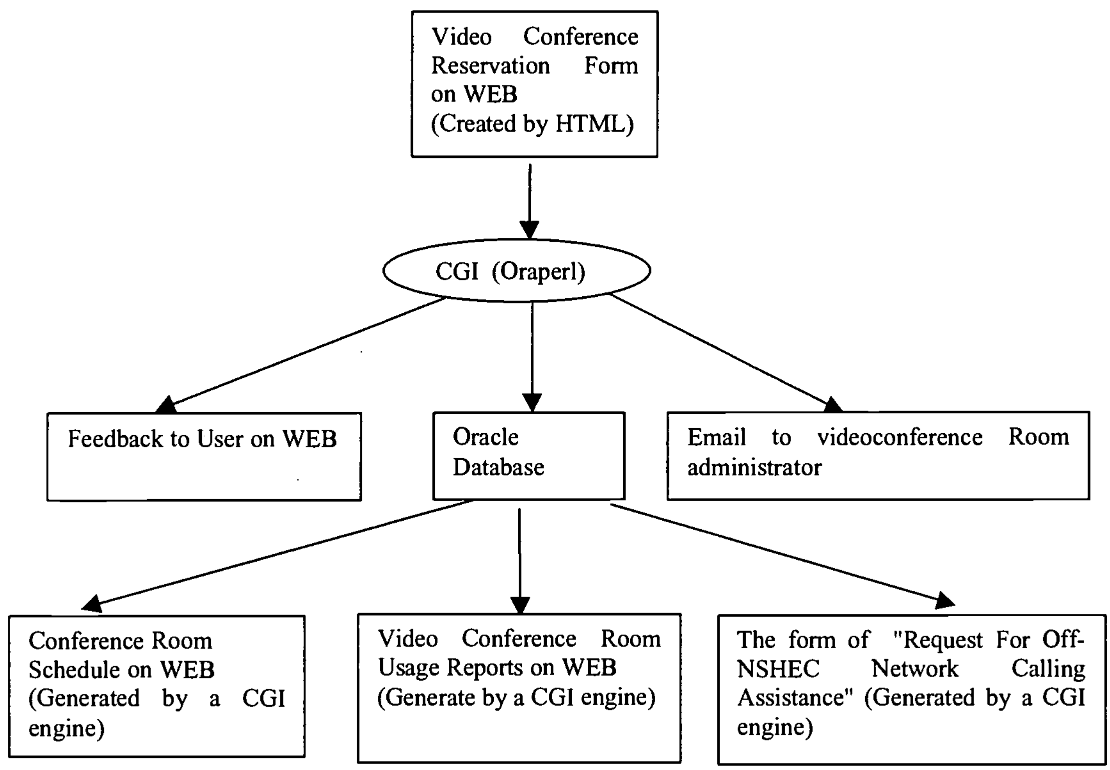
The system was created using WWW, CGI, and Oracle database technology. A user first looks at the videoconference schedule on the web to see if the time they want is available. Then, the user inputs the data about a conference (such as when, where, purpose, and contact person's name, email and phone) by using a reservation form on the WEB. After the web form receives the data, it automatically forwards the data to a

CGI engine. This CGI engine then does three things with the data: 1) generates a web page that sends confirmation and gives further instructions to the user, 2) generates email to send data to the videoconference room administrator, 3) puts the data into an Oracle database. (See attached diagram below)

When the users click on the link to the videoconference schedule on the web, the system sends a request to a CGI engine. This engine pulls the data from the database accordingly, and generates the schedule for the user. In this way, the schedule presented to the users is always up-to-date and tailored toward users' specific interest (See attached diagram).

To generate videoconference room usage reports, an administrator clicks corresponding buttons on the web, which sends a request to the CGI engine. This engine summarizes the data from the database and shows the results on the WEB. In a similar way, the system generates the form of "Request for Off-NSHEC Network

Diagram



"I Made You Look, You Dirty Crook, You Stole Your Mother's Pocketbook!" How To Surprise Your Students With the Opportunity To Learn.

Alfred Benney
Fairfield University
Fairfield CT 06430-5195
Benney@fair1.fairfield.edu

Introduction

Remember when you were a kid how the above taunt reflected youthful humor when you caught someone by surprise? Remember when you took great delight in such antics as "Your shoe's untied!" "Ha, ha, I made you look! April fool!" Or how with two or three of your friends you stood somewhere in public all gazing up at some imaginary thing-in-the-sky and laughed like crazy when passers-by would stop and try to see what you were looking at? Imagine my surprise after many years in the classroom suddenly to arrive at the conclusion that teaching is a lot like that! And to realize that with all its complexity, the real trick to teaching is getting students to really look at something.

My beginning point is the realization that in order to learn, a person must perceive the data as something new -- really to have a new "perception of." Humans tend to see what they expect to see and just looking is in itself boring -- unless we are surprised by what we see! Moreover, our system of education seems to foster the notion that study is boring because it creates the assumption that we won't be surprised. In some way we seem to have mistakenly defined classroom orderliness as quiet inactivity and classroom attentiveness to be a sort of dopey reticence.

The Problem

In an effort to "bring education into the twenty-first century," many educators have adopted without question the assumptions of industry managers who are not themselves educators.

> Walk the aisles of any training trade show and you'd think high-tech America had finally found the magic bullet that would solve the nation's educational crisis. If you can cram a course down an electronic pipe, and deliver it to the desktops of your employees, . . . well, that must be great teaching, right?
>
> Wrong. Corporate America has finally awakened to the need to teach employees how to do not just today's jobs, but the ones they'll inevitably wind up with tomorrow. Demand creates supply – bringing multimedia curricula out of the proverbial woodwork. But do these training programs teach? Today, most don't. And they won't, without sound instructional design – design that engages the student, simulates complex problems, helps her practice, guides her to learn through failure, and – depending upon your point of [1]

If we look upon applications of technology in education as oriented towards "a learning 'with'" model[2], and if we can use this "learning 'with'" model to interrupt student expectations about learning; and if this "interruption" gets their attention so that they really look at the data, the possibility of turning information into knowledge becomes significantly more real.

[1] Fryer, Bronwyn, "Powerhouses of Design," *Inside Technology Training*, April, 1998, p.25.
[2] Reeves, Thomas C., Answering Critics of Media and Technology in Education, *Proceedings of ED-MEDIA/ED-TELECOM 98* (Freiburg, Germany, June 20-25, 1998) pp. 1182-1183.

> Without [effective instructional design] . . . , the most sophisticated "training" in the world is simply information. And information, as M. David Merrill says, "is not instruction." And that's true whether you're sending a program down an electronic pipe or presenting it at the front of a classroom.[3]

The *Status Quo?*

If we define "culture" as simply "the way we do things around here,"[5] the objective would be to use multimedia presentations to interrupt the "business-as-usual" culture of today's student thereby facilitating their involvement in classroom rituals engaging them in the process of education rather than the task of gathering information.

> "It is not multimedia resources that make a difference in training, it is how they are used." Media is merely a way of representing subject matter content. Merely having multimedia objects included does not determine instructional effectiveness. If the media objects are relevant to the instruction, if they facilitate in implementing effective instructional strategies, then the effect is efficient, effective and appealing instruction. If, on the other hand, the media objects are merely decorative and serve no instructional purpose, then they may in fact interfere with, rather than facilitate, learning.[4]

Using technology to manipulate the "rituals" of the classroom could challenge the way students perceive their roles in the classroom and change the understanding they have about learning. Along with this new curiosity, students would discover that they have the ability to change information into knowledge – and can do so with greater flexibility, more efficiency and less pain!

The Strategies

This paper presents examples of nine strategic uses of technology that are effective in teaching an introductory course in Religious Studies. By using varied combinations of these strategies, student expectations about classroom performance are "interrupted" in such a way that the subject matter of each class session is perceived as in some way new. These strategies would be useful in any Humanities class and constitute what I would call "appropriate use of technology." They are (in no particular order):

1) Visuals and animations used to present a graphic definition of the problem or problems, which are the focus of each particular class.
2) A "language resource pool" – a database of questions and/or definitions of terms and complex ideas which are easily accessible in class to stimulate conversation.
Computer programming that maps the interrelationship of ideas and/or that connects layers of thought or information. Part of the problem with humanities courses is that it is often necessary to explain complex experiential events and to connect them with facts or hard data.
4) Animated presentations used to illustrate the development of a logical argument or an historical outline.
5) Interactive programming that challenges student assumptions; this strategy makes student responses public so that they can be perceived as being part of the problem.
6) "What ifs" -- show various hypotheses to stimulate debate about the value of different solutions to a problem – "there are no answers to questions, just hypotheses that suggest solutions to problems that need to be defined."
7) The display of obvious bits of data in ways (relationships) that may not be obvious (lateral thinking) – seeing the obvious juxtaposed in creative ways can create new questions.
8) Digital Video used to create conflict by having a teacher talk with a virtual self or argue a case with another.
9) Digital Video presenting short clips of "experts"/and or scholars commenting on a question or problem and used to illustrate different/contradictory points of view.

Distance Learners use of the Internet and Academic Libraries: Supplement or Replacement?

John Barnard
Library Instruction, Systems and Technology
Arizona State University
johnb@asu.edu

During the 1990's the Internet has evolved from primarily an electronic mail system for academics and the military to become the avenue of access for millions of databases worldwide. Web access to massive amounts of information once available only in libraries has impacted library use by adult learners. One sub-group of adults students. distance learners, have long been an underserved academic library population and have the potential to benefit greatly from the resources now available to anyone with web access. The proliferation of learning resources is now making it possible for many students be come at least partial distance learners with some classes and resources being accessed through alternative communications media. These changes are evidenced in the fact that the term "distance learning" is now often replaced with "distributed learning"

In 1998, in an attempt to gain some insight into these changes, I developed a survey that was sent out by the Library, Instruction, Systems and Technology department at Arizona State University. Surveys were sent to 800 students registered through ASU's College of Extended Education. These students had all registered to take classes via television, correspondence, CD-ROM, the Internet or at remote sites. One hundred thirty nine surveys were returned.

My goal was threefold: gather demographic information to tell us who these distance learners are; find out what library services they use and need; and learn how they use the Internet for their information needs.

The median age of the respondents was 32 with an age range extending from 18 to 53. Fifty-six percent were undergraduate and 66% were female. Fifty-two percent were fully employed, while 33% worked part time and 15%were not employed.

A wide variety of majors were represented with the largest group coming from Education with 30%, followed by Public Programs (17%), Social Work (15%), Business (11%), Engineering (10%) and Liberal Arts (9%). Five percent declared no major and Architecture, Fine Arts & Nursing were each represented by 1% of the respondents.

The respondents lived an average of 39 miles from an academic library and 10 miles from a public library. Eighty-five percent of them have Internet access, with 74% of them using e-mail and 67% having used online searches for course related information. In the area of library services 65% have used library web pages, 22% have used interlibrary loan and 14% have used document delivery services

The Internet has become the first information source of choice for 32% of the respondents followed by Academic Libraries (25%), Friend, Spouse, Colleague (16%), Public Library (13%) and Home Reference Books (8%).

While the Internet has become a significant resource for most these adult learners, with 81% agreeing that it is an important source of information to them, libraries are obviously still critical to them with 87% agreeing on there need for library services.

Sixty-seven percent agree that a 1 to 2 hour class on Internet search techniques would be valuable to them. Indicating that, although the vast majority of them use the Internet to some extent, most of them also feel they need to learn more about using it for information.

After the survey, interviews were conducted with 31 local community college students. This group was selected for three reasons: they were generally younger than the surveyed group; they had less need for scholarly information sources; and they were potential ASU students. A few rarely used the Internet but most of them felt that it was the easiest way to find the information that they were looking for. One quote from these interviews is typical of the viewpoint of many of these younger students:

> *I used to always go to the library to look up things in the encyclopedias but now, on-line service is too convenient. I stay at home and use the library. I can access any of the periodicals I want, just about and magazines—I can find back-issues I want on-line. The Internet has pretty much eliminated my library use.*

Conclusion

Searching the Internet has become the first means of finding new information for nearly one third of the adult learners in this survey, ahead of both academic and public libraries. The students still express a strong need for libraries. It is becoming clear that, with more and more information inundating students, the Internet, at least at this point, is mostly a supplement to libraries and not a replacement for them. Younger students with simpler academic needs, however, are often using the Internet as a library replacement.

The importance of resources available through most academic library web sites is the value added to the information by the librarians: the fact that the electronic resources have been selected specifically for academia and are reliable and appropriate sources of information for students. Anyone who has spent any time searching for information on the Web is well aware of the massive amount of information available and also just as aware how unreliable much of it is. Libraries can, any many are, providing network gateways to appropriate academic information resources, including links to many full text journal and news sources, that guide students to the material they need from either a library workstation or a personal computer at home.

The words of one librarian I interviewed illustrate the impact that the Internet has had on academic library use and the raised expectations it has created:

> *They (students) tend to think everything is on the Internet. They tend to think that everything is available the way they want it. They tend to think everything is cost-free... You will find that a lot of times people will come up to the reference desk and the first thing they will say to us is 'I looked on the Internet' and we are not sure they actually did, we are not sure they know what the Internet is, actually. They tend to want that more and more.*
>
> *There is a lot of information out there and it's a lot easier to get to and I think it's more confusing because there is so much -- it's like this overload of information and an overload of ways to find it. We're witnessing that just being at the reference desk with hundreds of databases and the scores of ways of looking for things....Some students are expecting instantaneous packaged information, quickly. They expect that they are going to be able to find this quickly without any problems, so they won't have to stay in the library, or they won't even have to come to the library."*

HYPERMEDIA AND STUDENTS' ACHIEVEMENT: A META-ANALYSIS

Yuen-kuang Cliff Liao
Department of Elementary Education
National Hsinchu Teachers College, Taiwan, Taiwan
Yliao@cc.nhctc.edu.tw

In spite of claims regarding the potential benefits of using hypermedia in education, and the controversial issues about the relationship between media and learning, research results comparing the effects of hypermedia and non-hypermedia instruction are conflicting. For example, Bain, Houghton, Sah, & Carroll (1992), Barnes (1994), Chen (1993), Delclos, & Hartman (1993), Gretes, & Green (1994), and Toro (1995) all report significant gains for hypermedia over non-hypermedia instruction. On the other side, Azevedo, Shaw, & Bret (1995), Barker (1988), D'lessandro, Galvin, Erkonen, Albanese, Michaelsen, Huntley, and Tabar (1991) have found no significant differences between hypermedia and non-hypermedia instruction. Yet, owing to the contradictory evidence provided by existing research in the area, it is important to conduct a meta-analysis to clarify the research conclusions. The results of this meta-analysis may also shed light on the debatable issue regarding the relationship between media and learning.

PROCEDURES

The research method used in this study is the meta-analytic approach which was similar to that described by Glass, McGaw, & Smith (1981). The studies considered for use in this meta-analysis came from three major sources and were published from 1986 to 1998. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of studies was retrieved by branching from bibliographies in the documents located through review and computer searches. Forty-seven studies were located through these search procedures; 14 studies came from ERIC, 26 studies were retrieved from published journals, and 7 studies were from Comprehensive Dissertation Abstracts. However, one study reported by Liu, & Reed (1995) had an Effect Size (ES) several times higher than mean ES of other studies included in the synthesis (i.e., ES = 6.54 for Liu, & Reed's study). The study was therefore considered as outlier and excluded from this meta-analysis.

Several criteria were established for inclusion of studies in the present analysis.

1. Studies had to compare the effects of hypermedia (HI) vs. non-hypermedia instruction (NHI) on student's achievement.
2. Studies had to take place in actual educational settings. There was no restriction on grade level.
3. Studies had to provide quantitative results from both hypermedia and traditional classes.
4. Studies had to be retrievable from university or college libraries by interlibrary loan or from ERIC, Dissertation Abstracts International, or University Microfiche International.
5. Studies were published between 1986 and 1998.

Outcome Measures

The instructional outcome measured most often in the 46 studies was student learning, as indicated on standard or researcher-develop achievement tests at the end of the program of instruction. For statistical analysis, outcomes from a variety of different studies with a variety of different instruments had to be expressed on a common scale. The transformation used for this purpose was the one recommended by Glass et al. (1981) and modified by others (e.g., Hunter, Schmidt, and Jackson, 1982). To reduce measurements to a common scale, each outcome was coded as an Effect Size (ES), defined as the difference between the mean scores of two groups divided by the pooled standard deviation of two groups. For those studies that did not report means and standard deviations, F values, t values, or proportion values were used to estimate the ES.

Variables Studied

Sixteen variables (type of publication, year of publication , subject area, grade level , sample size, instructor bias, instrumentation, reliability of measure, statistical power, statistics, type of research design, type of delivery system, comparison group, type of instruction for treatment, implementation of innovation, duration of treatment were coded for each study in the present synthesis. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there were significant differences within each variable on the ES.

RESULTS

Of the 46 studies included in the present synthesis, 28 (61%)of the study-weighted ESs were positive and favored the HI group, while 17 (37%) of them were negative and favored the NHI group. Only 1 (2%) of them showed no difference between HI and NHI groups. The range of the study-weighted ESs was from -0.91 to 3.13. The overall grand mean for all 46 study-weighted ESs was 0.41. When this mean ES was converted to percentiles, the percentiles on students' achievement were 66 for the HI group and 50 for the NHI group. The overall grand median for all 46 study-weighted ESs was 0.15, suggesting that percentiles on students' achievement were 56 for the HI group and 50 for the TI group. The standard deviation of 0.87 reflects the great variability of ESs across studies.

For ANOVA, four variables, instrumentation, type of research design, type of delivery system, and comparison group showed statistically significant impact. For each of these variables, a post hoc (Fisher Protected LSD) test was performed.

The post hoc test for instrumentation, ($F(2,43) = 3.241$, $P<.05$), showed that the mean comparison of studies in which the instrumentation was coded as unspecified was higher than the studies employed local or standardized instruments. There were no significant differences found between the mean comparison of studies using local instruments and standardized instruments.

The post hoc test for type of research design, ($F(3,42) = 6.998$, $p<.001$), showed that the mean comparison of studies coded as one group repeated measure was significantly higher than studies coded as pretest-posttest control group, nonequivalent control group, or posttest-only control group designs. There were no significant differences found among the mean comparison of studies coded as pretest-posttest control group, nonequivalent control group, and posttest-only control group designs.

For type of delivery system, ($F(2, 43) = 3.951$, $p<.05$), the post hoc test showed that the mean comparison of studies in which simulators were employed was significantly higher than studies in which interactive multimedia were employed as delivery systems. There were no significant differences found between the mean comparison of studies in which computer-based interactive videodisc and interactive multimedia were used. In addition, no significant differences were found between the mean comparison of studies in which simulators and computer-based interactive videodisc were employed.

Finally, the post hoc test for comparison group, ($F(5, 48) =4.876$, $p<.01$), showed that the mean comparison of studies with no comparison group (i.e., one group repeated measure) was significantly higher than studies in which the comparison groups using traditional instruction, CAI, textbooks only, or other types of instruction (e.g., audiotapes). In addition, the mean comparison of studies in which the comparison group using videotapes was significantly higher than the studies in which the comparison groups using CAI.

CONCLUSION

The results from this study suggest that the effects of using hypermedia in instruction are positive over non-hypermedia instruction as a whole, however, the effects may be varied depends on what type of instruction that hypermedia compares to. The results of this study also provide some evidences which disagree with Clark's viewpoint about the relationship between media and learning. While many educators devote tremendous efforts with great expectation that technology will dramatically increase students* academic achievement, the results of this study provide to classroom teachers an accumulated research-based evidence for using technology in instruction. Left unanswered is the question of what factors truly affect the diverse outcomes for different types of instructions. Studies of this question will require further clarification of the distinct attributes between hypermedia and various types of instructions, and their relationships with learning. This meta-analysis points out only that improvements of students* academic achievement are possible. That information by itself is useful.

GENDER DIFFERENCES ON ATTITUDES TOWARD COMPUTERS: A META-ANALYSIS

Yuen-kuang Cliff Liao
Department of Elementary Education
National Hsinchu Teachers College, Taiwan, Taiwan
Yliao@cc.nhctc.edu.tw

Although many studies have been conducted on the hypothesis that women and girls are more likely to hold more negative attitudes toward computers. (Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), the results of existing studies have reported a confusing picture. For example, Campbell (1990), Chen (1986), Colley, Gale, & Harris (1994), Jacobson (1991), Loyd & Gressard (1986), and Woodrow (1994) all reported significantly higher computer attitudes for males than females, while Blumer (1987), Campbell (1986;1989), Cantrell (1995), Chu & Spires (1991), Francis (1994), Koohang (1987;1989), Loyd & Gressard (1985), and Robertson, Calder, & Jones (1995) have indicated that there is little, if any, differences of computer attitudes between males and females. Owing to the mixed evidence provided by existing research in the area, this study attempts to use the meta-analytic approach to investigate the gender differences on attitudes toward computers. The results from this meta-analysis will help provide clearer conclusion.

PROCEDURES

The research method used in this study is the meta-analytic approach which was similar to that described by Glass, McGaw, & Smith (1981). The studies considered for use in this meta-analysis came from three major sources and were published from 1984 to 1997. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of studies was retrieved by branching from bibliographies in the documents located through review and computer searches. One hundred and six studies were located through these search procedures; 19 studies came from ERIC and conference proceedings, 80 studies were retrieved from published journals, 7 studies were from Comprehensive Dissertation Abstracts..

Several criteria were established for inclusion of studies in the present analysis.

1. Studies had to assess the differences between males and females on computer attitudes.
2. Studies had to provide quantitative results from both male and female subjects.
3. Studies had to be retrievable from university or college libraries by interlibrary loan or from ERIC, Dissertation Abstracts International, or University Microfiche International.

Outcome Measures

The outcome measured most often in the selected studies was survey data from participants, as indicated in various instruments for examining participants' computer attitudes. For statistical analysis, outcomes from a variety of different studies with a variety of different instruments had to be expressed on a common scale. The transformation used for this purpose is the one recommended by Glass et al. (1981). To reduce measurements to a common scale, Glass and his colleagues coded each outcome as an Effect Size (ES), defined as the difference between the mean scores of two groups divided by the standard deviation of the control group. For those studies that did not report means and standard deviations, F, or t, values were used for estimating the ES.

Variables Studied

Nine variables were selected for coding each study in the present synthesis. The first 2 variables (nation of Subject, population Group) were coded so that potential different effects for subjects with different background could be detected. The following 2 variables (i.e., type of publication and year of publication) were coded because it is important to know how effects are related to sources of information over time. The next 4 variables (sample Size, reliability of measure, statistical power, and statistics) were coded so that effects related to characteristics of research design could be detected. The last variable (type of Attitude) was coded because it is critical to know how effects are associated with different types of attitudes. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there were significant differences within each variable on the effect size.

RESULTS

Of the 106 studies included in the present synthesis, 85 or 80% of the study-weighted ESs were positive and favored the male subjects, while 21 or 20% of them were negative and favored the female subjects, indicating that males had lower computer anxiety than females. The range of the study-weighted ESs was from -0.85 to 0.881. The overall grand mean for all 106 study-weighted ESs was 0.192. When this mean ES was converted to percentiles, the percentiles on computer attitudes were 58 for the male subjects and 50 for the female subjects. The standard deviation of 0.286 reflects the small variability of ESs across studies.

Among the 489 ESs included in the present synthesis, 363 or 74% were positive and favored the male subjects, while 121 or 25% were negative and favored the female subjects. Only 1 or 1% of the ESs indicated no difference between male and female subjects. The range of the ESs was from -0.85 to 0.881.

The positive means for liking, belief/usefulness, confidence, and mixed indicate more positive attitudes favor male subjects; however, for sex stereotype and ability stereotype, the positive means indicate a higher sex and ability stereotype for male subjects.

For ANOVA, 1 variable, type of attitude, showed statistically significant impact. The post hoc test for type of attitude, ($F(6,232) = 2.554$, $P<.05$), showed that the mean comparison of studies that measured sex stereotype was significantly higher than studies that measured liking, anxiety, belief/usefulness, confidence, ability stereotype and mixed attitudes. In addition, the mean comparison of studies that measured belief was significantly higher than studies that measured mixed attitudes.

DISCUSSION

The results of this meta-analysis indicate that, overall, male subjects had slightly higher computer attitudes than female subjects. An effect is said to be small when ES = 0.2, medium when ES = 0.5 and large when ES = 0.8 (Cohen, 1977). Eighty percent of positive study-weighted ES values and 74% of positive ESs overall also confirm the gender differences on computer attitudes. The slightness of the differences must be keep in mind, however; the overall study-weighted mean ES of 0.192 only indicates 8 percentile scores higher than the female subjects. The percentile scores for the overall grand mean and median were identical, reflecting the small variability of ESs across studies.

The significant differences found among the mean comparison of studies that measured sex stereotype and studies that measured liking, anxiety, belief/usefulness, confidence, ability stereotype and mixed attitudes were quite interesting. It is possible because male subjects hold higher sex-related stereotype toward computer use, and this tendency influences female subjects' feelings about computers that results in females' overall more negative attitudes toward computers. In short, the gender differences on sex-related stereotype toward computer use may be the key factor that yields the gender differences on overall attitudes toward computers. More studies need to be addressed on this hypothesis.

CONCLUSION

Although many studies have been conducted to examine the hypothesis that women and girls are more likely to hold more negative attitudes toward computers (Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), and still fail to get a clearer picture, the results of this study provide an accumulated research-based evidence to support this hypothesis. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact characteristics of each type of computer attitude (e.g., anxiety, confidence, and sex-related stereotype) and their relationships with gender. This meta-analysis points out only that gender differences on attitudes toward computers exist. That information by itself is useful.

A Monitoring Program for Evaluation of Educational Software on the World Wide Web

Edna Ruckhaus
Department of Computer & Information Science
Universidad Simón Bolívar
Venezuela
edna@sa.omnes.net

Introduction

The evaluation of educational software can be divided into two phases: 1.- the formative evaluation which is done during software design and development, its aim is to determine the capability of the software to satisfy user learning needs, and 2.- the summative evaluation which is done once the software is implemented, its purpose is to relate the context of usage to learning effectiveness. In both phases, educators and software developers have relied on traditional methods of evaluation like interviews, direct observation, pre-tests and post-tests. During the past few years, the number of educational applications that is published on the World Wide Web has increased considerably, meaning that we can no more evaluatethe usage of software in a controlled environment.

The purpose of this project is the development of a monitoring program that automatically generates information that is useful for carrying out summative evaluation on educational software that is used on the World Wide Web. The program collects data (measures) on a group of variables, several of the results are expressed in terms of fixed parameters that represent the logical or recommended student performance. The monitoring program stores the measures in a database: raw data can be consulted, and statistics are produced on demand. In this way, the results are available for analysis and evaluation.

Experts in design and usage of educational software introduce the parameters. The final comparison and analysis should be done by experts in content, usage, and educational techniques, technical and graphical experts, and language communication experts. An important part of the project has been the development o a framework for analysis that relates measures to software characteristics: these include flexibility, legibility, consistency, grammatical correctness, interface, content, degree of interaction, browsing capabilities, media resources and technical features. For each characteristic there is a set of indicators of possible software flaws.

The implementation of variables has been done for a prototype tutorial course on Local Area Networks that is representative of a hybrid educational application (tutorial & drill). The course was developed in *HTML*. The Variables Database was developed in the *Informix* DBMS. The monitoring program includes code in both *JavaScript* and *Informix 4GL CGI (Common Gateway Interface)*. The next research phase will be the analysis of data collected by the monitoring program during its usage by a group of Systems Engineering Students. Simultaneously, data will be collected and analyzed through more traditional methods. By comparing both analysis, the monitoring program will be validated.

Use of hypermedia in educational applications

Multimedia becomes *Hypermedia* when the designer provides a structure of elements through which the user can browse interactively according to his interests (Vaughan 94).

The prefix "Hyper" refers to the methods for non-sequential browsing through an information content. The suffix "Media" is related to the availability of the information in different forms such as audio, video, graphics, animation and text. Two terms are considered fundamental in hypermedia systems: *link* and *node*. A *link* is a connection between conceptual elements, and a *node* contains text, graphics, sounds or any information related to the knowledge base.

The hypermedia concept has allowed to question the manner in which information is structured to produce learning (Rivard 95). Traditional instruction intend to create links between student's previous knowledge and new knowledge. These links are created step by step, in a manner that is conceptually sequential. *Hypermedia* structures information in a non sequential manner through associative links, causing individualized knowledge acquisition and manipulation.

Links are the navigation "guides". Navigation tends to become more complicated when an associative link connects to a node that has several associative links as well. The evaluation of Hypermedia educational applications should take into account the usage of media resources and the navigation path followed.

Monitoring Program

The variables established for the evaluation of educational software were determined from the inherent characteristics of an hypermedia educational software. Each variable takes values as a result of the measurement of student performance during software use.

The monitoring program takes the measures of each variable and stores them in a database. The interaction with the database was developed with the *Informix CGI Library* which extends *Informix 4GL* capabilities for the development of Web applications.Two different approaches were followed for programming the measures taken by the monitoring program:

- Directly in the *HTML* page belonging to the educational software, using a routine written in *Javascript*, and then stored in the database using *CGIs*.
- In the *CGIs* themselves

The measures are the following:

- Navigation Path: These are stored in the database as a string consisting of the names of the pages visited separated by a special character. The page name is brought from the page to the *CGI*.
- Time: The moment the browser loads the HTML page belonging to the educational software the time is stored and then, when the student leaves the page, the *CGI* script is called and the difference between both times is calculated.
- Questions & Answers: The answer is evaluated by the educational software, and then sent to the *CGI*.
- Ending: These measures are determined in the *HTML* page using a variable that indicates if it is the last page of the section.

Some of the measures are calculated using data already stored in the database. For example, the number of correct and incorrect answers, number of times a content or help page is visited, number of times an audio or video resource is invoked, and total execution time of the application.

The parameters establish standards or a value range for each of the variables against which the results can be analyzed and measured. A few of the parameters are the following:

- Recommended navigation path
- Estimated total time for each section
- Number of times a resource should be invoked
- Number of times the Help section should be visited
- Recommended execution time of each session

For instance, for the variable Navigation Path some of the results are the following:
R1. The navigation path is the same as the recommended navigation path.
R2. The navigation path is different form the recommended navigation path.
R3. The student visits several times the same section.
R4. The student did not visit a certain section.

The result R1 is related to the characteristics Flexibility and Sequence. Flexibility is the degree in which the software permits the student to work at his own pace or according to his interests, and Sequence has to do with structure, location indicators, ability to stop and resume in the same place, and exit options. These characteristics could lead to possible software flaws.

Conclusions

The design and development of educational software has been an important research area in many universities, specially in those that offer Distance Education; however, computerized evaluation has been an area little explored. The monitoring program described in this paper is the first phase of a project that is aimed to achieve evaluation in a context where other evaluation methods are not available.

The monitoring program not only allows evaluation by the design and usage experts that are related directly with a certain educational software, but also by any professor that uses the World Wide Web as a means of instruction for his Distance Education Students.

It should be noted that the time parameters can be affected by the variability of connection rates due to factors like the telephone network, the Internet service provider, and the Web Server demand.

It is recommended that pilot tests be done with the purpose of determining the parameters needed for further analysis and evaluation.

The Logo language (Harvey, B., 1997) has been ideal for students first approach to computer science: today the evolution of systems and programming languages has caused the evolution of its implementations including multimedia, graphics and concurrency features (Cisternino. et at., 1998) (Resnick 1990).

In this paper we propose a micro-world based on the Logo programming philosophy: the user may program interacting entities through a language that integrates the Logo turtles primitives with constructs to co-ordinate and synchronise concurrent agents. The power of this system is allowing a decentralised way of modelling the world: a creature has "conscience" of itself and interacts with the surrounding environment in explicit way using communication primitives. This approach is different, for instance, from that of the StarLogo system (Resnick 1990) where a turtle is view as part of a community.

The system we present, is an evolution of the Orespics system (Capretti. et al., 1998), an environment in which students guide the action of virtual robots through the Logo- PL language. The environment includes a friendly graphical interface by which students can use Orespics as a game. The language is provided with traditionally sequential constructs, constructs to control the concurrency and communication primitives (Hoare, 1978). In our experimentation, we have noted that this set of concurrent constructs is not sufficient to solve all problems that students fantasy suggests them. We have extended Orespics system to define the "Advanced Orespics" environment, a new system including non-deterministic features and other forms of communication; furthermore the students may define "creatures" appearance. This new type of interaction among creatures allows exploring the world in a decentralised way: a child has to modify his/her way of thinking according to this paradigm.

We present the spirit of Advanced Orespics through an example: we show how the classical problem of Hanoi towers may be programmed in our system by defining the behaviour of each disk in a decentralised way: each disk has its own identity and may interact with the word autonomously.

The well known Hanoi tower problem is the following: a monk has three pegs and has to move n disks of increasing dimension from a peg to another one with the constraint that a disk may be put on another one if and only if its dimension is smaller. The problem of Hanoi is a typical example of the power of recursion in the classic Logo language. We exploit the same problem to show the power of a decentralised way of thinking. We believe that an agent approach is intuitive for this problem: each disk is an agent that is capable to move from a peg to another peg in respect to the problem constraints. The disk is capable to receive the message "move to peg *x*" and knows the peg where it is located. In order to move from a peg *x* to a peg *y* there are two possibilities: the selected disk D is on top of *x* or not.

If *D* is on the top, we consider two sub-case: if the topmost disk on the destination peg is bigger then it, *D* moves from *X* to *Y* immediately, otherwise *D* asks to the lowest disk smaller than it on the destination peg, to move to the third peg *Z*. If *D* is not on the top, first it asks to the disk above to move to peg *Z* in order to become the topmost disk and then it behaves as describe above.

There is a starting process that tells to each disk starting from the biggest dimension one, that it must reach the goal peg.

This solution consists in creating a different creature for each disk and a monk creature that activates the disk movement: a different process is associated with each creature. We use Orespics PL syntax (Capretti et at. 1999) to write disks and monk programs. The programs are the following:

```
Agent monk
 i <- 1;
 while ( i <= n )
  send&wait C to disk_i;
  wait&receive OK from disk_i;
  i <-i+1;
 endwhile
end

Agent disk_i;
 myPeg <- A;
 myDim <- n-i+1;
 repeat
  wait&receiveAny peg;
  while (dimTop(peg)< myDim or seeUp() <> nil)
   if (seeUp() <> nil )
    receiver <- seeUp();
   else
    receiver <- Max_Of_Smaller(peg, myDim);
   endif
   send&wait third(peg, mypeg) to receiver;
   wait&receive OK from receiver;
  endwhile;
  I_go(peg);

  send&wait OK to Sender(peg);
 until (is_My_Right_Position());
end
```

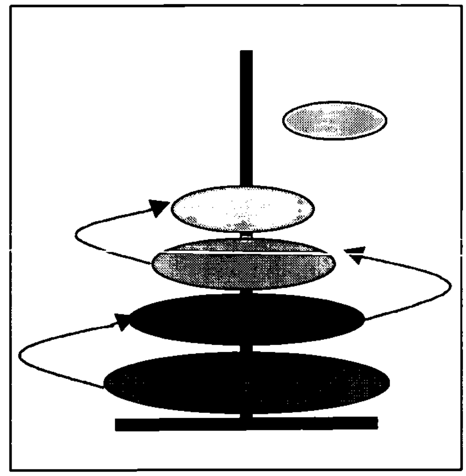

Figure 1: The first movement

where *seeUp*, *dimTop*, *max_Of_Smaller*, *third*, *is_My_Right_Position* and *I_Go* are macros created by the teacher. *seeUp()* returns the identification of the disk located above the disk invoking the function; *dimTop(P)* receives the identification of a peg *P* and returns the dimension of the disk on the *P* top; *Max_Of_Smaller(P, d)* function receives in input the identification of a peg *P* and a dimension d and returns the identification of the first disk on the peg *P* whose dimension is the greater of the smaller than d. The macro *third(x, y)* returns the identification of the peg different from *X*, *Y* pegs and *is_My_Right_Position()* returns true if the disk is in the right order on the peg *C*. The *I_Go(P)* macro manages the movement of the disk from the actual peg to the *P* one and updates the value of the *myPeg* variable with this new value.
We stress the fact that the disks are numbered from 1 to n, from the greatest to the smaller one.
The macro defined may be implemented through Orespics- PL language, for instance the teacher may implement a state manager, storing how the disks are distributed on the pegs. This means that the student is able to learn the laws of the worlds till he gains the skills to program all the problems.
In this program we use the primitives *send&wait* and *wait&receive* allowing a synchronous communication between agents: Orespics system includes a rich set of communications to describe better different real situations. For the first time these features are included in a language for teenagers.
Since the world may be perceived as a set of interacting entities, we think that it may be naturally modelled in our system through agents and communications.

Evaluating On-line Courses

Ulric Björck
Göteborg University, Department of Education, Göteborg, Sweden
ulric.bjorck@ped.gu.se

Introduction

A broader use of on-line courses has become more widespread in recent years. Virtual universities are popping up almost all over the world and the development towards more on-line education in higher education is continuing (Brown, 1998; Tomlinson-Keasey, 1998). The use of Computer Mediated Communication (CMC) is affecting and changing the society, as we know it. A common opinion and a frequent one in a lot of research is that the computer is simply a tool. We find that the computer indeed is a tool, and a very powerful one, but the computer and especially the use of the computer, is much more than a tool. In fact, the use of computers and especially the Internet is changing some of the fundamentals in the world today and it definitively affects several areas.

Dowling (1998) stresses that the use of CMC should be studied focusing more on the social and relational aspects of our virtual lives since they may very well prove to be important for learning. Research on the development and use of communication conventions in CMC has been going on for quite some years now (Murphy, 1997), but theoretical foundations of evaluating on-line courses have not been given a lot of room in the current research debate. In many cases, transcripts of asynchronous conferencing in instructional environments have been studied (Harasim, 1990; Henri, 1992). Analyzing transcripts has been established as a good way to study communication and cognition in coordination with the ideas within the scientific field of situated cognition. This can be recognized as guidelines and valuable information in evaluating on-line courses since the knowledge built and constructed within these particular frameworks could prove useful to the evaluator. Theories and writings about evaluations in a broader context are quite extensive (Lander, 1987). In this paper I will elaborate the views and writings that have proved to be significant in evaluating on-line courses. The focus will be on the use of formative evaluations.

Formative evaluations

Cronbach (1983) describes the design of an evaluative investigation as an art. There are several decisions to be made and the choices to be made are almost innumerable. The choices that are made will undoubtedly lead to particular advantages and disadvantages. It is therefore important to focus on considerations and choices behind the design of the evaluation. An evaluation plan is constructed to secure that the resources available for the evaluation, and the research, is used in such a way that as much useful and necessary data as possible are collected.

A single definite question is often the starting point of an evaluation, but this has begun to change when it comes to evaluating CMC (Kinzie, 1991; Tessmer, 1994). A single question assumes that the objective of the course has been fixed and that the aim of the evaluation is to assess its merit. Scriven (1967) christened such evaluations summative; to contrast them with the formative study which regards the program as fluid and seeks ways to improve it. The formative evaluation method could be described as a more diagnostic evaluation method than the summative. Cronbach (1983) stresses that in a formative evaluation what variables deserve close attention will be discovered as the fieldwork proceeds which is something that seems to suite the designers and evaluators of today's computer applications. The proper function of evaluation is to speed up the learning process by communicating what might otherwise be overlooked or wrongly perceived. The evaluator, then, is an educator. His success is to be judged by his success in communication; that is, by what he leads others to understand and believe. Payoff comes from the insight that the evaluator's work generates in others (p 8). Scriven claims that the "curriculum builder is almost automatically engaged in formative evaluation, except on a very strict definition of "evaluation". He is presumably doing what he is doing because he judges that the material being presented in the existing curriculum is unsatisfactory" (p 43).

Scriven's writings are particularly interesting today because an additional unsatisfactory part in evaluating on-line courses is the use of the on-line course environment in itself. It is obvious that this environment is not 100% satisfactory and as the unsatisfied evaluator it is therefore important to proceed and construct new solutions. Scriven holds the formative evaluation in favor of a traditional summative approach by the basic fact that the "ordinary" evaluator, while a professional in his own field, is usually not a professional in the field relevant to the curriculum being reformed. Scriven's description is often accurate today when computer scientists and designers are preparing new on-line course environments for students in other courses than their own subject. The meetings between the evaluator and the professional in the field often leads to the exchange of knowledge and a broader perspective on both accounts.

Results

Formative evaluations provide a sound and flexible possibility to evaluate on-line courses. The on-line course environment, which is supported by the Internet, is a continuously changing environment and therefore the formative evaluation method is particularly suitable to meet higher demands on quick changes of the course. An additional aspect supporting the formative evaluation approach is that a lot of on-line courses are not in a regular educational program, they are often done within a particular project environment. If these evaluations were summative, any suggestions of improving the courses would be too late for the current project.

The formative evaluation method has been given a diagnostic function, rather than a function of making final conclusions and standpoints. The curriculum builder is almost automatically engaged in formative evaluation, except on a very strict definition of "evaluation" (Scriven, 1967). The evaluator is presumably doing what he is doing because he judges that the material being presented in the existing curriculum is unsatisfactory. One unsatisfactory part of on-line courses could be said to be the use of the on-line course environment. It is obvious that this environment is not 100% satisfactory and because of this it is important to proceed to construct new solutions. In constructing new solutions and communicating them, meetings with the course management are crucial in succeeding as a formative evaluator.

Introduction

A Web-Based Instruction(WBI) approach employs a wide range of instructional strategies using the resources of the World Wide Web (Pernici et al. 1997), (Reeves & Reeves 1997). The Web environment promotes active knowledge acquisition and collaborative learning, allowing students to interact with a variety of information and to communicate with different people. In the process of designing a WBI application, we can explore the fact that instructional design does not have a rigid structure, due to its multiple paths to solutions. Course designers traditionally treat constructs as regular and well-structured, idealizing a best solution presented in a plan of action to be strictly followed by the students. A traditional instructional designer believes that there is a single, best way to conceive knowledge; in other words, there is a single schema or concept that best describes any object or event. That best method is revealed by task analysis. However, in order to comprehend concepts, learners should understand and personally form their own intentions based on different perspectives of content and action. The aim of this work is to provide controlled cognitive flexibility, in which different perspectives are explored and represented in a structure that allows distinct plans of action to be generated. Students should be able to follow their intentions, forming their own plans of action and at the same time be attracted to the expectations and requirements of the course. The students' intentions will be influenced by their instructor and by other students in order to improve performance. Students should have relative freedom of action, but there should be some way whereby it is possible to detect whether they are moving away from the objectives proposed by the course instructor and/or below the performance of the group of students attending the course. It should be possible to assess each student from time to time. If a student has a low grade, the instructor may impose some kind of behavior until the next assessment, by means of restricting the possibilities of creating his/her plan of action. In addition, at any point in the flow of action, a visualization of the information about the group's previous interaction and the different possible future paths of action should suggest the direction to be followed by the student.

Workflow Technology and Learningware

The subjacent technology used to pursue the proposed objectives is Workflow technology (Abbot & Sarin 1994), (Benjamin et al. 1995), (Dourish 1996), (Glance et al. 1996), (Khoshafian et al. 1995), (Miller et al. 1995), (Walters 1995), (Winograd et al. 1992). A Workflow has an infra-structure that facilitates the execution and control of work. A Workflow system automates plans of action, by means of a process model that addresses a sequence of tasks to be rigidly followed by its users. The users' actions are restricted to valid movements predicted in a flow of action. Workflow aids the rationalization and explanation of action, however its flow has to be strictly obeyed. Therefore, students are easily presented with the course objectives, however they are not able to be active in learning. A fundamental point in this work is to adapt Workflow technology to fit an appropriate cognitive flexibility in an educational context. The adapted Workflow structure must maintain advantages and eliminate disadvantages. The focus is to use a clear structure to present the material available and requirements as well as to provide multiple representation of content and different paths of action.

A central point in this work is the elaboration of a flexible Workflow structure related to learningware. The term *learningware* overwhelms the term *courseware*, not only because it is related to active interaction but also because it incorporates group collaboration. Characteristics should be adopted that make communication, coordination, cooperation and contributing to a group synergy feasible. On the whole, there are three complementary and inter-dependent aspects that form the starting point in our general problem solution. The three aspects to be investigated are a flexible Workflow structure, a coordination structure and a visual interface for communication and analysis of plans of action.

Firstly, the Workflow rigidity arises from viewing work processes as unfolding along a single line of temporally chained pre-fixed activities. A flexible Workflow structure should consider the possibilities of modifying a workflow, like changing the action sequence and altering, including, and excluding actions. We intend to work in a Workflow formalization, in which students will have active but predictable behavior; they will have the opportunity to change the action sequence at some pre-determined points in a workflow and to alter some pre-fixed actions. For example, if a causal dependency between two actions exits, there is no way to modify it, on the other hand if a dependency is an instruction suggested it may be followed or changed by the student. Students may alter the action hierarchy, to decide at which level of partonomy or specialization to act. They may navigate through different levels of knowledge taking action and subtracting detailed action or not. Our flexible Workflow approach allows users to control the way in which sequencing operations are carried out and allows some activities not to proceed, but to be recognizable in the system. This maintains a correspondence between user action and process representation. A mediating between the active user interaction and the work representation, rather than the enactment of a process, provides students with an opportunity to enter the work process and also gives students and instructors control over the way the work is organized. Our Workflow structure may be considered mobile, because it incorporates different possible plans of action. By reaching decisions students decide which learning strategy will be used. They have autonomy, independence, strategic initiatives and guidance.

Secondly, a coordination structure has been developed to overcome sources of misunderstanding among learners and to promote advanced knowledge acquisition, avoiding oversimplified behavior. Consider a Workflow instance for each student: suppose a student starts an interaction with the Workflow; at some pre-determined moment during the course an assessment should occur. If a student is not doing well, he/she will receive a new Workflow. This may contain restrictions of flexibility or changes in its structure. With respect to coordination, there is also an agent called Attractor. The Attractor is partially responsible for evaluating a flow context and signalizing it to the interface. We define a flow context as a flow between two different moments in time. Before reaching a decision that implies action, users may ask the Attractor to show the consequences of that decision, in other words, to show different possible future flow contexts as well as a partial evaluation. This evaluation may show, for instance, whether a flow context is oversimplified. Students may also see their previous flow contexts and/or the previous flow contexts of other students. In order to assess learners, instructors require context information from the Attractor. A principal concept is that the Attractor suggests instead of imposes.

Thirdly, there is a visual interface that visually presents the information provided by the Attractor. The interface visually distinguishes between a good or bad flow context. Moreover the interface is also used to present the workflow and to identify which points of its structure could be modified by students. By means of the interface, students are able to visually analyze their future perspectives and to compare their cognitive strategies with those of other students. Alternatively, they may create their plans of action as copies of other students' plans of action or as a combination of various students' plans of action.

Conclusion and Future Work

There are other approaches giving more flexibility to Workflow, but this subject has not been explored very much for educational purposes. There is no Workflow technology that is suitable for every domain. Our work is an attempt to fit this technology into an educational context.

From the Ivory Tower to Everyday Practice - Action Research and Co-operative Learning in an ICT-supported Learning Environment

Bodil Ask, Dept. of Technology, Høgskolen i Agder, Norway, bodil.ask@hia.no
Harald Haugen, Dept. of Teacher Education, Høgskolen Stord/Haugesund, Norway, harald.haugen@hsh.no

Background for the SULDAL[1] project

A recently established Norwegian 'NetUniversity' (NU) is a formal extension of a 5 years long collaborative project between four Norwegian institutions (universities), offering nearly 100 different ODL courses through Internet to nearly 5000 students every year. An important characteristic of the virtual NU is the mutual exchange and joint development of learning materials, where students can cross institutional borders in their choice of subjects, a flexibility that is of great value also to external students.

The staff at teacher training institutions needs experience from field trials where the different pedagogical ideas and technical solutions are tested in real educational situations. The danger is prevalent that bright ideas and perfect theories are borne and bred in academic isolation, well shielded from practical problems and disturbances. Only in real situations can new ideas prove their true value. ICT invites for new learning situations, changing the traditional 'teaching' into more student active 'learning' environments.

Some local communities are willing to invest considerable funds and up-to-date infrastructures in order to improve their local school systems and facilitate the lifelong learning process of their inhabitants. Suldal, is a scarcely populated municipality with 7 small schools, separated by deep fjords and steep mountains. A central objective of their investment in ICT is to strengthen contact and unity among the population, fostering collaboration and exchange of skills and ideas. The schools are expected to have central roles in this development.

Project methods and design

Project outline

Problem definitions for the research activity concentrate on two main areas:

1) Organisation and infrastructure for integration of ICT in the classroom, in the school and in the total community school system. What are the goals, and will the chosen structure lead to reaching the goals? How do we create an optimal learning environment?
2) Roles of the different actors in the practical work. What changes in roles and activities are observed during the project period? The primary actors are the teachers and students/pupils, but the roles of parents, employers and community are also of interest.

Action research and collaborative learning

Action research is chosen as the main method. It is based on close relations between practice, reflection, and change. The framework is most appropriate for participants who are willing to adopt some initial stance in regard to a problem, formulate a plan, carry out an intervention, evaluate the outcomes and then develop further strategies in an iterative fashion. Action research is by nature cyclical or iterative.

Action research empowers all participants. Involvement is of a knowing nature, with no hidden controls or preemption of direction by the researcher. All participants negotiate meaning in the analysis of the data and contribute to the selection of interventionary strategies. The method implies a situation where informal evaluation will be a continuously ongoing process, bringing about feedback of many kinds. In addition more

[1] SULDAL' = 'SkoleUtvikling, Lærarutdanning og Læringsmiljø'
= school development, teacher training and learning environment

formal evaluation in the form of systematic interviews and questionnaires will take place for groups of relevant actors.

In traditional, curriculum-based learning the learners work individually, without sharing their learning in a public forum, and work largely in isolation. The method of *collaborative learning,* which is focused here, engages the learner in thinking about *why* they are learning, and how the learning may benefit the group. This kind of learning has long been an interesting aspect in pedagogical theory, and is now gaining further interest in relation to new ICT, where the network is a major tool for collaboration (D. McConnell; 1998).

Who is learning from whom in this project? Naturally the students should be learning from their teachers. Equally important, however, is the learning that takes place between students - and between teachers, where they exchange experiences and information and construct their own knowledge through trial and error, by sharing the learning tasks and communicating results in a positive way. Furthermore, teachers will also learn from their students, particularly when it comes to technical skills and new ways of finding information on the web, where the new generation seems to have a much higher adaptability than their parents.

Collaboration among institutions is one of the strategic approaches given prominence in this project. The enormous efforts and resources needed for providing learning material to new groups of learners simply require that parallel work should be avoided. The participating schools will benefit from co-operation, exchange of material and sharing of duties. Internet increases the functionality and facilitates practical activities among co-operating institutions.

Practical approaches

The practical part of the project includes

1. Initiation and motivation, with installations, infrastructure, planning and basic training of all teachers, and starting further training of some interested 'resource teachers'.
2. Integration of ICT into subject matters and methods. The teachers are central actors, with researchers and other resource personnel as partners to help find the most rewarding applications of ICT
3. Making the technology transparent, i.e. working with the learning process in an electronic learning environment, without paying any attention to the ICT itself

Obstacles - and how to overcome them

Major difficulties are the wide variety of backgrounds among teachers involved. Some of them are ICT 'specialists' with a very high motivation, eager to start the activities. Others are more moderate, not too well prepared, but positive to trying new ways and methods in the teaching process. A third group even expressed a negative attitude from the beginning, but gradually seem to be more open and interested in the new possibilities.

Technical difficulties are not yet a story of the past. Despite new PCs, new networks, professional installations and local support, there are still problems. A support team has a vital role, and an on-line helpdesk is available.

Status

- Infrastructure and technical installations are functioning well
- Motivation and involvement of the teachers have increased throughout the period
- A training programme for the teachers has started, differentiated according to interests
- A common web site is available to all actors: http://hugin.hsh.no/lu/inf/suldal2/Suldal.htm
- Each school has provided a report of their activities and intermediate goals
- The web site functions as an evolving resource base for teachers, students and researchers
- Action research is carried out. Academic staff, MEd and PhD students participate in class and school activities, and revised plans and *actions* are made
- Gradual change of guidance and contact from physical visits to netbased communication & exchanges

Introduction

The purpose of this paper is to describe communication applications within the program *Intercambios*, using an integrated, server side software package called WebCT. *Intercambios: A technology, learning, community service and career awareness program* provides adolescent mentoring from career professionals and university students. WebCT's low learning curve and sophisticated communication features enhance each participant's ability to collaborate in the career mentoring process. This paper will briefly outline the grant's objectives, current projects, and future developments related to WebCT.

The Goal

The primary goal of the grant is to decrease the juvenile crime rate for the junior high school participants. Secondary program goals consist of increased leadership skills, more integrated curriculum projects involving the Internet, greater technology-related field experiences for university students, and exposure to career options by having pupils work with career and academic mentors. Program directors looked for a software program that would help them to achieve these objectives.

The Problem

The *Intercambios* program consists of the junior high pupils and teachers, university students and faculty, and local and world wide career mentors. The program required face-to-face mentoring combined with on-line resources to facilitate communication with career mentors. Since much of the participation involved on-line communication between adolescents and adults, it was vital to find a software application that could provide a monitored and secure communication environment. Another important need of the program and feature of the software was the ability to collaborate on a synchronous and asynchronous level. Email, or some other form of private electronic correspondence, was a highly desirable feature in order to maintain a supportive and confidential relationship between mentor and mentee. Additionally, discussion groups could introduce new careers and mentors to all participants, providing a continual renewal of fresh ideas. Therefore, a password-protected environment including private email, discussion lists, and chats are desired features in the software package.

Several possibilities exist for asynchronous and synchronous communication via the World Wide Web today. The project needed to focus on applications like self-contained email, discussion lists, chat sessions, and collaborative planning tools. Finally, if was imperative to find a single software package with a low learning curve in order to avoid the training and retraining of participants. Our primary challenge is to fulfill the gap created by the needs for *Intercambios* and the current state of innovative educational technologies. We believe WebCT can fulfill this gap.

Current Development

WebCT has been chosen as the innovative technology tool for this project, based upon university reviews of the software in comparison with other related courseware applications. After reviewing three top courseware contenders, Wayne Miller, Manager of the Humanities Computing Facility at UCLA stated, "It became clear to us, though, that WebCT offered by far the best ratio of cost to features [sic] and flexibility among the systems that we considered." Brian Morgan of Marshall University adds the observations that the strongest features of the software are its on-line testing and grading features. These desired features relate to pupils' preparation needs for future *Intercambios* program development. Morgan also noted that Marshall University's top three features sought in such an application were: ease of use, on-line testing and grading, as well as excellent technical support staff.

Although the program has regularly scheduled hours and meeting places, scheduling conflicts due to work and school obligations for all participants are common. As a solution to this conflict in time and space, career mentors establish initial contact via a discussion list or private email to interested pupils. Pupils will then be prepared to interview the career mentor in their choice of conferencing format and time schedule: email, discussion group, or chat sessions. The combination of WebCT's synchronous and asynchronous communication and a closed environment for email will best serve all schedules involved for a safe and optimal career mentoring experience.

The chat rooms, discussion groups, and private email can also be used by the university students. Personal emails to and from the academic mentors can provide a line of communication between junior high school participants and academic mentors. A self-contained asynchronous and synchronous email system is the only option for pupil communications within this program. WebCT has the three types of asynchronous and synchronous communication desired for this program within a safe, self-contained environment for junior high students.

Future Prospects

Other features desired in WebCT include the calendar, participant homepage creation, and quiz. The calendar will allow junior high school teachers and university students to collaboratively research and plan Texas Essential Knowledge and Skills (TEKS) standard-based lessons. University students can periodically check the calendar to find project themes and teachers' email to collaboratively plan any projects that can be used in the university student's classes and in the junior high school teacher's curriculum. A discussion group will be reserved for teachers and university students to exchange ideas and resources in the development of such pages. Participants will also be able to post original homepage creations. This may result from the discussion group's shared ideas and resources. Fully completed homepages will be posted to the main homepage of the web site for other Texas educators to review.

Finally, the program directors have begun collaborative efforts with the university's college of education to develop a Virtual Professional Development School (VPDS), which places preservice educators' lesson plans on the World Wide Web for K-12 educator use. Future goals include further development with the VPDS environment and its inclusion in the college's imminent professional development school (PDS) and the preservice education program.

Elements of Case Design for Hypermedia Environments in Teacher Education

Matthew J. Koehler, Anthony J. Petrosino, Richard Lehrer
Wisconsin Center for Education Research
1025 W. Johnson St.
Madison, WI, 53706
mkoehler@students.wisc.edu, ajpetrosino@facstaff.wisc.edu, lehrer@macc.wisc.edu

Introduction

Our interest in the design of cases is motivated by the need to develop tools for elementary teachers that will help them understand how students think about forms of mathematics typically unfamiliar to teachers, like geometry, space or measure. In designing case-based hypermedia tools, our goals are to exemplify not only student thinking, but also, core mathematical ideas. We agree with others (Merseth, 1996; Barnett & Friedman, 1997) that case-based methods for teacher education afford opportunities to develop knowledge of exemplary practices and to learn how to analyze and reflect about classroom contexts. Building off of our earlier work that focused on the design of mostly example-based hypermedia systems that helped teachers to learn (Koehler & Lehrer, 1998), we have developed a small number of design principles for selection and development of cases for case-based hypermedia systems for teachers. These design principles play a prominent role in our current work in progress in which we look closely at case-based hypermedia's role in the development of teachers' epistemology of measurement instruction in the primary grades.

Case Design

Following over five years of work in professional development conducted within the field of mathematics education, we have developed cases of *student reasoning* about elementary mathematics. Within this general locus, we have developed a number of selection principles for choosing among many hours of classroom video. These selection principles were informed by a triangulation of our previous years of experience, by literature in a variety of fields (cognitive psychology, education, educational technology, etc.), and by two empirical studies (Horvath 1998, Koehler & Lehrer, 1998). This triangulation has resulted in a set of design principles that at this point represent "lessons learned" that now guide our development efforts (Tab. 1).

Assessing the Design Principles

While our thinking about design principles for cases has been helpful, we found that these principles were of little use without an overarching design for the computer environment in which we planned to implement our professional development activities. Our previous work has suggested a small set of design principles that are important for creating hypermedia tools for teachers (see Koehler & Lehrer, 1998). The set of case design principles we have proposed here and elsewhere (Koehler, Petrosino, & Lehrer, 1998) are considered important next steps for incorporating cases into these hypermedia tools.

Our current efforts have focused on creating two versions of a hypermedia system aimed at helping elementary teachers think about measurement instruction in the primary grades. The first system is built around an earlier set of hypermedia design principles (Koehler & Lehrer, 1998). This system uses video footage primarily to exemplify the bigger ideas. The second system is being constructed in accordance with both the hypermedia design principles as well as the case design principles we have proposed here. Both of the systems share a large percentage of text and case video footage, but differ in the ways in which the video (cases) are used. Practically speaking, compared to video examples, video cases provide longer looks at classrooms, are accompanied by more interpretation, and have hypermedia links directly embedded in the digitized video to allow readers to explore ideas as they arise.

Studies in progress are aimed at investigating how participants using the case-based system differ from those using the example-based system on a variety of measures including: the ways in which they interact with the system itself, the order in which information is visited, how video is used, what is learned about the domain of measurement, what is learned about student thinking, and what is learned about classrooms.

Design Principle	Justification	Benefits
Cases Should be Grounded in Practice	Teaching is grounded in practice, so instructional cases about teaching should also be grounded in practice. It is for this reason that video cases should be created from footage that comes from real classrooms with full-time professional teachers	• Cases capture the richness and complexity of practice • Grounded cases are more realistic and relevant to practicing teachers
Cases Should Tell "Mathematics Stories"	We claim that cases are stories. As math stories, the actors should be teachers and students. The plot of the story should revolve around children's attempts, with the help of teachers to "mathematize" some aspect of experience and make sense of it. These stories can be historical, showing the development of children's thinking over time.	• Stories are engaging and more memorable • Stories facilitate the "mathematization" of experience • Stories can be used to show the history and development of student thinking
Cases Should be Annotated with Interpretation	Like stories, cases need to be interpreted: Video footage does not "speak for itself". Annotation should highlight the big ideas in the case: the encapsulated mathematics, the models of student thinking, and the decisions that teachers make.	• Interpretation helps teachers to understand the case • Interpretation helps teachers to see the big ideas contained within the case
Cases Should Anchor Further Exploration	Cases should anchor further exploration into other episodes of learning [CTGV 1990]. Episodes anchored to the main story line of the case provide a more varied developmental landscape than might be expected by simply following the main lines of the case narrative. Thus, cases should provide opportunities to explore both the current and related topics in depth.	• Cases can provide both the details of learning as well as the big picture • Cases permit connections to related ideas, other teachers, and other classrooms.

As the growth in the number of institutions offering web-based courses continues, faculty members are becoming increasingly challenged by the need to balance sound pedagogical strategy with the dynamics of the Internet environment. Some faculty are embracing this challenge, volunteering to teach web-based courses and participating in every available opportunity to learn how best to incorporate technology into instruction. Others have been assigned to teach web-based courses, with turnaround times ranging from 6-months to only several weeks. With the exception of those technology early adopters who have themselves developed tools and systems for web-based education, most faculty members are relatively new to web-based teaching and have neither the time nor the inclination to undertake an in-depth assessment of courseware development tools. The image of 24 x 7 learning certainly has its appeal; however, for those faculty members making the transition from the traditional classroom to the cyber-classroom, the road is often rockier than was anticipated. This paper offers some suggestions on facilitating that transition.

Getting Started

A review of the basics of instructional design is a logical starting point. Learner goals and objectives, content and instructional method and strategy remain the key drivers. These in turn raise a sea of issues in terms of implementation via the web: student support, faculty support, text, lab and library resources, office hours, advising, and copyright. In addition, faculty members often have to juggle multiple roles, particularly in these days of premium IT resources. Those roles include subject matter expert, instructional designer, media specialist, classroom manager, and even first-line technical support. Nevertheless, the objective is to apply pedagogical best practices regardless of the method of course delivery [Spear 98a].

Criteria for Evaluating Courseware

There is hope on the horizon, however. Published guidelines and standards offer guidance through the maze of commercial and proprietary software products for developing web-based courses. In November 1997, the Midwestern Higher Education Commission (MHEC) Interactive Courseware Committee noted four key criteria for evaluating courseware [HREF1]. First, the courseware should provide well-organized and dynamic interactivity between the student and the course content, the student and the teacher/facilitator, and among students sharing the learning experience. The human-computer interface should also allow the instructor and the students to navigate the material easily and effectively. Second, the courseware should be consistent with current knowledge on learning theories and precepts, providing strong support for instruction and the instructor, and facilitating instructor involvement in the learning process. It should allow varying "time on task" in the learning process and allow variable levels of faculty mediation based on the student's progress. Next, the courseware should provide highly motivating learning environments. Asynchronous, non-linear presentation branching in response to interaction with the learner and independent exploration are essential. Finally, the courseware should be faculty-friendly. Faculty members should need only basic computer skills and focus largely on the content, not the technology.

Creating Course Content and Materials

Creating course materials is the most time consuming, resource-intensive portion of faculty workflow and there are a variety of shrink-wrap products for authoring. However, nearly all of the PC-based authoring programs require a fairly robust technology skill set to get beyond on-line page turning; few provide development assistance and none integrate or interface with the institution's back office administrative information systems. A good authoring tool should provide step-by-step creation methods, templates, sample Web pages that can be adapted for individual use, automatic generation of CGI scripts, and basic instruction for creating standard components [Hansen and Frick, 1997]. But the authoring tool should also be flexible enough to provide the functionality and the benefits of multimedia tools and integrate seamlessly into whatever course management system the institution has selected.

Faculty members should take stock of the materials they currently have. While digitizing dog-eared lecture notes and putting them out on the web is certainly not the best approach, we need not throw the baby out with the bath water. Ideally, faculty would like to be able to gather their materials and place them in a "treasure chest" of resources that could be organized dynamically for use in web-based teaching and learning. Microcosm, a windows-based authoring software program, allows faculty to do exactly that [HREF2]. Created by a university consortium in the United Kingdom and winner of several international awards, Microcosm offers a repository from which a faculty member can create the same kind of multimedia, interactive courseware that a professional developer produces, but without the developer. The software allows faculty to integrate information and create courseware from virtually any resource, without having to learn programming. Instead of having to translate resources to suit the proprietary formats that most authoring tools use, Microcosm uses a series of built-in viewers to access the resource files. For example, there are viewers for each of the MS Office applications, for GIF and JPEG files, etc. When an instructor creates hypertext links, the links are stored separately from the data in their own link database. This means that the resource materials can remain in their native formats and in their native locations. Moreover, the courseware can be created and utilized in a non-linear fashion. Instead of page-turning, linear instruction, the course design is interactive and learner-centered. Task cards and wizards in plain English step the faculty through the process, with lots of positive reinforcement along the way. The structured "treasure chest" can then be "dropped" into the institution internet course management system via a Publish-&-Go wizard. At the moment, Microcosm is being evaluated by a group of colleges and universities in the United States.

Summary

To navigate the maze of products and ideas about tools for web-based course development, faculty members should keep their options open. Experimentation often reveals unexpected results, not the least of which is the lessons learned about a particular product or approach. Listservs such as ITFORUM and WWWDEV welcome all those interested in sharing ideas or simply seeing help in coping with the dynamics of education and technology. Importantly, students are an excellent resource. Computer Science faculty members have long known that getting students involved in the design of their own web-based courses is a win-win situation for both parties. Finally, to be called a technology novice is not an insult. The novice's open mind and freshness have traditionally been the engine behind the evolution of approaches discovered by the innovators and developed by the early adopters. The novice approaches the chalkboard and the chatroom in a positive fashion.

Co-operative Multimedia Authoring: European Logisticians and Their Educational Network

LogNet – The idea of a network to support logistics education

Some years ago, the on-going practical use of computer-based methods for planning, controlling and managing processes in industry and business as well as the availability of modern information and communication technologies at universities encouraged the development of an educational system tailor-made for the specific interests of university-level logistics education. As result of a long-lasting, ineffective and discontinuous developmental process a first small module was implemented in English and German language which was of interest to logistics educators from more than 20 universities and colleges from all over Europe. In the same time, students and educators who had tested, used and evaluated this "product" have been coming up with lots of comments, ideas and wishes for improvement and extension. But as we learned from experience, further developments of any kind (i. e. translation, modification, adaptation, or extension) would only become possible in a collaborative developmental process of internationally distributed authors on the basis of a joint communication network.

Realizing this tremendous demand for collaboration in developing educational multimedia, the idea of an educational network of persons and institutions engaged in logistics education and interested in supporting it by use of multimedia and information technologies (LogNet) arose. Since logistics educators are often not very familiar with those so-called new technologies and their potentials or limitations, the network must first of all bring together interested people and provide them with structured information about the technical and pedagogical state-of-the-art in educational multimedia, its development and use. So, first activities concentrate on organizing teacher training on these aspects. In addition to this LogNet wants to make multimedia resources of different logistics topics, educational targets, complexity, and forms of knowledge presentation available to logistics educators and to encourage the discussion about concepts for their use. As the overall objective the initiative is focused on initiating, setting up and establishing a co-operative, distributed development of educational multimedia in the field of logistics and enabling logistics educators to introduce those kinds of technologies to their educational processes as knowledgeable consumers or well acquainted supervisors or even to become enthusiastic multimedia developers.

For this, the network follows two different strategies: In the old, traditional way workshops, user group meetings and summer schools will frequently be organized to enable face-to-face contacts. In the new, modern way an Internet-based infrastructure will support all information, communication, collaboration, and exchange processes by forming a virtual community. Especially the latter requires to think in more detail about how to organize those kinds of distance training and co-operative developments.

The LogNet server – Logistics behind the logisticians' educational network

From a logistics point of view this educational network of logisticians can be seen as a structure of nodes and links (relationships) between them (both together forming the logistics system), that has to store, transfer, and handle objects (in a logistics process). Following fundamental logistics principles the network then must work in a way that it comfortably provides users with information, knowledge, and services in a purposeful, customized manner appropriate to the users' needs and intentions. As most reasonable solution for this an Internet-based infrastructure can be seen which should have a powerful heart for the purpose mentioned above – the LogNet server.

The LogNet server can be characterized as a forum for discussion, communication, and exchange in the form of an open information system. It is closely oriented towards the providing of maximum support to logistics educators and consists of three major sections: Information, application, and collaboration. The first section provides the user with general information about multimedia in logistics education and scenarios for its use, but also information about multimedia applications available to support logistics education as well as an overview of results from their evaluation. On the other hand it serves as meeting point of interested persons or institutions and news stand containing latest publications, conference reports and announcements, or other links of interest.

The application section deals with all aspects relevant for using multimedia material: This touches not only administrative information about the conditions for using and/or evaluating available educational systems, but also instructions about how to use or how to evaluate them including corresponding teacher training information and material. Last but not least, it contains a multilingual collection of educational multimedia on different logistics aspects and multimedia resources of varying complexity available in a knowledge pool and ready for being used.

This pool of resources forms also a very important component of an environment for supporting collaboration in multimedia authoring, which is the third main section of the LogNet server. The structure of this section is similar to the application section. It provides also both administrative information (e. g. possibilities and conditions for translating or expanding existing educational modules or creating a new one) as well as instructions and training material (in this case about how to work and which basic concepts and general guidelines are suggested to be followed). Authors could also get access to a collection of multimedia resources available for being translated or adapted. These modifiable resources represent a subset of the usable resources accessible from the application section. And in the other way round, all newly developed or modified resources have to be described in a way that they can become part of the knowledge pool and are available for use.

In this way the LogNet server is not only a stock of information, but also a framework for education and training as well as for enabling collaboration in distributed authoring processes. That is why it has to provide multiple functions within a user-friendly designed, context-sensitive operating management infrastructure.

Results so far, steps to do next and problems remaining for the future

Despite it was growing step-by-step the educational network is still in its infancy: At the moment its nature is changing from being a user group to becoming a supportive developmental (authoring) environment. This mutation is directly driven by the LogNet members themselves and their wishes, because the availability of the existing multimedia module in further languages and its adaptation or extension in contents becomes more and more important for its wider spreading. These kinds of activities are organized in two phases to separate the modification of resources from changing the application. For this, the developers are provided with the appropriate (original) resources via file transfer, which they translate or adapt according to general guidelines. These new resources are sent back to the original team of developers, who finally embed them into the existing module and make this new application available for further use.

Next steps we are going to do will aim on setting up the LogNet server and bringing some life into it by creating the initial stage of a pool of multimedia resources including the required management infrastructure. While the LogNet server in general will also work as the network's shop-window to the world, the access to the pool of resources will be limited to those LogNet members who play an active role in filling it. At the conference we will demonstrate this progress and report about lessons learned from the server's implementation and use. With this, special attention will be paid on explaining which criteria will have been proved as most suitable for describing and identifying resources as a particular piece of software containing a particular aspect of logistics knowledge and being usable for a specific category of students as well as a certain educational target.

But there are lots of additional problems remaining for future work. Some of them like e. g. the development of a comfortable environment enabling real co-operative authoring in the Internet, the definition of assisting guidelines from the pedagogical, software engineering or design point of view, or the creation of an evaluation procedure and technical framework for guaranteeing high quality of multimedia teaching and learning resources are still a matter of research. Other questions like e. g. the handling of copy rights should rather be the subject of more global agreements. And the financial perspective which is of special importance for future developments leads to the vision of transforming this mainly idealism-driven server into a self-supporting service.

Art and Technology integration:
Activity theory and after school multimedia education

J. David Betts, Ph.D.
University of Arizona
College of Education, Room 505
Tucson, AZ 85721
bettsj@u.arizona.edu

The Multimedia Arts Education Program at the Tucson Pima Arts Council in Tucson, AZ is a five-semester after school arts technology program for low-income middle school urban youth. This paper is based on the first year of a longitudinal study designed principally to determine the effects of the program on the high school careers and upon graduation rates of students who complete the program. Most started the 600-hour program as sixth graders. They finished their work in the five labs within two years, including a summer semester. Graduates earned skills and experience in art technology, and, on graduation, a computer of their own. Along the way they write, draw, shoot video, and use computers to design graphics, publish stories and articles, and create animations.

Our lens for this study is activity theory. Activity theory allows us to look at this group of teachers and learners as agents-in-a-context, in a Vygotskian cultural-historical sense, who are engaged in tool-mediated, goal directed action. Agency, context and genetic, or historical, development are the focus of this look at an apparently successful program for young people.

Population

Eight to ten middle school students are enrolled in each of the five labs each semester. Most are Hispanic and bi-lingual to some extent. Many come from single parent homes in the downtown areas of Tucson. Their families must qualify for free or reduced lunch program at their schools, and not have a computer at home. A balance of male and female students is maintained through admissions processes. Students are required to maintain a "c" average in school in order to continue in MAEP.

Students receive small educational incentives each semester for attaining the required skill levels ($25) and completing their independent projects ($25). Upon completion of the program, each student receives a desktop computer of his or her own.

Activity theory

Activity theory as a methodology can provide an integrating framework for linking a set of principals (Nardi, 1998) such as the concept of computers as mediating tools which allow us to interact with our environments. Activity theory (Rubtsov & Margolis, 1996) proposes that a learning environment can be best understood by taking activity as a unit of measurement. Activity includes working with others inside a system of culturally defined tools, signs, and symbols. Activity theory takes into account the goals and motives of the learners in the context of the setting and its social aspects.

"Activity theory holds that the integral units of human life - humans interacting with each other and the world - can be conceptualized as *activities* (Italics in original) which serve to fulfill distinctive motives." (Scribner, in Tobach, 1996, p. 231)

Activities have a structure consisting of motives, goals, actions and operations. Activity theory holds these to be the structural units of human behavior, and, accordingly, appropriate units of analysis for learning environments.

In the course of their *activities* in this setting, students engage in *actions*, such as designing and creating. The *operations*, which compose actions, may be both mental [learning new software] and behavioral [drawing]. Actions are carried out for particular purposes or *motives*. Students may wish to learn more about art technology, learn new computer skills. They may wish to please their parents, earn money, or get their own computer. Activities take place under particular conditions: in the multimedia lab, next to an art gallery, after school, and so on, and with particular technical means. In our case computers, cameras, application programs that support creativity in language arts, graphics, animation, etc. Activities are goal-directed. One salient *goal* for the students is the personal computer that will be theirs to take home when they graduate. Another is high school graduation. People engage in many activities concurrently. Activity theory accounts for learning in that as a task becomes automatized it forms part of an operation that upon mastery becomes an action that is part of an activity, which leads to goals.

Data collection

Our purpose was to gather information about the program in the contexts of the MAEP lab, the home, and the school. University students worked as teaching assistants in the labs doing participant observation focusing on activity patterns and the development of curriculum. Data is being analyzed for evidence of æsthetic response (Vygotsky, 1971) and correlation with student outcomes in terms of perceived self-efficacy and attitudes about art and technology.

Exit interviews were conducted with the graduating class during their final portfolio activity. Parents of graduates were interviewed to ascertain their awareness of the program, level of satisfaction and influences of the students' new skills on the family. Graduates and their parents will be interviewed again about eighteen months after graduation. English teachers at the high school were contacted.

Each semester students took pre- and post skills tests developed by their instructors. They completed questionnaires about their perceived self-efficacy (Bandura, 1993) and attitude. Students report on their favorite arts activities and books they've read, etc. Questions related to attitudes about collaboration, perceived self-efficacy in regard to creativity and technology, their expectations for the program, and their career plans. Each semester they worked with their teachers to fill out self-evaluations. Students and teachers kept reflective journals. In addition, students are evaluated by their teachers and evaluate their learning experience each semester. These young people produced high quality work in print and digital form, including graphic designs such as logos and story animations, poetry, newsletters and video programs

Summary

Parents reported that they were highly satisfied with the program and that the experience had helped their children mature. Students reported that they participated in the MAEP activities motivated by a new computer, a wish to learn new art skills, and to please their parents. Students learned to use the software programs as tools to design and produce. Many responded to the arts-based setting and enjoyed sketching a drawing by hand. The conditions of the class presented a unique opportunity to interact with peers. Students reported that they saw a benefit from the Language Arts lab in their English classes. The computer skills acquired were less often recognized by the students as advantageous in school, however, they were looking forward to taking more courses that utilized technology in high school and were more likely to select those courses for themselves.

Of course, this after school program takes place amid a great many other activities. Students and faculty each brought a history of educational experience and technological expertise with them and they each contributed to the culture of the MAEP and of each lab. The history and development of the students, the evolution of the program's rules and policies, the volatility of the technology all are a part of this equation and all are dynamic. This study hopes to shed some light on these phenomena. We have established the procedure for the longitudinal study. The exit interviews, the parent interviews, the role of the teaching assistants, the assembly of data from the various questionnaires are in place, and we have begun a baseline for further study.

Introduction

Today, educators have the technology to create an exciting student-centered learning environment that: a) accommodates different learning styles; b) accommodates different rates of learning; c) provides learning in context; and d) broadens the choice of learning and teaching partners. Yet most of the computer-based and computer-assisted courses developed to date are little more than electronic textbooks or lectures. Many educators are only using multimedia and information technology to do the same old thing - modify print or lecture-based courses, which are linear in their design - to a computer-based equivalent enhanced only with hyperlinks. This is not good education, and it does not address the learning style of many of today's youth.

Through computer games and programs like ICQ, today's student is accustomed to the interactivity that the computer and computer networks provide. They are accustomed to being able to complete a variety of tasks on a computer without referring to an instruction manual. They leap into games and scenarios going to the 'help' screens only when hopelessly lost and when the program is interesting enough to make it worthwhile. Mature distance learners are generally very busy with other responsibilities and commitments. They commonly have some level of practical experience in the discipline they are studying, and become frustrated by vast quantities of seemingly irrelevant on-line reading.

Philosophy/Concept

We believe that the real power of the computing environment in teaching is the ability to create real-life scenarios that engage the learner. Through the process of solving problems posed in a scenario, the mentor ensures that students have, or will acquire a basic set of skills or knowledge. The use of virtually unlimited navigation paths, along with multimedia presentation, and controlled access to information, allows the course developer to create a stimulating and positive learning experience for all students. This environment allows for learning to take place within a real-life context, and accommodates the different ways and rates students learn.

Project EdEx

With this in mind, Acadia University's Division of Continuing and Distance Education has embarked on project EdEx. The goal is to create a single prototype course which harnesses the power of the computing environment, and focuses on student-centered learning. Through the development of prototype courses we can develop a template that encourages instructors to break the old habits of "sage on the stage", and become the "guide on the side".

The development of these courses goes through stages. First, working with instructors, we establish the objectives for the entire course, and for the individual course modules. The second, and most important phase of the project, is identifying a series of problems or scenarios that: a) are relevant and current, b) are interesting and captivating, c) require students to apply a specific knowledge set, and d) require students to interact with learning and teaching partners anywhere on the planet. Finally, we use today's technology to present the scenarios.

As a prototype we are using a combination of HTML and Authorware to develop an environmental geology course. The course adopts a modular approach with each module incorporating a major topic area, e.g. geological hazards, earth resources, etc. The course is designed so students begin with a particular problem or scenario - not a lecture, and then access information as required to complete the tasks.

In each module, students face simulations of 'real-life' problems encountered by environmental geologists. For example, the student may be faced with the problem of building a shopping mall in southern Quebec. In order to make an informed decision about whether the mall should be built and the best location, students need to have knowledge of several key geological concepts, e.g. rock classification, geological environments, mass wasting, soil processes, etc.

As the level of prior knowledge for each student varies, the course is designed with all of the learning options up front so students may choose the one(s) they need to pursue. The problems are designed so that students must apply correct knowledge and concepts, but may enter the knowledge windows and help areas of their choice. Those who know how to identify rocks, for example, are not required to wade through the information presented on rock identification before continuing the scenario. To avoid the misconceptions which are often associated with prior knowledge, students will be required to periodically demonstrate a certain level of understanding before advancing to the next stage of the problem.

The scenarios and knowledge banks all take advantage of multimedia to accommodate different ways students learn. They can "see it", "hear it", and virtually "try it".

In order to develop cross-platform courseware we chose to use HTML as the front end of the course. Students can run the entire course through their browser with the QuickTime 3.0 and Authorware Shockwave plug-ins. Taking this approach allows us to deliver the course via the Internet and on CD-ROM, the latter being the more desirable approach. Menu options and navigation will be conducted through the HTML interface, with the interactive component of each module being controlled through a combination of HTML and Macromedia Authorware. Courseware developers without these tools should not be deterred from this model. Although the tools are an important factor in constructing the course, the key is the idea that students need to have ownership and control over their learning. The 'repaired' web allows courseware developers to give this control of learning back to the student.

We are very excited by this approach. By working through several prototypes our end goals are to develop a template that University instructors can adapt to any course, and to support a more dynamic learning environment both on and off campus.

DEVELOPING THE EASTERN VIRGINIA TELEMEDICINE NETWORK: SURPRISES ALONG THE WAY

C. Donald Combs, Ph.D.
Vice President for Planning and Program Development
Eastern Virginia Medical School
Norfolk, Virginia, U.S.A
Combs@planning.evms.edu

The Eastern Virginia Telemedicine Network (EVTN) is a health professions' distance learning, teleconsultation, and clinical telemedicine network established by the Eastern Virginia Medical School (EVMS) and the Eastern Shore Rural Health System, Inc., with major funding support provided by the Virginia Health Care Foundation, EVMS, and the Eastern Virginia Area Health Education Center (EVAHEC).

The network consists of two distinct telecommunications links between the Norfolk campus of EVMS and the greater eastern Virginia community. The first network utilizes a one-way video signal transmitted via microwave from EVMS to the control room of WHRO, the eastern Virginia public television station. WHRO then rebroadcasts this video signal over its wireless cable network throughout eastern Virginia. Participating institutions receiving this signal include hospitals, health departments, community health centers, community colleges, multi-physician private practice groups, and others. Viewers who would like to ask a question of the presenters, during a Grand Rounds session for example, direct-dial in to the EVMS studio over a toll-free telephone line. The second network consists of a two-way video, two-way audio, videoconferencing network linking many of the same institutional partners over digital telephone lines that allows for ad hoc communications to encourage teleconsultation among providers, to support health professions' student training in medically underserved areas, and to facilitate clinical telemedicine activities in the coming years.

The Eastern Virginia Telemedicine Network was established for several reasons: First, to improve the recruitment and retention of primary care health providers in medically underserved areas of eastern Virginia by reducing their sense of professional isolation. Second, to support the training of new primary care health providers in these areas by increasing the opportunity for health professions' students to train in those remote areas while being linked to their educational programs for didactic sessions. Third, to improve the quality of care provided in these areas by providing the most current medical information to providers and by increasing the amount of professional consultation among community and academic health center professionals. Fourth, the EVTN will ultimately reduce the cost of health care in remote areas by eliminating unnecessary patient referrals to distant treatment centers.

The Eastern Virginia Telemedicine Network provides a variety of programming to diverse audiences. Grand Rounds sessions at the academic health center are made available to a wider audience of health professionals in eastern Virginia, providing them with the opportunity to receive continuing professional education credits through program viewing. Health education programming will also be made available over the network to consumers of health care services in eastern Virginia. Quality health care programming produced by other entities throughout the United States, and indeed, the world, have been downlinked utilizing EVTN satellite facilities at EVMS and rebroadcast to eastern Virginia health providers and consumer viewers over the EVTN.

During the two-year development of the EVTN, a variety of surprises happened. These surprises involved factors such as the challenges posed by using existing space originally designed for other purposes; by working with limited (but adequate) funding; by technical integration; by long-standing presentation habits of faculty; by accreditation constraints; and by divergent concepts of need. Yet, the EVTN works. This presentation describes the development process and the lessons learned so that future development efforts might suffer fewer surprises – both technical and human.

EASTERN VIRGINIA TELEMEDICINE NETWORK "LESSONS LEARNED"

1. Unless you are a techno-whiz, utilize a technology consultant to help you.
2. Utilize a consultant who is unbiased concerning telecommunications medium and hardware selection.
3. Attend national conferences on telemedicine and distance learning—also good hunting grounds to find a consultant.
4. Attend a minimum of 20 sessions of whatever type of program—classes, Grand Rounds, etc., you want to broadcast before talking to a consultant.
5. Write down for the consultant the functionalities you want your project to accomplish.
6. Make sure that the audio portion of the project is not forgotten due to the usual focus on the video portion of the project.
7. Schedule construction work during organizational "down-times", such as summers and winter breaks for educational organizations, to minimize disruption.
8. Prioritize project tasks so that the most time-consuming tasks, i.e., communications licensing issues, accreditation issues, are handled first.
9. Don't underestimate the impact that small changes in audio-visual equipment will have on presenters using the new equipment.
10. Don't underestimate the impact that non-technical human factors can have on the success or failure of your project.

Coaching Educators to Use Telecommunications: Lessons Learned from a Statewide Telecommunications Education Training Project

Janis H. Bruwelheide, Ed.D.
Professor
Project Director, US WEST Montana Teacher Network
College of Education, Health, and Human Development
Montana State University-Bozeman
United States
janisb@montana.edu

Background

The US WEST Montana Teacher Network (hereafter referred to as the MTN) is a project funded by US WEST as part of its Teacher Networks initiative. Beginning in 1995 and ending in 2000, the US WEST Foundation has provided funding on a competitive basis to help one percent of the teaching force in each of its fourteen state region prepare to use telecommunications and to train an additional ten percent of the state teachers through peer coaching and training. States were brought into the projects on a phased basis. The lead states which served as pilots and received the first wave of funding in 1995 were Colorado, Idaho, and Utah. Montana is a part of the second group of states to be funded. The third group of states received its initial funding in 1998. A goal of all of the projects was to prepare eleven percent of each state's teachers to use telecommunications in schools.

State affiliates of the National Education Association worked with state US WEST teams to plan and implement the networks. Each state was given funds to provide one percent of the teaching force in each state with a notebook computer, a graduate course in using telecommunications, and online support and networking to facilitate the peer coaching of the additional ten percent of the teaching force. Some funding was also provided for administration, project evaluation, and participant expenses. The grantees and fiscal agents in the networks were to be schools or colleges of education although a few states were able to run the networks through a state office of public instruction or equivalent by partnering with schools or colleges of education. It was hoped that the states would be able to supplement project funding through other sources but this task usually proved difficult as many of the states are economically depressed and face tremendous geographical and telecommunications obstacles. However, the project teams and teachers have been very creative in delivering training and the projects have been successful.

Teachers have a great deal of subject knowledge and classroom expertise. However, they do not often have an opportunity to share what they know with colleagues in a networking manner when geographical challenges make physical meetings so difficult. Educators can feel very isolated--especially in smaller schools where h/she may be the only technology "guru." The beauty and power of the Montana Teacher Network is that in a low-cost manner, it is helping educators access a technology which will allow a far greater sharing of professional knowledge and allow them to also expand their personal professional development. Through its model of "peer coaching" in small groups or one on one, over 1300 Montana educators have learned to apply telecommunications technologies in their classrooms. Students and communities are the beneficiaries of such a model.

The Montana Teacher Network

Montana is a large, sparsely populated, economically depressed rural state with a <u>total</u> population of @ 800,000. This population translates into less than four people per square mile.

Geographic centers and populous areas are separated by vast land mass which is often mountainous. As a comparison, the sister city in Kumamoto, Japan, has over one million people. Travel in Montana is often difficult due to poor weather conditions during much of the year and air access is limited beyond a few cities. To provide a perspective of the size of Montana which is the fourth largest state, readers are informed that the entire New England states in the United States could fit into Montana physically and Montana is two thirds the size of France. Montana Office of Public Instruction data have indicated that the public school population, K-12, is @164,560. More than two-thirds of the public schools enroll fewer than two hundred students. In the 1996-97 school year, students were enrolled in schools ranging in size from 1 student to 2,400 students. In Montana, there are 56 counties and 900 public schools in 460 districts. School districts are located in an area the size of New Jersey, New York, Pennsylvania, and Ohio combined. These comparisons provide some perspective as to the challenges facing teachers to remain technologically current as well as the difficulties in providing training opportunities for teachers with or without credit attached. Thus, the opportunities and peer coaching approach provided through the Montana Teacher Network have filled a needed gap for professional development and training in Montana.

Montana State University-Bozeman is the fiscal and intellectual property agent for the Montana Teacher Network. During the first year of the project which began in late May, 1997, 132 teachers were selected through an application process to be the first wave of coaches. Each received a notebook computer for their use as long as they are public school teachers in Montana. The teachers were divided into five workshop groups to attend a three day summer workshop which provided an overview of telecommunications and hands-on Web basics. The workshop was the first part of a three credit course. Teachers could choose to take the course for graduate credit, renewal credits or not-for-credit. However, as part of the grant award participation , the teachers signed contracts to complete the course and grant requirements of "each one coach 10." by end of 1999. During summer, 1997, four workshops were held at the Montana State University-Bozeman, Burns Telecommunication Center in Bozeman. One workshop was held at the University of Montana campus.

The online course component began in September, 1997 and finished in May, 1998. It was delivered over MSULINK, a First Class Intranet Client computer conferencing software housed on a server at the Burns Telecommunication Center.

During the second year of the MTN project, the teacher coaches were required to execute their training plan for coaching at least ten peers in using telecommunications in education. A web site and MTN conference was established on the state telecommunication network, the METNET which uses First Class Intranet Client computer conferencing software with which the teachers were already familiar. The coaches and their ten colleagues had access to a wide variety of resources, information, and online conversation about incorporating online resources into their respective curricula and communities. The URL for the Montana Teacher Network is:
http://www.metnet.state.mt.us/~MTN/). The teachers also have access to all the information and resources available at the METNet website which can be accessed at the following URL: http://www.metnet.state.mt.us/MAIN.html. Since the First Class Intranet Client software is easy to learn and use, this vehicle fulfilled US WEST grant requirements of building on existing infrastructure and networks within a state since the METNet is housed on a server at the Montana Office of Public Instruction. In addition to serving education the METNet is used as the state server for government and other entities such as museums, projects, state information, and distance education opportunities offered by several higher education units in Montana.

To date, the Montana Teacher Network has been a success. Plans are underway to find additional financial support in order to expand the project to more educators and local communities. Teacher participants are being encouraged to present sessions at state and local educational conferences and meetings and to continue their peer coaching efforts and remain actively involved with the MTN website.

Technology Transfer and Web Course Augmentation Based on Learner Attributes

Dennis Moore, Ed.D. and Elizabeth M. Corbitt, Ph.D.
Wright State University
Eileen Wolkstein, Ph.D. and Rebecca Bausch, M.P.H.
New York University

Introduction

As education and training increasingly move into the realm of distance learning, research is needed to determine the impact of computer-based instruction on individual learning needs and styles. Whereas the ultimate goal for some settings is total technology transfer and electronic delivery of course materials, experiential and non-computerized interactive components have been shown to be important for many persons. This concept may be particularly applicable in fields demanding that active professionals upgrade their education despite the lack of appropriate degree granting programs immediately available. Thus, despite these professionals' potential difficulty in utilizing computer-based instruction, they may be constrained by circumstances to attempt this kind of course. Research on the effectiveness of different web course features for persons with different learning needs is therefore timely and of great potential utility. We are reporting the results of preliminary data based on a web course utilized as one component of a classroom course, hypothesizing that variables associated with learner characteristics would differentially influence learners' satisfaction with and successful completion of the web course.

Description of Web Course. The web course on which this research is based, entitled Drug Abuse, Disability, and Vocational Rehabilitation, has evolved from the work of the Rehabilitation Research and Training Center (RRTC) on Drugs and Disability, funded by the National Institute on Disability and Rehabilitation Research (NIDRR). Our epidemiology research has indicated a high prevalence of unidentified substance abuse among customers of Vocational Rehabilitation (VR) services, leading to higher failure rates and expenditures of funds without successful outcomes. Through meetings and training sessions with VR agencies across the country, a pressing need has emerged to inform counselors about the high rates of substance abuse, and to provide training in assessment, treatment planning, and VR counseling with customers with substance abuse issues. The decrease in training resources combined with advances in technology and the need to get information to more remote VR offices has led to the creation of this course.

Method

Participants in this pilot study were 37 individuals completing the web course in two separate classes (New York University, N = 20; Virginia Commonwealth University, N = 17) who filled out questionnaires before and after participation. Learners were graduate students in university rehabilitation departments, but had a wide range of backgrounds, including a number of professionals in the fields of substance abuse and/or vocational rehabilitation. When the course structure is finalized, learner characteristics, including age, gender, educational level, years post-matriculation, levels of computer expertise, and learning styles, will be measured on initial registration for the course. Outcome variables will include course grade, percentage of course completed, learner satisfaction with the course and with different aspects of the course, learner ratings of their own success and learning, and learner ratings of the utility of the course and of different course aspects. Additional course variables will also be measured, including time and frequency using various web course features, and level of participation in "real time" activities for course augmentation. For the purposes of this pilot study, outcome variables included course grade, and knowledge-based questions regarding course content, which were administered before and after course participation. A sub-sample of participants answered questions regarding their age and gender, as well as their satisfaction with the course, ratings of their own success, and ratings of the utility of face-to-face interactions in contributing to their course experience.

Results

For the NYU sample, age was negatively correlated with enjoyment of the computer at Time 1 ($r = -.75$, $p = .021$), and showed strong negative relationships to enjoyment of the internet ($r = -.544$, $p = .13$), comfort with using a computer ($r = -.597$, $p = .09$), and comfort with using the internet ($r = -.47$, $p = .20$). These correlations were no longer present at Time 2. For all participants at NYU, regardless of age, comfort with the internet increased significantly (mean T1=6.89, mean T2=8.32; $t = 2.19$, $p = .044$). Course grade was not related to comfort with computers or the internet. For the group analyses performed for the VCU sample, ratings of enjoyment of and comfort with computers and the internet increased between T1 and T2, with group means increasing from around 5 to around 7 on a 10-point scale for each of the four items (see Figure 1). An additional set of items related to knowledge of course material. For the NYU sample, the mean score of participants increased significantly from T1 to T2 (mean T1=6.6, mean T2=7.9; $t = 3.15$, $p = .005$). At VCU, the mean knowledge score increased from 5.3 at pretest to 6.6 at posttest. Knowledge scores were not related to comfort with computers or the internet at Time 1 or Time 2. Information regarding learner opinions regarding the utility of face-to-face meetings was collected for a small subsample of participants (N=9) at NYU on post-test. On a ten-point scale (where 1=extremely unimportant and 10=extremely important), these participants were highly variable in their responses, ranging from 1 to 10 (mode = 9).

Discussion

There currently exists a paucity of information regarding how specific elements of electronic learning differentially affect learner outcomes, especially as mediated by demographic and other learner attributes. The research reported in this paper relates to a web course that is likely to be offered to a number of simultaneous groups of traditional and non-traditional students in the future, and results from this study will be utilized in tailoring future revisions of the web course to groups of learners based on the modalities and approaches proven most efficacious for learner characteristics. These preliminary results suggest that older students may feel initially less comfortable with web-based learning, but become more comfortable with exposure. On the other hand, comfort with the computer or the internet did not appear to relate to course grade or to knowledge gained from the course. It is interesting to note as well that the two samples of students in this pilot investigation had different initial comfort/enjoyment levels with computers, suggesting that different classes will be quite variable. Although information regarding learner opinions regarding the utility of face-to-face meetings was collected for only a small subsample of participants, the high variability of responses was somewhat surprising, with answers ranging across both ends of the scale. While preliminary, these results suggest that learners do indeed have widely varying levels of comfort with computer-based learning, and may thus react quite differently to different course aspects.

VR Studying Business Education

Prof. Dr. Peter Baumgartner
Institute for Organisation and Learning (IOL)
Department of Business Education and Evaluation Research
University of Innsbruck (Austria)
peter.baumgartner@uibk.ac.at

Detlef Wydra
Wydra Grafik Design, Dortmund (Germany)
wydra@wydra.de

Introduction

At the department of business education and human resource management (University of Innsbruck; Austria) we offer all relevant information services for the students via the internet with a 3-D interface. Students (but also other visitors) can choose an avatar and move around in the virtual reality environment. They cannot only explore all the relevant information for their study in an interactive way, e.g. knocking at the door of a professor and asking for the outline of her lecture but they can also start the necessary action for the university administration, e.g. booking the lecture, download the literature etc.

This is a pilot project not on the technical but on the organizational level. Linking all the relevant information together is primarily an organizational task which will change the university structure. The project is embedded in a three year development project funded by the Austrian government which will restructure the whole university.

Background information

The University of Innsbruck, situated in the center of Innsbruck (130.000 inhabitants), has about 30.000 students. The faculty of Social and Economic Sciences has 5.000 students and consists of five major fields of studies: Business Administration, Economics, Business Education, International Economics and Business Studies and a doctoral program. The idea to build a virtual faculty is linked to three major university developments:

Firstly more autonomy for Austrian Universities. With a new law (University Organization Act 1993) all Austrian universities will get more autonomy in a transition period of about 10 year. Formerly all major decisions like budget, areas of specialization, appointment procedures were directed by the ministry of science in Vienna. Now we are building different university organs that will overtake these responsibilities. This process is very complex and has different phases; one of them is a kind of dual control of the old and new bodies. The new self-governing bodies are preparing their statutes but do not yet have the decision power for everyday business. The transfer of power from the old to the new bodies is a crucial process. Currently the University of Innsbruck is undergoing this difficult transition period.

Secondly, the move towards greater autonomy is accompanied by a strategic initiative of the senate (the self-governing body at the executive level at the university). In a three-year project, funded by the ministry of science, the members of the university are discussing organizational changes and future alternatives with regard to the content of services and performances. The main idea of this project is to motivate as many members of the university as possible to participate and cooperate in the transition process. Within the project ten different subgroups work on issues such as "Teaching & Research", "Personnel Management", "Central Information Services", "Financing & Controlling etc. One subgroup "New Media" investigates the future possibilities and organizational consequences of New Media for teaching and will provide the ruling body of the university with all the necessary information for strategic decisions.

Thirdly, in February the complete faculty has moved to a new building. This building was designed, constructed and built by a more than ten year participatory process. The new university building has not only already won some architectural prizes but has also led to a certain mood of awakening of faculty members.

Business Education as a virtual world

In this atmosphere of change our project tries to collect and concentrate all the different information for the studies of Business Education in one common interface. At the moment we have different approaches (database, booklets, internet services, introductory information by the faculty and student union, etc.) coming from different sources (ministry, center of EDP, initiatives of the department, individual information via a personal homepage, etc.). Most of this information is text-based with just a small amount of interactivity and time control. Redundant and complicated access to the relevant information are the consequences.

Virtual worlds are three-dimensional representations of objects in the space and their reproduction on display. To program virtual worlds the *Virtual Reality Modeling Language (acronym VRML)* is used as a standard platform-independent language for describing interactive 3-D objects and worlds delivered across the Internet.An extended type of the virtual worlds are the so-called *multi-user worlds*. In a multi-user world the visitors are shown by so-called avatars, so that visitors of multi-user worlds can see themselves among themselves.

This pilot project offers service performances for the students (in particular those in their first-year), the instructors and the administration. Beyond that it should also promote communication by using multimedia between instructors and students and among the students themselves. The three-dimensional reproduction of the faculty building and selected interiors and the virtual world resulting from it form the basis for the planned supplies and service performances. The information will also be callable in a pure HTML page version for faster access to the data.

Study plan: The compilation of the complicated study plan can be done comfortably from home by the accessible list of lectures and linked cgi-based HTML forms.
Virtual information: Students can receive closer information about lectures, seminars and exercises on-line at the virtual information boards. At any date modifications can be placed by the instructors. This up-to-date information can help to avoid unnecessary journeys.
Meeting allocation: At the virtual information boards the students can themselves into the lists for the respective meeting. This must not be done anymore at the real faculty in Innsbruck.
Email pool: By the collection of the email addresses of the students in an email pool, indicated for the entry to a meeting, the instructors and the students receive the possibility of taking up with all users of the appropriate meeting by email contact.
Virtual self-manifestation of the institute and its areas: Here instructors can publish up-to-date information about their institute e.g. research results, new book publications or job advertisements for projects, tutors or a scientific co-worker. Over an appropriate HTML form and email the application can be dispatched on-line.
Virtual consulting hour: In the lecture-free time the students can discuss any problems after previous log-on by HTML form with the instructors in the virtual consulting hour.
Virtual office for examination: Through a link to the examination office the students can check what documents are needed for the examination and request the missing ones by email or develop at least a precise routing plan to get all certificates.
Virtual communication: By the implementation of the virtual faculty as a multi-user world, the possibility of a communication among themselves exists for the students. When meeting at the points of information or in the cafeteria experiences can be exchanged, seminars be selected and occupied together.
Virtual "black boards": Students can enter themselves at the virtual black boards into different lists (room search, riding along opportunity, teaching materials etc.) and/or look up relevant information.

The administration of the updateable sections in the virtual faculty is made in each case by the responsible persons (e.g. office for examination, secretariat, instructors) over the Internet/Intranet by using a simple and self-describing interface. The updated virtual world is available directly, without further maintenance by a system administrator from the outside. A virtual information world developed in such a way can be administered by the users (the lecturers) themselves. When the system is accepted by students and faculty members it can be extended to other major field of studies, faculties or universities.

Global Warming: A Problem-Based Approach to Teaching Science

Jeffrey Bell, Department of Biology, California State University, Chico, jbell@csuchico.edu

James Pushnik, Department of Biology, California State University, Chico, jpushnik@csuchico.edu

Randy Miller, Department of Chemistry, California State University, Chico, rmmiller@csuchico.edu

There are a number of new issues that science educators have been grappling with over the past few years. Three of these issues are the introduction and increased use of educational technology in the classroom, the teaching of science in an integrated format, and the use of problem-based learning (Ramsey, 1997). To address these issues we have designed a course for non-science majors that is based on the very real problem of global warming, an issue of relevance to the students. To understand the various scientific issues involved in the global warming phenomenon necessitates a basic understanding of physics, chemistry, geoscience and biology, thus requiring an integrated approach to the sciences.

Presently, a student, whether a science major or not, receives an introduction to college-level science by taking a basic science course in one discipline, be it chemistry, biology, physics, or geoscience. It is perhaps only after several courses that students begin to be able to integrate knowledge across the sciences and see the larger, holistic picture - that the sciences have commonalties such as the scientific method, a need for quantifiable and verifiable data, the use of statistics and probabilities, and a healthy skepticism tied to the process of critical thinking. Only after several courses do students see the interface and overlap between chemistry and biology, geology and chemistry, physics and math, and the quantitative skills needed for good science. If they only take a couple of courses, they may never see this.

Problem based learning starts with the premise that students will learn better if they learn by solving ``real" problems as opposed to learning by rote memorization or solving artificial problems of little interest to the student (Arumbula-Greenfield, 1996). The sciences have always had a strong component of problem based learning in the traditional laboratory experiments. Unfortunately, two problems with the usual science laboratories are a lack of relevance to the student and little connection between one weeks experiments and the next, making it difficult for the student to tie everything together. Problems where the student wants to know the answer and needs to learn the science to find that answer are in very short supply.

Technology is critically important in almost all current scientific endeavors, however, little of this technology can be found in the typical undergraduate science laboratory, especially in classes for non-majors. Two explanations for this are the expense of the technology and the lack of time and motivation for the students to learn proper use of the technology. Current scientific problems and access to the appropriate equipment for studying these problems is needed to teach modern science.

With funding from the NSF we have designed a course organized around the scientific controversy of global warming. This course will introduce the students, both science majors and not, to the scientific method. Emphasis is placed on the collection and analyses of data, simple statistical evaluations and basic mathematical modeling techniques. This approach encourages the evaluation of ideas and critical thinking, questioning, hypothesis testing, and theories vs. hypotheses, all related to the same scientific and societal problem. By focusing the course on an extensive and complex issue, basic concepts and principles of science will arise naturally through the student's inquiry-based investigations and attempts to understand the various problems involved in the issue. Using a theme such as global warming, they will discover that they need to learn about concepts such as radiation, photosynthesis, the greenhouse effect, gas absorption, and the laws of thermodynamics. They will also have to consider the implications of this knowledge, and the limits of our current knowledge. An added benefit of studying a complex problem such as global warming is that, in addition to teaching some basic science, it will introduce the students to some of the techniques for dealing with complex systems, in particular, systems thinking and the use of dynamic models.

An introduction to systems thinking and mathematical modeling of global warming will be accomplished with the modeling program Stella®. A team of students, at the culmination of the course, will demonstrate and justify the final form of their model. The subject area of each scientific discipline would be substantially represented in the simulation. Chemistry will be represented by information, data, and interactive demonstrations on carbon dioxide, photochemical reactions, and gaseous exchange between air and water. Physics will have instructional components dealing with radiation, the greenhouse effect, and thermal loading. Geoscience will be represented by information on volcanic activity, precipitation data, satellite images, the use of fossil fuels, and long-term climate projections. Biology would have data on photosynthesis, the effects of deforestation on the atmosphere, and simulations of plant growth in varying concentrations of carbon dioxide. Mathematics will be represented in all of these areas as students learn how to quantify various aspects of the model using basic mathematical modeling techniques. Students will access data from satellite photos and international databases available over the web, these will be integrated into their models along with their own experiments in the laboratory.

The goal of the course is to stimulate students to learn science by becoming involved in a large, complex scientific problem that requires their actively learning many aspects of science in their efforts to find a solution to the problem. The specific problem for the students will be to determine the atmospheric composition, global temperature, and effect on the planet of a fifty-year period of carbon dioxide increases. They will create a model of biogeochemical cycles and weather phenomena, and collect information on fossil fuel use, methane generated by cattle feedlots and biomass burning, CFCs, etc. They will use their textbook, their instructor, the WWW, the results of their experiments, and specific data sources posted by instructors to gather information. Then they will use the modeling program to analyze the connections between these different components and to make predictions. In the process of solving this problem, students would have to understand and interrelate a variety of ideas without the typical discipline-based focus.

Students will do various experiments to learn about the scientific method and how experiments can be designed and used to quantify the parameters and relationships that interact to determine the earth's temperature. These will include black body experiments, infrared absorption, solubility studies and measurements of photosynthesis and respiration. Students will analyze their results and incorporate the experimentally determined parameters into their models at computer workstations that will be part of the laboratory. A special laboratory is being constructed for this course and will include both computer workstations and traditional lab benches. This studio-type classroom/laboratory is similar to those used at other institutions such as Rensselaer Polytechnic Institute and California Polytechnic State University, San Luis Obispo.

Our eventual goal is to use educational technology to teach science, and some math, in an integrated way by tying together several courses, faculty, and departments into an integrated curriculum which uses computer software simulations and models to help interrelate concepts, ideas, and principles across the science disciplines in a problem solving format. This curriculum, we believe, will address the needs of a wide variety of students with diverse backgrounds. Whether the students have a strong interest in math and science, are inadequately prepared, or have little interest or aptitude in math and science, the format of this course will encourage them to become deeply involved in the processes of science.

Educational Multimedia Accessibility and the Americans with Disabilities Act

By Scott Standifer, Media Specialist & Instructional Designer, Region 7 Rehabilitation Continuing Education Program, University of Missouri, Columbia, Missouri, USA. C529163@showme.missouri.edu

An informal poll at the 1998 EDMEDIA conference suggested that there is little awareness of disability access issues among AACE members. A report by the US National Council on Disability (1998) reported a similar lack of awareness among US multimedia developers. The NCD report also found that most multimedia developers were happy to comply with accessibility guidelines once the issues were explained. This paper is intended to raise awareness of disability access issues and point readers to resources for more specific information on achieving accessibility.

When asked about disability access, developers at the 1998 EDMEDIA conference gave two consistent responses: "People with disabilities are not part of our audience" and, "It is too difficult to accommodate them." These objections are both incorrect and, in many countries, illegal.

"Not Our Audience" - The Moral and Legal Mandate

The US National Council on Disability (1996a) called people with disabilities the largest minority group in the United States. There are an estimated 30 million US citizens with functional disabilities that limit their access to multimedia products (Vanderheiden 1990). The abilities and interests of this population are as diverse as those of the "normal" population. It is unlikely that any educational topic addressed by a multimedia product will not be of interest to some individuals with disabilities.

The proportion of the population that experiences functional disabilities rises dramatically with age, from 10% of adults age 25 to 34, to 45% of adults age 65, and 72% for adults aged 75 and older (Vanderheiden 1990). These figures suggest that the number of people with disabilities will dramatically rise as the US population ages. These figures also suggest that the odds of any particular individual (such as the reader) needing accommodations increases as that individual ages.

Different disabilities will limit in different ways a person's ability to interact with multimedia software. Relevant sensory disabilities include low vision, blindness, color blindness, reduced hearing, and deafness. Relevant physical disabilities that limit a person's fine muscle control and hand-eye coordination include spinal cord injuries, arthritis, cerebral palsy, various degenerative nerve and muscle conditions and other disorders. A variety of cognitive disabilities can limit how well an individual deals with rapidly changing situations.

Several researchers have pointed out that accommodation features for people with disabilities often improve a product's general utility (Bergman & Johnson 1995; Newell 1995). One classic case is sidewalk curbcuts for wheelchair access. Unexpectedly, curbcuts have also improved access for people pushing strollers, shopping carts, movers' dollies, or any wheeled device. Another example is books on tape that were originally developed as an accommodation for the blind but are now widely used by people on long car trips.

The latter example illustrates that, in some situations, individuals without a disability may have situational limitations similar to individuals with a disability. The driver of a car is visually limited by the need to watch the road. Similarly, accommodations for color blindness in a computer interface will also solve potential problems of users with black and white monitors. Alternative text-based versions of Web pages to accommodate individuals with vision problems will also improve access for individuals with slow modem connections. Captioned video clips for users with hearing loss will also improve use for individuals viewing in a quiet library or a very noisy computer lab. The provision of information in multiple formats (audio, graphic, text, etc.) from which the user can choose is useful to accommodate both users with different disabilities and users with different learning styles. Because of these general utility aspects, some researchers call computer accessibility features "electronic curbcuts" (Bergman & Johnson 1995; Campbell & Waddell 1997)

The archetype for many laws regarding disability access is the US's Americans With Disabilities Act (ADA) passed in 1990. This law requires (among other things) that all public facilities and services be accessible to people with disabilities. In the wake of this law, it has become standard in many US universities to include on course syllabi a statement describing the right of any student to accommodation for a disability. This has direct relevance to educational multimedia products. Any US educational institution that purchases or develops a computer-based educational product that is not accessible to individuals with disabilities is open to a lawsuit under the ADA.

Over the last decade, many countries have passed similar laws requiring access and accommodation for people with disabilities, including Australia, New Zealand, Canada and Britain. There is no single list of countries with such laws, but it is likely most countries have them at least on the books (personal communication, Mark Behrendt, World Institute on Disability, February 1999).

"Accommodation is too difficult"

The ADA and similar laws do not require expensive, burdensome accommodations for all possible disabilities. Instead, the ADA requires that software developers make a "reasonable" effort. Put another way, if there is something basic that is not too hard to do, you need to do it. What a developer cannot do is claim that nothing can be done. If access issues are addressed early in the development process, solutions are generally simple and inexpensive to implement. Accommodation only becomes expensive if it is left until after the product is finished.

The ideal approach to accommodation is built-in access to multiple media formats within the product. This "universal design" concept is most appropriate to developers working "from scratch" on entirely new software products that do not depend on existing software platforms. Approaches to universal design are currently the focus of more literature than can be reviewed here. A list of resources is available at the author's website at tiger.coe.missouri.edu/~rcep7/access.

A second approach, "Adaptive accommodation, " depends on the use of third party "accommodation software" (National Council on Disability 1996b; Bergman & Johnson 1995). There are many types of accommodation software products, ranging from screen readers and Braille readers for the blind to alternative mouse and keyboard controls for those with physical disabilities. Resources for such software are also at the author's website. If developers provide features accessible to these programs, a variety of disabilities can be accommodated to some extent. Below are some general guideline for developers and educators using adaptive accommodation:

1. Provide ASCII text (or text-only) alternatives for all information. ASCII text functions as a "presentation independent" format for a variety of accommodation software products. Many individuals with blindness use "screen reader" software that translates on-screen ASCII text to spoken language or Braille. Unfortunately, multiple-column text layouts can confuse screen readers. In addition, graphic images of text are inaccessible to screen readers. Developers should provide simple ASCII text files that accommodation software can accurately process. The problem of layouts has become especially significant in developing HTML accessibility guidelines. It should be noted that PDF files are not currently accessible to accommodation software.

2. Provide captioning and alternative audio tracks for video clips. Many video formats (including Quicktime and SMIL) now allow closed captioning of the narration for users with deafness. In addition, these formats allow an alternative audio track, similar to closed captioning, to provide additional descriptions for users with blindness. As mentioned, this can also prove useful for users in extremely noisy environments.

3. Provide text descriptions of all graphic and audio information. Besides text versions of images of text, text descriptions of all images, charts, and sounds must be provided. In HTML, use ALT labels for this.

4. Distinguish interface elements with more than one type of coding. Use a combination of media elements for all significant features of a multimedia product. If screen elements are distinguished only by different colors (colored parts of a map, for instance) people with color blindness may not be able to read it. This problem would also arise for people using a black and white monitor.

5. Be aware of local disability access resources. Many universities have disability access offices, which are a good source of information on accommodation software. The staff is frequently willing to demonstrate software and evaluate multimedia projects. Most educators and developers will find it enlightening to meet with the staff of a disability access office even before a specific need arises.

Building Web Courses with Instructional Immediacy (www.telecommunication.msu.edu/faculty/larose/websection.htm)

Robert LaRose, Ph.D. (larose@pilot.msu.edu)

Pamela Whitten, Ph.D. (pwhitten@pilot.msu.edu)
Department of Telecommunication
Michigan State University
East Lansing, MI 48824, United States

Prior research on live classroom teaching in higher education has found that the degree of closeness between instructors and students, or *teacher immediacy* (Hackman & Walker, 1990) can increase affective learning (or student attitudes towards instruction), which in turn increases cognitive learning. Immediacy behaviors that are easy to perform in class are difficult to even imagine in a Web course, such as smiling at students and calling them by name. Earlier research (LaRose, Gregg & Eastin, 1999) showed that Web courses can match the immediacy of live instruction when at least some of these features are present. Interactions with other students and interactions with computers may also affect outcomes, we refer to these factors collectively as *instructional immediacy* (LaRose & Whitten, 1999). Here we examine how Web courses might be improved by assessing the state of the art, adding immediacy features to web courses and understanding the immediacy needs of learners on the Web.

Web Course Content Today

We searched the World Lecture Hall for standalone Web courses delivered during the 1998 calendar year and that had at least one of their lessons available for public viewing. We found 48 and performed a content analysis of their immediacy features using a standard coding guide that yielded 90 percent inter-coder reliability. Few courses employ the multimedia capabilities aside from providing hyperlinks to additional information. Only a third include graphics in their lessons while less than 10 percent used video or animations and none of the courses used audio lessons. Aside from providing an email address, publication of the instructor's phone number was the only course-level immediacy feature found in over half the cases, although discussion areas are common to about a third. Few courses invite student contact outside of scheduled office hours. About two-fifths attempt to convey the personality of the instructor by posting snapshots or personal information. Opportunities for student interaction are minimal. There was only a single instance of a "students only" communications option. The most common immediacy feature in the lessons themselves is content that refers to the class in the second person (e.g., by using "we" or "our"), a third of the lessons did that. Open-ended questions and (delayed) feedback on student quizzes and assignments are in only a fourth of the lessons. To quantify immediacy, we computed an additive index of 24 immediacy features and found an average of less than six per course. Our sample was limited to publicly accessible material and perhaps better ones are hidden behind password protection barriers. With the permission of their instructors, we peered behind the password barriers at five Web courses on our own campus. The five courses averaged 13 immediacy features each and one contained 21 of the 24 immediacy cues in our index. Informal comments from other Web instructors with whom we shared our results confirm that the best features are often hidden from public view.

Improving Web Course Immediacy

We asked a sample of net-savvy college students from one of our on-campus courses to visit three Web courses and to "think out loud" as they surfed. One was entirely text and graphics, a second added audio and a third had video. Then our surfers joined focus groups to identify characteristics of "best courses" in the conventional classroom mode and to compare them with Web courses. Immediate feedback is what students crave. They want instant feedback, even if limited to finding out the answer to a multiple choice question or to a "roll call" feature that acknowledges them by name. Email is insufficient, responses are too slow and it requires opening a separate application. One virtual instructor encouraged students to use the AOL "instant messenger" system so that they could reach him any time he was on-line. But the "Help" button needs to be ever present in the lessons and (ultimately) lead to a real person. Many comments related to text-laden lessons. It's hard to stay focused on text or static graphics, but attention wanders even with Web video -- especially the talking head variety common today. Changing visual course outlines add to immediacy by locating learners in the course. Animated gifs and mouseover events can help. Failing that, students want an easy way to print sections of the course (as opposed to each individual page) so they can read from paper. Learners also criticize marginally relevant links to volumnious text resources. Teacher immediacy comes from personal information about the instructor that invites learners to imagine what kind of people instructors are, especially candid personal information, snapshots and personal comments about lesson material. Chatrooms do not create sufficient immediacy with other students. Providing pictures and bios of students is a way of "getting to know" others better, but some of our female students had a problem with that. Navigation issues include dead and misdirected links and secondary browser windows that completely overlap the lesson page. An on-site search engine and basic navigation and instructor contact buttons on every lesson page are also desired. Learners also like to save notes on-line, automatically go back to where they left off in the previous session, and launch the next page automatically (i.e., instead of hitting the "next" button).

Reaching Nontraditional Learners

We sampled email addresses at random from Bigfoot and directed respondents to our Web survey site. We received 25 responses to our pretest that give a preliminary indication of the factors in Web course adoption. Half of our respondents are interested in taking courses over the Web. The convenience of taking courses whenever and wherever the learner might want are two important advantages of Web courses. General convenience, the ability to work at one's own pace, the elimination of travel to campus and the ability to take the course in different places also received multiple mentions. Other advantages included the ability to concentrate and organize better in the home environment and to get better feedback than in the conventional classroom. Most saw the loss of instructor and student interaction as major disadvantages. Concerns about the quality of Web instruction and the acceptance of credits by employers are also widespread. Other are concerned about the difficulty of reading text off the computer screen and typing out course interactions, overcoming the distractions of the home environment, finding the motivation for self-paced lessons, and obtaining technical help. According to our respondents, providing feedback and praise to students are the most important teacher immediacy needs, followed by the opportunity to hold conversations before class, asking questions of students, organizing activities outside of class and smiling at the class. Some of the instructor behaviors thought to increase immediacy in the classroom are not very important to potential Web students, including inviting contact outside the classroom, displaying a relaxed posture, gesturing and allowing students to call the instructor by his or her first name. Interactions with other students are not as important as interactions with instructors but two stand out: Garnering praise from other students and having others sit near you in class.

1. Introduction

WebReCourse [5], the Retargetable Course Generator enables creation and reuse of Web courses. It is a secure software system for online course management, allowing instructors to increase the accessibility of online course material and to create a convenient means of communication between instructors and students. It provides many of the enhancements missing in the World Wide Web implementation of hypertext.
Previous papers [6,7] have analyzed student use and response to these tools.

2. ReCourse: the Student Perspective

ReCourse requires the student to login with a username and password. (Students who just want to see the pages, and don't plan on using the tools can bypass this login.) Once entered, the student sees the course web pages and icons representing the tools. Although the instructor can turn off any of the tools, the available tools are: *Add New User*, *Home Page Link*, *Chat Room*, *Search Tool*, *Grade Access*, *Site Map*, *Bulletin Board*, *Quiz Tool*, *Password Tool*, and *Help.* For further details on these tools, see [5].

3. ReCourse: the Instructor Perspective

We characterize faculty characteristics below:

Faculty Status (!) When the ReCourse team (students) sent an email invitation to faculty, inviting them to try out and then use the system, there was virtually zero response. When the author (faculty) sent the same message, many people responded.

Faculty Chaos & Inertia Of the faculty who did respond and declined to use the system, no one had time to even look at it. All mentioned wanting to use it "in the future." All appeared overworked - one mentioned being overwhelmed that term

Missing functionality One faculty used it for one term and did not choose to use it again. One of these wanted a feature not yet available (the grading system does not operate with full spreadsheet features yet).

No instructor help One factor is that some instructors have no teaching assistants to help them.

Unknown One other faculty member responded to our request, said he would like to use it, but, even with urging and help from the ReCourse team, failed to use the tools.

3. Author Characteristics

Although we continue to gather information and statistics, we know the following:

- The more computer literate an instructor/author is, the more apt they are to use the system, and the more apt they are to use more of the available tools.
- The more helpful the assigned ReCourse team member is, the more apt the author/instructor is to use the tool in its entirety.
- Newer faculty are much more apt to respond to the invitation, to use more of the tools, and to return to use it again. This is due to more experienced instructors having (existing, but not as appropriate) tools they are used to using and the general chaos that surrounds faculty members as they find themselves with more service activities. The ReCourse team believes as they hear that the tool is an asset, they will make the (small) effort to use it.

4. Conclusions

Using the Web to enhance or as the sole medium for teaching has produced a new range of problems and opportunities. Tools that facilitate such teaching are appearing and enhancing the delivery and activities of these courses. Studies have been made on how readers (usually students) use such material and tools. Systems have been developed that analyze the student profile, adapting both the pages and the navigation. Tools such as chat rooms, bulletin boards, cooperative learning techniques have all been designed, implemented, used, and studied from the student perspective. This paper explored the other side of these issues: the perspective from the author (usually an instructor).

ReCourse, the Retargetable Course Generation system, has had the instructor as a focus from inception. We reported on what we have discovered, what we have done as a result of these studies, and how these changes have improved and will continue to improve the system for students as well.

ReCourse is documentably popular and useful for web courses. Students like it. But students have grown up in a computer world and, now, even in a web world. Instructor/authors have more inertia. We are continuing to gather statistics from both the users and non-users in an attempt to encourage use of a system which improves the delivery of web courses.

Video Case methodology for Facilitating Technology Integration into Teacher Education.

Debra Kurth
Center for Technology in Learning and Teaching
Iowa State University, USA,
dkurth@iastate.edu

Background

Teacher education programs are a catalyst for producing quality educators for the preK-12 environments. It is through the classroom experiences and the guidance of teacher educators that can assist preservice teachers in the formulation of their philosophical beliefs regarding teaching and learning (Harrington, 1993). New teachers are quickly confronted with many classroom and administrative demands which requires them to have a firm grasp on their philosophical beliefs so that they can handle educational issues effectively. Technology is an increasingly important issue for preK-12 schools and has the potential to have immense impact on the learning and teaching environments. Because of the expedient growth in technology, it is critical for educators to be cognizant of technological uses, impacts, and creative integrative strategies.

Teacher educators in higher education are finding themselves inadequately prepared for technological uses, let alone having the capacity to integrate it as part of the curriculum (Panel on Educational Technology, 1997). Many agree that integrating technology into the curriculum is very consequential and vital to the survival of our educational institutions, yet it continues to be insufficient for many (OTA, 1996). Fortunately, there are quality institutions implementing innovative ways to use technology. No longer are just televisions and VCRs being used, but various technologies are surfacing in higher education learning environments creating rich and fertile grounds from which students and educators are constructing and building knowledge collaboratively (Thomas & Boysen, 1984). Using technology to transform classrooms evolves into changing the philosophy of the schools, and ultimately the overall view of education (Sheingold, 1991). Thomas & Boysen (1984) contend that in utilizing computers in the most meaningful capacity, there is the potential to create a context in which students are learning to educate themselves through the use of computers.

Objective/Purpose/Project Description

Since teacher educators are receiving insufficient exposure to learning technological uses, preservice teachers are denied learning opportunities, which ultimately impacts preK-12 education. There are periodic workshops offered for teacher educators in higher education, but they lack the situational learning that is needed so that they can adapt and transfer learning to their own environment. The poignant question that now stares at us is: What can be done to provide concrete examples and promote situational learning on the uses and integration techniques of technology for higher educators?

It is our contention that the construction of knowledge through the use of technology may be the most feasible, meaningful, and integrative method in which to learn methods of technology integration in the classroom. Educators need and desire concrete examples of what technology integration looks like and how it affects learning.

A research team at Iowa State University in the College of Education in the Center for Technology in Learning and Teaching (CTLT) has begun to address this problem. This research team has designed a multimedia program with video case studies on CD-ROM format that models exemplary uses of technology in various learning environments. The purpose of this study is to design, develop, evaluate, and implement this program in a learning environment for teacher educators to provide them with rich examples of how technology can fertilize, stimulate, and flourish a learning environment.

The video cases will be used as an anchor in the learning environment to provide a situation where the learners share a common experience (Hasselbring, 1996). Within this shared experience among the participants, the learners will collaboratively build knowledge by pulling from past experiences and merging that with new information received from the video cases. This approach of using the conceptual anchor in the form of video can produce a common frame of reference better than any verbal explanation (Blackhurst; Morse, 1996). The video captures a rich and flavorful environment from which the participants can see the emotion, energy, and body language (from both students and the educator) which prospers in a learning environment interwoven with technology.

Procedure

During Phase one, teacher educators were video taped in the College of Education who demonstrated exemplary technology uses in their teaching methods. These tapings were then viewed, edited, and constructed into video vignettes through the use of Adobe Premiere. The clips for the vignettes were carefully chosen in order to provide the richest examples that would be meaningful for the audience. A portion of the spectrum of video examples obtained include a math class using the Iowa Communications Network (ICN), a language arts class using Powerbooks, a math class using the Jasper series, and a special education class using the Discourse groupware system. Through utilizing a variety of content areas, we will be able to more adequately reach the diversity of the end-user.

The design and development occurred during Phase two and was formulated simultaneously with the video editing portion of the project. Many hours were spent within the participatory design team to create the most suitable interface for the end user. Drawings were initially compiled so that the group had a conceptual idea of the overall look of the program and navigation abilities that would be provided for the user. An initial pilot program was created to obtain expert appraisal and end-user feedback from Iowa State faculty and audience participants in various conferences. Suggestions were taken back to the participatory design team and revisions were made. As this project is continually under revision as we add new video cases and involve more end-users, this feedback is critical to the continual design and development of our final program.

The template for the interface of the multimedia program was developed in Adobe Photoshop and Authorware was used as the authoring tool. The multimedia program is constructed in such a way that each participant can navigate according to his/her interests and have the opportunity to experience realistic examples of technology integration and begin to reflect and construct knowledge for their personal usefulness.

Our intention for Phase 3 is to formulate a workshop for higher educators where the video cases, accessed through the multimedia program, are used as the anchor for instruction. The combination of group discussions, individual navigation within the multimedia program, and individual and group reflections will contribute to the ability of the participants to transfer newly acquired knowledge to their present situation. Rather than just using their imagination, educators will have the ability to obtain a realistic picture of what a learner-centered, technology rich environment looks like.

Data Collection

Research members will conduct detailed observations as participants interact with the program, noting reactions, comments, interest level, and the time spent navigating through the program. In addition, a follow up interview will be completed to determine if any of the perceptions and uses of technology of the participants have changed.

Preliminary Conclusions

The utilization of this video case multimedia product will not address all of the problems that staff development sustains for teacher educators in higher education. However, the modeling of learner-centered technology-rich environments will procure the missing element that many training situations desperately crave. This type of learning environment allows the educators to gain the knowledge needed to integrate technology, but is presented in such a way that each learner can construct how technology utilization can fit into his/her particular classroom. Through the rich examples of various technology uses, the learning environment becomes more meaningful and realistic for the teacher educator. This collaborative effort of viewing the videos, reflection, problem-solving, and construction of meaning will reinforce that the technologies used can improve the learning and transfer of knowledge to the participants classroom environment.

The Virtual Cell: An Interactive, Virtual Environment for Cell Biology

Alan R White[1] Phillip E. McClean[2] and Brian M. Slator[3]
Departments of Botany/Biology[1], Plant Science[2], and Computer Science[3]
North Dakota State University, Fargo, ND 58105 USA
alwhite@plains.nodak.edu; mcclean@beangenes.cws.ndsu.nodak.edu; slator@badlands.nodak.edu

Introduction: Learning by Doing

The Virtual Cell is being developed by the NDSU World Wide Web Instructional Committee (WWWIC), a multi-disciplinary group of faculty engaged in the development of virtual/visual worlds for science education (Slator et al. 1999). Other WWWIC projects include The Geology Explorer, The Visual Computer Program and ProgrammingLand MOO. Each of these projects share a common objective: to teach scientific problem-solving skills (deductive reasoning, experimental design, hypothesis formation) through immersion in learn-by-doing virtual environments. These projects are designed to support discovery-based learning in a self-paced, role-based, and goal-oriented framework. They are also learner oriented, immersive, and exploratory in nature. Each project aims toward highly interactive, highly graphical systems employing software tutors to guide and remediate in the event of student failure. In addition, each project individually pursues the objective of teaching discipline-specific science content through the achievement of authentic problem-solving goals, but using uniquely different approaches. The projects are designed to employ consistent elements across disciplines and, as a consequence, foster the sharing of development plans and development tools. More information about WWWIC and related projects is available at http://www.ndsu.nodak.edu/wwwic/.

One goal of post-secondary science education is to train future scientists. One problem with science education is the standard lecture/laboratory format. In lecture, the professor speaks, and the student passively listens. In the worst case, lectures are no better for learning than television: a totally passive, non-interactive experience. Meanwhile, laboratories are intended to afford students with an interactive, experimental experience, but in reality these are usually rigidly structured by the laboratory outline where the intended outcome is known and the procedure is inflexible. These are not experimental experiences. If laboratories were to be truly experimental, question- and hypothesis-driven experiences, then students would need access to modern laboratory equipment and instrumentation, an array of expensive laboratory reagents, and a wealth of instructor time that the university cannot possibly afford. Active learning can be expensive, yet the value of active versus passive learning has become increasingly clear (Reid, 1994).

The Virtual Cell

The Virtual Cell is a virtual, multi-user space where students "fly" around and practice being cell biologists in a role-based, goal-oriented environment. The Virtual Cell development project can be visited at http://www.ndsu.nodak.edu/instruct/mcclean/vc/. Working individually, or with others, students learn fundamental concepts of cell biology and strategies for deductive problem solving through their experiences in the exploratory environment, where they can make observations, manipulate the interactive objects, and design and perform experiments. This pedagogical approach gives students an authentic experience that includes elements of practical, experimental design and decision making, while introducing them to discipline content. By practical applications of the scientific method, students learn how to think, act, and react as cell biologists (Slator and Chaput, 1996).

The Virtual Cell is populated with subcellular components: nucleus, endoplasmic reticulum, Golgi apparatus, mitochondria, chloroplast and vacuoles. Each structure is rendered as a 3D object using the Virtual Reality Modeling Language (VRML), a computer language for specifying three-dimensional worlds that can be displayed and, most importantly, interacted with via the Internet. The Virtual Cell consists of a VRML-based laboratory and a cell. In the laboratory, the learner receives a specific assignment (learners are always assigned motivating goals in our learning-by-doing environments), performs simple experiments, and learns the basic physical and chemical features of the cell and its components. The virtual laboratory procedures require a voyage into a VRML cell, where experimental science meets virtual reality. The learner is supplied with a toolbox of measuring devices that assay various cellular processes. These tools include an O_2 meter, CO_2 meter, pH meter, sugar assay, protein assay, various stains, and enzyme assays. As the students progress, they revisit the laboratory, bring cellular samples back for experimentation, and subsequently receive more assignments.

The virtual cell contains 3D representations of all the components and organelles of a cell (nucleus, mitochondria, chloroplasts, etc). The user "flies" among these organelles and uses virtual instruments to conduct experiments. All navigation is learner directed; there is no predetermined exploratory path. This feature empowers the student to direct their own learning. The student is also able to travel into linked VRML worlds that represent the interior of each of the cellular organelles. Further experimentation inside each organelle allows the student to learn about their specific functions. For example, the learner may confront the nucleus and perform several simple experiments via touch sensitive points. The nucleus is not consuming or generating O_2 or CO_2 and it has a positive DNA Synthesis assay. Putting this and information from additional experiments together, the learner should deduce that the object is the nucleus and that DNA is contained there. Additional pertinent data about the nucleus and other cellular organelles can be collected in the same manner.

More advanced levels of the Virtual Cell include the introduction of cellular perturbations and the investigation of the functions of various cellular structures or processes. In the second level, a simulation will change the cell by either introducing a mutation or adding an inhibitor that disrupts a cellular process. An alarm will sound, some cellular process will malfunction, and the learner will be given the goal of diagnosing the problem. Using the same tools as in the previous level, the learner will navigate through the cell, make observations, and perform measurements and experiments. The learner will attempt to identify the affected area, the perturbed process, and the nature of the mutation or inhibitor that is causing the problem. As a result, the user will learn details of cellular processes and functions and become familiar with the importance of various mutations and inhibitors for cell biology experimentation. In the third level of the Virtual Cell, the learner will be given a set of goals to investigate a specific cellular structure or process. The learner will have at their disposal the tools from the first level and the mutations and inhibitors from the second level. Using these in various combinations, the student will form hypotheses, design experiments, and employ the toolbox items to perform these experiments.

The implementation of the Virtual Cell depends on coordinating three technologies: 1) VRML visualization, 2) a text-based MOO server (Curtis, 1992), and 3) Java client and simulation software. Students use a standard WWW browser to launch a Java applet, which provides a connection to an object-oriented, multi-user domain (a MOO; see below) where cellular processes are simulated and multi-user viewpoints are synchronized. The Java applet also launches an interface to the VRML representation of the Virtual Cell, allowing the student to explore and experiment within the 3D representation. The object-oriented multi-user domain (MOO) simulation on which the cell is established allows students to interact directly with one another within the cell, providing advice to one another or even working together to achieve particular goals. Because the MOO is internet-based, students from separate and distant locations can simultaneously interact with the cell and with one another. Unintrusive but proactive software agents act as tutors, monitoring students' actions and "visiting" the students as the need arises. Tutor agents provide advice on equipment choices, navigation, and scientific conclusions. Tutors neither mandate or insist on student actions nor do they block or prevent student actions.

Global Perspectives in the Political Science Classroom

Margaret E. Martín, Dept. of Political Science, St. Thomas University, USA memartin1@stthomas.edu

In attempting to get my students to engage with the actual conditions of the countries we study in an introductory comparative politics course, I have created assignments based around exchanges between my students (mostly from the US, 18-23 years old) and students in our case countries. The exchanges took place over in 3 different ways with different levels of instructor participation. The first exchange was between myself, my Comparative Political regimes class and Professor Nicolai Petrov who was teaching at Novgorod State University in Russia and his Political Philosophy class. The second exchange was a one to one "keypal" match between my comparative students and individual students from an ESL class in the Ukraine and the third exchange took place between my students and an introductory class in Foreign Affairs taught by Greg Poelzer at the University of Northern British Columbia, Canada.

The Carleton-Novgarod Exchange

I responded to a post on the Political Science Teaching e-mail list from Professor Nicolai Petro from the University of Rhode Island who was on a Fulbright Teaching fellowship at Novgarod State University in Russia. We arranged a class to class exchange where students composed questions as groups, which he translated from English into Russian. The result was a series of interesting question and answers between the students, which I posted onto our web site along with additional material about the class, and pictures of the students. Nicolai Petro sent me scanned images of his students and I put them up on our site. The exchange fit well into our week on Political Culture since I asked the students, not only to think of questions but also to reflect on the Novgarod students' responses in their "lab assignment." The exchange that we undertook with the Novgarod students was a fairly static affair, due to the constraints on the situation (the fact that the Novgarod students didn't have individual access to the internet and the need for translation.) Nevertheless, the students enjoyed the interaction and I was even able to use the assignment as a learning tool the following term when I had my students evaluate the exchange, focusing on the questions that were asked, how they were answered and if there were noticeable differences in political culture. The students found that there were. There were also interesting differences in the way my students perceived what was going on in Russia versus what the students perceptions were, living there. A great deal of attention was given to Ultra-Nationalist figure Vladimir Zhirinovsky in the US, compared to his actual draw at the polls in the 1996 elections. The Russian students felt that Zhirinovsky was "stupid" and "comical" and said they were not surprised that he lost the elections. The Russian students also looked at the effect of the economic crisis from their own perspective, they commented on how their instructors were not receiving their paychecks regularly and the students were not getting their stipends either.

The Carleton-Ukraine Exchange

After this positive experience with an exchange I began to search out other opportunities for exchanges. A matching service at by St. Olaf College (http://www.stolaf.edu/network/iecc/) for teachers and students seeking "keypals" (matching students with e-mail addresses for direct correspondence) although the process of identifying and setting up potential exchanges proved to be a frustrating process with this method. The main reason I discovered was that most of those interested in exchanges were high school classes, which were not at my students' level or ESL classes. I was eventually successful in establishing a "keypal" link up with an ESL class at the Technological University of Podillia in Khmelnitskiy, Ukraine. I developed some simple questions that the students could ask about living under economic reform in the Ukraine.

Although two of my students reported positive and interesting interactions with the Ukrainian students, the rest of my students complained that they had been disappointed with the assignment on a number of counts. Students that initiated the contacts late discovered that some of the Ukrainian students only seemed to check their e-mail about once a week. Some never seemed to check their e-mail at all. When I questioned the teachers about this, they replied that a few students had been "sick" a great deal or that they really had no idea what the problem was with the student. Such low accountability led to an imbalance in the exchange and except for the two aforementioned students, the exchange was not a success. The University of Podillia also apparently experienced a massive failure with their external internet connection late in the term which further complicated the exchange. In principle, an ESL class could have worked, however, ESL teachers are notoriously overworked and underpaid nearly everywhere in the world, it seems and thus, the amount of effort that teachers can devote to such a project is limited. Of the two students who did exchange e-mail with the Ukrainians, it must be said that the exchanges were extraordinarily beneficial. One student was puzzled that her keypal didn't seem to be suffering much from the Economic situation. After several exchanges, my student learned that this woman's parents were both business people in the new capitalist economy, and were relatively successful. From this, my student learned that in the economic reform in the former Soviet Union, some people are doing better, even though many are doing a lot worse in the immediate context and that experiences are likely to be different across society. The other student who was successful found common ground with his partner in that both came from families who had struggled. My student was from an Hispanic neighborhood in east Los Angeles and had come to Carleton on a Scholarship.

The Carleton- UNBC Exchange

This last exchange was probably the most effective in terms of the quality and quantity of information traded back and forth. I put my request for an exchange on the political science research and teaching list that I had discovered Nicolai Petro's request on and received a response from a Canadian political scientist, Greg Poelzer who had been forwarded my request by a colleague. Greg took the initiative to set up a simple, threaded web based forum in which both of our classes could input questions and responses on topics that he put up. We put up political culture and the Quebec issue on the board and both got interesting responses. My students were perplexed to learn that the British Columbia based students could care less about Quebec separatism and were more interested in issues involving their own province, such as Native rights. From this they learned about Canadian Federalism, as a cultural and institutional separateness that already exists in Canada, quite apart from Quebec's bid to be sovereign.

Some Concluding Remarks and Suggestions

Not all courses benefit from this kind of exchange, but such interactions can be extremely worthwhile. The role of the instructor is transformed to some extent. I am less of a gatekeeper and more like a guide. Although I still present the student with information selected and "pre-packaged" by me, with these exchanges they are also faced with "raw data" (comments from their "keypals" or classes in other countries) that they must attempt to evaluate. The three different formats for exchanges provided acceptable communication conduits, although it was clear that the human component had to be committed to insuring a quality exchange. Exchanges with other political science classes worked better since the students were already primed for discussing political science topics. If greater attention were given to creating specific types of discussion exchanges in higher education, higher quality exchanges involving complex topics and cross-cultural themes could result. There are a number of ways that the potential for the internet media exchanges could be realized: These types of exchanges could benefit students at various types of institutions and could be tailored to fit the needs of both a small liberal arts college environment like Carleton, or a large university setting. Small liberal arts colleges focus on the character building, rather than training in a specific discipline. Exchanges could allow the liberal arts student to gain knowledge from external perspectives. The large university student who typically has less means and opportunity to travel abroad for enrichment can learn much from a discussion with individuals in other countries that could be put to use later professionally in the increasingly global work environment. Exchanges based around an event might also prove to an excellent way to mobilize teachers for multi-lateral exchanges. Disciplinary Academic Organizations could attempt to foster classroom exchanges using inter-institutional contacts that they already have. This would help them fulfill one of their roles as a bridge between the classroom and the research environment, which all too often remain distant from each other in higher education.

Creating a Global, Interdisciplinary Classroom

Cary Staples
Associate Professor, Art
University of Tennessee
staples@utk.edu

Russel Hirst
Associate Professor, English
University of Tennessee
rkh@utk.edu

By way of a grant and a summer workshop on information technologies sponsored by the Innovative Technologies Center at the University of Tennessee, Knoxville, we (Cary Staples, Art; Russel Hirst, English) have created a class that we call "Verbal + Non.Verbal Communication." It began in January and ends in May, 1999. The students are Graphic Design majors and English majors--about half and half.

The purpose of the class is to provide students with a highly collaborative and technologically enhanced classroom setting wherein they can learn how to combine textual and visual elements for effective communication in business and industry. A special concern is that communications be as "global" as possible--that is, easily understood by, or easily translatable to, other cultures and countries.

We have approached this rather ambitious goal by way of three phases. In the first phase, the English majors learned something about the technological tools at their disposal (Quark Express, PhotoShop, etc.) and about basic principles of visual design. Design majors got some review on principles of mechanics and style. Both sets of majors were encouraged to draw upon each other's expertise in the months ahead. In the first assignment, writer/designer teams created business cards--at this point, with no particular attention to international communication.

Phase two saw us ushering in the international theme by way of an exercise that required students to "create a new country" by merging the characteristics of two real countries. The idea was to define and advertise the new country so as to attract tourism. Some students chose to create web sites to satisfy the assignment; others produced hard copy. Students created countries such as "The Enlightened People's Republic" (Egypt and India) and "Taiwon-on" (pronounced "tie one on," a country born of a combination of characteristics evidently inspired by Taiwon and Lebanon--a haven for those who love to party). We asked students to critique each other's productions as we ourselves were doing for them. At the same time, we began to ask our students for contributions to the class web site. For example, each student was asked to submit three annotated URLs of sites that they consider valuable for communicators.

Phase three has focused on documents for business and industry. The first assignment in this phase was to create a set of instructions. Some students produced instructions with direct business/industry application, but others were quite playful, coming up with instructions such as "how to juggle," "how to put on a pair of pants," and "how to avoid conversion into fanatical religious organizations."

Our final assignment, however, has left no room for anything but direct application to business and industry on an international level. Though our original idea was to have students work as writer/designer teams to develop a series of warning labels and instructions, we actually have them doing something even more sophisticated than this: they are, in their hypothetical roles as industry consultants or in-house technical communication managers and designers, creating policy-defining handbooks or web sites that *show fellow communicators* how best to write and design warning labels and instructions for their company's products. This exercise requires them to define company communication goals and policies and to create individual warning labels and instruction "posters" by way of illustration. Their concerns are to communicate clearly, to create the best possible marriage of text and graphics, to communicate so as to avoid/reduce legal difficulties, and to be culturally sensitive and intelligent. They must also coach their fellow communicators about how to create warnings and instructions that will avoid or reduce litigation for their companies. We invited a colleague who has doctorates in both linguistics and law to speak with our students on this theme.

This current, and last, assignment involves much research into international communication. Once again, we have asked students to share their research with their colleagues. For example: each student has sent us information about a particular country or culture that could help communicators to communicate well in that country or culture. This involves information about politics, race, history, gender issues, etc. as well as special meanings of color, gestures, symbols, and so on. All this information has gone onto the class web page for use by all the students.

Our next guest speaker, the president of a company that makes warnings labels for international companies, will provide an important "reality check" to students--though we have deliberately delayed his arrival until late in the semester lest the creativity of students be curtailed in any degree! Students will get feedback on their work not only from our speakers and from us and from their fellow students, but from professionals abroad. These professionals will use our class web site to evaluate our students' work. This evaluation by internationals will be very important, since students need to know whether their products really do communicate effectively to a variety of cultures.

Each student team will compose a "brief" for these international reviewers--that is, an explanation about what they are trying to accomplish in their communication. However, the reviewers will post their initial reaction to the work generated by the students *before* they have access to the briefs. Later, after reading the briefs, the reviewers will be able to post additional comments. Students can then make modifications based on both sets of feedback.

Our hope is to initiate an ongoing dialogue between educational institutions and industries in developing clear, understandable warnings, instructions, and other documents. We want to teach our next course to students at a number of universities via distance learning technologies. The hope is that the later classes will provide a more diverse pool of images and terminology and will allow the discussion to progress further.

To summarize--our class has several purposes:

• To offer insight into the complexity of global communication problems.

• To allow students to work in multi-disciplinary teams without head-to-head competition.

• To create an a technologically enhanced, non-traditional classroom.

• To experiment with, and review, communication efforts.

• To create an environment that will live beyond the framework of a traditional semester and become an ongoing resource for education and industry.

Previous classes that used a web site as a class outline, and that used student research to complete the site, have been very successful. This is our first attempt to create a site that is both cross disciplinary and international. We have been helped tremendously in the creation of this site by the superb staff of UTK's SunSITE (http://www.sunsite.utk.edu). The website we've created in collaboration with them is at http://sunsite.utk.edu/neighborhoods/verbal.

During our presentation, we will give you a tour of our web site and display and discuss examples of student work and feedback they received.

Designing in a Structured World: Instructional Design and Course Development within an SGML/Structured Information Environment—The Open School Experience

Solvig Norman
Course Development, Open School, Open Learning Agency
Canada
snorman@opcnschool.bc.ca

Michelle Nicholson
Course Development, Open School, Open Learning Agency
Canada
mnichols@openschool.bc.ca

The Context

Open School, a service of the Open Learning Agency, develops Kindergarten to Grade 12 distance education courses and resources for approximately 48,000 students located throughout British Columbia and Canada. These courses have traditionally been print-based, supplemented with some additional media (e.g., audio, video), and delivered to students via the postal service. More recently, however, Open School has been attempting to develop a new distributed learning environment which would allow for more flexible design and distribution of course materials to meet the various and ever expanding needs of our learners. Features of this new environment include a learner-centred approach to development of materials, electronic communications between students and instructors, a modular course development process based on structured information, choice and flexibility of different delivery formats, a resource-rich environment for students, different media being used in parallel, and synchronous and asynchronous interaction between students and instructors.

Using SGML as an Underlying Framework

The framework underlying Open School's new distributed learning environment is a technology called SGML (Standard Generalized Mark-up Language). SGML is an international standard (ISO 8879) published in 1986 and has been used extensively for producing documentation within high technology and publishing industries. It is an approach used in the design and creation of documents where the focus is on specifying a standardized approach to identifying the components of a document and how they relate to each other. Documents are independent of any specific hardware or software, so exchange of files between users who have different SGML systems is quite seamless. SGML allows for the separation of a document into three layers: structure, content, and style—but deals mainly with the relationship between structure and content. Structure, which is at the core of SGML, is embodied in the Document Type Definition or DTD. Content is the information itself such as titles, paragraphs, lists, tables, graphics, and audio. SGML does not try to store information about the way a document looks— instead it tries to describe a document according to its content (Arbortext 1999). The separation of structure and content of a document from the appearance or style, enables a variety of instructional media to be produced using the same source material; for example one can simultaneously produce a print instance with italicized words and an on-line version of the same content with hypertext link to a glossary.

SGML was selected as the foundational framework for Open School's new distributed learning environment because it can effectively:

- provide a structured approach to the development of course materials,
- enable an easy customization of courses for different student needs,

- facilitate the re-purposing of content,
- provide flexibility beyond print-based publishing (e.g., multiple formats—such as print, WWW, CD ROM).

The intent is that all of these features will help support the development and sustainability of the Open School distributed learning environment.

Instructional Design within a Structured Information Framework

Instructional design is an eclectic integration of principles and procedures from many theoretical fields historically based on hard sciences and social sciences. At the heart of it, however, is the design and development of learning experiences to support learners' success. Open School's instructional design process, as based on structured information and SGML, consists of four main stages of development; Stage 1 learning outcomes/content outline, Stage 2 resources, Stage 3 activities/assessment, and Stage 4 authored course [see Figure 1]. The first three stages of Open School's development process represents core features of instructional design which include extensive planning based on learning outcomes and learner profiles (Stage 1). The result of Stages 1 to 3 is a very structured and detailed plan for Stage 4 that comprises of a fully written and fleshed out course. This process allows for detailed planning of content to be delivered using different media (e.g., print and the Web) while allowing for flexibility and customization in order to the needs of the learners.

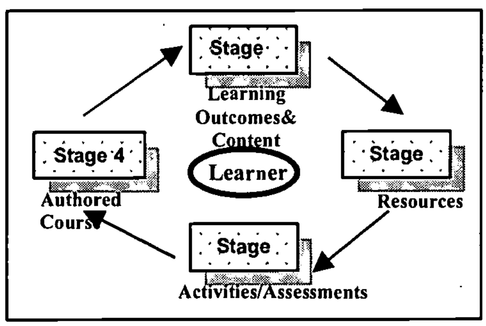

Figure 1. Open School's Development Process

The implementation of a structured framework based on SGML has prompted a closer examination of instructional design and specifically instructional design plans (e.g., Stages 1 to 3). The implementation of a structured framework has explicitly enforced a consistent way of describing learner profiles, learning outcomes, creating subject/topic associations, suggesting instructional strategies, and assessment strategies (e.g., via instructional design document type definition—DTDs). Structure within varies courses is consistent, but the content will vary depending on the outcomes and subject matter. Each instructional design plan becomes a foundation for all subsequent development. Learning outcomes, content, activities, assessment, and resources are attached directly to the plan, incrementally growing the resulting document set. A "course" ultimately becomes the complete set of documents surrounding a given instructional design plan. The result is a manageable base of course materials. This entire process is still in a prototype stage within Open School. The test bed for implementing SGML is presently on going with the development of thirteen high school level courses within the structured information model. These thirteen courses will be delivered entirely in print and on the Web in the near future.

Teaching Data Communications Concepts in a Practical Way

Vishwa N.Shukla
Computing Systems and Technology, Department of Business
Auckland Institute of Technology, Auckland, New Zealand

Ken Surendran,
Department of Information Systems and Computing
UNITEC Institute of Technology, Auckland, New Zealand

Background:

In Polytechnic curriculum, equal emphasis is placed on both practical and conceptual aspects of a subject. With regard to the conceptual aspects, better results are realised when practical demonstrations are used in the facilitation process. This paper illustrates the use of several simple gadgets in the classroom to help the students of Business Computing (National Diploma in Business Computing) get a better feel for complexities of the modern-day computer data communications. The students in this group have no engineering background, even though they have been exposed to the basic layers of OSI model, the operation of asynchronous communication link, use Linux for networking, and an overview of network management. Without the understanding of the *engineering aspects* of data communications and networks, these students are handicapped in appreciating the complexities of modern computer networks using Fibre Distributed Data Interface, Asynchronous Transfer Mode, etc.. Further, they fail to get *a feel* for the benefits - such as higher signal-to-noise ratio, larger bandwidth, low channel noise, data transportation at a constant rate, etc. – offered by these multi-service wide-band networks.

Possible Facilitation Enhancements:

Normally, analytical models and theoretical explanations are used as part of the facilitation process, when dealing with such topics. However, such techniques are not very appealing to the students who have no exposure to the Communication Theory and as such they soon lose interest and motivation. In some institutions with on-going engineering curriculum, one might consider a visit to the communications engineering lab., where some of these expensive high technology equipment and tools are available. However, the authors do not have access to such facilities and hence have resorted to the use of simple commonly available electronic gadgets to demonstrate these concepts. In the following, an illustration is provided which uses a Laser Pointer (used with Over Head Projections), a couple of AM/FM radios, Headphones and a Light Dependent Resistor (LDR) coupled to a pre-amplifier.

The schematic in Fig.1 shows the actual arrangement of these gadgets for demonstrating some of the key concepts in Data Communications. As pointed out earlier, the objective of the Data Communications Demonstrator (DCD) is to provide *a feel* for the following practical aspects relating to Data Communications:

- Laser beam as a *data carrier*
- Wireless *point-to-point* communication
- Modulation/demodulation of a *carrier* using a *signal*
- *Noise pick-up* by the communication channel and *signal-to-noise ratio*
- The effect of *bandwidth* limitation.

Referring to Fig. 1, the headphones with a flat polished metallic diaphragm work as a reflector for the laser beam. (The front side of one earpiece of a common stereo headphones is chopped-off, to expose the metallic diaphragm.) The Laser Pointer is positioned in such a way, that the narrow light beam is reflected (at about 90 deg.) from the exposed diaphragm of earpiece. The headphones' jack is connected to one of the AM/FM radios, and the radio tuned to a FM channel playing music. The musical note causes the diaphragm to vibrate and thus *Amplitude Modulate* the reflected Laser beam. The LDR, functioning as a *demodulator,* reproduces the electrical signal corresponding to the original audio signal. This received signal is processed through a preamplifier to prevent the loading of demodulator

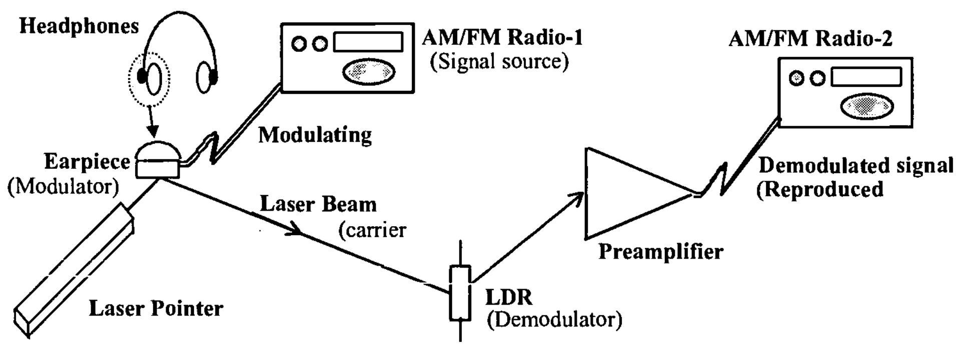

Fig. - 1, Schematic of the Data Communication Demonstrator

and fed to the audio section of the second AM/FM radio for reproducing the musical notes. The circuit schematic of the pre-amplifier is shown in Fig. 2. This is constructed with two LM324 type operational amplifiers with an overall voltage gain of 10. The power for this circuit is derived from the second AM/FM radio.

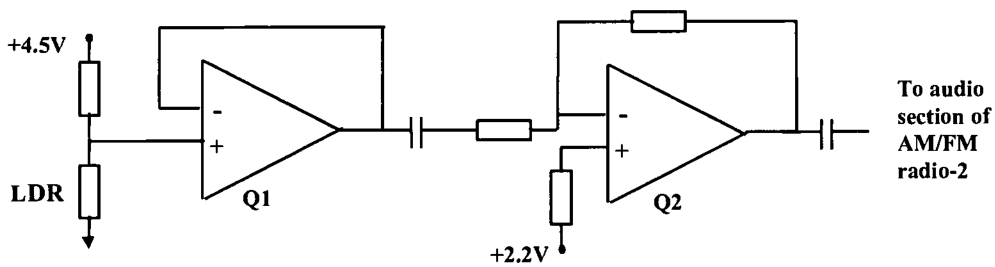

Fig. – 2, Circuit schematic of the Pre-amplifier

The following is a description of how the DCD setup is used to demonstrate the key practical aspects of computer data communication –

- A laser beam is used as a *data carrier*. At the headphones, the electrical signal (corresponding to the music) *modulates* the carrier. The LDR *demodulates* the carrier to extract back the signal.
- The data is transported with a *wireless* (light) link. As the light can not bend, the transmitter and receiver must have line of sight. This arrangement thus illustrates point-to-point communications.
- The florescent room lighting is a source of *noise* for this set up. For a fixed signal strength (i.e., keeping the music volume constant), switching off the room light improves the quality of music signal received. By varying the music volume (signal strength) the significance of *signal-to-noise ratio* is demonstrated.
- The *environmental noise pick-up* is demonstrated by moving a clear plastic film (even reading glasses) in the path of the laser beam. The minute scratches / impurities in the clear film produce a 'scratching' noise in the received audio signal.
- Displacing the laser beam away from the LDR has the effect of reduced *bandwidth*, which results in a poorer quality of the received signal.

Conclusion:

Following the practical demonstration using DCD, the data communication concepts were discussed in the class. After session, the participants were given a questionnaire to evaluate the usefulness of the demo. In their response, 80% of the students considered that the DCD demo had contributed significantly to their learning, compared to the theoretical discussion. Some even indicated that they would like to perform these experiments themselves. On the whole, 50% rated good (and 30% average) understanding of the data communications concepts contained in the DCD demo. Specifically, the aspect on wireless was appealing to about 80%, media / noise aspect to about 60%, modulation/demodulation to 50% and signal-to-noise ratio to only 30%.

Teaching Students about Online Facilitation: Hosting a Virtual Conference

Joanna C. Dunlap
School of Education
University of Colorado at Denver
U. S. A.
Joni_Dunlap@ceo.cudenver.edu

It is difficult to teach people to be good online courseware developers if they don't know what it is like to be on the receiving end of their designs -- either as a student or an instructor. In a graduate-level course on Designing Web-based Instruction for Distance Education, students are typically involved in a number of design and development projects, in which they function as instructional designers hired to build a Web-based lesson, module, or course for a distance learning audience. In the past, students would excel in (1) Web site and page layout and functionality and (2) the distribution of content and activity/project descriptions, but would fail to address issues of social interaction, student collaboration, student motivation to return to the Web site over and over, etc. In fact, it was difficult for them to understand why focusing on Web teaching and learning strategies was necessary for them in their roles as "WBI designers". Unfortunately, the class did not have access to pre-existing Web-based courses that they could be required to facilitate in order to gain experience in Web teaching and learning. Therefore, students are required to host a virtual conference. By hosting the virtual conference, students are exposed to the triumphs and frustrations of creating an interactive learning experience delivered via the Web.

Thus far, two Virtual Conferences have been hosted by two different groups of students: one in Fall 1997 and one in Fall 1998 (the 3rd Annual Virtual Conference will be held in Fall 1999). Comparing students' work prior to and after the Virtual Conference assignment revealed that WBI students/designers:

- moved from creating professional-looking "page turning" Web sites that simply delivered textual/graphical content to developing interactive, student-centered activities (such as games, case studies, and problem-based learning activities) for learners to work through; and
- utilized communication technologies differently: instead of simply posting discussion questions on an asynchronous threaded discussion forum for learners to respond to, both asynchronous and synchronous communication technologies (threaded discussions, reflective journals/forms, chat and whiteboard) were being used for debates, collaborative project/product development, peer teaching, and presentations.

The Virtual Conference assignment has been so effective as a learning experience for WBI designers/students -- as well as providing a good learning experience for the virtual conference participants -- that the Fall Virtual Conference is now an on-going staple of the Distance Education track of the Instructional Technology graduate program, with plans to host a virtual conference every Fall.

The Virtual Conference Assignment

For the Virtual Conference assignment, students collaboratively develop and deliver an online/virtual professional conference on various aspects of designing distance education for the WWW. Besides the actual conference, documentation (1) describing the strategies and tactics used to promote, organize, facilitate, evaluate, etc. the conference and (2) supporting the design decisions made based on front-end analysis data is required. Results of the conference are debriefed in class, and students are required to reflect on the overall experience and on what they learned from the process; their reflection was structured by an online assessment (see http://www.cudenver.edu/~jdunlap/5990/conferencejournal.htm) they helped to develop (see an example of a student's evaluation of the virtual conference experience at http://clem.mscd.edu/~woodleyx/wbi/online.htm).

Description of Student Activities

The objective of this project is for students to collaboratively develop and deliver an online/virtual professional conference covering issues related to designing distance education on the WWW. To make this happen students have to take responsibility for a number of activities and deliverables:

- As a class, students have to select five topics that represented important issues of Web-based distance education. They then have to determine who will be responsible for which topic/s. Responsibility for topics requires students to research, prepare (includes, but is not limited to, developing a Web-based presentation and/or paper), manage, and facilitate the portion of the virtual conference related to those topics. The conference runs for four days during each Fall semester; topics, activities, and facilitators have to be scheduled by the students for each day of the virtual conference.
- As a class, students have to decide what Web-based communication technologies are needed to conduct the online conference and create or contract those technologies.
- Students need to determine what strategies and tactics should be employed to ensure conference attendee participation throughout the duration of the conference. This includes lining up "guest speakers" and/or developing presentations, debates, case studies, and other engaging activities that will keep conference participants involved.
- Students also need to develop an evaluation tool so participants can let them know what they think. Students must analyze the evaluation findings to determine "lessons learned".
- Students develop and upload the conference site.
- Students promote the conference to classes, students, and faculty in the School of Education and any others deemed appropriate, and to outside educational and professional groups.
- Students are responsible for providing technical support throughout the conference.
- Students document in writing the decisions they make on the above issues.

1st and 2nd Annual Virtual Conferences: The Students' Conference Sites

There have been two virtual conferences hosted by graduate students in the Designing Web-based Instruction for Distance Education course:

1st Annual Virtual Conference: Instructional Strategies and Delivery Issues of Web-Based Instruction – http://carbon.cudenver.edu/~jdunlap/seminar/

2nd Annual Virtual Conference: Beyond Page Turning and Lecture Techniques: Effective Instructional Strategies for Web-based Learning Environments – http://web-education.net/fall98conf/

[**Note:** For notification of future Virtual Conferences, see http://ceo.cudenver.edu/~Joni_Dunlap/AACE/virtualexamples.html]

Reusable Web Sites for Content Delivery

Roland Hübscher
Computer Science and Engineering
Auburn University
roland@eng.auburn.edu

Introduction

The rapid advancement of the World Wide Web and hypermedia systems puts educators more and more under pressure to provide some of their course material on the web. But given the time constraints of the faculty and the necessary skills in electronic media production, it cannot be expected that many useful systems will be built and used by them. Most available systems support a great deal of activity that goes into the development of an electronically enhanced course with features which support testing, interfacing with other university-based systems, tracking of students, assignments, chat rooms and some instruction. However, explicit support for the development of a web-based environment for learning is rare at best. One of the exceptions is an adaptive hypermedia system provide navigation support that adapts to the user's action and learning (Brusilowski et al., 1997). However, the provided navigation space tends to constrain the learner's possibilities for exploration.

Our system attempts to provide hypermedia sites that minimize such constraints on exploration, yet still providing a flexible site structure optimized for the used teaching method. A possibly radically different site structure is necessary to support various teaching methodologies. But who creates all the web pages for the courses and keeps them also up-to-date? And how do we make sure that the students exploring the site don't get lost and frustrated instead of learn from them?

Reuse and Exploration

Once a reasonable fraction of a course's content is put on the web, the site is rather difficult to adapt to new situations due to the static structure of web sites. Thus, the reusability of web sites is minimal. The organization of the pages, navigation support and links to related issues or prerequisites are static and optimized for this course's topic, time frame, emphasis, and the educator's teaching style. However, the course should be reusable in many different ways: when moving from the quarter system to the semester system; when the senior-level course is upgraded to a graduate-level course; when the focus of the course changes; or when a related course is designed. If a different faculty member teaches the same course it probably needs to be restructured due to a different teaching style and other preferences. Thus, providing the same course material for everybody and every situation is in general not feasible because it does not support what the educator and the students need. However, changing a web site to accommodate another teacher can cause a major reorganization of the web site, which, in general, is not feasible either. Current tools do not support reuse in any interesting way.

The second problem addressed by our approach is to provide a hypermedia system that provides a large exploration space. All those and only those paths that are consistent with the pedagogical method used by the educator should be available to the learner. The user is supported in selecting paths consistent with the pedagogical method by the organization of the site and by dynamic navigation support.

Our approach is based on the observation that the order in which content is taught depends on both, the content and the teaching methodology employed. Whereas most other tools have a "correct" teaching methodology built-in, our tool provides a simple mechanism to describe such methodologies.

The educator uses the tool as follows. First, she represents the content independent of what teaching methodology she will use. Then, the teaching methodology is formalized in such a way that it can be applied to any content resulting in an organization of this content supporting the selected teaching methodology. The content is represented in a semi-formal using concept maps. The claim that teaching methodologies can be formalized may come as a surprise. This paper will describe in some detail how we formalize those (only) parts of a teaching methodology relevant for the content organization. It is an empirical question whether the resulting web sites are indeed educationally well organized.

Content Description

The course content is described independent of how it will be organized in the web site, allowing the user to concentrate on content only. We have chosen a semi-formal representation that many educators are quite familiar with. We use a hierarchical concept map containing descriptions of content units like concepts, skills, activities, etc. and their relationships as a graph. The interface allows an incremental development of the content without having to deal with the constraints of the course and the teaching methodology employed. Furthermore, content units can also be assembled from other content units, i.e., content units range from a single idea to topics to courses and even to whole curricula. These units can be related to each other with relations like "*a* is prerequisite of *b*" or "*a* is part of *b*". We are using semantic zooming and fractal display techniques to deal with the potentially large concept maps (Furnas & Bedersen, 1995).

Description of Organization

The teaching methodology is represented in terms of rules that generate the temporal organization for the course content. There is more to a pedagogical methodology than ordering the content, however, organizing the content for a course can be viewed, slightly simplifying, as providing all the educationally appropriate sequences in which the course material may be traversed. Most often, when a faculty prepares a course, he or she chooses one of the many sequences that seem to be adequate.

Instead of providing a number of built-in methodologies, the user can describe a methodology reflecting her own teaching. This description can then be applied to any content. The methodologies are described with simple if-then rules. In a later phase, we will provide a more appropriate interface to the end user. Although we can only express the temporal relationships *before*, *after* and *during* we believe, based on some informal tests with a prototype, that we can describe a large part of interesting relationships for content organization. For instance, if a *x* and *y* are two concepts, then the rule "**if** *x* is a prerequisite of *y* **then** *x* is before *y*" says that prerequisites must be visited before what they are prerequisite for. Another rule could rule say that related issues should be visited parallel to the main topic "**if** *x* is strongly related to *y* **then** *x* is during *y*".

These rules transform the concepts into an and-or graph that can be traversed in any order that is consistent with the rules selected. This organization is then transformed into web site and navigation support in form of an applet makes sure that exactly those links are accessible consistent with the selected methodology. In this way we maximize the space the learner can effectively explore. For instance, given above rules, the student can look at a part-whole hierarchy moving from the whole to the parts.

Conclusions

A prototype is currently being implemented as a Java applet with a visual interface that can deal with large concept maps to describe the content. We have developed an efficient graph algorithm that accomplishes the guidance of the exploring student. Finally, the resulting organization is mapped to a web site. This part will take advantage of work on multimedia roles (Recker & Ram, 1994). Thus, the educator is required to deal with content and pedagogical issues, but not with HTML, CGI, and other details irrelevant for him.

Several important questions need to be answered empirically. First, can we represent large and complicated concept maps so that educators can use them effectively? Second and more central to the topic of this paper, can all interesting pedagogical methodologies be expressed with our simple, rule-based language? Third and most importantly, is the resulting organization of the content indeed supporting these methodologies?

Bringing Students into the Community of Practice

Teresa Hübscher-Younger
Department of Computer Science and Engineering
Auburn University
United States
teresa@eng.auburn.edu

ResearchAid, an interactive, dynamic hypertext system, is being developed to help students become members of a working scientific research community. The system has students editing, creating and researching content using a Web browser. ResearchAid strives to make students become active members in a scientific research community through aiding the following activities: it helps make explicit and available the goals of a research community; it helps provide a structure for learning and using the communities' discourse and reasoning strategies; and it helps make explicit some of the distributed knowledge within that community.

ResearchAid started with the goal of having students learn to operate a complex machine, a meniscus coater, in a manufacturing environment from a computer system. However, a contextual inquiry into a manufacturing research environment at Georgia Institute of Technology found that the way students learn to operate the machine, a one-on-one apprenticeship with a graduate student, is entwined with their learning other practices in the research laboratory. Through this apprenticeship, students get to know other members of the research community and receive advice on different aspects of their project. Having these students learn how to operate the machinery from a computer tutorial system may prevent them from learning the other practices and especially from learning how the practices are related.

It was also realized during the contextual inquiry that what did need support was a different learning activity — the planning, running and reporting of independent research by undergraduate students. Undergraduate students were told that they would be doing independent research projects in the laboratory. However, they were not encouraged to design their own experiments. Instead, they were told roughly what they would be doing, given the procedures for collecting data and would run the experiment on their own. It was not until they were analyzing the data that they got a sense of what the design of the experiment they were running was. They were not trusted to design a relevant experiment for the community, because becoming a member of that community of practice is a long and difficult process for the undergraduate students.

To improve undergraduate students' learning experiences in research laboratories students need to develop the abilities that are required for taking a more active role in their research. As Scardamalia, Bereiter et al. emphasize, "Educationally irrelevant burdens, should be minimized, but not in ways that deprive students of occasions to develop the planning, monitoring, goal-setting, problem-solving and other higher-order abilities that are important objectives of education," (1989, p. 53). The practices seen in the research laboratory studied took away the students ability to participate in these higher-order objectives.

The computer can help develop communities of practice when it acts as a mediational technology, which "emphasizes the possibilities of using the computer not simply as an individual tool but as a medium through which individuals and groups can collaborate with others," (Bannon, 1995 , p. 272). ResearchAid acts as a resource and aid for collaborating students, but does not itself collaborate with students or create problems for the students to work on collaboratively.

The students in the research laboratory needed help in becoming a member of the research community more than they needed help with any particular machine. As Lave and Wenger (1991) have argued, becoming a member of a research community requires familiarity with its current goals, strategies and knowledge. Lack of familiarity with these goals, strategies and knowledge made it difficult for these students to take an active role in their research projects beyond the collections and analysis of data.

ResearchAid helps scaffold new students' participation in the manufacturing research community in the following ways:

- It presents prior research (experimental designs and reports), so that students can understand how it developed from the lab's goals and can use it as a model for creating new research. The application presents the research in the framework of research problems that have been or are being explored by the research community. This helps students formulate a problem they would like to explore that fits within the research community's goals.

- It helps students practice and understand the discourse strategies of the community by designing experiments in an environment which explains the elements of an experiment.
- It provides the means for members of the community to asynchronously communicate, monitor each others' progress and give feedback through adding commentary to the experimental design.
- It promotes students revising and refining of their initial experimental design and promotes reflection about alternatives to their design.
- It gives students a way to collect data on the flexible database accessible by the World Wide Web (WWW) and makes it available for analysis. This way others can research the data collected by students, examine progress being made and use old data to explore different interpretations.
- It helps the research community analyze and discuss experimental results.

ResearchAid uses the WWW to have students present, collect and edit information, through editable WWW pages and forms. Using the WWW for ResearchAid helps provide students with access to distant faculty and students for advise and feedback. The research laboratory that was the subject of the initial investigation had influential members of the research community located on different parts of the campus and the undergraduate students had little access to these people. To become a member of a community of researchers, a students needs to be able to meet with other students to work, discuss and create a shared understanding of their common needs and experiences (Selfe & Eilola, 1988). Because computer-mediated communication helps peripheral members of a community, such as undergraduate students in a university research laboratory, become more active in that community, it is hypothesized that these members will feel like a more important member of the organization and will be more committed to it (Eveland & Bikson, 1988; Sproull & Kiesler, 1990).

Future work on ResearchAid involves development of the final system (only a working prototype exists right now) and evaluation of how students actually use it in scientific research laboratories should also be conducted.

Acknowledgements

ResearchAid began as my thesis for the degree Master of Science in Human-Computer Interaction at Georgia Institute of Technology. My advisor, Joseph Petraglia, Assistant Professor, School of Literature, Communication, and Culture, provided a lot of aid and direction for this project as did the other committee members, Matthew Realff, Assistant Professor, Chemical Engineering, and Mark Guzdial, Assistant Professor, College of Computing. Roland Hübscher, Assistant Professor, Computer Science and Engineering at Auburn University, also provided a lot of support and advice during this project.

Delivering Technology Education to Teachers via Web-Based Distance Learning

Wilhelmina C. Savenye, Ph.D.
Division of Psychology in Education, Arizona State University, USA
savenye@asu.edu

Introduction

Our university has offered distance learning courses for several decades. Like many universities, ours has in recent years encouraged faculty to explore uses of the internet for instruction. We currently have over sixty courses which use the internet in some way to deliver instructional materials, however most courses are web-supported, rather than fully web-based.

This paper provides a brief overview of the development, implementation, evaluation and implications of one of our university's first fully web-based courses, Teaching with Technology. This is a graduate course for teachers which includes both theory, design and considerable hands-on components. The presentation will describe in detail how the course was designed to prepare teachers to integrate many forms of technology, both computer and non-computer-based, into their teaching. Thorny development and implementation issues will be described.

We have been conducting ongoing developmental research while teaching the course. We conducted a case study evaluation of the course, and compared the results of the internet-only section with those of a campus-based section which utilized the same web materials. The course was offered again, in internet-only form, with refinements, during the spring semester of 1999, and we again collected qualitative and quantitative data to help us in evaluating and revising the course for delivery later in 1999.

The Teaching with Technology Course

Development of the course began in the spring of 1998. Although we have taught technology courses for teachers for many years, we began by analyzing the technology knowledge and skills teachers need currently to ensure that the course is up to date. We then determined the overall goals and objectives of the course.

The university's Distance Learning Division of the College of Extended Education was our partner in delivering the course. Distance Learning in 1998 used a "custom programming" approach to deliver internet instructional materials. The course instructor wrote the course materials and worked with the small Distance Learning programming staff to implement the web-based version of the course. The staff used web programming software and languages to build custom courseware wrapped around a commercial discussion software. This approach had its advantages, but also yielded several drawbacks which will be discussed in the presentation. For instance, we needed to develop a supplementary web site to support the course, and also used email communications considerably to ensure student learning and satisfaction. The course was next implemented, spring of 1999, using commercial web course development, with some custom elements.

The course is primarily designed for K-12 teachers and community college or university instructors. Some students enrolled in the course are typically also trainers from business and industry, therefore examples from both education and training are included.

This course provides students with an overview of the most effective ways to teach using various learning technologies. The course begins with a broad view of learning technologies and the research and theory related to using them. Students then learn how to apply instructional planning techniques to integrating technology into their instruction. We cover: advantages and disadvantages of various learning technologies, planning for technology, evaluation, and basic principles of educational technology development. The course consists of quizzes, short papers and projects, and a hands-on final project.

Course Components, Internet-Only Section:

The fully online course section initially included assigned readings in textbooks to provide the basic information, email communications software for instructors and students and a web site that is part of

Distance Learning's ASU ONLINE offering, which includes features such as "News" or announcements, an "Assignments" posting and submission area, "Test" features, a "Discussion" thread component for asynchonous postings, a "Chat Room" for synchronous discussions, and "Web Resources" and a course "Calendar" component.

During the initial course offering we revised components on an ongoing basis. One concern, for example, was that we did not truly know the needs of the students before they signed on for their first class, so we conducted a needs assessment with the students and revised the course topics somewhat to reflect their professional needs

Another particular concern was the need to have hands-on projects for teachers who have many different types of hardware and software, as well as resources and constraints, represented in their off-campus work settings. We have tackled this issue by allowing students a large degree of control in determining and completing projects, while providing them flexible guidelines and clear evaluation criteria.

We developed video clips included in a new "Media" component of the course. Clips show demonstrations of applications, technical processes and procedures, guest speakers and "virtual field trips."

We also developed a supplementary web site in response to the relatively long turn around time for custom programming. The site is used to provide information such as mini-lectures, extra text materials and handouts. It also serves as a substitute delivery medium for directions and assignments at times when the online course site components are not functioning as expected.

During the second semester of the course, spring 1999, we began to use CourseInfo 2.0 by Blackboard, Inc. This software provides us with easily updateable components and faculty can do these updates themselves. Another new feature is the provision of student home pages, allows students to easily present information about themselves and about projects they would like to work on collaboratively. The CourseInfo software will be described in more detail in the presentation.

Evaluation Methods

During the first pilot semester, Fall of 1998, we evaluated the effectiveness of web-based online delivery of this technology course for teachers using various methods.

We collected data on student learning by comparing overall student grades in the online and the campus section. We reviewed the quality of students' technology integration plans and final development projects. In addition, students' ratings of how much they perceived they learned were compared, along with their evaluation of the learning value of the course.

Student attitudes were measured using several means. Students in both sections completed a survey at the beginning of the semester in order to determine their needs and interests and incorporate these into the course. Students were asked at the mid-semester point to discuss aspects of the course and how the course could be improved for them. Finally, students in both sections completed a detailed course evaluation, focussed on determining the factors that helped them learn and what motivated them to learn.

Communication among students, the instructor and staff were analyzed. The discourse in the discussion threads was captured and these communications data were analyzed using qualitative methods, particularly content and pattern analysis. Also, patterns of communication and issues that arose in the email communications between the instructor and students and staff were analyzed.

The instructor and development team also kept ongoing logs of the issues and solutions that evolved during the course

Conclusion

Teacher educators are struggling with determining how best to deliver instruction to teachers on how they can integrate technology to help their students learn. In our presentation we discuss how this method is providing technology education to teachers who could not otherwise receive it. It is hoped that our discussion will provide other teacher educators with guidance for providing web-based technology instruction for teachers.

Network-based, High Bandwidth Multimedia in a 3rd Year Marine Botany Course Module

Jocelyn Collins & Derek Keats
Botany Department, University of the Western Cape, South Africa
e-mail: jcollins@uwc.ac.za & dkeats@uwc.ac.za

Introduction

In South Africa under Apartheid educational institutions were segregated according to pseudoracial categories. "White" institutions had the greatest advantage in terms of funding and long-term investment opportunities, while institutions categorised as "black," "Indian," or "coloured" were generally established much more recently and lacked the funding traditions and potential to develop their own investments. These institutions continue to draw their student population largely from a school system that was deliberately created under Apartheid to be inferior. This is particularly a problem in the sciences, an area that was previously denied access by the broader South African population.

We believe that the educational needs of students from disadvantaged backgrounds can be addressed by designing interactive, educational multimedia. This will allow students with different learning abilities to acquire a body of skills and knowledge at their own pace. In this context, we embarked on a programme of using computers and web-based technology within the context of mainstream teaching-and-learning.

The Educational Principles Followed

All course materials aim to promote meaningful learning (Ausubel et al. 1978), so that students come to exercise the higher intellectual processes of analysis, synthesis and evaluation. There is a tremendous inertia among students at UWC to focus on the process of memorisation (personal observation). Both multimedia and conventional resources for the course were designed in an effort to move students away from rote learning (Keats & Boughey 1993). The meaningful construction of learning is an active process, involving an interaction of students with a variety of learning resources (Jones et al. 1987, Moust et al. 1987). Knowledge construction can be improved through the use of preliminary organisers, such as statement of objectives and background knowledge required, as well as an overview of the material to be covered and the problems to be addressed (Melton 1984). Hence, web and multimedia resources are designed with clearly stated objectives as to what was expected of the learner.

The Technology and Development Methods

With a broadband network, the creation of deliverance of a full multimedia course becomes possible. A fairly static HTML webpage was created to allow basic concepts to be explored from workstations outside the ATM network. Multimedia is then used to add depth to the resources when they are accessed via workstations with higher speed connection to a network.

A small multimedia lab was established with all computers having a dedicated 10 Mb/s of Ethernet bandwidth linked to a 155 Mb/s ATM network. A multimedia web server is connected to the same Ethernet switch and the ATM network. In addition, a computer lab is available via the campus Ethernet backbone. For the first time this gives us the ability to provide students access to both web and multimedia facilities.

We have adopted an approach of developing teaching-and-learning resources that have the following goals:

1. At one level resources should be bandwidth-friendly. One of our goals in developing this course material is to have it available globally.

2. At another level resources should exploit the full potential of a high-speed network, and provide an exciting learning opportunity motivating students to break out of the bounds of conventional learning.
3. Resources should exploit the full potential of HTML and scripting to incorporate interactivity, thereby reducing dependence on additional software wherever possible.

On the surface, the first two goals seem to be mutually exclusive. How is it possible to minimise bandwidth use, while at the same time maximising the potential of a high bandwidth network? The answer that follows from these competing goals is a layered approach, whereby learning topics are covered using relatively static HTML, but in which users with high-speed access can go to another level with animation, sound, video and greater interactive control. This approach then provides the guidelines for a layered development of web-based learning resources.

The Research and Instruments

The work is being carried out under the framework of *Action Research* which is qualitative and cyclical, leading to ongoing improvements in action (Davidoff & Van den Berg 1991). Thus it is a suitable mode of research to inform on-going development, such as this project involves.

Two main research instruments are being used during this project: the interview and the questionnaire. In this project, a semi-structured interview is used as a means to gather information. Pre-formulated questions will guide the interview, but they will be open-ended ones which Cohen & Manion (1980) defined as "those that supply a frame of reference for respondent answers, but put a minimum of restraint on the answers and their expression". Interview results are used to inform the Action Research in that the data and recommendations will be subjected to evaluation and the actions within the project (multimedia content and activities) subjected to revision accordingly. The lecturer will be interviewed to determine content that is most appropriate to be enhanced using multimedia activities, and the students to determine their area of greatest difficulty that can be addressed by incorporating more interactivity. Once the students are using the facilities, they will be given structured questionnaires, and will be observed and interviewed as they use the multimedia lab.

Effective Distance Education Via Interactive Video

Kara L. Nance and Mahla Strohmaier
University of Alaska Fairbanks, U.S.A.
ffkln@uaf.edu ffms@uaf.edu

Introduction

Educational opportunities are reaching populations heretofore left out of the equation thanks to distance education technologies and institutional desire to expand the student base. Once a component of only the richest universities, distance education technologies are becoming more affordable, enabling incorporation by a significant proportion of the university community. One of the most popular technologies, and the one compared most directly to face-to-face interaction, is interactive video. This relatively new technology has provided instructors with the ability to reach new student populations as well as expose traditional students to new peer groups. Although many institutions have interactive video equipment and are using it, the focus in training remains on the course content. The interactive dimensions are rarely touched upon during faculty training for those using interactive video to conduct courses. As with other forms of distance education, the acquiring of delivery skills associated with interactive video teaching is generally through practice, or trial and error might be more descriptive. In essence, the classroom becomes the testing laboratory, influencing the learning process during that preliminary stage. To facilitate effective learning for the students, and to alleviate unnecessary aspects of teaching and credibility problems for the instructor, faculty training must be targeted directly and appropriately at the technological and social dimensions involved in interactive video instruction.

Course Integration

When using interactive video in teaching, the interactive video is so much a part of the course that it influences the course content and structure directly. In order to construct an effective syllabus, the instructor must have a working knowledge of all the dimensions of the influence the interactive video format will have. Interactive video, as a mode of communication, can be very effective if it is a tool that has been mastered. An instructor who does not have an understanding of the technology involved will find it a hindrance that can actually block the educational process.

When selecting a person to teach a course, there is no doubt that the credentials of that person will be thoroughly examined. That person will be expected to have college degrees, generally in a field containing or directly related to the course being taught. Previous experience in the classroom is examined, including sample student and peer evaluations, as to the goodness of fit for the applicant and the institution and class. However, when selecting the person to teach via interactive video, where did the inquisitiveness go? Generally the person assigned to the interactive video course is the person who happens to already be teaching the course that is desired, the person who has the desired time-slot available, or the person who seems to mind the imposition the least. Once that person begins to teach, it is still unclear where they can go for help—with the possible exception of technological problems that can be asked of attendants on duty during the class. Thus, the students see the instructor less than prepared, asking questions, and showing inadequacies. This appearance will then lower the perceived credibility of the instructor, even though it is based on non-content issues.

Student Dynamics

The classroom interaction dynamics are greatly effected in a class delivered via interactive video. Although the individual compositions may vary, the "group" of students is generally at least two separate groups, sometimes three or four, attempting to merge into one class group. "The primary group is that which is physically with the instructor. The secondary group is that which perceptually resides in the television" (Nance & Strohmaier, 1998). For effective interaction in the classroom, the students must perceive the physically separate groups as one class group. Accomplishing this goal can be difficult for an instructor, especially if he or she is unaware of this potentially disastrous dynamic issue. Faculty development could address this issue.

Another major area of impact lies in the visual perception engendered in interactive video. As a member of the primary group, the instructor sees fluid movement in the physically present group, and visual compression with the secondary group images. As the students are listening, this visual compression does not appear to have a significant impact. If the instructor was to trade places with a student in a secondary group, he or she would see the magnitude of the impact of visual compression. The visual cues of the instructor are not fluid, thus dividing the focus of those students. Other interaction components are also effected by this lack of visual flow, such as with turn-taking behaviors. "The way an individual knows that it is his or her turn to speak in a conversation is through pause time, eye contact changes, altering the tonal pattern of the voice, and posture adjustment. Although the students can note the pause time and tonal differences in an interactive video setting, the eye contact and posture adjustment are not easily read" (Nance and Strohmaier, 1998). The vocal aspects of the interaction are however generally in real time, which can compensate for some of the interaction cues that are taken away in the visual mode.

Just as the dynamic effects of the interactive video mode have far-reaching consequences, the potential confusion regarding turn-taking behavior has several ramifications. When faced with a long pause time people feel uncomfortable and begin to get restless. To alleviate the situation, someone will end the pause through verbal interaction. In an interactive class, the primary group will be privy to all of the pertinent interaction cues as to turn-taking behavior. They will have the insider information as to when the instructor is actually looking for an answer, versus stating a hypothetical question. The students in the secondary groups will not be sure which is the case, and will therefore choose the polite path and wait longer before answering. In this situation, then, the students in the primary group will generally always be the ones to break the pause-time. The routine will become standard, and the secondary groups will be both perceptually and actively removed from the discussion core. To avoid this scenario, the instructor must overtly draw in the members of the secondary group through directed discussion. Again, faculty development should address these issues to ensure that the faculty member is adequately prepared to handle these situations and facilitate meaningful interaction between groups.

Conclusion

Distance education is a timely concept. Although in existence for decades, technological developments have created many new dimensions and possibilities for distance education. Much research is being done on the potential and use of distance education, with a focus improving the technologies. Research must branch out and enhancing the capabilities of the instructors through formalized faculty development programs as well. Rather than instructing faculty based on crises that arise during interactive video classes, faculty development should be approached in a proactive manner to avoid the crises before they occur. In this age of serious budget considerations, the institution would benefit financially with this approach as well.

Weipers Centre for Equine Welfare, University of Glasgow

Section 1: Introduction

This paper reports on an initial and on-going study into the use of haptic (Schiff & Foulke, 1982) technology in veterinary education. The University of Glasgow has a commitment to the implementation of non-invasive procedures for diagnostic and education purposes in Veterinary Medicine, wherever possible. As part of the continued development in the use of technology in veterinary education, Virtual Reality is now being explored as a possible aid to teaching and in particular to replace invasive examination procedures.

Section 1.1: The problems

One major problem in the education of veterinary students is the danger faced by animals when being examined by inexperienced students. The students need to gain experience in internal examinations (a key method for diagnosing problems and diseases) but it can be dangerous. The animals may become stressed, be injured or may even die because of unskilled internal examinations. Large classes of students mean that each person may only get a very limited amount to time learn the practical examination skills required. Another problem is that the students must learn about a whole range of diseases and problems as part of their education. At the time during their training when they are learning about a particular disease there may be no animal available with the particular disease in question. This means that students may not be able to consolidate their learning with practical experience.

Section 1.2: The solutions

We are investigating ways to solve these problems by using haptic devices that allow users to feel virtual objects. There are three main benefits from our solution:

Safety: The use of haptic models to simulate problems allows the students to learn in a safe environment. They can learn on the models without endangering any animals. Once they have gained sufficient skills on the models they can then move on to the live animals with much less chance of doing harm.

Cost: The cost of education is also reduced. A large number of students can interact with the haptic models very quickly and cheaply. They can also do this much more frequently than would be possible with live animals.

Flexibility: The flexibility of the models is great. It is possible to simulate a range of diseases that the students would not normally experience. Different stages in the progress of a disease or condition can also be simulated. This can be done at the time the students are learning, allowing them to try out their theoretical knowledge immediately in a practical setting.

Section 2: The technology

The technology to feel virtual objects is just now becoming available (Massie & Salisbury, 1994, Bryson, 1995).

It was first developed so that users could feel objects in virtual environments. Minsky (in Blattner & Dannenberg, 1992) describes the technology thus: "Force display technology works by using mechanical actuators to apply forces to the user. By simulating the physics of the user's virtual world, we can compute these forces in real-time, and then send them to the actuators so that the user feels them". The device used for the work described is a PHANToM. This is a very high resolution, six degrees-of-freedom device in which the user puts his/her finger in a thimble or holds a pen at the end of a motor-controlled, jointed arm. It provides a programmable sense of touch that allows users to feel textures and shapes of virtual objects, modulate and deform objects.

Section 3: The haptic models

As mentioned, we are developing haptic software models that will simulate the feel of parts of a horse under examination. This shows two horse ovaries. The ovaries feel correct and they move in appropriate ways (if pressure is applied they can be moved in three dimensions in a realistic way). Both ovaries have very smooth, taut surfaces. The left ovary is softer and slightly smaller than the right one. A follicle can be seen on the left ovary (indicating ovulation is about to take place). This sticks out from and is much softer than the rest of the surface. The visual representation of the ovaries is built in OpenGL. The haptic representation is built using the GHoST software toolkit from SensAble. When vets are doing internal examinations they cannot see the ovaries, so the visual images are mainly for illustrative purposes. However, a visual representation is beneficial when learning to use the system. Our software allows the visual representation to be removed as required. The PHANToM device only allows the user to feel with one finger, not the whole hand. This, however, is not a limitation as vets will only use their thumb when feeling the ovary in a real examination.

Section 4: Evaluation

The development of the models has been performed using an iterative, participatory approach. Computing scientists have been working closely with vets to ensure that the models are correct. This has involved the building of initial prototype models and their continual refinement via expert user evaluation. The next stage in our work is to carry out evaluations with vet students. We will discover if the models are usable: can the vet students interact with them, use the device, etc. We will also be able to find out how effective they are: can students correctly identify the particular diseases and conditions we have simulated in our models.

Section 5: Conclusions

One problem in veterinary education is that students must learn how to do internal examinations of animals but in doing so can be dangerous for the animals. Another difficulty is that there may not be an animal available with a particular disease when the students are studying it. The availability of haptic devices means that these problems can now be overcome. We have developed a set of haptic models of horse ovaries that will allow students to learn in a safe, cheap and flexible environment. Once they have learned the necessary skills they can move to working with live animals with much less risk of danger.

A System of Designing User Interface to Promote Collaborative Learning in Cyberspace

Kaname Takamori
Graduate School of Media & Governance, Keio University,
Japan
kaname@sfc.keio.ac.jp

Introduction

With the spread of Internet, the source of information surrounding us diversifies. As a result the burden for gathering and sharing information for analyzing problems suddenly increases in a real business. Such a change gives a big influence to learning environment for both an individual and a business organization. For one of representative cases we can point out the trend that "Knowledge Management" attracts many people in the field of business. In other words, they need a continuous collaborative learning that is attached great importance to experience in a real business in order to cope with such a difficult situation. Teams are organized according to interest domains, and we expect that participants in teams search information from their various points of view. By exchanging many opinions with members, they will share a hypothesis and information furthermore, and through collaborative activities they will share a lot of experience and learn how to make a new concept. Such a learning method is called "Collaborative Learning" or "Action Learning", and many people trend t think that this is a kind of team learning (or team teaching), that attached great importance to such a process. The purpose of this paper is to show the usefulness for the system of designing user interface to promote and support a practice of them.

Problems of "Collaborative Learning" or "Action Learning"

Judging from examples of education in a corporation as before, the biggest problem is that "long time is necessary in order to get effect" when we practice "Collaborative Learning" or "Action Learning".

The result of our experiment clearly shows that an equal characteristic was found in apportioning time according to an activity process in inspection experiment of two sets. The graph in Figure 1 shows that in both sets the ratio of a process of gathering information (including Experiencing and Publishing) is very high, and a ratio of a process of opinion exchange and the logic construction (including Processing and Generalizing) is lower. As this reason, when learning persons accessed the various source of information that they hadn't used, they tended to have a long time to gather information (including grasp of characteristic information and the way to access to every the source of information). We used the analysis of the log of experiments and questionnaire investigation to learning persons in order to report this result.

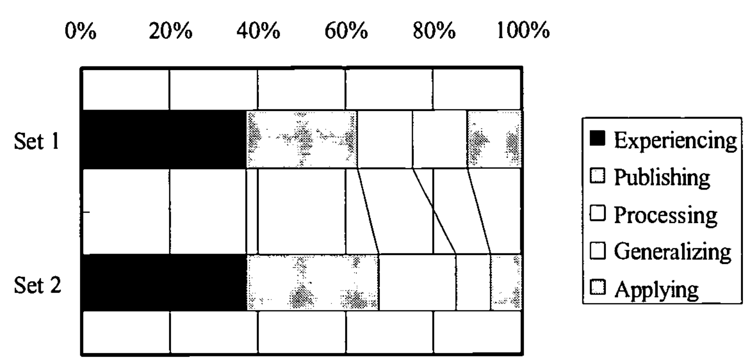

Figure 1: The ratio of apportioning time

Schemes and Effects of the system

In this study, we establish the following point of view of solving problems of these learning methods.

- By filtering necessary information from the various source of information, several learning persons and teacher (facilitator) build the structure that gathering and sharing information become possible effectively.
- By re-organizing much information collected by all the participants, we build database environment to structuralize the information flexibly according to a purpose.

According to basic concept of a system, we build a system with C/S application of Web base shown by Figure 2. The system has the following characteristic.

This system collects interest of learning persons with questionnaire system beforehand. Based on these interest profile databases, this system can automatically form interface for every learning person and a team. In next, by the key word they prepare, they can search several database and WWW simultaneously and output search results. And, on the basis of interest profile and their rating, this system has a function to recommend information that other learning person collected (utilized by push technology and collaborative filtering technology). Facilitators can manage monitoring of access situation. Finally this system has a database including input interface of outline processor type. This database can organize it accounting to own participant's logic for all the information that they collected again.

In the whole activity, about around 5 % ratios of gathering information did decrease as a result of having introduced this system in practice process of Action Learning. By sharing gathering information process with other participants, reduction of about around 10 % gathering information costs was more effective than experiments before introducing system.

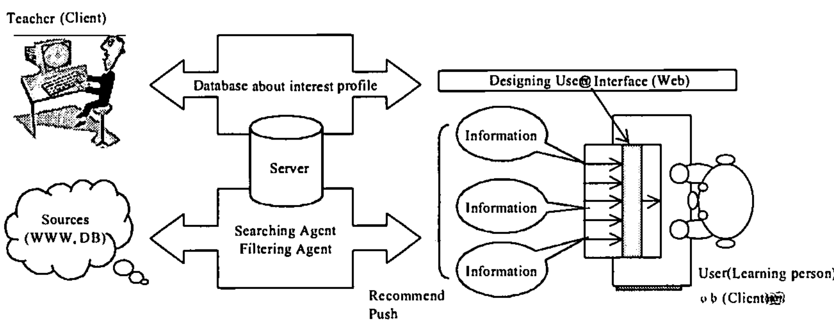

Figure 2: Characteristic of the system

Conclusion

So far we have outlined the concept and design of system. In concluding, we should note that this system principally effective for shortening an apportionment of gathering information process when practicing these methods. The Future direction of this study will be to extend this system examine structure clearing and managing a copyright of digital content.

MULTIMEDIA SYSTEMS: A NEW TECHNOLOGY IN THE HEALTH EDUCATIONAL CONTEXT

Elomar Christina Vieira Castilho Barilli
Oswaldo Cruz Fundation –Public Health School – Secretary of Educational Technology Coordinator R. Leopoldo Bulhões –térreo –CEP. 21045-900 –Rio de Janeiro –Brazil. barilli@ensp.fiocruz.br

1. Introduction

In thc sphere of health, the introduction of new technologies in the educational context is taking place in an international scale, with the development and adequation of computer systems that deal with informations in an optimized way, as relates to the efficiency of access, recovery, presentation and dissemination, at the same time that they treat in an adequate way the psychopedagogical issues involved in the learning process. This is certainly not only due to the complex and diversified nature of the information that is always in expansion in the field of health, but also to the very quantity of information that needs to be dealt with in this field, allied with the advancements in computer sciences and telecommunications. All these facts result in the need of development of products related specifically to the health field, carried out by professionals that should not only dominate the theoretical and practical knowledge of the relevant aspects, but should also be in close contact with the main advances in this field. The Oswaldo Cruz Fundation - FIOCRUZ, well known for its experience in teaching and research, with highly qualified professionals, turns its interests towards the education and training in the field of the health sciences, developing, distributing and evaluating educational products based on multimidia technology (hipertexts), focussing on the theoretical- practical knowledge of the targets that are most in demand from the scientific community, including graduate and undergraduate students from the Brazilian institutions of teaching and research.
The spheres of development of these systems are necessarily multidisciplinary, demanding an interdependence of knowledge. That is why, besides the team that is considered the *basis* (biologists, system engineer, visual programmers) other teams composed of pedagogues, psychologists, computer science professionals and fotographers will be formed in accordance with the subject to be dealt with. The encounter of the teams is taking place in the National Public Health Scholl -Secretary of Educational Development (SDE/ENSP), a point of intra and interinstitutional integration, where efforts are joined in order to promote a qualitative leap in the educational products issued by the society.

2.Projects in Course

A. HIPERGIS: a hypermedia system on techniques of spatial mapping and systems of geographical informations for the health field. CASTILHO-BARILLI ECV[1]; NOBRE FF[2]; CARVALHO MS[3] / [1]Nacional Publuc Health School /FIOCRUZ; [2] Biomedical Engineering Program COPPE/UFRJ;[3]Nacional Publuc Health School
The main objective of this work is to favour the routine employment of spatial analysis in managing processes of public health with the usage of techniques of spatial mapping through computerized Geographical Information Systems, as it is believed that this type of analysis facilitates its steps in relation to time spent, costs involved and also in what concerns the broadcasting of its results. The HIPERGIS is a hipermedia system, whose aim is to aid in the acquisition of knowledge about the techniques of spatial representation of data, as well as in the employment of computerized geographical information systems, through the training and/or improvement of the professionals who work in the health field and undergraduate and graduate students, therefore mending a gap in the knowledge of these people who, in general, do not have access to these subjects in their graduation studies. The data basis of the hipermedia is composed by specialized mainly derived from textbooks on cartography and scientific articles. The so-called "authorship tool" used for implementing the basis of knowledge of the HIPERGIS was the Multimedia software Toolbool 4.0, since it was easily handled and it presented a good cost-benefit relationship. HIPERGIS is divided in 4 main modules: 1) *Help*- subdivided in: a) descriptions on its navigation and b) Hipertexts: historical, definitions and applications; 2) *Basic Concepts* - topics on cartography; 3) *Spatial Representation* - descriptions of the spatial mapping techniques with graphic examples (maps) and 4) *Systems of Spatial Informations*- in this topic one includes the GIS. The buttons constitute the main means of navigation of the system. They are disposed, in a pattern, at the inferior left corner of each screen, being divided in: *Fluxogram* - presents the topics and subtopics, *navegate??* - summary-screen that explains the function of each botton, *return to the beginning button*- sends the user to the page or the introduction screen of each topic or chapter; *Main Menu*- presents the main modules; send *page forwards and backwards* and *exit button*- ends the system. The system still offers a screen or page of glossary, with a list of words in alphabetical order. The minimal technical requirements for the HIPERGIS use with a good

performance are: a microcomputer PC-486, with 16 Megabytes of memory, 12 Megabytes of free space in hard disk, SVGA monitor with a 1 Megabyte plaque configured for 256 colours, as well as an MS-Windows 3.1 File Manager (which fits perfectly well the more modern versions, like Windows 95).

B. *Development, Application and Evaluation of Multimedia Systems on the Main Human Parasitic Disseases for Health Education* . [1]ELOMAR CHRISTINA VIEIRA CASTILHO BARILLI; [2]LUIS REY; [3] ANTÔNIO J S DE PAIVA; [4]LUCIANO DE PAULA /[1]ENSP -Oswaldo Cruz Fundation; [2]Tropical Medicine Department - IOC/FIOCRUZ; [3,4]SDE/ENSP The main HUMAN PARASITIC DISEASES constitute the central target of this work, which is meant for graduate and undergraduate students of the national institutions dedicated to teaching and research. The first theme to be dealt with is Human Malaria, its meaning, characteristics, ways of treatment and control of the disease. The level of information to bc followed is the basic one, and, as information source, the texts of the following books are being employed: Parasitologia, Bases da Parasitologia Médica and Dicionário de Termos Técnicos de Medicina e Saúde, all being written by Dr. Luís Rey. The multimedia is divided into five main modules: *Introduction*-made up of a video; *historical*- with a slide show linking an audio file with historical photos that are presented on the screen; *the parasite*- morphology, evolutive cycle and physiology; *the mosquitos*- morphology, biology, collecting and control and *the disease*- pathology, diagnostics and therapeutics, epidemiology and control. The system contains, besides the strong textual content, schemes, videos, photos, and, animations. The basic programme used for the implementation of hte system is the AuthorWare 4.0. It will be applied in samples students from the graduate courses of FIOCRUZ, undergraduate Medicine students from Rio de Janeiro Federal University, as well as in opinion and suggestion surveys with teachers and researchers linked to the teaching of the health sciences. This work will bring, as final result, a product of multimedia software, available, initially, under the form of CD-ROM and, after the revision step, at the Internet. This work is being developed with the purpose of offering a facilitating means of cognition that could be applied as an optimizing factor in the acquisition of specialized knowledge in an individual and pleasant mode, thus favouring the introduction of new environments of teaching/ learning and recycling in Parasitology.

C. *WARNING SIGNAL: an integrating signal between environment and health.* DANIELLI GRYNSZPAN; ELOMAR CHRISTINA VIEIRA CASTILHO BARILLI/ Oswaldo Cruz Fundation

This work seeks to present a dynamic and interactive pedagogical product, which might contribute to the raising of the consciousness of the intrinsic relationship between ecology and health. Through education and reflection on the triad : human being, health and environment. WARNING SIGNAL will be put at the general disposal in The Biodiscovery Space, that belongs to the Science and Technology Museum, *The Museum of Life*, that is being implanted at the *campus* of FIOCRUZ. This work presents an effort made towards offering teachers, pupils and other citizens, that should come to the Museum, a starting point for the exploration of themes linked to health and environment that would lead to a basic principle, linked to both, that is the constant fight for improvement in the quality of life. This work still intends to develop in the user a critical posture in relation to his rights and duties as an individual, of fighting for good life conditions, for himself and the community. Summing up, one intends the Warning Signal to develop in the visitor of the Biodiscovery Space of the Museum of Life/FIOCRUZ a holistic perception of the touchstones of education in health and ecology

3. General Conclusion and Perspectives

The multimedia technology was selected as the adequated environment to implement the systems because permit its utilization for people without previous experience in the use of computers and its efficient manipulation of large volumes of text and images. At the present stage the system has been implemented only in Portuguese. These products, at first, will be implemented in CD-ROM, and, later (after the evaluation methodology), made available through Internet. The methodology evaluation will be carried out with professionals whose specialities are linked to the theme dealt with by the system in relation to the technology employed, as well as the target public of the system, according to these steps: *preliminary questionnaire* (that seeks to collect information on the user experience within the theme to be presented, computational experience etc), " and *evaluation questionnaire* (collecting of opinions, observations and criticism). The intention of the professionals from SDE/ENSP is that it should not only be a place that would produce tools to sustain and amplify cognition, but also contribute for research on the efficacy of its very function: that of the knowledge communication and integration of FIOCRUZ researchers with professionals from other institutions. Our hope, in fact, is that it may contribute both for technical - scientific development and for the educational development in the field of health.

SCALING INFORMATION LITERACY AT THE UNIVERSITY OF IOWA: WEB-BASED APPROACHES

Barbara I. Dewey, University of Iowa Libraries, University of Iowa, U.S.A., barbara-dewey@uiowa.edu

This short paper discusses issues and strategies related to scaling information literary programs in the large university setting. The University of Iowa Libraries' multi-format approach in attempting to reach more of its 28,000 students will be described with a focus on web-based delivery systems developed in partnership with Colleges and academic programs.

THE NEED:

- The information environment is too complex and changing too rapidly to expect students to acquire information literacy without a planned, systematic, cumulative instructional program.
- Students must learn critical thinking and research skills as preparation for a lifetime of changing information needs.
- Effective learning about information retrieval, use, and analysis is tied to a particular information need, often discipline-specific.
- Students have different learning styles and acquire information in different ways. Any information literacy program must accommodate these differences by using a variety of approaches that provide practice in these skills.
- The most effective way to reach students is through collaboration between the Libraries and academic departments and faculty in integrating information skills into the curriculum and evaluating outcomes through a variety of means.

INFORMATION LITERACY LEARNING OBJECTIVES:

- Identify and articulate needs that require information solutions;
- Identify appropriate information sources and execute search strategies appropriate for each resource;
- Interpret and analyze search results;
- Critically evaluate the information retrieved;
- Organize, synthesize, and apply the information;
- Understand the structure of the information environment and the process by which both scholarly and popular information is produced and disseminated; and
- Understand the ethical issues related to access and use of information.

TIER ONE: A tiered approach that builds on knowledge acquired throughout the students' career has been developed including strengthening the current introductory research and information seeking components in two products:

- *Online Iowa* – updating/enhancing library section of a general university CD-ROM orientation program that provides a basic understanding of Main Library service points and examples of where to search for information resources (http://www.uiowa.edu~online/).

- *Library Explorer* – strengthening the existing partnership where library staff provide instruction on how to integrate the use of Library Explorer, a computer-based library instruction program with automated "quick tests of knowledge", other information sources, search strategies, and development of effective research-related assignments for teaching assistants within their training program. Librarians are subsequently paired one-on-one with Teaching Assistants to provide customized support. Extensions underway for Library Explorer include subject-specific "chapters" for different disciplines and special CD-ROM "cuts" from Library Explorer to use with distance education students who do not have access to the Internet (http://www.lib.uiowa.edu/libexp/).

TIER TWO – UTRIPLE I: Librarians work with faculty to determine a desirable combination of instructional formats, assignments, and outcome evaluation methods building on experience derived from current and past partnerships with GER and upper division course instruction for tier two components in an initiative called UTripleI (University of Iowa Information Literacy Initiative) for:

- *General Education Requirement Courses* -- introductory subject-based information literacy component developed with faculty and built into selected GER courses selected from the Departments of English, Geography, History, Political Science, and Psychology including query formulation, information seeking strategies, basic evaluation of information sources, and a basic understanding of copyright and intellectual freedom issues.

- *Science Information Literacy Initiative Project* – development of specific information literacy components related to the special needs of science disciplines and their courses.

- *Undergraduate "Majors" Component* -- advanced and more complex subject-based information seeking, retrieval, and analysis components built into selected courses for undergraduate majors.

TIER THREE – FACULTY TRAINING AND SUPPPORT: Efforts to scale information literacy efforts through faculty training include programs for on the application of learning technologies in their courses:

- *nTITLE* (New Technologies in the Teaching and Learning Environment – website noted below) is a summer faculty training program taught largely by librarians. The Center also provides input into the University Libraries' TWIST (Teaching with Innovative Style and Technology) project (http://www.uiowa.edu/~ntitle).

- *TWIST (Teaching with Style and Innovative Technology)* is a three year grant funded program whose major goal is to create a model program for training faculty to integrate networked information into teaching as well as information literacy components. TWIST project staff are sponsoring a series of late summer workshops for faculty and staff to explore ways of fully using information technology in instructional settings. The sessions focus on building learning environments for students - how to help students learn to use electronic resources via OASIS (the University Libraries' online catalog), the Web or CD -ROM; how to build instructional Web sites to guide students as they learn critical thinking skills. One "scaling" factor in this program is the development of web-based tutorials for faculty to use at anytime. Another scaling factor is the development of a TWIST "template" for faculty to develop course web pages with an emphasis on linkages to resources and information literacy-based lessons (http://twist.lib.uiowa.edu).

SUMMARY

Issues and challenges to scaling efforts with be reviewed including the need to "mine" partnerships with faculty and technologists, the need for improved marketing of the inherent benefits of integrating an information literacy component into one's course, the difficulty of measuring and evaluating the success of a "scaled" information literacy program, and the challenge of putting together a coherent program or curriculum in an easily translatable modular form.

Multimedia Communication - A National Program for High Schools to Develop Professional Multimedia Skills

Ricardo Dal Farra
Multimedia Communication
National Institute of Technology Education (INET)
National Ministry of Culture and Education - Argentina
dalfarra@clacso.edu.ar and dalfarra@inet.edu.ar
http://music.dartmouth.edu/~ricardo/index.html

The New Educational System of Argentina

In Argentina we are living an advanced stage of what we call "educative transformation". This embraces from student's early years, when them goes to the General Basic Education (GBE) right after the kindergarten, and includes also the high school level, both technical and non-technical.

Our new system introduce 9 years of general education organized in 3 stages of 3 years each (GBE I, GBE II and GBE III), while the previous one had only 7 years. After this, the project includes Polimodal Education (PE), another 3 years where students receives more advanced general education while at the same time follows one of five basic orientations we call "modalities", that can be chosen between: Communications and Art, Management and Economy, Natural Sciences, Production, Humanities and Social Sciences.

To receive a technical diploma is possible to take (parallel to the "Polimodal Education") one of a series of "Technical-Vocational Pathways" (TVP) pointing directly to develop professional skills around different professional areas of the work world of today.

Technical-Vocational Pathways

The education by competences is on the basis of all the "Technical-Vocational Pathways" developed. These programs were created considering the present situation of the educational system in our country and the neccesities for the future. We worked consulting permanently both to the different levels of the educational system as well as the productive world.

Each "Technical-Vocational Pathways" (TVP) focuses on a work area of the real world and the professional skills needed there. Among the **TVPs** developed are: Informatics, Agriculture, Industrial Process, Organizations' Management, Electronics, Health and Environment, and Multimedia Communication.

Each **TVP** proposes a modular organization where each module focuses on certain competences related to the field of work involved, developing a coherent body of competences to receive the diploma on the specific technical area of interest.

TVPs are between 1200 and 1800 hours long, and the modules of their structure can be organized in three years, following steps of progressive complexity.

A partial option to the technical diploma are the "Itineraries", when students takes only certain modules limiting the general field of study to develop only a group of competences coherent with an specific trimming of the field focused by the **TVP**.

Multimedia Communication

The "Technical-Vocational Pathway on Multimedia Communication" have been developed by a small group of multimedia producers, artists and pedagogues working since 1996 on the program.

A national program on multimedia communication for high schools in our country needs to solve several problems to start, being faculty training on new areas of knowledge and work, and the equipments required just some of them. Also must be considered the social situation of a very large country where almost half of the population is concentrated on the capital city (Buenos Aires), thinking that while there are small to big companies based there around the wide multimedia market, mainly small groups are working on this field on the rest of the geography. So related areas to multimedia should be considered into the project's structure considering the employment opportunities in small cities while the specific multimedia field grows there.

The modular structure is built with 16 modules of 96 hours each, plus one of 144 hours (total = 1584 hours). These modules are organized in 6 modular areas: Script, Images, Sound and Music, Multimedia, Management and Technologies that groups them.

While the other "Technical-Vocational Pathways" are only technically oriented, this program joins art and sciences concepts with direct experiences on new technologies. Not all modules on Multimedia Communication looks for specific competences, some of them on the first level of complexity (= first year) serve as an analytical introduction with artistic elements to the visual and the sound/music world (Visual Morphology, Sound Morphology), while others (Science and Technology Elements) put the basis to understand many processes involved on modules of the second and third level. Modules like Script, Desktop Publishing, Image Synthesis and Animation, AudioVisual Realization, Sound Technology, Production, Multimedia Introduction, Closed Multimedia Systems, Open Multimedia Systems, Management and Marketing of Micro-Enterprises and Equipments Maintenance focuses on specific competences of the field. On the last step of complexity, Integration Project and Training on Work Centers modules looks both for coordination and integration of efforts as well as for complex experiencies useful on the real world.

About the modules, there are no breaks between theory and practice on them; learning is taken as a process where different aspects are necessary to reach the knowledege and skills to work on the multimedia field. Basic science concepts are important, as well as practice with suitable technologies to solve real world problems using a creative approach. About each module itself: on the **first** level of complexity, Script starts with traditional, linear scripting for different medias, goes through parallel and multiple stories, ending on hypermedia scripting; Visual Morphology takes both, fixed images and moving images, approaching also the relationships between images and sound; Sound Morphology focuses on sound and music perception, analysis and creation; Multimedia Introduction goes from the perceptual, aesthetical and technical analysis of multimedia projects to the production of basic hypermedia works; Science and Technology Elements works over the basis of light, sound, electricity and electronics to understand processes learned and technologies used through the TVP; on the **second** level of complexity, Desktop Publishing is focused on the visual articulation between text and fixed images; Image Synthesis and Animation takes both, the 2 and 3D worlds; AudioVisual Realization works over the full process of capturing and editing real moving images and their integration with the sound world; Sound Technology is focused on synthesis, recording, processing and mixing of sounds and music; Closed Multimedia Systems points to multimedia/hypermedia products where information flows mainly inside closed environments of use (as in most CD-ROMs products); Production is focused on the management of each project step; and on the **third** level of complexity, Open Multimedia Systems points to multimedia/hypermedia products where information flows on open, distributed environments of use (WWW); Management and Marketing of Micro-Enterprises points specifically to those wishing to start their own business; Equipments Maintenance is planned to help to identify and solve simple computer and AV fails; Integration Project is where the more complex and interdisciplinary projects happens; and Training on Work Centers put students on the real world of work so they can make their own experiences, using this to analyze techniques, processes, products and situations to help them to progress from there and complete this stage of learning.

Together with the 16 modules, students needs to take some subjects from the "Polimodal Education" too: Communication, and English I-II-III. It must be considered here that in spite is mandatory to receive a "Technical-Vocational Pathways" diploma to complete also the "Polimodal Education", there are some electives subjects on this system, making neccesary to remark those two areas (Communication and English) as essentials to fufil the goals. While in Argentina the official language is Spanish, students could study French, Portuguese, English, German or Italian as foreign language on the high school, thus making necessary for us to take a decission regarding which is the language needed at present for those starting on the multimedia field: (at least, three levels of) English. About the high significance of Communication for this TVP, it must be remarked that settle fundamental (communication) concepts needed for most of the modules of the second and third level of complexity.

As a shorter option to the technical diploma on Multimedia Communication, students can receive a certificate on Desktop Publishing, Image Synthesis and Animation, Audiovisual Realization or Sound Recording and Processing approving only certain modules to develop a group of competences coherent with the named specific fields ("Itineraries"). As an example, to receive a basic certification on Image Synthesis and Animation (an "Itinerary" with a total of 576 hours) students must to approve the following modules: Script, Visual Morphology, Image Synthesis and Animation, Multimedia Introduction, Science and Technology Elements and Equipment Maintenance; in addition, is highly recommended (not mandatory as for the full technical diploma) to take the Communication, and English I-II-III courses.

This program starts in public schools of Argentina in March 1999.

A large scale Internet based course for computer beginners

Dr. M. J. Weller
Faculty of Technology
The Open University
Milton Keynes

United Kingdom
e-mail: m.j.weller@open.ac.uk

Introduction

T171 *You, your computer and the Net,* is a distance education course presented at the Open University in the UK. The course was piloted in 1999 with 900 students. It is a foundation course, which provides a grounding in computer skills and knowledge of the personal computer and the Internet. It is a broad appeal course aimed not just at Technology students, but students of all Faculties, as well as a general audience who may only take this one course. The course is presented entirely over the Internet, with most of the material being web based, and extensive use is made of computer conferencing.

The course was developed to reflect a Kolbian iterative learning model [1], which had been used successfully in other OU courses [2]. The model has the following three main phases:

- Conceptualisation - the learner receives information about other people's concepts;
- Construction - the learner uses such concepts to perform meaningful tasks;
- Dialogue - the learner tests existing concepts and creates new ones through dialogue with other learners.

With this model as a basis, and the following aims, the course structure could be developed. The initial aims of the course team were as follows:

1. To produce a large scale, broad appeal ICT course
2. To make the Internet the central delivery mechanism
3. To produce a course in a relatively short time scale
4. To make students feel comfortable in the 'wired world'
5. To bring the OU's traditional standards of production to the Internet.

There is an initial face to face session, which operates as an introduction to the University as a whole, and to distance learning. This is not course specific, and the emphasis on face to face was kept to a minimum in order to utilise the advantages of computer mediated communication (CMC) tuition for distance learners with diverse lifestyles.

Course structure

T171 is based around three modules, two of which have a set book. The web site is then used to add academic material exploring issues raised in a chapter of the book. Students also have access to a number of conferences. The modules are outlined below:

Module 1 You: Computing with confidence

This starts from the beginning and assumes that at least some students are completely new to computing. It covers general computer skills such as: the basic operating principles of a PC; the *Windows* interface; an introduction to standard office-type programs for word-processing, database operations, spreadsheet calculations and simple charts and graphs; the use of modems, electronic mail and conferencing; connecting to the Internet; using a Web browser; searching the World Wide Web on specific topics; planning, designing and authoring Web pages; Netiquette and principles of online behaviour.

Module 2 Your Computer: The story of the PC

This module is based around the story of how the personal computer came to be one the dominant technologies of our age. It starts with the invention of the microprocessor and leads up to the present dominance of Microsoft. It is based around an accessible set book [3] and a web site containing a large amount of additional material, study guides, links, resources and assessment material.

The module looks at the key technologies involved with the PC such as the microprocessor and the operating system and explains their importance and how they work. It also looks at the social implications of the IT revolution, the nature of the computer industry and the reasons behind the success and failure of computer products.

Module 3 The Net: Where it came from, what it is

This covers the evolution of the Internet from its origins in the inter-war years through to the explosive growth of the World Wide Web in the 1990s. It is again based around a set book [4] and a web site.
The Module covers the history of the Net in four stages:

- Prehistory: the evolution of ideas about computing and communications from the 1930s to the 1960s
- The ARPANET: the creation of the first packet-switched wide area network
- From ARPANET to Internet: the metamorphosis of the original ARPANET concept into the 'global network of networks' which constitutes today's Internet
- The World Wide Web: the evolution of the Web from its invention in 1989 to its current form.

Module 1 is largely activity based, and thus incorporates both the conceptualisation and construction phases of the learning model within the material. Modules 2 and 3 are more content based. In this respect, the web based material represents the conceptualisation phase. In order to make it active for the student it is necessary for them to engage with the material in a manner which personalises it for them. This was achieved through the use of a study journal, as well as assessment.. All modules need to make use of a dialogue stage, whereby students test their understanding of a concept against that of others. This is done through the use of computer conferencing. The course thus makes extensive use of conferences throughout the material.

The Study Model

One of the problems with any material which is studied at a distance is that of pacing. In order for students to gain the maximum benefit from the material they need to work through all of it, but when all of the material is available there can be a temptation to rush through it. In the traditional distance learning model this has been accommodated with regular mailings, timing of key events (such as assignment submission and so forth). Similarly distance education must deal with the issue of 'information overload'. Level 1 students may be studying for the first time, or returning to study after a long time. They thus need to be made to feel comfortable with the material, and what is required of them. These two considerations led us to develop the following study model, which is broadly analogous to the traditional model.

The web site is revealed as students progress through the course. As students have different demands on their time, it is necessary to make material available which is ahead of the current study schedule. Thus material is available up to four weeks ahead of where students are currently recommended to be. This pacing is reinforced through the use of study guides, which are e-mailed as an attachment to students every two weeks. These study guides provide a detailed breakdown of exactly what is required of students during the specified study period.

Assessment

The assessment of T171 is based around four tutor marked assignments (TMAs) and an end of course assessment. All of these are submitted electronically. The first two TMAs occur in module one and are based on collections of exercises students perform during the module. The last two TMAs occur at the ends of modules two and three, and are web-based reports which explore key issues raised during the modules.
The final assessment is based around a web site which students construct. There are two key components to this. The first is a portfolio of material produced during the course. This includes examples of the study journal, reflection on one TMA, conference messages and so forth. It thus represents a way of reinforcing the importance of these skills to students. The second component is a scenario based web site, which requires students to use material from all three modules, and with modules two and three in particular examine similarities and differences in the two stories. This encourages them to use new skills they will have developed such as writing for the web, page layout, website structure and use of links, rather than the more traditional essay type assessment.

Study Skills

As a Level 1 course within the OU, T171 has a role to perform in developing student's general study skills which will help them with any further study. As part of its aims to produce students, who are comfortable in using and dealing with the new technologies, it also needed to develop skills which would allow students to use computer tools effectively. Module one was based around a generic method of teaching, that is it was not specific to one software package. Students are thus provided with information and activities germane to all brands of the broad software type, e.g. spreadsheets. The skills developed are those of transferable ones between different software packages.
General study skills are developed in module two through the use of exercises in the material. These include skills such as note taking, critical reading, producing effective explanations and so on. The requirement of the end of course assessment is that students provide evidence of having completed at least some of these exercises. These exercises represent the traditional study skills which any Level 1 course has to address to some degree.
Skills which have not been developed in other courses, but which will become increasingly important for students are developed in module three. These include finding and evaluating information on the Internet, organising large amounts of information through the use of hyperlink documents, effective writing for the web, and so forth.

Conclusions

T171 was produced in one year, compared with the traditional production cycle of three to four years in the OU. It has proved extremely popular with a broad range of students, many of them new to the University. Estimated student numbers for 2000 are in excess of 5,000. It has managed to combine many of the successful elements of traditional OU course production with the benefits offered by the new technology.
The course uses a three stage learning model, which encourages students to engage with the learning material, and to discuss this in computer conferences. The course uses accessible set books as the basis for teaching and adds academic material to these in the form of a web site. Students are directed through this by means of explicit study guides. Their contact with their tutor is mainly through a tutor group conference.
A number of study skills, both new and traditional are developed through the use of exercises. These are reinforced by inclusion in an end of course assessment.
The advantages of this method of presentation are that it allows course teams to present up to date courses in a rapidly changing field. It gives students experience in using the new technologies, and allows them to access the material anywhere they can find an Internet connection. Problems of attendance at face to face tutorials are also removed by using online methods.
Alternative software methods are currently being investigated. A full scale evaluation of the tutor and student experience is being performed, which will influence alterations to the course material for presentation in 2000.

The magic lantern, film-strips, tape recorders, 16mm films, teaching machines, audio labs, television, video-discs, and teleconferencing have all, at one time or another, been touted as technologies that would have a significant impact on education (Saettler, 1990). The history of technology in education contains extensive documentation of the reasons why such innovations have failed or have had limited success. These reasons are as varied as the technologies themselves. However, there are common threads running through all of the attempts to transform education through the use of technology. The factors related to success or failure are well known and include administrative support and understanding of technology, teacher training, sufficient funds and release time, and effective technical and instructional support. Today the technology that is receiving the most attention is the computer. The question is, will this technology achieve the success that other high-profile innovations of the past have not?

This short paper on a work in progress responds to the lack of information about real-world situations where teachers are trying to apply computer technology in instruction. It is based on a case study that documents the experiences of Dr. John Adams, a community college English instructor, who, over a period of five years, progressed from teaching composition in a computer laboratory setting to teaching seven classes on-line. It is a record of the experiences that he had dealing with the challenges of applying computer technology in his classes with little administrative support, almost no training, little technical or instructional support, and no release time or financial assistance -- the same factors that limited the success of previous educational technologies.

In the 1993-94 semester, his first at his present position, Adams was asked by his division chair to teach one class each semester in a computer lab. The lab contained 24 PC's placed on regular straight tables arranged in four rows with six computers to a row. The computer screens were facing away from Adams (i.e., not visible to Adams); the room was also used for storing discarded miscellany from other rooms. For his classes, Adams used the tools (handouts, reading book, test/quizzes, etc.) and methods (lecturing, answering questions, grading papers outside of class) that he used in the traditional classroom. Adams expressed a high degree of frustration with the computer lab setup. He felt that it was a major hindrance to communicating with the students, and he missed the conferencing orientation that he was accustomed to in his other classes.

In the fall of 1996, Adams began putting his course materials on the Internet, with the assistance of his wife. These initial materials were copies of the ones he was using in his classes. Then, in the fall of 1997, Adams negotiated with representatives of Old Dominion University's Teletechnet program to teach advanced composition on the Internet. For this class, he not only had to create a completely new course (for him), but one that was appropriate for on-line use. In addition, that same semester, he gave his freshman composition students the alternative of being taught in a traditional classroom setting or via the Internet (with an option for one class meeting per week). Most students opted for the Internet-based course. Teaching these courses on the Internet involved revising old materials, creating new materials, and getting everything organized effectively and put on the Internet. It also required Adams to develop a new method of dealing with students, students whom, for the most part, he never met face-to-face. And it meant learning different organizational skills to keep track of the e-mail messages that he was receiving from his students.

With the 1998 summer session, Adams taught all four of his classes via the Internet only. This included one section each of college composition I, college composition II, advanced composition, and short fiction. The first three courses required a number of revisions and additions to the course websites to make them effective as Internet-only courses. For the short fiction course, however, Adams had to create and organize a completely new set of materials to be put on the Internet. During the fall 1998 and spring 1999 semesters, Adams taught seven sections of courses on-line. These included the same four classes that he had taught during the summer as well as African-American Literature I (fall 1998) & II (spring 1999) and a technical writing course (both semesters). Once again, for these three new courses, Adams had to create and organize the materials and assist his wife in the process of creating the webpages for the course websites.

Administrative support is a critical element to the success of any academic endeavor. In Adams' situation, this support has been negligible. The first semester that Adams taught in the computer lab, he felt that the administrative position was, in essence, "There's the lab. Use it." As long as there were no complaints from students, the administration seemed to be satisfied. Over the course of several years, the administration continued to request that Adams use the computer lab for classes, but they expressed a strong opposition to Internet classes. Adams felt that this opposition was based in part on the assumption that students could only receive a quality education in the classroom. Adams felt that another factor was a lack of knowledge about computers on the part of top-level administrators. Until the fall of 1997, none of them had a computer on their desks, and, as a result, they had a limited understanding of how computers operate or of the potential of computers in education. Because of their opposition to Internet courses, Adams established his Internet classes surreptitiously, with only spoken approval from his division chair. Not until the summer of 1998, with very positive enrollment results from his on-line classes, did they begin to publicly state their acceptance of such courses.

Technical and instructional support is also critical to the effective application of educational technology. Unfortunately, this has been lacking in Adams' experience. During the semesters that he was teaching in the computer lab, technical support was minimal, just basic maintenance. When he moved to Internet classes, the situation did not improve. While the technician on staff has the qualifications to handle the responsibilities of computer maintenance and those of web master, he does not have a background in education. As such, he is unable to provide effective instructional support on the applications of computer technology.

Adams has received neither release time nor financial assistance from his college for his work related to the application of computers in his instruction. Since the fall of 1996, Adams has developed materials for seven on-line courses, and with his wife's assistance, has created and updated a comprehensive website with these materials and links to other resources. Adams purchased his own laptop computer and zip drive because of problems with his office computer (it could not handle the workload and broke down; after it was fixed, it was given to another instructor). He also purchased critical software and instructional manuals.

Year after year, the literature on instructional technology has documented the problems and has provided the solutions. However, in the real world of education, the problems are often not recognized by the people in positions of authority and, thus, the appropriate solutions are not applied. At the end of one interview, Adams commented that, in his present situation, he spends all of his time maintaining what he has developed so far, and that he has no time to keep up with new advances in technology. As a result, he feels he that is actually falling behind rather than progressing. Unless there is sufficient administrative support, adequate teacher training, effective technical and instructional support, and appropriate compensation through release time and financial assistance, those who are trying to advance the effective use of computer technology in education will also find themselves falling behind rather than progressing.

Practical & Low Cost Methodology for Internet Classroom Presentations

Kenneth J. Ekegren, P.E.
Engineering Technology Division
North Central Technical College
Mansfield, Ohio U.S.A
kekegren@nctc.tec.oh.us

Introduction

Current technology is now available that can remove the restriction of time from the delivery of classroom lectures. By utilizing Microsoft's PowerPoint software along with RealNetwork's RealPresenter plug-in, any school can easily provide a low cost, efficient way to offer recorded lectures over the Internet. With the emphasis on life long learning and the increase in non-traditional students in classrooms, Internet accessible lectures let students "attend" a class lecture that they may have missed due to shift change, unexpected overtime, or an out-of-town business trip. This gives them the flexibility to listen to any recorded lecture at their convenience, from a computer lab on campus or from any Internet accessible computer.

The Web Enhanced Audio System

During Winter Quarter, 1999, North Central Technical College offered recorded lectures from seven different courses using the Web Enhanced Audio System. Using conventional portable audio tape recorders, lectures were recorded and then processed through a computer into single-slide, PowerPoint presentations, with up to one hour of lecture embedded into the slide. NCTC already had a standard web server and network on campus and were also using Microsoft's Office 97 software. Adding to this, the College purchased RealPresenter software ($39) and a number of portable audiocassette recorders ($50 each). The only other hardware used was an audio cassette player for playback into the computer ($70). With an outlay of less than $500, the school was able to offer asynchronous delivery of course material via the Internet.

There seems to be two major roadblocks that hinder the development of Internet accessible course material: time and money. This Web Enhanced Audio System was designed to overcome these two obstacles. The nominal amount of hardware required, assuming a school has an existing web server and Office 97 software, eliminates the financial portion of the problem. And the other roadblock is finding the time and expertise to create or develop web accessible material. The Web Enhanced Audio System solves this by not requiring instructors to have computer expertise, nor burdening them with additional class preparation, aside from wearing a recorder during class. A web course coordinator can perform all of the processing and must simply have a working knowledge of PowerPoint and be familiar with standard audio equipment.

The Process

Once a lecture is recorded, it is sent to the web course coordinator and downloaded into a one-slide PowerPoint presentation using the "Record Narration" function. The single slide identifies the course number, date, and lecture subject. The software captures the audio lecture as large wave file (up to 70 megabytes for a typical one-hour lecture). The RealPresenter plug-in software then compresses the lecture (about 2 megabytes per lecture) and creates a web page suitable for publishing onto a standard server. A Table of Contents web page is created for each course and linked to the instructor's home page. The Table is then updated with the addition of each new lecture, acting as a directory for locating class meetings by date. To access a lecture, the students simply go to their instructor's web page, click the appropriate audio course button, and select the date of the desired lecture. Students can access their lectures from any campus computer lab by plugging head phones into the computer speakers, or from their own home, at their convenience.

Benefits

There are many benefits to this Web Enhanced Audio System. The low start-up cost in hardware and software for any college that already has a website makes this system possible without causing a major impact on the budget. The level of expertise for instructors is limited to the ability to push the record button on a portable tape recorder. The level of expertise for the Web Course Coordinator is limited to knowledge in PowerPoint software, simple web page creation and revision, and some audio equipment expertise. In addition, the impact on the web server and network infrastructure is minor due to the gradual increase of storage requirements and activity as the quarter progresses. And the benefit to students is the removal of thc time barrier associated with traditional class schedules. Plus, they can use this material for review purposes as well.

New Advances

One drawback to this system had been the slow download time found with traditional audio tape recording media. With the availability of new portable digital recorders, even the transfer of recorded media has been reduced for a "real time" 45-minute lecture down to about 4 minutes. Digital recorders are now available that can record up to two hours on a flash memory card, which can be handled like any other electronic file, and can be converted into a wave file in a matter of minutes.

The level of web enhanced lecture can also be upgraded by adding pictures or text to the web pages to be seen during the lecture. In addition, instructors already using PowerPoint slide shows during class can include the entire slide show, time-encoded so that it appears on the web just like it was given in class. The software used in this system could even be used to embed video of a process or procedure into the slide show if desired.

Conclusion

The Web Enhanced Audio System is a practical and low cost method of placing lecture material onto the Web. Using cutting edge tools that are inexpensive, coupled with a technique that is time efficient and extremely user friendly, any school can develop a web presence without the typical obstacles associated with new ventures. The Web Enhanced Audio System can also be used to augment independent study courses and can become the first step in developing complete online courses at any college. The insignificant impact on faculty's time and the low hardware cost make it a practical and economical method of converting and delivering lecture material over the Internet.

Developing Reading and Writing: Learning About Literacy in a Virtual Environment

Viv Ellis, School of Education, University of Brighton, UK <v.ellis@bton.ac.uk>

Simon Shurville, School of Languages, University of Brighton, UK <sjs16@itri.bton.ac.uk>

This paper outlines the context and rationale for a piece of curriculum development at the University of Brighton which is also the site for collaborative research by a teacher educator and a learning technologist. The development relates to 'Developing Reading and Writing,' a first year module on an English education degree for intending high school English teachers.

The aims of the module are: i. to investigate literacy as a sociocultural practice; ii. to investigate the ways in which technology changes both the nature of text and the ways texts are produced; and iii. to explore the pedagogical possibilities that would enable high school teachers of English to use digital technologies to enhance pupils' learning. The context for the development includes a commitment to a pre-existing and successful model of a learning environment for English/Language Arts education shared by the development team and the recent curriculum prescription contained in the UK Department for Education and Employment's Initial Teacher Training National Curricula in Secondary English and the use of Information and Communications Technology (DfEE 1998). The current development is an evolution of previous work at the university and not a reaction to this prescription. The aims of 'Developing Reading and Writing' have remained consistent for the last two years.

The shared model of a learning environment for English/Language Arts can best be described with the metaphor of the *atelier*, a place for *artisanal* activity. This metaphor was explored by one of the authors in previous collaborative work with Claire Woods and Patrick Dias (Woods et al. 1996) and, in relation to learning about literacy, is useful in conveying a sense of a shared purpose and of the dependence and interdependence of the *artisans* who work within it. The metaphor of the *atelier* allows for notions of expertise in a learning environment, expertise that is shifting and dynamic between teacher and students. It suggests the assumption of responsibility on the part of the learner. It also assumes that experience - read and lived - can be 'crafted' by language.

An important implication of the use of this model for learning about literacy is the positioning of learners as 'ethnographers of their own situations.' This is not to say that students spend much time talking about ethnographic research but they do talk about key terms and, in view of the module's aim to examine literacy as a sociocultural practice, they are encouraged to refer to the work of some of the more celebrated ethnographers of literacy such as Brian Street (Street 1992). This is not a research methods module, however, so what exactly does the phrase 'ethnographers of their own situations' mean? Woods et al. suggested that this involves positioning students as observers and researchers of contexts, recording data and observations and making decisions about the selection of details, leading students to a critical experiencing of texts, contexts and discourses (Woods et al. 1996: 12). This was our aim in immersing our students in the digital literacy practices of the internet and its associated technologies.

As resources for internet-based learning in UK higher education evolved in the political climate following the comprehensive review of higher education provision conducted by Lord Dearing, it became possible to extend the 'on-line' dimension of this module in line with current theory in computer-assisted learning. We decided to embed an existing on-line discussion forum within a World Wide Web environment which provides contextualised access to the technologies associated with the face-to-face 'classes'. In line with theories of constructivist internet-based learning (see, for example, Laurillard 1998), the module's web-based environment contains: home-produced materials, suggested links to external materials and search engines which enable students to seek authentic materials on the net. There are also synchronous and asynchronous forms of communications technologies embedded in the site.

As part of the curriculum development process, and at the beginning of the academic year, we conducted a questionnaire survey with the cohort of students who were to take the module in the second semester. Our questionnaire revealed a cohort in their late teens and early twenties with very limited skills in Information and Communications Technology. This finding influenced a number of design choices.

Firstly, in terms of genre, we chose to present the environment as an on-line magazine with one 'story' each week surrounded by links to resources, tools and activities. Second, the navigation of the site was initially made very linear. This was to support the skills development of the students with the intention that the navigation would become increasingly heterogeneous with external linking via 'spin-off' windows. Third, among the tools available would be on-line instructions for synchronous and asynchronous conferencing, an archive of previous 'stories', additional readings and the facility for students to publish their own texts on the site. Through the use of various 'seed' questions dispersed throughout the site, we invited the students to comment on all aspects of the design of the environment in the discussion forum and to speculate on the pedagogic reasons for these design choices. This was one aspect of positioning students as ethnographers. Others include immersing the students in the texts, contexts and discourses of fantasy role-playing MOOs.

In line with our concerns about hype and the new technnologies, our environment is being critically evaluated with our students. Their reactions will be reported and used to refine our subsequent approach to learning about literacy in a virtual environment.

Opportunities for Collaborative Learning

The opening of the Internet and the World Wide Web (WWW) to businesses has introduced an entirely new specialized area in Management Information Systems (MIS) called Electronic Commerce (EC). This paper illustrates how EC provides rich pedagogical possibilities for collaborative learning using hypermedia, active learning by doing, and constructivist teaching approaches. Selected universities in the country introduced EC courses in their MIS programs to address new developments taking place in the Internet-enabled marketspace. Content analysis of the course materials put out on the WWW by these selected universities in the ISWorldNet Web site was the primary technique used in writing this paper. Kosiur (1997) defines EC as "...a system that includes not only those transactions that center on buying and selling goods and services to directly generate revenue, but also those transactions that support revenue generation such as..offering sales support and customer service, or facilitating communications between business partners."

The technological platform for conducting EC in the marketplace could also be used for student instruction in recreating business Web sites. This is perhaps one of the course's primary strengths. Furthermore, it lends itself to the pedagogy of collaborative learning where student teams take an active role in constructing the knowledge they gain. Research is clearly supporting the efficacy of this technique in effectively engaging student attention and energies. In a cooperative learning environment, the instructor organizes content and topical activities around tasks, problems, and projects that student teams with a balanced mix of abilities and backgrounds are designed to undertake (Adams and Hamm, 1998). Team members' social skills, also called "interpersonal intelligence" according to Howard Gardner, encompassing interpersonal communication, task management, group interaction, and conflict resolution are constantly honed throughout the process.

Class Activities

The first set of activities involves a cognitive appreciation of the potential of EC for generating innovative Web-based products and services: assembling Web-based business plans used to justify potential online businesses; designing small business Web sites; writing reports on such topics as EC technologies or industries that lend themselves well to EC; doing case analysis on firms pioneering the use of the WWW; creating Web pages with a variety of content, and undertaking Internet activities. All these activities are to be conducted within a context that is meaningful to the student and one that builds on their specific business major, prior experience, and knowledge following the constructivist pedagogical approach as opposed to the traditional objectivist method (Cheek, 1992). Students will be asked to choose topics to explore and practical hands-on projects that most directly connect to their line of work in the office or personal interests.

Learning by Doing

"The yeast of knowledge, openness, and enterprise raises the need for a multiplicity of learning media and technological tools "(Adams and Hamm, 1996). The very wealth of Web site building tools that is now available allows students to experiment and "play" through "learning by doing" activities and significantly changes the whole instructional experience. Students have more control over the end product via the software tools and they assume greater responsibility over their learning process (Adams and Hamm, 1996). The "standard" activity for the beginner-level EC course is having students build small business Web sites using publishing software like HTML editors, Netscape Composer; Microsoft Publisher 98, FrontPage Express, or FrontPage 98; Cold Fusion; and other such tools. Web site design issues appear to be the emphasis of courses at this level. Courses for the more advanced EC course could look into Web site features that facilitate the actual sale transaction. Thus, students may be asked to perform more advanced E-Commerce activities like developing online order entry forms that actually accept data at the backend via a database package using tools like Symantec's Visual Café employing visual programming. Another small project is using CGI scripts for writing shopping cart application consisting of an item catalog interface, item description pages, and a main checkout page. There are Web sites such as those of Data Transfer Associates, Inc. (http://www.dtastore.com) and iCat (http://www.iCat.com) where demo software is available so that students can experience building online retail stores and act like online merchants. Both companies allow students to build prototype online stores. The site is customized so that it reflects the store owner's name, products sold, their descriptions, prices, and code numbers. The store is set up so that there are different departments showing the appropriate product line. An online shopper goes through these departments, chooses products to buy, and then, checks out desired items. The service also makes the online merchant capable of processing shipping and billing and credit card information. The server of Data Transfer Associates runs tests to verify customer addresses and check credit card approvals using CyberCash, Secure Socket Layer (SSL), and other technologies.

Students could also be asked to enhance their business Web sites by adding features that promote a "virtual community" using software packages like VirtualSuburbia (http://www.virtualsuburbia.com). Hagel and Armstrong (1997) define "virtual communities" as online communities allowing customers with the same interests to congregate, create content, and communicate on an ongoing basis. VirtualSuburbia allows students to create a collaborative environment for groups of people by allowing them to chat online and to show any Web location in the world for comment and evaluation.

Perhaps, the greatest strength of the EC course activities is that they lend themselves to authentic student learning assessment using the portfolio approach (Adams and Hamm, 1998). Since the course will be heavily project- and activity-based, outcomes of student learning are constantly being produced and collected. There are even a few instances in these courses where student teams actually went into business using their pilot projects for the course. This is, perhaps, the best measure of course success even though it is rare.

Instructional Applications of Information Architecture

Stephen P. Victor
BMC Software, Inc.
2101 CityWest Blvd.
Houston, TX 77042 USA
Email: svictor@bmc.com

It is commonly stated that we live in an age of "information overload." Increasingly advanced communication tools, including the Internet and digital telecommunication technologies, allow us to transmit more and more information at faster and faster rates. A discipline—known variously as information design or information architecture—has evolved to meet the challenge of using information to provide meaningful communication. The discipline embraces such diverse fields as business administration, computer science, cognitive psychology, graphic and typographic design, and technical communication.

Information architecture is the structuring of data to meet the informational and management requirements of an organization or group of people. For example, in their work on designing web sites, Rosenfeld and Morville (1998) state that the information architect is responsible for clarifying the mission and vision of a web site; for determining the site's content and functionality; for specifying how users will find information by defining the site's organization, navigation, labeling, and searching systems; and for mapping how the site will change and grow over time (Rosenfeld & Morville, 1998, p. 11).

This paper briefly examines some theoretical underpinnings of information architecture, considers the application of the principles of information architecture to instructional theory and practice, and describes ongoing research to evaluate the efficacy of such an application.

Theoretical Background

Information Theory

Building on the seminal work of Shannon (1948), information and communication theorists have proposed a model that describes the transmission of information from source to recipient. Current information theory is concerned primarily with the binary coding of transmitted messages in ways that minimize "noise" (Ash, 1965; Gallager, 1968). Information designers have drawn on the theory to suggest that information be designed in ways that reduce confusion and enhance the transmission of meaning to the recipient of the information (Senechal, 1997).

Perception and Cognition

Stern and Robinson (1994) define perception as the gathering of information through the senses and the organizing of that information to create meaning. All sorts of factors—such as personal characteristics, past experiences, and present feelings—can influence how sensory information is interpreted. Kosslyn and Chabris (1993) demonstrate the use of principles of cognitive psychology to improve the effectiveness of informational graphics, such as charts and graphs. With an understanding of cognitive principles, the designer can create graphics that influence how viewers will perceive graphical elements and the meaning of the relations of those elements to each other.

The Social Construction of Knowledge

Vygotsky and others have suggested that knowledge is socially constructed: a conversion of social relations into psychological functions (Driscoll, 1994, p. 229). Learning takes place as learners are moved, through social interaction with more advanced peers and adults, to higher levels of development.

Constructing an Information Architecture

The literature suggests the following guidelines for designing an information architecture:

- Center the process on the needs of the users of the information.
- Perform a structured user task analysis to determine the user's information requirements.
- Involve users at all stages: analysis, design, and implementation.
- Map specific information needs to information elements in the web site or instructional piece.
- Structure information so that meaning is conveyed effectively. Consider whether design elements could detract from meaning without providing some benefit such as increasing motivation.
- Organize information so that the user can easily find it. Create labeling and navigational systems that are logical, consistent, and easy to use.
- Organize information in ways that facilitate the user's learning and schema creation.
- Consider personal or cultural factors that might affect perception of information.
- As ideas take shape, create storyboards, mockups, and flowcharts. Eventually, map the entire site with detailed architectural blueprints.

Instructional Applications: Ongoing Research

Proponents of constructivism state that learners construct their own knowledge in ways that are personally meaningful. Some constructivists also suggest that the constructivist instructor guides learners to integrate their personally-constructed knowledge into the larger body of socially-constructed knowledge. I suggest that instructors can use information architecture to allow students to structure their learning in ways that foster their own construction of meaning.

To evaluate my suggestion, I have designed a class entitled "The Instructional Applications of Information Architecture." The class will be offered to graduate students in the Curriculum and Instruction department (Instructional Technology concentration area) at the University of Houston, and I will co-teach the class with Dr. Sara McNeil. The expected population will be mature graduate students who are conversant with computer and Internet technology. At or near the beginning of the term, we will conduct an exercise in which students will map the types of learning they wish to achieve. Students will map out the instructional sequence and build an information architecture for the course using the guidelines listed above. This architecture will be collaboratively negotiated by instructors and students. Using a web site management program, such as Microsoft FrontPage or Adobe PageMill, students will create the basic architecture of the course. As the term proceeds, students will flesh out the web site with articles, assignments, and projects. At the conclusion of the course, I suggest, students will have designed and completed an information architecture that gives tangible form to the cognitive maps they have built.

The PASSENGER CSCL Tool for Distributed Learning in a Multimedia Environment

Axel Hunger, Frank Schwarz, Stefan Werner
Gerhard Mercator University of Duisburg
Department of Data Processing
Germany
Swerner@uni-duisburg.de

Introduction

Nowadays, a new component is added to the complex task of industrial Software-Engineering: the development in worldwide distributed teams. This paper describes new concepts and tools based on this scenario that are developed for the Software-Engineering-Education. This tools give the students the ability of shortening their study-time, but also they have the chance of obtaining knowledge in systems known as Compuer Supported Collaborative Working (CSCW) Environments (Kremar, in Salvendy, Smith, 1991).The practical training aims at applying subject matters which were imparted in the lecture in a realistic scenario. During the semester the teams will experience the entire life cycle of Software-Engineering. Problems given in the past were amongst others simulating an elevator control for a high-rise or the simulation of a car-production-plant.

The Passenger Concept

The organization of the Software Engineering lab is supposed to be extended by aspects of distributed teams in the future. This scenario has long become reality in the Software-Engineering industry and is well-known in the literature (Nakatani, Nishida and Takeda, in Salvendy, Smith, 1991). Following this scenario, the Passenger-Concept defines four modules for the conduction of the Software-Engineering course. In this paper we will focus on the development of the Passenger Case & Video Tool. A description of the other modules can be found in (Hunger and Werner, in Gil-Mendieta, Hamza, 1998).

The implementation of the concept requires efficient CSCL-tools to transfer the knowledge of the lecture and to conduct the practical training in a distributed manner. A condition for conducting the practical training is the availability of tools for a synchronous communication and for common document processing. Altogether the following modules have to be realized:

1. Synchronous communication tools for text, audio and video.
2. A session handling to control the synchronous sessions.
3. Protocol stacks to meet the required network services.
4. A Software-Engineering-Case-Tool for common document processing.
5. A control system to handle different kinds of permissions.
6. A version control system for the common documents.

Commercial available videoconference tools do not offer all of the above mentioned functions. Therefore those tools can not be considered for the conduction of the practical training.

The scenario of distributed Software-Engineering places additional demands on the students. Apart from learning the actual contents and how to work in a team, the following three aspects will lead to a steeper learning curve.

1) The students are not used to applying Software-Engineering Case-Tools (Boloix, G. & Robillard, P.N., in IEEE, 1998).
2) For the students, discussing by the means of video conferencing represents a completely new form of communication (Hunger & Werner, in Verbraeck, Al-Akaidi, 1998).
3) Common document processing over a network is new to the students.

The Passenger Case & Video concept sees windows based systems as its target platform and the global internet as its transport medium. For the clients a multimedia data interface represents the interface to the input and output peripherals like keyboard, mouse, video camera, speaker and monitor. A Case-Tool is used for common software development. During the conceptional considerations of the Passenger-System-Architecture, different possibilities for the data transfer were discussed. As a result of the discussion several methods of data transfer have been implemented: several unicast-connections for client/server-communications and several multicast-connections for interclient-communications.

The requirements which individual connections place upon a service are: Client/Server connections require reliable services, inter-client connections on the other hand only require unreliable services, but a guaranteed bandwidth and delay. In order to achieve these guaranteed quality-of-service we make use of resource reservation. In a first step a protocol stack based on the Internet Protocol Version 6 (Deering & Hinden, 1998) for the realisation of multicast connections in the Internet, associated with the Resource ReSerVation Protocol (RSVP) (Braden, Zhang, Berson, Herzog, Jamin, 1997) for quality-of-service support is developed. Measures to increase performance arise in this first step by strictly splitting the connection types in reliable and unreliable services and implement them in several parallel protocol stacks. Measures like adapting certain protocols should be considered later.

Summary and Outlook

This paper presented a new concept concerning the University-Education on the subject Software-Engineering. Based on this concept new tools were developed and implemented. The essential innovations of the presented idea in comparison with known concepts are in this case the integration of different tools under a common user interface, the way in which face-to-face discussions are taken into account, the development and integration of case tools especially for the usage in a practical training and the assembly of parallel protocol stacks with usage of given protocol structures.

The first version of the communication tools is expected during the summer of 1999. Concerning the practical training of Software-Engineering, the tools are supposed to be put into practice during the summer-semester 2000

Discovering Science: a Distance-Learning Course with Integrated Interactive Multimedia

Stuart Freake
Faculty of Science
The Open University
United Kingdom
s.m.freake@open.ac.uk

Introduction

Discovering Science is a new introductory science course from the Open University (OU) that makes extensive use of interactive multimedia activities on CD-ROM (The Open University 1998). It was first presented in 1998 to over 3000 students in the UK and Western Europe, and is the first OU science course that requires students to have access to a computer in their homes. 25 CD-ROM activities were produced, requiring about 40 hours of study time, making this the largest single educational multimedia project in the world. This paper outlines the scope of these materials, how they are integrated with the course, and some issues arising from their production and presentation.

The CD-ROM Materials

The role of the CD-ROM activities is to teach science, and the range of topics reflects the scope of the course, which covers aspects of biology, chemistry, Earth science, physics and astronomy. Activities include:

- an interactive computer model of the Earth's atmosphere that allows students to modify factors such as the carbon dioxide level or the cloud cover and to investigate the effects of these changes on the global temperature;
- a virtual field trip to the Galapagos Islands, following in the footsteps of Charles Darwin, to investigate adaptation, speciation and evolution; and a virtual trip in a submersible to explore the Mid Atlantic Ridge;
- use of molecular viewer software to visualize the 3D structure of molecules, ranging from the simple methane molecule to complex proteins;
- interactive maps and models that are used to investigate past and future motion of the Earth's tectonic plates;
- a virtual telescope, used to determine the distances and speeds of galaxies, and hence the age of the Universe.

All of these CD-ROM materials are highly interactive and they make use of the ability of a multimedia computer to present a mix of video, audio, computer simulation, graphics, text, questions, etc. They are integrated with the other distance-learning components of the course, which include 11 books (1300 pages), a loose-leaf study file (500 pages), five hours of video material, ten half hour TV programmes transmitted by the BBC, a small home practical kit, and a one-week residential school.

Production of the CD-ROM Materials

This was the first major venture into production of interactive multimedia CD-ROMs for teaching by the Open University. Many lessons were learnt, and a few of these are outlined here.

- There were long discussions about whether to use an existing interface/shell/navigation system, or whether to develop a system of our own for use with all packages. We eventually decided that both of these routes would restrict the scope and variety of the materials that we wanted to produce. Broad guidelines for the interfaces were drawn up, but these guidelines were interpreted quite flexibly, so the different activities have very different looks and feels.
- With 25 CD-ROM activities (plus CAL software for developing mathematics skills, and interactive self-assessment questions covering the whole of the course), it was essential to devise a simple way for students to access the computer-based material. We developed so-called CD-ROM Guides that students installed on their hard drive, and these not only made it very straightforward to access each of the activities but also helped to integrate the different CD-ROM activities with the rest of the course.
- Production of alpha versions of some CD-ROM activities used most of the time and resources that had been allocated for completing the activities, leaving limited scope to make changes following developmental testing. In future projects we will ensure that 30% of the time and resource are held back for revisions following testing of the alpha version of the software.

• OU students' computers have a wide range of hardware specifications, they are configured in a variety of ways, and they are running many different software applications. We had to find a compromise between producing state-of-the-art multimedia software, which would only run successfully on high-specification machines, and producing software that would run on low-specification machines but which would look and feel rather dated. The software went through thorough QA testing on a range of machines, but even so a small proportion of the thousands of students who used it experienced problems. Our telephone helpdesk sorted out many of these problems, though some required changes to CD-ROMs that could only be made for the second year of the course.

Studying CD-ROM Material

Surveys of students and tutors highlighted a number of issues relating to use of the CD-ROM materials.

- Most students enjoyed studying the CD-ROM material, and found it interesting and motivating.
- Studying CD-ROM material is very different from studying text, watching a video or listening to a lecture, and many students found it more difficult to learn from the CD-ROM material. Students have little experience of learning from CD-ROM, and they need advice about note taking and time management in particular.
- Students like to be able to browse freely through a CD-ROM activity, to dip into it at any point, and to move backwards through an activity as well as forwards, just as they can with a book. Some of our CD-ROM activities constrained students' freedom of navigation, and were criticized by students and tutors for this reason.
- The ability to specify where you are in a CD-ROM activity is extremely useful, particularly when you are remote from a person with whom you want to discuss the activity, e.g. your course tutor. Page/screen numbers are far more convenient than specifying 'the third screen after the second question in part three'.
- We integrated the CD-ROM material with the other components of the course, so that students wouldn't perceive it as an optional extra. However, some topics were only covered in CD-ROM activities, and it was then necessary to emphasize the importance and relevance of these activities. Assignment questions and exam questions were an effective way of doing this.

Ongoing Evaluation

Student surveys in 1998 concentrated on identifying any problems that students had with using the CD-ROM material, but further evaluation is now underway. One survey is investigating how students study CD-ROM material and how their study methods correlate with their learning style, as determined by responses to an 'Approaches to Study Inventory'. It is clear from data obtained in the first year that a small proportion of students dislike using this medium and had difficulty learning effectively with it. Information from this survey should help us produce advice for distance-learning students about developing appropriate learning strategies.

A second survey is investigating cognitive gain from these CD-ROM activities, and the dependence of this on the level of interactivity in the activities. Our assumption is that interactivity promotes effective learning, and we will test this hypothesis in this study, and compare cognitive gains from different types of interactivity.

Conclusion

The CD-ROM activities produced for *Discovering Science* demonstrated some of the benefits of incorporating interactive multimedia activities in introductory science courses. The lessons learnt during production and presentation of this course will feed through into the production of CD-ROM material that the Open University is now producing for its future science courses.

INTRODUCTION

With the rapid evolution of Internet technologies, and the advent of WEB TV and hybrid cable/modem systems that promise ever-increasing data throughput, Virtual Reality Modeling Language (VRML), is rapidly approaching viability as a medium for educational program delivery and interactive learning. As the industry furthers its resolve on standards for VRML, a few stepwise approaches to VR for exploring virtual learning environments are being embraced and utilized by creative netizens. Apple computer's QuickTime VR "virtual panorama and virtual objects" technology is an intriguing step in the right direction, and offers VR learning on the halfshell, sort of. There are hundreds of websites employing QTVR already; from Apple's Store, to The Wrinkle in Time Project's "day in the life" global simultaneous QTVR galley, to numerous online catalogs portraying virtual (rotate-able) sale items, etc.... But what are the uses for this VR steppingstone technology for education? Or for that matter, what educational use VR in general?

VIRTUAL REALITY MODELING LANGUAGE: *ROOTS*

Virtual Reality Modeling Language (VRML, commonly called "vermel") is an evolving Internet and web-based scene description language. Since its inception in 1994, VRML has been an open standard. In August of 1996 the VRML Consortium Working Group (CWG) was formed following a meeting at the AMC SIGGRAPH annual convention, and in 1997 the Consortiums' efforts to continue honing VRML, increasing its capabilities and streamlining protocols resulted in the present incarnation specification VRML '97. <http://www.vrml.org/>

Like its hypertext sibling, (HTML), VRML comprises a scripting strategy for describing the layout or arrangement of objects in a virtual environment; scene descriptors which in most cases are formulas for geometric solids, lines and planes, and scene metadata, as well as applied surface textures. Unlike HTML pages VRML documents describe a virtual space or three dimensional (3D) environment in which objects are located and around and through which the user can navigate by pointing and clicking, dragging and rotating or engaging controls on a navigation bar. In other words, VRML instructs a user's computer in how to arrange a file's contents in the web browser window, but that window is *really a window* or portal into a 3D space not just a flat surface on which text and graphics are situated. VRML works because relatively simple geometric shapes can often approximate fairly complex objects with textures mapped onto their surfaces, like wallpapering a simple box to simulate a fully decorated room. Once the size and shape of basic objects along with simple texture maps is downloaded, the browser builds those objects in 3D space locally. Moving around in the virtual space is then just a matter of the local computer reshaping and changing the relative positioning of objects to match changing perspectives of the viewer. All or most of the data is already passed off to the local machine for rendering, so individual scenes can hold many possible perspectives, and new information is retrieved only when needed to render as yet unseen areas of the 3D environment, or ever closer detail in an object.

The computer script and code of VRML is still evolving and as with HTML, SHTML DHTML, and XML, enhancements and additions to the standard are being proposed continuously. The first efforts to standardize a description of VR environments for the web took place at an adhoc meeting in the spring of '94 at the first International WWW Conference in Geneva, Switzerland. Shortly thereafter a www-VRML mailing list was opened and a draft version of the specification for VRML was collectively and collaboratively produced for the Fall 1994 WWW Conference (Pesce, 1994). Over a thousand individuals, researchers, technicians and users remain on this and other related www-VRML mailing lists.

VRML's roots are deeply entwined in the 3D design and architecture world, and the emergent "modeling language" may be described as only a recent means of streamlining scene layout descriptions for distributing those worlds on a network. The roots of "Virtual Reality" can be traced to the spatial design and rendering work of Ivan Sutherland and others in the late '60s (Sutherland, 1965). Numerous issues of the Association for Computing Machinery's Special Interest Group on Graphics (ACM SIGGRAPH) have been devoted to VR and visualization. Conn, Lanier, and others (1989) describe the future of virtual environments and interactivity on the Internet as an exciting and powerful opportunity for communication, collaboration and participation that will play a significant part of our future.

A perpetual challenge for VR and VRML is in the rendering and display of increasingly detailed and rich environments. Scene detail is highly dependent upon the computer's ability to quickly describe geometric primitives (or polygons), and arrange, highlight and render them with enough speed to permit successive adjustments and differing perspectives of the described world every few fractions of a second. As complexity in a scene builds, e.g. landscape details, increasing numbers of objects in view, and degrees of transparency and reflectivity, rendering times of individual scenes often cause even the fastest of PCs to grind to a halt. Effective VRML scene navigation depends on available RAM, VRAM and clockspeed of the viewing computer and the speed and bandwidth of the connection through which scene parameters and object descriptions are transmitted. Addressing this limitation, ongoing negotiations among Cable TV signal carriers and Internet providers, and a new incarnation of WEB TV devices and hybrid cable/modems may soon make a variety of virtual experiences more widely available than otherwise possible (solving part of the bandwidth and throughput problem).

VRML FOR EDUCATION

Aside from simulated military missions and video games (a common and very well institutionalized use of virtual reality technologies), VR "worlds", broadcast over the Internet have many potential uses in instructional and educational settings. VR is showing outstanding promise for teaching, demonstrating and learning in the medical profession, in the engineering and structural design fields, as well as in projects where "being there" is all but impossible.

VRML in education will likely find utility as a means of exploring complex mathematical "terraines", giving unique views of very small, very large or otherwise inaccessible spaces such as navigating along a DNA helix, probing inside an ant's brain, a human heart, and/or at the other extreme, exploring virtual astronomical spaces like solar systems and galaxies. Other unique roles VRML can play in enhancing education at first may seem trivial. Some educators are beginning to explore its use in the classroom in the form of MOOS or MUDs (Multi User Dimensions) or virtual chatrooms. Finally, the exploration and "mapping" of real terraines and physical places, is a possible use of VRML that in conjunction with "chat" or narrative exchanges, and as an adjunct to shared web-portfolios (especially where QTVR panorama and objects are linked) may really open doors to learning as topics can be put into local community context and differing strategies for dealing with common issues can be shared among reporting students. In describing and sharing each unique community's sense of place or "view-from-here", including student-made local detailed maps, GIS data layers, imagery, QTVR and narratives, students and teachers can create a very dynamic and engaging virtual collaborative.

Design of a Distance System for Professional ESL Teachers' Support

Peter I. Serdiukov
Department of Educational Studies
School of Education
University of Utah
United States
Serdiu_p@gse.utah.edu

A teacher of English in Ukraine, as well as in any other non-English language country, is constantly facing a number of problems that are associated with his/her professional competency support. Taking into account the complexity of this competency which embraces pedagogical, linguistic, sociolinguistic, and communicative subcompetencies, we realize the enormity of the task of upgrading or, at least, supporting the knowledge and skills that the teacher needs to possess in order to be efficient in the teaching process at school.

In order to develop a system that could provide life-long professional support for the teachers of English as a Second Language (ESL), we need to define these problems. The most urgent among them are:
- Limited opportunities to practice live English and develop communicative competency in the target language in the non-English-speaking country;
- Insufficient inventory of up-to-date, authentic, effective teaching materials and aids for the teachers (textbooks, readers, audio tapes, video tapes, computer courseware);
- Almost total lack of qualified methodological assistance in tackling everyday classroom issues.

To a larger extent these questions concern teachers of remote urban and, especially, rural schools.

Our task was to design and develop a specific support system that could offer all the necessary means for an ESL school teacher to upgrade his/her professional competency without abandoning the teaching process and investing unrealistic time and funds.

Analysis of specific requirements of the ESL teacher regarding support of his/her professional competency reveals that the teacher needs a complex program allowing him/her to systematically upgrade his/her vocabulary and grammar, reading, writing and communication skills; to communicate in English with his supervisor, co-learners, colleagues, native speakers of English; to obtain different learning materials (texts, audio, video and computer courses); to use informational resources like reference books, dictionaries, encyclopedias, journals etc. The teacher also has to have access to a bank of the teaching materials he/she can use in the class activities, to the existing methodologies on how to teach specific subjects and topics, and to the expert who can offer qualified assistance or advice. This system must also meet the following criteria: affordability, accessibility and openness, professional orientation and functionality, continuity, flexibility and self-sufficiency, availability of feedback and of the communication mode.

It is evident that we need to build a non-traditional, powerful informational and learning system based on contemporary pedagogical theories and advanced computer and telecommunication technologies. This system has to be available for any teacher at any school to link to for obtaining the necessary support in any form. Such a system is being currently developed as a Ukrainian national distance system for ESL school teachers' professional competency support .

The system includes the following components:
1. Multilevel subsystem of language training and competency development;
2. A complex of English courses and other learning materials;

3. Reference subsystem with dictionaries, grammar, cultural and other data bases;
4. Methodological support subsystem;
5. Internet facilities for group collaboration and communication.

The system is actually an informational and learning environment that offers the ESL teacher all the materials, means and help he/she needs for successful professional teaching activity in the class. The basic English course that is one of its main components is closely coordinated with the current Program in Foreign Languages for Ukrainian Schools and includes the following topics:

1) Education (system of education, education in Great Britain and USA, high school);
2) Curriculum (school subjects, lesson, English as an tool of international communication);
3) People (I, my family, friends);
4) Life (my work day, studies, free time, vacations);
5) Work (plans for the future, professions);
6) Country and city (basic facts about Great Britain and the USA, London and Washington, DC, Ukraine, Kiev, my home town);
7) World (the planet, geography, environment);
8) Arts;
9) Literature of the English-speaking countries;
10) Sports.

The course is composed in such a way as to offer the user maximum learning materials and activities together with the efficiency and comfort of navigation and use. Modular structure is the main organizational principle of the course according to which it is divided into separate but interconnected modules. Each module is self-sufficient: it comprises all the necessary texts, exercises, tests, additional materials, vocabulary and reference materials, recommendations for the student teacher how to study and for the practicing teacher how to use it in the class. The materials assembled in the module are supplied with such essential characteristics as the topic, summary, level of training, volume (the number of texts and exercises in the module, the number of words in the text, the number of questions in the test, etc.).

Three types of activities are recommended in the system: informational, training and communication. Informational activities are focused on the search, processing and purposeful use of the desired information. Training offers various cognitive activities - individual and group solution of linguistic and pedagogical problems, writing and editing essays and projects, creating and distributing learning materials, submitting entries for the on-line dialogue journal, and working with the computer courses and other materials. Communication activities include exchanging information, writing letters, participating in the on-line dialogues, group discussions, interest group activities and conferences, and peer consultations. Some of the activities are to be done independently, many are to be implemented in collaboration with other members of the group, a few require tutor participation or guidance and supervision. All these activities are aimed at the collective construction of a particular knowledge and development of a common ESL teacher's professional competency in a specific distant informational, learning and social format.

The system for professional competency support of ESL school teachers described in this paper is currently in its development phase. It is supported by the Ministry of Education of Ukraine, the British Council, Institute of Cybernetics of the Ukrainian Academy of Sciences and Kiev State Linguistic University. While working on the project we provide training in Educational Technology for teachers, and conduct research in the course development and methodology of Distance Learning.

Asynchronous Learning Environment for Integrating Technical Communication into Engineering Courses

Patricia A. Carlson
Humanities and Social Sciences
Rose-Hulman Institute of Technology
Terre Haute, Indiana 47803
Patricia.Carlson@Rose-Hulman.edu

Frederick C. Berry
Department of Electrical & Computer Engineering
Rose-Hulman Institute of Technology
Frederick.Berry@Rose-Hulman.edu

This work-in-progress describes a collaborative effort between two faculty members at Rose-Hulman Institute of Technology to build a web-supported integration of technical communication into a sophomore-level course in engineering practices. The collaboration was begun in the summer of 1998. While the integrated delivery environment is still in its formative stages, we believe this presentation is appropriate for ED-MEDIA because it covers two timely issues for engineering education: (1) the efficacy of asynchronous modules for course delivery, and (2) the meaningful integration of technical communication at early levels in the engineering curriculum.

EC 260 -- "Engineering Practice" -- is a two-credit experience designed to prepare Electrical Engineering students both for the senior design sequence and for the world of work. Course goals include:

1. To begin the integration of knowledge through the solution of an industry-sponsored engineering problem.

2. To improve oral and written communication skills.

3. To gain experience in working as a team.

4. To become proficient in using both traditional and information-age resources, enacting a need-to-learn approach.

During the Fall Quarter of 1998, portions of the course were delivered via a web-site, containing assignments, course maintenance materials, resource and supplemental documents, as well as such facilitating features as a chatroom, electronic file transfer, and the potential for online commentary on student-submitted work.

Much of the student's success in this course is highly dependent upon abilities to use sophisticated communication skills. However, at this point in the students' education, most will not have taken a course in Technical Communication (which is offered as a junior-level course at Rose-Hulman). Thus, having access to basic instruction in the oral and written forms of communication required in the course is vitally important.

A series of five web-delivered modules were constructed -- each having interactive/transactional capabilities -- so that students can have on-demand instruction in the verbal aspects of the course. The five modules are listed below. Each highlights a set of "information processing skills" (represented on the left), as instantiated in a specific communication form (represented below on the right).

1. Document Design / Formal Program Report

2. Interpreting and Presenting Data / Feasibility Study

3. Integrating Text and Graphics / Technical Description

4. Audience Analysis and Persuasion / The Proposal

5. Information & Audience Engagement / The Oral Report

While our assessment of the Fall Quarter experience is currently (4/1499) in progress, we believe that the basic premises of the cross-disciplinary collaboration were satisfied and that the web-based learning environment meet the following objectives:

- *Enhanced active learning* -- students had an active role in problem-solving and in discovery learning. Scaffolding and interactive feedback helped students to adjust and consolidate gains in learning.

- *Provided opportunities for collaboration* -- opportunities to share information artifacts and to enhance abilities to work/communicate with peers by providing commentary and accepting constructive criticism.

- *Accommodated transfer of learning* -- course skills and concepts generalized in that the pedagogy encouraged the learner to make connections and extrapolations.

Acknowledgements

Development of this course was funded by a grant from the Foundation Coalition (sponsored by the National Science Foundation). The authors express their gratitude for this support.

ATM-Based Distance Education in Germany

Freimut Bodendorf
Department of Information Systems, University of Erlangen-Nuremberg, Germany
bodendorf@wiso.uni-erlangen.de

Introduction

Broadband communication systems and enhanced tools for transmission of video/audio and multimedia data pave the way for new concepts of distance teaching and learning. Especially ATM-based networks allow online teleteaching applications of high quality. In various countries there are strong efforts to establish a broadband communication infrastructure for education and research, e. g. the Internet-2 project in the United States. In Germany the Federal Department of Education, Science, Research and Technology initiated the construction of the so-called B-WIN (Broadband Scientific Network) which started working in 1996 with the secretary of education and research cutting the virtual red ribbon at the CeBit fair in Hannover. Adequate teleteaching environments have been implemented at several universities. Preliminary evaluation results show that students as well as teachers accept the technical add-ons and take profit from the added-values of ' virtual lectures'.

Broadband Scientific Network in Germany

The German Scientific Network is based on ATM technology and connects nearly all of the 70 universities of unified Germany as well as several research institutions (Fig. 1). The ATM backbone operates at 155 to 622 Mbit/s. Universities are hooked up by at least 34 Mbit/s. Actually a Gigabit testbed (2.4 Gbit/s) is being run between Berlin, Nuremberg and Munich. By the year 2000 a nationwide Gigabit communication platform for universities and other institutions concerned with education and research shall be at hand. There are also links to the public ISDN network used as a ramp to that information highway, for instance by high schools. The German Scientific Network is linked to the European ATM backbone called TEN34 (Trans European Network, 34 Mbit/s) as well as to networks in other continents like North America, Asia or Australia.

Experiences

Due to high installation costs for teleteaching lecture theatres and multimedia teacher terminals there are few universities in Germany offering complete 'virtual courses' at the moment. At the University of Erlangen-Nuremberg pilot applications have been run since 1995. Now, teleteaching is in routine operation. First experiences made at the University of Erlangen-Nuremberg are similar to those of projects dealing with distance learning in virtual classrooms. Powerful and stable audio and video tools are crucial to realise an online teleteaching environment which is accepted by teachers and students. After this being achieved first empirical studies have been completed. Different groups of students involved in the teleteaching applications as well as teachers have been observed and questioned.
Here some characteristics:
Remote students: The major advantage they expressed is increased flexibility in place. Especially this means saved travel time which goes together with saved money for public and private transportation. A secondary positive effect for the students is the opportunity to get in touch with innovative computer-based communication and cooperation systems.
Local Students: They don't feel affected by the virtual presence of remote students. Neither positive nor negative influences could be observed. As a side effect digitized lecture recordings, stored on a video server, are highly appreciated for the preparation of exams or simply to refresh knowledge.
Teachers: On the one hand the handling of the technical equipment and the coordination of multiple audiences is demanding, on the other hand a positive aspect is the higher mutual incentive for local and remote participants. The zeal for learning is believed to be better than in conventional lectures.

The on-going evaluation process is accordingly divided into the phases design (definition of goals and objectives), development (analysis of effectiveness and quality), and operation (analysis of costs and benefits). Table 1 shows some selected results coming from an enquiry to characterise the students' basic attitudes towards the teleteaching project. A 1-to-7 scale was used (1 = very bad, 7 = excellent, M = mean, D = standard deviation).

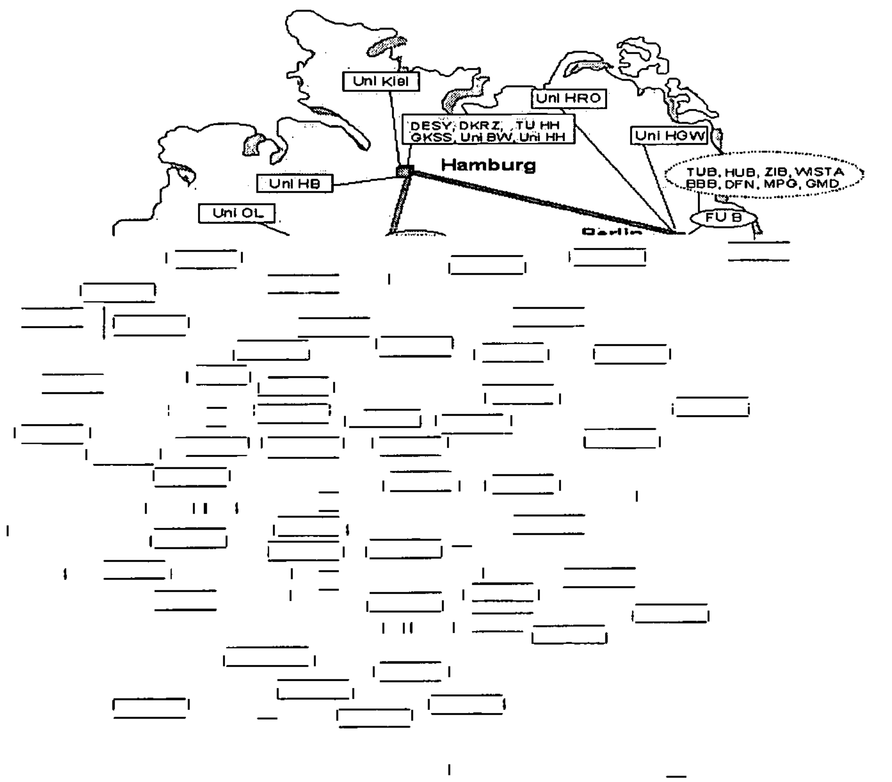

Figure 1: German Scientific Network Architecture

Question #	Aspect	Rating (M)	Dev. (D)
3	overall impression of the teleteaching project	6.21	1.30
5a	improvement of flexibility in place	6.73	0.43
5b	savings of travel / commuting expenses	6.51	0.55
6a	ease of use of the communication and software tools	3.23	1.92
6b	contact with the remote teacher, trainer, or tutor	3.11	1.00
6c	contact with other remote students	3.57	1.51
16	demand for remote access from home	5.00	3.53
19a	learning efficiency compared to conventional courses	4.33	0.47
19b	opportunity and realisation of interaction	4.07	1.04

Table 1: Statistics of Selected Students' Comments

subgroup of children with a home computer, 20.1 % never of rarely used a computer, 15.3 % used the computer about once a month, 37.9 % on a weekly basis, and 26.6 % daily. The older the respondent, the higher the frequency of daily use ($X^2 = 13.9$, $p < .05$).
Chi^2 testing revealed significant differences between gender and computer presence at home ($X^2 = 14.1$, $p < .001$). Of the males, 85.0 % had a home computer, as compared to only 76.9 % of the females. Although more boys owned a home computer in all age groups, the gender gap was only statistically significant for 12-, 16- and 17-year olds. So the assumption that gender disparities are increasing with age could not be confirmed. Overall, girls had significantly less computer experience (29.3 months) than boys (37.1 months) ($F = 23.2$, $p < .001$). When controlled for computer presence at home, this association remained significant ($F = 10.8$, $p < .01$). In addition, males (32.2 %) were found to make more use of a computer on a daily basis than girls (12.0 %) ($X^2 = 78.8$, $p < .001$).
Results indicate that gender disparities depend on the nature of tasks being performed with computers. The use of computers for leisure activities is clearly reported as being a masculine activity. Significantly more boys (73.7 %) reported to use a computer for leisure activities than girls (58.6 %). This gap remained significant when children without a home computer were excluded from the sample: 86.3 % of the boys versus 75.5 % of the girls ($X^2 = 20.2$, $p < .001$). The situation appears to be different when considering computer use for school activities. Similar proportions of girls (58.5 %) and boys (58.1 %) use a computer at home for school activities, but if respondents without home computer were not taken into account, significantly more girls (75.3 %) reported to use computers than boys (67.9 %) ($X^2 = 7.17$, $p < .01$).
The presence of a home computer was significantly lower among children of non-Belgian origin: 73.9 % versus 82.5 % ($X^2 = 8.0$, $p < .01$). The association was only apparent for the oldest among the respondents (17 years or older).
Overall, Belgian respondents reported to have six months longer experience with computers ($F = 6.8$, $p < .01$). However, when the effect of computer ownership was imported as a covariate in the test, no significance was found between the two groups ($F = 1.4$, $p = .23$). Moreover, no differences between groups could be demonstrated for frequency of computer use variable. Respondents of Belgian origin did not report to use the computer more often on a daily basis than non-Belgian respondents. This finding is confirmed for both males and females. Comparing Belgian and non-Belgian respondents, in general Belgian students accounted for a wider use of computers: 8 % more made use of a computer for school activities ($X^2 = 8.8$, $p < .05$) and 12 % more for leisure activities ($X^2 = 12.3$, $p < .01$). The presence of a computer at home seemed responsible for the difference in use for school tasks. In other words, if respondents without a home computer were removed from the sample, no significance was found. This finding could not be confirmed for leisure use: non-Belgian respondents made significantly less computer use for free time activities, even when controlled for computer presence at home ($X^2 = 4.1$, $p < .05$).

Discussion and conclusion

The present findings confirm other studies which clearly have demonstrated gender differences in computing. Besides, this study suggests the existence of cultural differences in computing. Although there are many social and psychological factors responsible for gender and cultural inequalities, the absence of a home computer seems to accentuate the differences between groups.

Evaluation of IT Course Material in the Context of an Acoustic Design Project

Pieter Vandaele, Dick Botteldooren, INTEC, Ghent University, Belgium
Els Van Zele, Josephina Lenaerts, Center for research in physics education, Ghent University, Belgium
Raoul Meuldermans, KaHo Sint Lieven, Belgium
Marc Van Overmeire, WERK, Vrije Universiteit Brussel, Belgium
Gerrit Vermeir, Laboratory for Building Physics, K.U.Leuven, Belgium

Abstract: To evaluate the use of newly developed IT course material in the domain of acoustics, (http://educinno.rug.ac.be/wetenschapsmuseum), the students had to perform an open design project. The way engineering students at Ghent University tackled the problem and used the available tools to do so, is evaluated through their results and their opinion expressed in a survey. At the same time, their global ideas about the usefulness of information technology in education are explored.

Introduction

To evaluate the learning environments from the project "Distributed Development of a Virtual Science Museum with Guide Applied to education in Acoustics" [1] and test their effectiveness in improving students' insight in complex formulas and concepts, a suitable student project had to be built. A design project seemed the ideal option considering the numerous alternatives and various possible ways to achieve an acceptable result and the different learning paths and styles to be used. The specifications of the project corresponded to what an engineer can expect in real life situations. Students were instructed to design Helmholtz resonator: basic acoustics were known in advance, but the students had to explore more specific information on the Helmholtz resonator themselves. The IT project provided them with learning objects containing illustration of concepts, mathematics, models, model limitation, simulation tools, etc.

To solve the problem the students could follow five different problem solving paths. The path of ...

1. the rote experimenter: look briefly at the general operation principle and use the virtual experiment to accidentally come up with a reasonably good solution.
2. more intelligent trial and error: derive a mathematical relation between a few design parameters from the general operation principle and investigate only valuable combinations experimentally.
3. a meaningful experimenter: start with some trial and error, realize there must be a reason why some parameters do not seem to have any influence, turn to the theory to find out if there is a theoretical background for this and eventually return to experiments to determine the last degree of freedom.
4. a theorist (pure mathematics): combine the available mathematics to come to a result possibly using some numerical solvers.
5. an expert: use the formula to relate some parameters, investigate more detailed theory to find some physical and technical restrictions, solve the last degree of freedom using mathematics and their own software or the applet, finally turning to the derivation to find out if their design is well within the limits of applicability of the theory.

Survey and exam results

The students reported their ideas about the importance of the several factors for solving the problem: the virtual experiment, derivation of equations, limits of the theory, other Internet pages, communication with peers, literature, and their perception of the insight they gained in some acoustic concepts. Despite a small statistical population of 27 students, some interesting conclusions can be drawn:

- Part of the goal of the design project was to urge students to learn the theoretical background by exploration of additional resources. About 66% of the students state that they gained insight into the theoretical background. We consider this a reasonable success.

- Students focussing on experiments affirmed they gained insight in the problem at hand but they did not learn about the theoretical background. They probably followed paths 1 or 2 mentioned above.
- The more students perceive the equations and underlying derivations as important (solution paths 3, 4 and 5), the more they get the impression they understand related theoretical topics. However the correlation with their impression of understanding how a Helmholtz resonator really works gets lower and even becomes negative, although this tendency is not reflected in the students' exam result of questions related to the topic. Perhaps students only realize the complexity of the matter when they study the topic thoroughly.
- There is a negative correlation between the student's global result and his perception of insight gained. This can mean several things: the material is not good enough and better students are left somewhat unsatisfied, or better students do not easily state understand something completely, or the students who perform well in the current educational system are not inclined to put much effort in an alternative project. One thing is sure: it is a question of perception since there is no negative correlation with their examination score on the question related to the subject.

This project forced students into using IT. After this (for some students 'first') IT-experience for educational purposes some general questions about the appreciation of IT were asked. The following trends reflect their ideas:

- there is a strong negative correlation between the wish to get more interactive multimedia material (as was presented to them) and the student's performance in the current system.
- the students almost unanimously approve the usefulness of self-assessment tools to evaluate the level of understanding they have reached.
- applets allowing students to explore the influence of parameters in a mathematical theory are highly appreciated, as are additional self-assessment tools.
- the possibilities of hypertext to hide unessential information or to cross-link different topics is not estimated very high by the average Flemish engineering student.

Conclusions

In general students appreciate the collaboration and the exploration type of approach of a design problem on a subject they had no prior knowledge of. The exploration stopped at an earlier stage than hoped for. This could be due to the way the problem and the tools were presented, but "the study culture" of Flemish engineering students probably explains a lot. It is not a habit of these students to consult literature, search the web, etc. When using IT in education one has to be considering the study culture of the students, which is hard to change.

There was an unexpected negative correlation between the general performance of students in the traditional educational model and their appreciation of the project and IT in education in general. Since one of the initial goals of this project was to make sure "better" students had the opportunity to learn more than in the traditional educational approach, some tuning seems appropriate, in order not to loose those students.

As we expected, there is some fear of loosing track and of doing things that are not really essential in order to be able to pass the exam. In the first semester of 1999-2000 we try to respond to this by structuring the software agent we called "the guide" in such a way that a clear path through the material is outlined and that the structure becomes more evident. Hyperlinks are applied in a more structured way by the use of icons indicating which type of hyperlink can be expected: example, practical application, additional explanation, more background, etc.

Malaysian Smart School – Vision Vs. Reality

Vijaya Kumaran K.K.Nair
Multimedia University
Cyberjaya, 63000 Selangor, Malaysia
vj@hypermedia.com.my

Abstract: The Smart School Project is one of the flagships of the Multimedia Super Corridor. The Malaysian government has established partnerships with the private sector through the Concept Request for Proposals (CRFP) process. This paper will critically analyze the concept of Smart School in the Malaysian environment and look into the issues relating to implementation of this concept as per the vision of the Ministry of Education Malaysia. The paper will go further to provide empirical proof with regards to the mind set and the response to the Teaching-Learning component of the Smart School Concept, from the view point of in service teachers.

Introduction

In July 1997 the Prime Minister launched the Flagship Application documents to invite proposals for solutions from the private sector within and from outside the country. The Education Ministry based on critical and creative teaching-learning approach planned the Smart School concept. Technology as an enabler became an important component of this flagship. The exercise is to help the Malaysian student community to cope with the Information Age.

The main components in the Malaysian Smart School are:

1. Teaching - Learning Process - here self-accessed and self-directed learning will be encouraged
2. Management and Administration - the school Management and Administration will be technology driven for efficient and effective management of resources and to support the teaching-learning process in 1 above.
3. Human Resources, Skills and Responsibilities - active role play by Parents, Community and the private sector as Stakeholders
4. Processes - review of input and output
5. Technology - to be used as an enabler i.e. as a means to the end and not as an end to the problem
6. Policies - changes in existing policies and regulations over and above new policies and regulations

Objectives

The objectives of the Smart School Project are:

1. To produce a thinking and technology - literate workforce
2. To democratize education
3. To increase participation of stakeholders
4. To provide all-round development of the individual
5. To provide opportunities to enhance individual strengths and abilities

Implementation

The Ministry of Education has planned for a three-year Smart School Pilot Project through the CRFP process. Ninety (90) pilot schools have been picked for the pilot stage which will involve three levels of technology, i.e. level A, B+, and B.

Level	Total Number of Computers	Description
A	Primary – 406 Secondary – 479	Schools in this level will be equipped with state –of-the-art technology. Each school will have two computer labs and each classroom and science lab will be equipped with computers.
B+	86	This level is based on classroom model. This model is based on group-based activities and project work. Computers are available whenever needed for information access, writing reports, developing presentations, e-mailing etc.
B	42	The majority of schools will implement technology supported learning by use of a computer lab. Students will use the facility to access information, use software application for various purposes and work on available courseware in the four subjects.

The Government intends to play a role as an architect and driver for the Smart School Project. The Ministry of Education will prepare guidelines and provide the basic amenities to schools according to their individual needs. The Ministry is also actively encouraging schools to become Smart Schools on their own initiative by using their own financial resources and expertise. The Pilot Project period is three (3) years from 28th July 1999 to 22nd July 2002. It is projected that all schools in Malaysia will be Smart Schools by the year 2010.

Reality

The Malaysian government is spending over RM. 300 million for only 90 schools to be wired, of which RM. 183,573,737 for Capital Expenditure and RM. 116,426,263 for Operating Expenditure. As per the time line set, from 13th March – 22nd March 2000, the installation of Release 1 software (Teaching-Learning Materials and the Smart School management System) is to take place.

However on 20th February 2000, The Star (National Daily) reported the Director – General of Education saying that the "smart school" project in 90 schools nationwide will be further delayed because of hitches in the software development for the lessons. He had said that the "slight delay" was due to the fact that it took time to develop the courseware. The pilot project was suppose to take off on Jan 1st 1999, but was delayed for several reasons including lack of funds and courseware. The infrastructure for the implementation is ready in `80 of the 90 schools for the full implementation. The Education Deputy Director General stated that the software for the 4 subjects took time to write, and to evaluate them. He went on to say that it will take about 4 years to fully develop and implement the program.

Among the reasons for the delay were:

- lack of fully developed smart school curriculum
- lessons being rejected several times
- difficulty in contacting evaluators(Ministry of Education)
- lack of communications
- rejection after many rounds of evaluation
- evaluators not exposed to technological limitations

Should the consortium entrusted with the development of the courseware implement software engineering principles in developing the courseware? If the basic software engineering principles had been incorporated, couldn't most of the above reasons for rejection be done away with?

Evaluation throughout the Life Cycle of a Multimedia Tutoring System

Maria Virvou, Victoria Tsiriga
Department of Informatics,
University of Piraeus,
Piraeus 18534, Greece
E-mail: {mvirvou | vtsir}@unipi.gr

Introduction

One of the primary aims of educational software is to be used in real school classrooms. However, a lot of educational software has been criticised that has not been designed to meet the needs of real schools settings. The above criticisms show that there is a need to introduce research results of educational technology into the environment of real classrooms. A solution to this problem may be the involvement of school teachers in the development of an ITS (Virvou & Tsiriga 1999a) and the application of evaluation methods on every stage of the tutoring system's life cycle. In this way we can ensure usability and learning effects.

For the purpose of this research, a multimedia tutoring system was developed. The system is called EasyMath and incorporates intelligence. EasyMath's model of life cycle has been based on Object Unified Process (Kruchten 1999), an object oriented process that suggests multiple iterations of the software development phases. In this way, we have ensured multiple iterations of evaluation of the design and executable releases of EasyMath.

Evaluation of the Design

Evaluation of the design of EasyMath was considered very important in order to ensure that the expertise incorporated in the error diagnosis component would be acceptable by the majority of school teachers. EasyMath's error diagnosis and student modelling have been based on reconstructive approaches which have been used in many ITSs such as (Brown & Burton 1978). These systems reconstruct the problem solving process and generate mal-rules from hypothesized faulty solution paths which are used for the modelling of students' misconceptions or procedural bugs.

At this stage we aimed at evaluating the error diagnosis component in terms of its cognitive principles and completeness. Therefore, ten school teachers were given a computer based questionnaire with questions that had been answered erroneously. The faulty answers were produced using the library of the most common misconceptions that were encoded in EasyMath. The questions covered the whole range of exercises included in EasyMath. The questionnaire consisted of ten questions. In each one of the questions, each teacher had to provide a justification of what s/he thought the underlying misconception was. One problem in this stage of the evaluation process was that many teachers did not provide any explanation and just gave the correct answer to the question.

Evaluation of a Primary Executable Release

In an early stage of the development, a prototype of the tutor was ready to be used by its end users. This prototype was used in order to perform a primary evaluation of the system. In the phase of the primary release evaluation, two school teachers along with ten students were involved. The evaluation methods employed comprised qualitative techniques, such as direct observation and questionnaires.

The main focus of this phase was on the evaluation of the user interface and the several types of the exercises provided by the system. Teachers and students were asked to comment on the working environment of EasyMath. Furthermore, they had to express their opinion about whether the amount of different exercises encoded as well as the form of these exercises were adequate.

The teachers and the students involved in this phase were introduced to EasyMath and were then asked to use it for about an hour. During their interaction with the system, an evaluator was present, trying to note down the difficulties that the users had encountered while performing predefined tasks. After the interaction with EasyMath, both the teacher and the students were given a questionnaire to answer. The questionnaire was designed taking into account a set of "usability heuristics" presented in (Nielsen 1994). The questionnaire included questions such as:

1. Were instructions for use of the system visible or easily retrievable whenever appropriate?
2. Were the symbols and the words used in the different components of EasyMath consistent?

The first question corresponds to the need for recognition rather than recall, while the second question is related to the need for consistency and standards. The comments made during this stage of EasyMath's development were used as the basis for the refinement of the requirements of the system and the construction of the final product.

Formative Evaluation Using a Set of "Learning with Software" Heuristics

The involvement of school teachers in the phase of the evaluation of an ITS was considered crucial. In addition, it is also important to track students' use of resource based packages very closely to uncover the problems and successes. For the above reasons, in the phase of the formative evaluation of EasyMath, 10 school teachers as well as 240 students were involved. Both students and teachers were asked to evaluate EasyMath in terms of the purpose of education. In addition, teachers were asked to evaluate the overall performance of the system and express their opinion about the usability of such an ITS in a real classroom.

In the stage of the students' evaluation of EasyMath, the students were separated in two portions. The first 120 students were introduced to EasyMath and were asked to use it for an hour. Then, they were given a questionnaire to complete. For a more detailed description of the results of the questionnaire, the reader is referred to (Virvou & Tsiriga 1999b). As for the rest 120 students, they were taught half of the syllabus in algebraic powers without the use of EasyMath and they were given a written test. Then they used EasyMath while being taught the rest of the syllabus. In the end they were given another written test and the grades of their first and second test were compared. The results showed that 46% of the students obtained a better grade in the second test, 43% obtained the same grade and only 11% obtained a lower grade in the second test.

The evaluation questionnaires used in this phase were constructed based on a set of "learning with software" heuristics, introduced by (Squires & Preece 1999). These heuristics are an adaptation of "usability heuristics" (Nielsen 1994), so as to relate to socio-constructivist criteria for learning. "Learning with software" heuristics have been suggested by their inventors as a method for performing predictive evaluation. However, we have used them to construct a formative evaluation questionnaire, that would give us insight about the integration of both usability and learning issues.

In the phase of the overall evaluation of EasyMath, the teachers who participated in the evaluation were asked to role play an average student interacting with EasyMath. Next, they were given a questionnaire to fill in. The questionnaire was carefully designed so as to ensure that questions are related to as many of the "learning with software" heuristics as possible.

Conclusions

To produce efficient educational software, there is a need to ensure the correctness of the domain knowledge as well as to evaluate the usability of the product. One way to achieve the above goals may be the application of evaluation methods on every stage of the tutoring system's life cycle. In addition, evaluation should involve both human teachers and students in order to maximise usability in real classroom settings.

Abstract. This work in progress paper reports on whether hybrid CD-ROM technology used to train or supplement the training of mentors of beginning teachers in Vocational Education and Training is an improvement upon traditional face to face and print-based delivery. It argues that the shifting ground in pedagogical models can confuse educational software developers but an understanding of a theoretically driven level of explanation of learning may assist decisions about learning approaches and choice of technology.

Introduction.

Faced with a climate of change, educational institutions are under increasing pressure to explore new ways of learning. Emerging trends in Information and Communication Technologies (ICTs), combined with national governments initiatives to use ICT and widen participation in lifelong learning (in the case of the UK, the influential Dearing, Higginson and Kennedy reports), have created a framework for supporting an increasing community of participants in education and training.

The development and introduction of ICTs into the further and higher education and training sectors has stirred debate about pedagogical performance versus educational efficiency. In training, the debate has focused on issues of *Return on Investment* (Hawkins, et al 1997). Factors of cost and value for money versus amount of learning and quality of learning characterise educational and training evaluations A lack of separation of these factors has created a cloud of confusion, and decisions about allocations of scarce resources are not always made in a manner that maximises the collective benefit of the community.

Many would contend that ICTs are not only cost efficient (Boulet & Sene,1997; Greenwood & Recker, 1996) but they also promote more effective learning (Resnick, 1987; Fjuk & Dirckinck-Holmfield 1999). Others call for more caution to be exercised about such claims. In the UK, the push towards the integration of computer-based education within education and training has been made at the highest levels with funding to match. The premise is that ICT can deliver more effective learning than traditional media.

There is no one single recognised right way of thinking about learning; theories constantly change and tend to reflect the attitudes and technologies of their time. The literature points to shifting ground in pedagogical models.(Reiguluth 1999; Herrington & Standen, 1999). Currently the debate is influenced by ICT.

It is of some concern therefore, that educational software developers have an understanding of a theoretically-driven level of explanation that identifies the kinds of cognitive activities (such as learning, memory tasks and problem-solving) that could take place through the physical activities provided by an interface. To produce successful tools for learning, it is necessary to understand the nature of the learning process and the impact of context within which learning operates.

Background

There is a particular need at the University of Greenwich each year to train up to 250 new and existing workplace mentors who support trainee teachers on the Post Graduate Certificate of Education (PGCE) in Post 16 Vocational Education and Training (VET) during their teaching practice.

The learning demands and needs of these mentors are relatively different to the more conventional learner and it may be argued that the instructional approach is different. Firstly, it concerns the training of trainers. Secondly, there is no set curriculum to follow, or assessments to be made; thirdly, there are no prerequisites other than being a teacher/trainer within the selected institution and lastly, whilst the institution is paid for the efforts of their staff, the mentors personally go largely unrewarded either by time, cash or qualification inducements.

Although some mentors may work within the same organisation, many others do not and generally they work largely independently of one another. Institutions span a large geographical area across London and the South East of England and mentors rarely meet with one another to discuss their role.

There is no substantial proof to suggest that a trained mentor is more effective than an untrained one (Jowett 1998), however, training does enhance an understanding of the stages of a relationship, the mentoring process and it enables critical reflection on professional practice. Conventional mentor training, by virtue of location, time and resources, can only address a small number of aspects of the mentoring process - the tip of the iceberg. Malderez and Bodoczky (1998), take the image of the iceberg further and draw a parallel between the tip, which is out in the air and represents the visible 'good professional' and the main body of the iceberg, which lays unseen and represents all that the professional engages in as an expert in their subject and as a mentor. The submerged part represents the mentor's thinking, planning, and engagement in process, and draws upon their knowledge, understanding, values, feelings and attitudes. The mentor's ability to respond to the student teacher's professional development hinges on their understanding of the role and on their own development as mentors. An analysis of these elements forms the content of the interactive tool.

Project Objectives and Scope.

In its current form, training is administered through a combination of print-based distance material and a single workshop session for *some* mentors at the beginning of the academic year. Our initial research showed that the majority of mentors would be willing to use IT for training purposes, although we identified a number of constraints; some were institutional such as the limitations of the technical specification of equipment provided by colleges (processor speed, CD-ROM drives, soundcards, the ability to play video, etc) and some personal constraints such as knowledge about ICT and confidence in using the computer. The pursuit of a technological solution to provide support and training, independent of time and location was compelling.

In 1998 the *Mentor in cyberspace* project undertook to produce an alternative means of supplementing the existing mentor training and support. Interactive multimedia, it appeared to us, offered the best chance of developing a range of tools and resources to support mentor processes such as thinking, creativity, self-reflection, problem solving and the development of professional attitudes & approaches over time. At the start of the project only a small number of academic institutions which were not universities had organised individual internet access for their staff. We considered the lead-in time for the project to be sufficiently long to utilise the hybrid function of CD-ROM technology with its ability to connect on-line. Furthermore, the University's on-line Campus (OLC) was under construction and the idea of extending the range and type of tools available to mentors was attractive.

Learning approaches.

Selecting instructional methods on the basis of the theories has not easy because little agreement exists between the main protagonists. The constructivists attack instructivist design approaches as formulaic and mechanistic. Defenders of instructivist design have attempted to re-establish its authority at the expense of all other approaches. They take a staunch position against the infringements of, in Merill's words, "these persons who claim that knowledge is founded on collaboration rather than empirical science, or who claim that all truth is relative" (Merill, cited in Wild and Quinn 1998, p 74). In much of the current and recurring debate about the role of learning theory in educational interactive multimedia there appears to be a readiness to assert one theory of learning over another - to present one as being deficient and the other as the only credible explanation of learning.

The important issue is to match the instructional approach to learning need whatever the level, whether this is the efficient dissemination and testing of knowledge, the creation of new personal knowledge or the development of opportunities for networking and collaboration. In a professional context where the goal is to encourage the acquisition of reproductive *and* productive skills and knowledge, a balance must be struck between those methods that appear to work best.

Our approach has been to try to strike a balance between these two ostensibly opposing theories and adapt the technology to suit the perceived learning needs of the mentors. On analysis of the strengths of each learning approach in relation to our purposes, we saw that instead of contradicting and negating each other, these two approaches could be complementary. We perceived that the use of hybrid CD-ROM would combine both learning approaches. CD-ROM is a relatively closed technology, limited by its content and design. Our design here draws upon the strengths of Instructional Systems Design (ISD): its emphasis on presentation, information, structure and reinforcement is useful for the reproduction of knowledge (Boyle 1998) and is suited to interactive multimedia on CD-ROM. Web technology, on the other hand, is characterised by an open, explorative architecture. Accordingly we have used web technology, specifically Computer Mediated Communications (CMC) which supports a more constructivist approach: it is able to provide a set of tools and methods for the mentor to construct new knowledge within ill-structured, authentic, real contexts (Brown,J.S., Collins, A., & Duguid 1989). Hybrid CD-ROM offers the possibility of combining the reproduction of knowledge with the production of 'knowledgeability' (Guile & Young 1998).

This work in progress will report the findings of a pilot study ending in June 2000 with approximately 20 mentors who will have utilised the various tools and approaches during this academic year. The particular focus of the research will examine whether:

- mentors preferred to use the hybrid CD-ROM or the print based material for learning about their role
- one instructional approach or technology was more successful than the other.

I will attempt to draw conclusions about the success of introducing interactive multimedia and whether the use of ICT in this context is an advantage for training and supporting mentors of beginning teachers in VET

Abstract: This paper proposes an open architecture of Visual Lab on WWW and focuses on scientific experiment for the asynchronous mode of distance learning. Visual Lab is a virtual experiment environment by using video-media. A complete scientific experiment in Visual Lab includes four essential stages: phenomenon observation, experiment process observation, data measurement and experiment recording. In Visual Lab, students can carry out experiments remotely with the toolbox designed on Internet. A system architecture built on World-Wide Web demonstrates the feasibility and flexibility of our idea.
Keywords: Distance Learning, visual lab, scientific experiment, World Wide Web.

1. Analysis of Scientific Experiment in Visual Lab

For a full scientific experiment, there are several essential stages: *phenomenon observation, experiment process observation, data measurement* and *experiment recording.* These essential stages are analyzed details in the following.

Phenomenon Observation: With such knowledge, phenomenon observation can be divided into two categories

(a) **Static Observation.**
(b) **Dynamic Observation.**

Experiment Process Observation: It is very important to practice with one's own hands. After experimenting themselves, students can gain much impression.

(a) **Traditional Process Observation.**
(b) **Video Observation.**

Data Measurement: Data measurement is the key to prove a physics theory.

(a) **Equipment Usage in a Traditional Lab.**
(b) **Usage of Simulation Tools.**

Experiment Recording: The formats of experiment records have to be designed.

Problems Analysis of Four Essential Conditions on WWW: The formats of experiment records have to be designed.

(a) **Video Format:**

	Compress	Network Transfer
MPEG	No	No
Real Video	No	Yes

AVI	Optional	No

Table 1: Video formats comparison.

(b) **Component Format:**

	Download	Security	Control Operation	Browser Support
Java Applet	Light	No	Can not access local files	Both IE and Netscape
Real Video	Heavy	No	Can not control	Both IE and Netscape
Window Object embedded in Web page	No	No	Can not control	IE
ActiveX	Heavy	Yes	Full control	IE
Application	Heavy	No	Full control	Both IE and Netscape

Table 2: Comparisons table of web technologies.

(c) **Experiment Record:** Students can record data what they want to measure and send out these data to teacher. Then teachers can gather all the student learning information via the function provided by experiment record.

2. Design the Platform of Visual Lab

In this section, several toolboxes will be discussed. Each measurement and observe components must applied these toolboxes in Visual Lab platform.

Measuring and Observing Tools: For a Visual Lab System, measuring and observing tools are helpful to both students and teachers

(a) **Video Controller:** To play some experiments video.
(b) **Scale:** In order to measure the actual length from the experiment video.
(c) **Ruler:** Students can adjust the length of this ruler tool to can get the length what they adjust when they saw in the video.
(d) **Protractor:** Students can measure the angular magnitude.
(e) **Calculator:** Students can input the data and get the result just like a calculator.
(f) **Timer:** A timer is needed to measure time in scientific experiment.

Components of Visual Lab: Each learning work is implemented by an independent component, and our architecture can be illustrated as (Fig. 1) shown.

3. Implement the Visual Lab on WWW

We designed a platform using open architecture technology. Our purpose is that all of the physics experiments can apply in Visual Lab without any modification. As long as teachers film the experiment and join in Visual Lab, students can experiment in Visual Lab environment and record with Microsoft Excel 2000, as show in (Fig. 2).

4. Conclusion

This paper proposes an open and reusable architecture of Visual Lab on WWW. All of the scientific experiments can apply to Visual Lab based on the architecture of Visual Lab had been accomplished. Learners can learn knowledge by experiment in the Visual Lab even they are not at school. Solution for transferring video stream through network should be the next research direction to enhance Visual Lab.

jsflores@ucla.edu

Abstract. Two groups of teachers, 50 K-12 History teachers from California and 20 K-12 teachers in a Masters program in Massachusetts, participated in an online experience to develop instructional materials which integrate technology into the curriculum. Each groups' level of participation in online communication activities and the method that their instructional design process was developed predicted the quality of the final materials. Recommendations for structuring online collaborative activities for teachers to develop instructional materials are given.

Introduction

This is a comparison of two on-line collaboratives with the same purpose -- to have teachers develop K-12 technology-integrated instructional materials -- but significantly different approaches. The two projects we are using for this comparison are a California statewide professional development project in K-12 History (CH-SSP) and an on-line course in Project Based Learning for a Masters degree program in Educational Technology at Framingham State College in Framingham, Massachusetts.

Key Factor - Participation in Communication Activities

For all participants, developing instructional materials was a process that involved participant to participant, and participant to facilitator/instructor communication using an online space and several forms of electronic communication. There were six different forms -- online chat, face-to-face, online submission of original written material, online response to others written material, participation in the online discussion forums and e-mail. The greater the participation in online activities, the more probable that the lesson plan was completed and the more likely that those lesson plans were of high quality. There were significant differences between the groups in their participation in on-line activities. The professional development group participated significantly less than the online course group. There were two primary reasons for this. Although both groups were required to participate, there was no tangible consequence for not participating for the professional development group. Second, technical resources and technical help were more readily available for the online course participants than the professional development participants.

The greatest disparity between the groups was in the discussion area. The postings for the professional development group were sparse to non-existent. No discussion ever emerged. For the online course, this was unquestionably the most successful communication. The discussions were interesting, in-depth, meaningful and at the Masters level. The major difference between these groups is that the discussion was participant driven for the professional development group and instructor driven for the online course group. We find this to be problematic, as one of the goals of the professional development is to have the participants drive the interaction.

Key Factor - Instructional Design Process

An important component of the CH-SSP project was the development of the instructional design process. CHSSP was interested in having the different grade level groups develop their own process for the development of the lesson plans. In the Project Based Learning course, conversely, the instructor strictly imposed the process and the students were, in part, evaluated on how they used this imposed process. We refer to this difference as a self-generated process (CHSSP) vs. an imposed process (Framingham).

The different process experience led to significant differences in the final product. The self-generated process group spent a great deal of time developing the process. As this was a new experience for them, there was confusion regarding what was being asked of them. This detracted from the application of those processes to the instructional materials development. We still feel strongly that we would like to see the process of materials development arise from the teachers that are using the materials. We feel changes need to be made to focus more on the development of the materials themselves.

Recommendations

We have several recommendations. There were many difficulties with the professional development institute, most of them centered around participants actively engaging in the online communications, and participants understanding facilitator expectations in relationship to the process of instructional materials development. We would prefer, encourage and work towards that process being developed by the participants themselves. However, many of the participants, from both groups, felt the need for more structure and more direction in how to go about developing the materials. We do not know if this was because they were using a new environment and felt unsure about how to proceed, or if they would have difficulty developing instructional materials without an imposed process in any environment. In the future, In the professional development project, some direction needs to be provided for the development process, however, this process should remain fluid for the participants. In the online course, we would recommend that a portion of the beginning of the course be spent with the participants examining their own practices of instructional materials development.

The professional development institute needs to provide a more concrete reason for the participants to actively participate in the online environment. Providing participants with a 'reward' at the end, such as a stipend, University Extension credit towards salary points, or the like may be an important component to motivate participants. Technical support is also essential. It may be best that technical support be pledged from the district as that is frequently the ISP for the teacher. It also provides a district commitment to the project.

In general, online instructional materials development, in a group, collaborative setting, needs a structure to support it which includes facilitator support for the multiple forms of online communication, technical support, and clear guidelines for the participants process. In addition, participants need a tangible motivation for completing the project, such as salary points or a stipend. These online development projects differ from traditional development projects in that they can be conducted asynchronously and between participants who are at a geographic distance. For the future, we hope that the communities that are formed can continue on, develop further materials and expand to provide online support for other teachers in their subject areas or grade levels.

Using a Wrench to Pound in a Screw:
The Misapplication of Communication Technologies in Education

Eric Wignall
Instructional Design & Educational Media Labs
Purdue University Calumet
United States
Wignall@calumet.purdue.edu

Abstract: This short paper illustrates a framework for examining the application, and misapplication, of media types and contexts in educational settings. It illustrates a relationship between form, format and function that is useful in determining the effectiveness of new media technologies in educational contexts.

Your home has a drawer or box in some convenient place where you can always reach the most useful tools; a flashlight, a ruler, a roll of tape. But there have been occasions where rummaging around in that drawer didn't get you the desired tools. You want to hang a picture on the wall but you can't find a nail, only some screws. You realize that a screw would work for hanging the picture, only to find you don't have a screwdriver. You rationalize that the picture isn't all that heavy so you could just pound the screw into the wall and take care of it, but there isn't a hammer to be found either, only a wrench. This tool, clearly not designed for the task, is pressed into service and with a little effort, hopefully without broken fingers, you indeed hang the picture. You may not have used the right tool for the job but the job was done. Because the picture now hangs over and covers the screw you are also able to hide this odd choice of a mounting device from visitors who would admire the picture.

This short paper is meant as a starting point for examining educational effectiveness of technology applications by matching format, function, and context. In far too many cases today the wrong tools are being used in the wrong context, supporting the educational process in ways that are left unexamined by educational researchers and instructional designers. We are getting the job done with whatever we have available and no one is looking at the inventory of tools in the drawer. The efficiency and effectiveness of technology in educational settings cannot be measured solely through the final output of an educational process. The latest studies of the use of computers for educational purposes, now focusing on the role of the Internet, have provided a confusing mix of contradictory results. Most of the studies are hopeful in tone but unclear about the benefits, or even the overall value, of using the Internet as a medium of education. It can be used, so it is being used.

Educators have a long history of adopting and adapting to new communication technologies as they enter society-- sometimes with great effect. Other communication technologies have been misused in specific applications by teachers and learners and abandoned for all other uses. The awareness that a communication tool can be used in an educational setting is related to the need that could potentially be satisfied by the new technology. If the tool does not not immediately satisfy the need, it runs the risk of being abandoned. If the tool can satisfy an educational need even through a use that was unintended, even inefficiently, it will be adapted to suit the purpose. The effectiveness of this use can be improved through an understanding of the educational process, its context, and the effects of communication tools on teaching and learning.

Communication formats and settings

Linking communication environments with educational settings is a valuable starting point for comparing the operational effectiveness of a new technology tool in context. the following six educational/communication environments are based on mass communication theories that grew from research efforts through the 1940s and 50s .

Figure 1. Formats & Settings

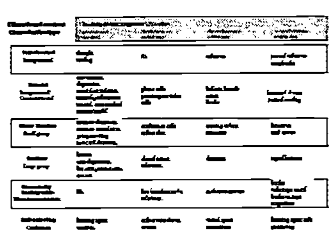

Figure 1. If the effectiveness of educational technology is to be measured it must take place, necessarily, at one of these levels, and perhaps be used as a tool at several levels. The understanding that different types of communication contexts offer differing levels of interaction with educational material, and thus provide a variable basis for learning, is essential for measuring the effectiveness of the application of technology tools at each level of interaction.

Figure 2.

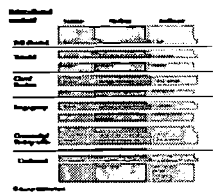

Figure 2. The quality of educational interaction breaks down when at lower levels of activity, and cannot be applied at all at higher levels of interactivity. Interpersonal communication cannot take place over mass broadcast technology, but lectures can be misapplied to interpersonal tutorials. Media technology is most effective for education when context and type match interactivity.

Media types and technology tools

The historical development of multimedia, the combination of moving images, sound, and graphic information, begins with the development of motion pictures and extends to today's subscription television cable systems. The impact of these multisensory media on viewers in the immersive environment of a darkened theater or near the electronic hearth of individual homes is complex and impressive. Multimedia technology has become more sophisticated and multilayered, allowing for multiple languages, commentary, text, and audio input and feedback. This is all the more remarkable in view of the almost total lack of feedback in early silent movie production, mass broadcast television monopolies, and linear videotape media.

Coalescent media is the result of both technology and media convergence. It represents the development of a new, digital, component-based medium. Coalescent media have emerged from the development of computational and data management tools, publishing software, digital audio and media, hypertext, and hypermedia. The linkage of different components occurs in contexts provided by the user in ways determined through navigational choices made on the spot by the user. Today web pages can be built by relational databases on demand. Users select options and the database engine places the requested information in an HTML document using preselected parameters. The limitations of current database technology combine with bandwidth restrictions to limit the potential of this early technology to combine and recombine data, in numerous forms, based on searches of worldwide resources. Coalescent media will be first relational, drawn together through user demand and user selected interaction parameters. Later developments may find hypertextual hypermedia coalescing into forms of communication that extends the capabilities of text, audio, or info-graphics by extending the interactions users have with new combinations of that media. This hyperlinking of other media types, in constantly shifting referential and contextual frames, is creating a new type of medium that demonstrates the characteristics of each level of interaction and uses each previous type of medium. As technology escapes the limitations of keyboards and screens we will see new types of interactions take place in contexts wholly created and invented by the user, not producer, of the content. New technologies being developed are allowing different types of interactions with content in contexts not imagined by the author. We are only beginning to see the curve rise in the growth of computational efficiency and the rise of new computational technologies.

Educational institutions are currently setting learning requirements, and designing the curricula to reach them, through interactions with government, professional and industry interests. These may be anything from international professional societies to locally elected school boards. What will education look like with information age learning requirements and learner-defined knowledge building? If the individualization of economic activity continues, what role will educational institutions play in defining or providing education? Does the personalization of education erode or enhance the role of educational institutions?

Conclusion

Driven by a need for improved commercial skills and abilities learners are rejecting the constraints of semesters and grades for the realities of deadlines and competencies. The growth of asynchronous distant learning systems has been dramatic, reflecting both the new availability of learning through new technologies, and the growing demand for training and education. Knowledge workers need to respond to demands for new, more valuable, knowledge on an accelerating time scale. Traditional educational institutions entering the distance education marketplace are now faced with a similar dilemma; the multifaceted role of information provider, curricular coordinator, skill assessor, and content producer. Institutions are now faced with competition not from other institutions or organizations, but from individuals operating outside of traditional knowledge production frameworks. Without the capital investment needed to create a scriptorium, library, or research lab entrepreneurs can respond to the demands of a new economy in ways that slow moving institutions cannot. Research into the improvement of learning using new media technologies, in different contexts, is not just important. It is vital to the improvement of educational systems that take advantage of each medium.

Formative Evaluation of Learner-Centered Web Course Design: A Strategic Analysis

C. James Wong
Instructional Technology & Distance Learning, Learning Resources Division
Southwestern Illinois College
cjwong@mail.southwestern.cc.il.us

Introduction

A poorly planned and developed distance education program will lead to negative learning outcome. For example, when a Texas college began to offer on-line courses taught by instructors without the skills and experience to teach on the Internet, only about 40% of students who enrolled in the on-line courses completed them (Simpson, McCann, & Head, 1999). From the same logic, a poorly designed Web course interface will have a negative impact on the entire distance education program.

This paper discusses the roles of instructional design and interface design in the development process of a Web course. Although the principles of both instructional design and interface design emphasize the importance of formative evaluation, formative evaluation (which should be conducted to assess the quality of the Web course instruction and interface) is often overlooked or ignored in this process. Formative evaluation involves (1) collecting a third party content expert's feedback to the instruction and target learners' experiences with the instruction and interface and (2) taking these evaluation results into consideration when revising the Web course. The purpose of conducting such formative evaluation is to further improve the Web course instruction and interface to maximize learner comfort and thus their learning outcome.

Instructional Design and Interface Design

In the ideal context of Web-based instruction development, instructional design is a process in which a content expert (the instructor), a distance learning instructional designer, and a course production team (that composes of an editor, a Web programmer, and a multimedia developer) work together developing a pedagogically sound Web course. According to the Dick and Carey systems approach model (Dick & Carey, 1996), the instructional design process involves determination of the instructional goal, analysis of the instructional goal, learner and context analysis, development of performance objectives, development of assessment instruments, development of instructional strategy, development and selection of instruction, formative evaluation, revision of instruction, and summative evaluation.

In this instructional design model, if the instructional strategy has been determined to be Web delivery, then the next stage--development and selection of instruction--will focus on the instructional content level of the Web course, such as choosing the appropriate instructional materials for the intended learners, modifying the existing format, structure and sequence of these materials to which learners are presented, and adding links to Web-based instructional resources.

The literature indicates that an important factor to the success of Web-based instruction is the integration of interface usability design into the development process (Henke, 1997). A Web course interface design defines the surface level of the Web course (that is, the visible structure that helps learners accomplish the goal of content learning). Web courses produced by using HTML coding, Web Course in a Box, WebCT, or other tools appear differently, due to their unique interfaces. An interface includes the following features:
(1) what students will see and hear on a web page within the Web browser (e.g. hyperlinks, text, images, animations, audio and video clips, streaming audio and video media, frames), and
(2) any responses (e.g. feedback, change of web page, error message) to students' actions such as clicking on a hyperlink on a Web page or the "Back" button in the Web browser.

Regardless which Web course production tool one uses (HTML coding or Web course delivery software like CourseInfo, Lotus LearningSpace, Web Course in a Box, or WebCT), it is crucial that a learner-centered Web course interface should address the goals of user-interface design: time to learn, speed of performance, rate of errors by users, retention over time, and subjective satisfaction (Shneiderman, 1998). As mentioned earlier, Wedman is concerned of students' "subjective satisfaction" of his School's on-line master's program.

Formative Evaluation

In the Web course development process, an in-house review of a Web course that can be called an alpha testing (in software engineering, the first test that is often performed only by users within the organization developing the software) consists of instructional designer's initial review and feedback to faculty, faculty's revision, editor's editing, instructional designer's review and feedback to editor, editor's re-editing, programmer's HTML coding, instructional designer's review and feedback to programmer, programmer's revision, faculty's final review, programmer's final revision. What is usually missing is the beta testing which requires a group of learners who are representatives of the target learners due to practical difficulty. Beta tests, usability tests, or formative evaluations (in the instructional design process) have one thing similar--the evaluation of the use of instruction and interface by actual learners or users.

A formative evaluation can be conducted to assess the quality of the Web course interface that includes the Web pages of general course information, and the first two lessons (if time permits, the entire course). The following is an example of an ideal formative evaluation of a Web course based on Dick and Carey systems approach model of instructional design (Dick & Carey, 1996): (1) subject matter expert evaluation, (2) one-to-one evaluation, (3) small-group evaluation, and (4) field trial.

Data Collection and Analysis

Technology plays a number of roles in the data collection and analysis processes during the formative evaluation. First of all, for the subject matter expert evaluation, the subject matter expert may live in a remote town away from the institution, so frequent travel to the institution will not be a feasible practice. As long as the subject matter expert has access to the Internet, he or she can review and evaluate the course content on the web, and make comments, corrections, and/or questions in an e-mail message sent to the instructor who developed the course. Through e-mail exchange between the subject matter expert and the instructor when discussing possible revisions in the course, the instructional designer will eventually be notified on actual changes needed for the course based on these two parties consensus.

Second, for the one-to-one evaluation, the technologies used are similar to an interface usability test. The entire evaluation will be taped by using a video camera, and the video tape will be reviewed and studied to observe the learner's facial expression, emotion changes, body language, and spoken language (while the think aloud protocol will be used) which will be also transcribed into words for further qualitative text analysis. The text analysis will make use of a software called HyperQual or a similar text coding/analysis software.

Third, for the one-to-one evaluation, small-group evaluation, and field Trial, a web-based testing software (which can be used for survey purpose) like QuestionMark Perception will be used to collect both quantitative data and qualitative data. If a 5-point Likert scale of attitude questionnaire is used, the questions can be entered in Perception. After learners complete the questionnaire, Perception is capable of conducting basic statistical analyses of the quantitative data collected such as mean scores, medium scores, standard deviations, and frequencies. Such data can be also transferred to a statistical software (e.g. SPSS for windows) for further statistical analyses or a database software (e.g. Microsoft Access) for data storage and possible future retrieval for further analyses. Likewise, if the lessons contain some form of objective posttests, Perception can be used to administer these tests, and thus results of student performance can be obtained by looking at the test/measurement analyses Perception conducted and by further analyzing the data in other software packages mentioned earlier.

Perception can also allow learners to enter open-ended information when answering attitude questions or answering subjective lesson assignment questions. The answers will be either kept on the Perception database on the web or sent to the instructor or the instructional designer for grading or evaluation. Again, for responses to attitudinal questions, the responses can be sorted or coded in a text analysis that will make use of a software called HyperQual or a similar text coding/analysis software.

Fourth, for the one-to-one evaluation, small-group evaluation, and field Trial, the instructional designer can use e-mail or phone to follow up with the learners to check on the accuracy of the designer's interpretation of their comments, suggestions, criticisms, and/or questions.

Conclusions

In order for the Web-based instruction design department to process the same number of courses with the inclusion of formative evaluation, more staff members will need to be employed, and the Web-based instruction design department will need to identify sources that can allocate such money for additional staff recruitment. If it is impossible to secure adequate funding for more staff, a compromised formative evaluation will have to be tailored (that is, to cut portions of the evaluation as outlined above) to fit the existing monetary and human resource structure.

Implementing a Professional Development Program in Instructional Design & Technology

C. James Wong
Instructional Technology & Distance Learning, Learning Resources Division
Southwestern Illinois College
cjwong@mail.southwestern.cc.il.us

Introduction

As noted by Speziale and Kachurick (1996), "advances in technology have provided numerous opportunities for educational integration; however, inadequate professional development programs have seriously limited teachers' knowledge of techniques for integrating instructional technologies." In an effort to solve this problem, instructional technology professional development programs have been founded in many major universities and large community colleges in the United States (Stoloff, 1999).

Recognizing the emerging needs for distance learning and the integration of instructional technology, Southwestern Illinois College has launched a professional development program in instructional design and technology, an innovative service to its faculty, in the summer of 1999. The new program is operated by the Instructional Technology and Distance Learning department under the Learning Resources Division, with a mission to assist members in planning, developing, implementing, and evaluating their instruction and to facilitate innovative integration of instructional technology into their on-campus and on-line courses. This institution-specific case study describes the implementation process of this new program and reports its recent performance assessment.

Program Services and Facilities

The professional development program is led by the instructional technologist/design specialist with assistance from and collaboration with other staff members (including the associate director of distance learning, the Internet systems manager, a Web-based instruction coordinator, a Web programmer, an Internet support technician, and a network technician) in the Instructional Technology and Distance Learning department.

A. Facilities: The long-term goal of the program is to implement a faculty development facility called the "Instructional Design & Technology Center" that consists of a computer lab for training purpose and a multimedia work area for production purpose. To get things started, a computer workstation with a Pentium II dual processor has been built and is available for faculty use. Additional hardware includes: a video capture card, a flatbed scanner, a CD writer, a ZIP drive, a JAZ drive, two digital cameras, a color printer, and a laser printer. Software titles installed are Microsoft Windows NT 4.0 Workstation, Microsoft Office, Microsoft FrontPage, Adobe PhotoShop, OCR Software, and other multimedia applications. In addition, a Macintosh G3 computer has been recently included in the Center with some general purpose software such as Microsoft Office.

B. Consultation: The program offers one-to-one consultation to faculty with tailored information about theory and practice in technology applications for instruction. A customized small group session can be arranged when there are two or more faculty members interested in a certain design and technology issue.

C. Training: Hands-on instructional technology workshops on how to use various instructional software are offered to faculty, in addition to pedagogical seminars for faculty to facilitate information sharing and discussion of current issues on design, development, implementation, and evaluation of instructional technology applications.

Program Performance

A. Instructional Design Consultation: To increase the visibility of the innovation--the new professional development program, a small but concise Web site was built in the summer of 1999 to publicize the services and facilities being offered to the faculty. As words about the innovation regarding the professional development program spread out, the number of faculty who came to the program for consultation on instructional design and technology has increased:

June 1999: 1 faculty on 1 occasion
August 1999: 2 faculty on 2 occasions
September 1999: 2 faculty on 2 occasions
October 1999: 7 faculty on 14 occasions
November 1999: 4 faculty on 9 occasions
December 1999: 1 faculty on 2 occasions
January 2000: 2 faculty on 3 occasions

The average length of a consultation meeting is about two hours. It shows faculty's enthusiasm and willingness to devote their time commitment. Issues faculty members have brought to the consultation meetings are diverse. The following list demonstrates the variety of such topics:

- Developing web pages for a campus course in FrontPage
- Working with WebCT for an online course
- Discussing design issues on Social Science departmental website
- Discussing and planning a Faculty Web Directory
- Designing a welcome template for an online course
- Designing a telecourse support Web site in Frontpage
- Working with PowerPoint to develop a student orientation session

B. Training to Meet Faculty Needs: In order to understand faculty members' needs in instructional design and technology and to prioritize offerings of workshops and seminars, a needs assessment was conducted in the form of a brief survey (Dick & Carey, 1996) to 130 full-time faculty members in August, 1999. The survey included questions asking faculty to rate (on a 1-3 scale, with 3 being highly interested, 2 being interested, and 3 being not interested) their interest in a range of workshop and seminar topics derived from the text by Newby, Stepich, Lehman, and Russell (2000). 68 faculty members returned the survey. The response rate of the survey is, therefore, 52.3%. The top rated topics are listed below in the descending order of the mean of their rating:

Rating	Topic
2.27	Using presentation software in the classroom
2.24	Creating instructional web pages
2.1	Integrating instructional technology in the classroom
1.96	Using Internet communication tools
1.87	Digitizing and editing images
1.83	Lessons learned from teaching an on-line course
1.83	Creating an electronic gradebook
1.69	Fair use of copyrighted materials in on-line instruction
1.36	Introduction to distance education technologies

Meeting the faculty needs, the program developed and delivered four hands-on workshops and two pedagogical seminars till February 2000. Workshop training materials, with step-by-step instructions and screenshot illustration on how to use the software applications, were produced by the workshop trainer (who is the instructional technologist/design specialist) and pilot tested by other staff in the department. With the intention to reduce faculty's computer anxiety level and not to overwhelm faculty by teaching them every single feature of the software applications, the workshops and training materials were tailored to invite faculty members to practice some the most commonly used functions to get started. During the hands-on workshops, pedagogical issues such as design principles were discussed before the hands-on practice sessions.

The following table illustrates a brief evaluation of the training delivered from September 1999 till February 2000. The "No." column is the number of faculty who participated; the "Overall" column is the participants' average rating of the overall evaluation of the workshop based on a 1-5 scale (with 5 being the highest rating); the "Usefulness" column is the mean of their rating to the statement "What I learned in the workshop has useful applications for my classroom and/or work".

Title of Training	No.	Overall	Usefulness
Workshop - Creating Instructional Web Pages with Microsoft FrontPage 98: An Introduction	30	4.77	4.73
Workshop - Designing Classroom Presentations: Basics of Microsoft PowerPoint	23	4.87	4.96
Workshop - Designing Classroom Presentations: Advanced Microsoft PowerPoint	13	4.85	4.77
Seminar - Integration of Instructional Technology into Teaching & Learning: An Overview	15	4.13	4.40
Seminar - Interaction, Instruction, and Research Via the Internet	12	5.00	4.91
Workshop - Image Digitizing and Editing	26	4.92	4.77

More workshops and seminars are under development and will be soon offered to faculty members in the future so as to address one of the commonly complained drawbacks of a professional development program according to national findings regarding to professional development: infrequency of training (Speziale & Kachurick, 1996).

Summary

Instructional technology are great tools that offer possibilities for improving the learning process, but such possibilities will not be realized automatically unless the teacher will have to integrate these tools into the curriculum in a way to facilitate teaching and learning (Heinich, Molenda, Russell, & Smaldino, 1999). The professional development program in instructional design and technology fills this gap between the tools and the people by helping faculty use the tools to teach in a more effective and efficient manner.

WALTS: Web-based Adaptive programming Language Tutoring System

Chong W. Woo and Jinwoo Choi
Kookmin University
861-1 Chongnung-dong, Sungbuk-ku
Seoul, Korea
cwwoo@kmu.kookmin.ac.kr

Abstract: Many recent web-based educational systems couldn't provide individualized instruction or interactive problem solving, since they are mostly built upon static hypertext. One possible solution for this problem could be adapting existing proven techniques from the stand-alone Intelligent Tutoring Systems(ITS) into the web-based educational systems. Recent web-based ITS research shows this direction by employing the existing ITS techniques minimally. And this needs to be studied further to support more adaptive instruction. In this paper we describe the development of a Web based Adaptive programming Language Tutoring System(WALTS) which is designed by ITS structure primarily, and adapting many successful ITS techniques into the system. In addition, the system adapted CORBA infrastructure to support the user more consistent and reliable performance. Together, the system behaves more adaptive and interactive than the existing static web-based educational systems.

Introduction

Many recent web-based educational systems could not provide an individualized instruction or interactive problem solving, since they are mostly built upon static hypertext. One possible solution might be adapting the existing techniques from the stand-alone Intelligent Tutoring System(ITS). However, most of the recent web-based ITS research show the efforts by employing the techniques selectively(Kay & Kummerfeld, 1994; Brusilovsky et al. 1996; Nakabayashi et al. 1997). And this needs to be studied further to enhance the overall capabilities of the system at the previous stand-alone ITS level. In this paper we will describe development of Web-based Adaptive programming Language Tutoring System(WALTS). The main goal of the development of the system is to provide the first year computer science student a comprehensive instruction for learning C programming language, by porting many successful ITS techniques into the system. In addition, the system is designed to support the user more consistent and reliable performance by employing CORBA(Common Object Request Broker Architecture) structure.

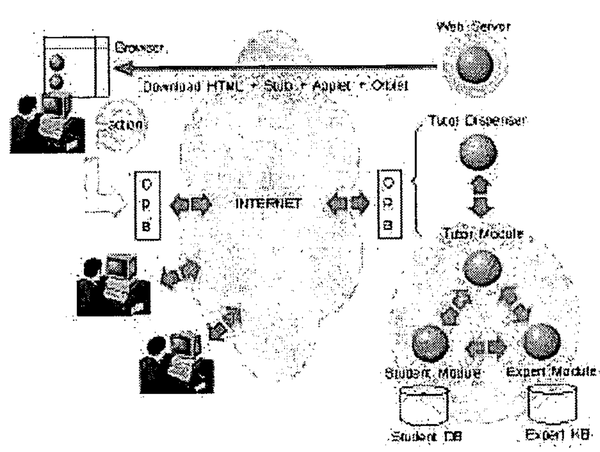

Figure1: The main Architecture of WALTS

Basic architecture of the system

The basic architecture of WALTS is designed by typical ITS structure primarily, including expert module, the student modeler module, and the instructional planning module.

The *expert* module consists of the *object-oriented knowledge base* and the *problem solver*. Since the domain of the system is the C programming language concepts, which may not require any complex causal relationships and only requires mostly simple concepts, we used the frame knowledge representation. The object-oriented approach of designing the knowledge base make it easy to understand and can provide more flexibility for updating or manipulating tutoring strategy in the construction of ITS. The problem solver creates problem table by referencing the problem template from the current *lesson unit* 's content table, which is the form of hashtable. The solver stores the correct answer, and then it presents the generated questions to the user in appropriate HTML form through the HTML generator. This method can provide different styles of questions for different users even though they are accessing the same lesson unit. Since the column name of the table is object's name, the planner can reply to the user's request, such as hint or help, by referencing this table.

The method of building the student modeler is the simple overlay. The modeler keeps all the necessary administrative information on the server, such as initial student's ID, password, e-mail address, the access time. And the information regarding the student's learning process is also stored in the student model. And each parameters has unique meanings; for example, the HelpCount, and HintCount can be updated only when the unitLesson is quiz, increase of ReferenceCount means the user is weak at the current unitLesson, the lessonLevel stores information about how many times the user visited the current unitLesson, and so on.

The Instructional Planning

The existing web based educational systems mostly employ the hypertext techniques, which is hard to make hyperlink in every HTML pages, such that it may be inappropriate for adaptive learning environment. Therefore we need to devise a method that can generate adaptive lesson unit dynamically. The instructional planning of the WALTS can be further divided into 3 steps, a curriculum planning, a lesson planning, and a delivery planning. The curriculum planning of WALTS generates a curriculum in tree structure; the curriculum planner extracts information from the knowledge base and creates a curriculum hierarchically in the order of prerequisites. Then the lesson planning sets up the lesson sequence within a single lesson unit. The role of delivery planning is limited to presenting the selected lesson content to the user.

Conclusion

The main goal of this paper is the adaptation of the existing ITS techniques to the web platform. Therefore, we have designed and implemented the system based on the major ITS architecture, and this brings us several advantages over traditional HTML-based educational systems. First, the main knowledge base is created as an object-oriented concept, which can provide more flexibility for updating or manipulating tutoring strategy. Second, the system can generate a problem dynamically by the problem solver and also can solve the problem intelligently. Third, the instructional planning mechanism can generate an instructional plan dynamically. The secondary goal is the designing of the system as a distributed infrastructure using CORBA as backbone. This structure solves the bottleneck problem of previous CGI dependent systems, and also gives some benefits of better performance and also gives flexibility in the case of further enhancement of the system.

Abstract: Online learning communities are an excellent means of integrating collaboration in online learning environments. After a brief introduction we [the authors] define collaboration and learning communities and address their theoretical foundations. We then discuss the benefits of collaboration and learning communities in online learning environments. Finally, we provide a case study of a new online learning community at Western Governors University.

Definitions and Theoretical Foundations

Learning communities are environments that encourage mutual exchange between the community members to support their individual and collective learning. Learning communities are founded on the aspect of social negotiation of meaning. Collaboration is the key tenet of constructivist and small-group theories (Springer Springer, Stanne, & Donovan, 1999; Grabinger, 1995; Duffy & Jonassen, 1992) that explains the social component of learning and demonstrates that "conceptual growth comes from sharing perspectives and modifying our internal representations in response to that sharing" (Grabinger, 1995, p. 669). Online learning communities provide the collaborative means for achieving the desired "shared creation" and "shared understanding" (Shrage, 1991, p. 40).

Benefits of Online Learning Communities

Collaborative learning and learning communities benefit learners because they encourage shared ways of knowing, promote active participation, improve achievement, contribute to the creation of knowledge, and challenge learners' cognitive abilities (Springer, Stanne, and Donovan, 1999; Moller, 1998; Lave & Wenger, 1991; Slavin, 1990).

Through new Internet technology, synchronous and asynchronous online collaboration now provides many of the benefits that exist in traditional face-to-face collaborative and learning community environments. Our recent literature review produced evidence that online collaboration and online learning communities:

- Allow learners and instructors to work together to create knowledge constructions from their combined experience (Jonassen, 1998; Reeves, 1997)
- Encourage learners to evaluate complex issues from multiple perspectives and change their perspective based on others' input (Sherry, 1998; Stone, 1996; Honebein, Duffy, and Fishman, 1993)
- Hold learners individually accountable while striving toward group goals so that students help one another and assess one another's learning (Springer, Stanne, and Donovan, 1999)
- Provide opportunities for learners to reflect on their learning experiences and upon others' input (Stone, 1996)
- Demonstrate that meaning and reality is socially constructed and negotiated through the exchange of ideas, information, and feelings among the members of the community (Hiltz,1998)
- Improve student achievement through increased motivation, peer support and communication, and commitment to participate and finish (Hiltz, 1998; Sherry, 1998; Stone, 1996)

The above evidence demonstrates that online collaboration and online learning communities can impact and enhance the learning process. We have personally witnessed the impact of a self-initiated online learning community at

Western Governors University. Although the WGU online learning community is relatively new, we have already seen positive effects ripple through the community members.

Case Study of an Online Learning Community at Western Governors University

In August 1999, Western Governors University (WGU) began enrolling students in its new competency-based Master of Arts in Learning and Technology program (MLT). A cohort of 50 students, primarily K-12 teachers, geographically dispersed throughout Utah were some of WGU's initial MLT students. In October 1999, a small group of 15 cohort students created their own collaborative online learning community utilizing a listserv since all students had ready access to e-mail.

The WGU online learning community provides a fascinating case study because it was initiated by the students themselves who by and large had no previous experience working together. Of the 15 original members of the community, only five had previous experience working with each other on previous projects; the majority of the learning community members had only met each other briefly at a WGU reception in September 1999.

As we watch the WGU online learning community develop, we are paying attention to the ways that the community members negotiate roles and establish rules and standards for communication, interaction, and entrance into the community. We are eager to compare learning community members' performance to the performance of students who do not participate in the online learning community. We are also interested in determining why some learning community members remain inactive or decide to leave the community.

Conclusion

Salomon and Perkins (1998) state that "learning to learn... fundamentally involves learning to learn *from* others, learning to learn *with* others, learning to draw the most from cultural artifacts besides books, learning to mediate others' learning not only for their sake but for what that will teach oneself, and learning to contribute to the learning of a collective" (p. 17). Collaborative online learning communities provide community members the chance to learn *from* and *with* others and to *contribute* to others' learning. As a result, they are important means of integrating the social aspect of learning into online learning environments. Our literature review and personal research of the WGU online learning community provide valuable insight into issues surrounding online collaboration and online learning communities' development, communication patterns, member roles, rules, flexibility, sustainability, and reproducibility.

Abstract: Encouraging effective collaborative learning supported by computer technology requires coordination among faculty, administrators, technical and instructional support staff, and library staff. This paper describes the roles of each of these groups in the design and use of computer technology to support collaborative learning. This paper draws on collective experience from implementing Project Vision and Project Empower, two computer-supported collaborative learning programs in Commonwealth College, Penn State University.

Too often the discussion of collaborative learning and use of computer technology to support instruction focuses solely on the classroom; in fact, successful efforts in the classroom rest on a foundation of collaboration and support from administrators, technical and instructional support staff, and library staff. Over the last several years Penn State University Delaware County has developed teaching methods that incorporate the best features of distance education and collaborative learning in undergraduate education. The two projects most directly responsible for the development of collaborative, technology-enhanced instruction were Project Vision and Project Empower, both programs for freshmen and sophomores in general education courses.

Administrators

Important administrative support issues include motivating, training, and supporting faculty to take on new teaching roles and new responsibilities, since collaborative teaching and use of computer technologies differ significantly from the standard lecture/discussion format. Administrators must make sure that the reward system for faculty recognizes the effort necessary to change from the old to the new model; we provided release time and training for faculty to learn new roles. Administrators are also responsible for making sure that appropriate equipment and software for courses is installed properly and works efficiently. Persuading faculty to work cooperatively with librarians and with technical and instructional support personnel is also an administrative role. Administrators may also be responsible for the selection and orientation of technical and instructional support personnel, who must understand the academic mission and the instructional process. Finally, administrators must be well versed in designing and conducting collaborative learning in technology-enhanced classrooms, because they are responsible for the evaluation of the quality as well as the economic viability of these efforts.

Faculty

Graduate training seldom includes a component on teaching collaborative, technology-enhanced courses. Hence, faculty must learn how to design, manage, and evaluate collaborative assignments, as well as how to choose appropriate technologies to enhance learning in their specific venues. Faculty must be expert users of the technology in order to explain the technology to inexperienced students who are struggling concurrently with course content. Faculty always balance the advantages of new instructional media against many constraints, including the students' abilities and interests, classroom facilitics, and thc quality of technical support. They must also balance the time they spend in these activities against other responsibilities of teaching, service, and research. Computer technologies are constantly changing; therefore, faculty who are committed to these pedagogies know that the process of learning new technologies and the balancing act are never-ending.

Technical/Instructional Support Staff

Technical and instructional support staff work with faculty from a wide variety of disciplines, as well as with administrators and students. Math, social sciences, humanities, and business all have different content and different pedagogies. Technical and instructional support staff must understand a wide variety of technologies and software programs appropriate for specific disciplines to help faculty make informed choices. Support staff often advise faculty in designing assignments that make the best use of collaboration and computer technologies. Technical and instructional support staff must understand students' abilities and interests in order to recommend the most appropriate technologies for each particular instructional situation, keeping in mind budgetary constraints. They train faculty and students and trouble-shoot daily problems which inevitably arise. Close collaboration with faculty, administrators, and students requires superior communication skills. A sense of humor doesn't hurt either.

Library Staff

The new technology-enhanced and collaborative classrooms are changing the roles of librarians as well as faculty. Library staff must constantly keep up to date with emerging technologies, a not inconsiderable task with the rapid development of electronic media. Librarians are responsible for designing systems for accessing information that make sense to users. Increasingly, librarians find themselves acting as coaches and collaborators for instructors who are learning to teach in collaborative and technology-enhanced modes. Library staff also train, coach, and support students in learning to use search technologies to find information. Library staff share responsibility with faculty for teaching critical thinking skills as they teach students to evaluate the quality and usefulness of the information students are using.

Conclusions

Commonwealth College of Penn State University created Project Vision to encourage faculty to redesign courses to incorporate collaborative and active learning strategies supported by appropriate technology in teaching undergraduate education courses. The administration offered release time, extra compensation, and training to prepare selected faculty for the pilot program which was designed by faculty. Over the four years of this program, the faculty tried several models for offering courses. Once all the students took only Project Vision courses for the first year as a cohort; in other years, students took some Project Vision courses and some regular courses. For two years, the faculty offered courses coordinated across two different locations. Usually, the courses were offered as a package. For example, students took Speech Communication to learn how to work in groups, Library Studies to learn how to do research, and Health Science as the content of the research project. The technologies included FirstClass computer conferencing, Eudora e-mail, PowerPoint, and video conferencing.

Synchronized Notes for Digital Class Video

Michirou Yabuki
Faculty of Informatics, Meisei University, Japan, yabuki@ei.meisei-u.ac.jp

Akira Watanabe
Faculty of Informatics, Meisei University, Japan, akira@ei.meisei-u.ac.jp

Introduction

We proposed a method using digital class video for review and self-studying and applied it to some subjects. We believe our method is successful in actual education. Students will make their own notes watching digital class video in the same way they make their own notes during ordinary classes. If students watch digital class video for their study many times over, their notes will be essential. In addition to digital class video, we propose synchronized notes for digital class video.

Digital Class Video

In many educational organizations, networks are used for educational support. On the other hand, there are many traditional classes that have no educational support using computer networks. When one intends to utilize computer networks or the Internet for traditional classes, he/she will suffer from various problems such as time for investigating teaching materials, manpower, arrangements of equipment and preparation of presentation data.

To solve those problems, we proposed a method using digital class video for introducing educational support utilizing computer networks for traditional classes. Our five goals of the proposed method are: the purpose of the method is review and self-studying; the method could preserve the various teaching style of teachers; the method should be simple so that the number of staffs and a budget should not be large; the method is able to be adopted to traditional lectures and computer exercises; more than one simultaneous classes should be supported using the method.

To achieve above goals,

- The scene of a class is recorded on video tape as it is.
- The camera for recording teacher's movements has fixed view and never follows of teacher's movements.
- A written material or a computer screen of the teacher operates is also recorded on another video tape.

These two videos are synthesized to a single image for publication.

As experiments, we applied our proposed method to five subjects in 1998. The experiments are still continued in 1999. The number of total access times to the video was 1300 in 1998. We believe that our educational assistance method is successful.

Synchronized Notes

To study subjects, just watching class is not enough for studying. Students ordinarily make notes on class with a notebook and a pen. (Nowadays, some students use their own lap-top computer for their notes in classes.) When students watch class video on the computer, it is preferable for students to make notes on the computer. To make notes on the computer while watching digital class video is simple because they can easily use another window for a text editor or something like that. In that way, students are able to review their lessons again, by watching video and their notes. As Notes is, however, "static" information, students should synchronize notes and video by themselves during watching video.

To synchronize notes and video, we implemented a telop function to our MPEG video viewer software. Users are able to put comments or notes to video as a telop just when they are needed. Once users put comments or notes to video, the telop come up on the screen at the designated time whenever they watch video. Fig. 1 shows an example of telop function.

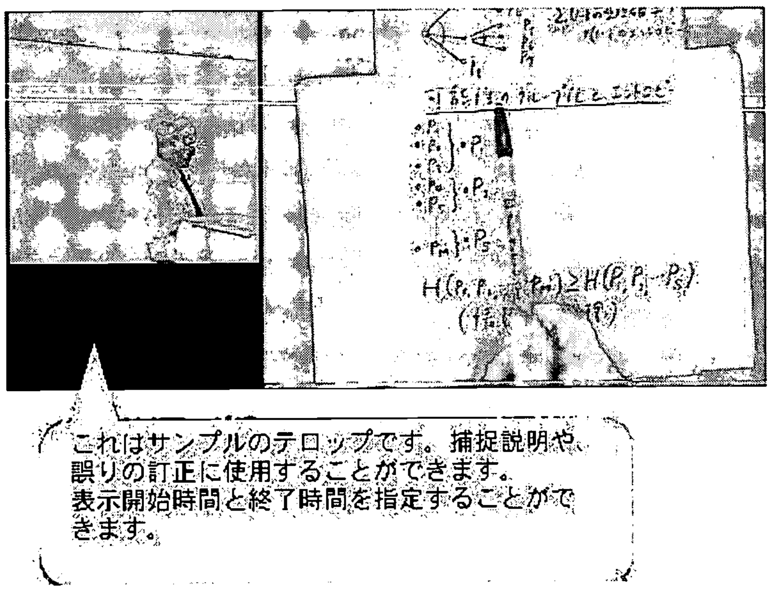

Figure 1. An example of synchronized notes

If user put comments to video, a mark is shown on the scroll bar so that users are able to find where they put their comments. Scroll bar of the MPEG viewer is used to forwarding and rewinding video.

The mark on the scroll bar is also used to find important points of the video. In our method, the entire class is recorded on the video. Usually teachers use a lot of time for thinking, joking or something like that. The mark is used to avoid overhead of watching unnecessary parts of video.

In the same way, not only users (students) but also teachers are able to put comments to video. After the class, teachers sometime notice there were mistakes or insufficient explanation during the class. In such case, teachers are able to add additional explanation or corrections to video as a telop.

Conclusion

We implemented synchronized notes to MPEG viewer. Users are easily able to add comments and notes to class video for their self-studying. After the class, teachers are also able to add additional comments or explanation to their class video. The softwares are implemented as WindowsNT and UNIX (FreeBSD) X-window applications so that students are able to study on any plathome.

Abstract: In recent years, popularized technologies such as "Multimedia" and "Internet" came to be used in various fields. The field of education is not an exception either, and these technologies are adopted by CAL (Computer Assisted Learning). Especially, the successful introduction of these technologies into Japanese education is being looked forward to. Since Japanese as the 2nd language is said to be high in the degree of difficulty in acquisition, an improvement in the study efficiency through adopting such technologies is expected. This paper focuses on Kanji of Japanese language education and discusses the multimedia Kanji dictionary.

Introduction & Background

At present, there are many non-Japanese who are learning Japanese in the world. However, with a limited time allocated for study in classes, the present condition does not offer sufficient education for mastering Japanese. For, not only are there problems related to the basic grammar such as the word order in Japanese is sometimes different and the use of the auxiliary verb is more complicated in comparison with other languages but also there are three kinds of characters used: "Hiragana," "Katakana" and "Kanji." Especially, quantity in Kanji is voluminous and the shapes are complicated. Even for Japanese, it takes 6 years to learn over 1000 Kanji characters. Furthermore, so much information is contained in Kanji (for example, reading, meaning, radical and the stroke count, etc.). Therefore, the more efficient Japanese education system is necessary because it is excruciating for people in the countries where Kanji are not used to learn them in a short period of time. When people in the countries where Kanji are not used learn their mother tongue, they emphasize "conversation." Therefore, even when they learn Japanese, they emphasize "conversation." In comparison with Japanese, a one byte code language, in the first place, has a fewer number of characters but has a number of types of pronunciation. Therefore, such a language can be mastered mainly by improving conversation ability.

From such a reason, for people of the countries where Kanji are not used inevitably neglect learning of Kanji. To effectively learn Kanji, the multimedia Kanji dictionary was developed. Since the electronic dictionary facilitates the understanding of Kanji by using animation and sound, it can improve learning efficiency much more than a conventional paper dictionary. Also, the characters of the index are so small that we sometimes become fed up with looking up Kanji in the paper dictionary. However, people will become able to search Kanji more easily by just clicking if they use the multimedia Kanji dictionary. This electronic dictionary is functioning as the dictionary module of an integrated Japanese learning system called "Terakoya."

URL: http://www.narita.elec.waseda.ac.jp/~fujita/terakoya.html

Kanji Dictionary

This dictionary system can be divided into the Kanji searching part and dictionary database part. In the searching part, there are three kinds of functions "Read," "Stroke count" and "Radical." Here, we can find a Kanji character for which we are searching, and we can read out detailed information from the dictionary database that is stored as a CSV file. On the one hand, this system contains detailed information such as radicals and the stroke count for people who want to learn detailed information. On the other hand, this system facilitates easy learning of Kanji by including items for children such as pictures and figures that look similar to Kanji. This system has become an interactive system that has more mobile capability by using animation and sound, which is in contrast to the conventional dictionary system that emphasized text data. Animation is used to display the order of strokes of a Kanji, and voice is used to let the learner hear the data of "Reading" and "Examples." Furthermore, in order to have the users learn a large quantity of Kanji, this system understands Kanji through graphic means by recognizing each Kanji as a picture or a figure to improve learning efficiency.

And, because this system is using WWW, it is not dependent on a particular type of platform. A learner can use it through the Internet from PC regardless of whether the person is at home or in a class. Even if there was no such environment, in such case information of Kanji can be read by printing the contents out on paper as a conventional dictionary. Although this system is developed with Shockwave of Macromedia Company, the browser is not able to function as a printer when the movie that was made with Shockwave is loaded into the browser. Therefore, a page where Kanji information is transformed into an HTML has been made. If the hard copy of Kanji information can be made, it can be used at places where there is no computer nor a network environment. This function comes from the requests of the Japanese language teachers and also of Japanese language learners.

Future Plans

Although this dictionary system has searching functions of "Read," "Stroke count" and "Radical," these searching methods are used conventionally in the conventional paper dictionary. However, there must be cases where a beginner of Kanji learning has no idea about the reading, the stroke count nor the radical of the Kanji that he/she wants to find out. To this end, we are studying the functions by which a Kanji can be searched through handwritten letter recognition. If this searching method is created, a learner can search for the Kanji by the action that is similar to drawing a picture of the Kanji whose detailed information is not known to the learner. Also, although the present system has registered 80 Kanji characters in the database, in order to maintain coordination with the "Terakoya" system, it is necessary to classify Kanji by the degree of difficulty or by the use frequency in daily life to offer data to the user in an easy-to-understand manner. Furthermore, because there are some cases where the requests of teachers differ from the contents of a dictionary, we should add such function that enables the teachers to freely select the words and pronunciations, etc. that he/she wants to use in the lesson. If there is such a function, a lesson will become very effective. At last, we need to evaluate this Kanji dictionary. This system will be tested by the Center for Japanese Language of Waseda University and the Richmond school in Portland. And, we want to advance to further improvement by asking advices from teachers and students.

Abstract: The purpose of this study was to identify the similarities and differences of online and traditional foreign language courses and to determine the advantages and disadvantages of the online courses. Using a random sample of 20 courses, ten on-line and ten traditional, this study examined the online and traditional courses in terms of five constructs and compared the methods and strategies used in online courses with regular classroom instruction. With a rubric developed for the study, the online and traditional course were rated in a 4-point scale and analyzed with independent t-tests. The findings of the study indicated that online and traditional courses had about the same weight in teaching foreign language and suggested that they each had its advantages and disadvantages. The study concluded that traditional courses had better defined and more specific goals and objectives for both teaching and learning and was more effective in teaching conversation and listening comprehension, while in online courses, students could learn at varying rates and explore material to whatever depth they desire, and Internet technology made it possible for students in different areas and from different countries to access online courses.

Introduction

With the rapid development and fast growing adoption of technology, the use of technology in education has been dramatically increasing over the past few years. In the area of language education, various technologies are being utilized by language teachers and learners in and out of the classroom (Warschauer, 1996). These uses would include the traditional use of audio and films; however they are now being supplemented by computer-assisted instruction and interactive media technologies (Richards, 1996). Computer-based programs, as well as other computer-related interactive technologies, have been specifically developed to provide students with visual and audio support. These applications have shown potential for helping students develop their language abilities and improve classroom performance (Pennington, 1996).

Among a variety of instructional delivery media, the Internet, especially the World Wide Web, has been commonly adopted by many educators in higher education (Khan, 1997; Porter, 1997). However, little research results have shown to support claims for the effectiveness of Web-based instruction (Nunan, 1999). The focus of this study was an analysis of existing web-based foreign language courses and a comparison of the methods and strategies used in online courses and regular classroom instruction to determine the common and unique methods and strategies used to achieve the educational objectives in each environment.

Purpose of the Study

The purpose for conducting this study was to identify the similarities and differences of online and traditional courses of teaching foreign languages and to determine the advantages and disadvantages of the online courses. Methods, strategies, and technologies used in online foreign language courses were examined and compared with those of the traditional foreign language courses. In order to achieve the purpose of the study, the current study addressed the following research questions:

1. Based on the courses examined, what methods, techniques and strategies were used for teaching online foreign language courses and traditional foreign language courses?
2. What were the differences between traditional foreign language courses and online foreign language courses in terms of goal/objectives, strategies, interaction, feedback, and resources?
3. What were the advantages and disadvantages of the online courses?

Method

The sample for this study consisted of twenty foreign language courses, with ten on-line courses and ten traditional courses. Thirty online courses were first identified directly from foreign language courses available on the Internet, which included listening, speaking, reading, and writing courses. The following systematic procedure was used to randomly select ten courses from the thirty previously identified online courses: First, a random list of the thirty online courses was generated. Then a start point for the selection was randomly chosen on the list. From that point every third course was selected until a total of ten online courses were identified for the study. Among the ten courses that were chosen were two listening courses, one speaking course, two reading courses, two grammar courses, and three writing courses.

With the same procedure, the ten traditional courses used for this study were randomly selected from foreign language courses offered by the Intensive English Programs and foreign languages departments at various universities. The course materials of these ten courses were available at the University of Louisville, the University of Alabama, Southeast Missouri State University, and North Carolina Wesleyan College. They were three listening courses, two speaking courses, two reading courses, one grammar course, and two writing courses, which comprised the traditional foreign language course group for data analysis. With a rubric developed for the study, the online and traditional course were rated on a 4-point scale and analyzed with independent t-tests.

Results and Discussion

The comparison by means of the rubric indicated that the online courses and the traditional courses had about the same weight in teaching foreign languages in general. Online courses had a total score of 147, while the score of the traditional classroom teaching was 153. However, the independent t-tests, which were performed to identify any possible significant difference between the online and traditional courses, found that significant differences existed between the two types of courses in two of the five constructs measured.

Conclusion

A foreign language acquisition process consists of listening, speaking, reading, and writing skills. In order to facilitate the success of second language teaching and learning, modern technologies have been used in the classroom to promote teaching performance and student learning. Online courses, which have been developed for that purpose, have proved their advantages in foreign language teaching and learning. However, when comparing traditional classroom teaching with online courses, the results of this study suggest that each had its advantages and disadvantages. For traditional courses, better defined and more specific goals and objectives were given for both teaching and learning. Delivering course material through the Web, on the other hand, afforded some advantages over traditional classroom teaching. In online courses, students could learn at varying rates and explore material to whatever depth they desire. There were new ways to guide students through tutorials and to provide them with instant feedback. Using Internet technology made it possible for students in different areas, different countries to use varying computer types to have access to the course.

However, as far as a foreign language is concerned, it is obvious that traditional classroom teaching was better in teaching conversation and listening comprehension courses when students needed face-to-face interactions with the instructor and instant verbal feedback from the instructor. Computer-mediated communication had been criticized as lacking the human social interaction necessary for human learning (Gilbert, 1996) although Lemke (1993) claimed that "cyberspace will be a virtual place FOR human social interaction." It seems that web-based courses might not be able to provide as effective or efficient a means of learning a language as one-on-one human interaction. Without such non-verbal cues as body language and the tone and pitch of one's voice, it is possible to misconstrue messages (Berge & Collins, 1995; Gilbert, 1996).

In summary, neither of the two types of courses is absolutely good or faulty. Each had its own advantages and disadvantages. As an instructional designer, we should be aware of the advantages and disadvantages of both types of courses and make full use of their advantages in the design and development of the courses, based on different student needs, student characteristics, and skill requirements, to achieve the goals of our education.

Abstract: The paper proposes and explains five common mistakes which institutions often make in implementing distance education: using packaged courses and low-level instructors, using one technology to deliver all distance education, not monitoring student satisfaction and retention, assuming that all courses can and should be offered via distance technology, and focusing marketing only on the technology-literate.

Racing along the Road

The shape of distance education is changing daily as more and more institutions embrace the technologies now available to deliver remote instruction. One estimate by Robert Tucker (1997) quoted recently in Forbes, is that about 90% of US four-year institutions will have technology-based distance learning offerings by 2000. Even in 1996, over a million students took distance learning courses of the 14 million attending post-secondary educational institutions. And, although these courses use many different technologies, there is rapidly-increasing focus on internet delivery. In this rush to get on the bandwagon, the authors, who have been involved with emerging distance education in Texas for the last ten years, have observed several common assumptions which cause great concern. The focus of this paper will be to identify and call into question some frequent phenomena which, we believe, threaten to undermine the success of cyberlearning.

Wrong Turn One: Buy a packaged course and hire a TA or two to run it

One of the driving forces behind the charge to cyberlearning is the common perception that cyberlearning will be a cash cow for traditional institutions, allowing them to cut costs. In a rush to milk, institutions are sometimes choosing to dispense with home-grown courses run by local professors. This choice threatens to result in a world of cyberlearning where there are many institutions to choose from, but all are teaching the same course. Losing the personal enrichment, the personal mentoring and the constant updating which an experienced teacher puts into a course is equivalent to losing the personal voice or identity of an institution. Cyberlearning should increase the diversity of the educational ecosystem, not decrease it.

Wrong Turn Two: Buy one technology and use it for everything.

Because the costs for establishing technology-based distance learning can be large, institutions are prone to make an initial commitment to a technology (VHS with two-way audio, or TV, or compressed video, or web) then force all course offerings to fit themselves to that technology. Institutions have been known to simply buy whatever was pitched to them most intensely in the hopes of not having to face the bewildering array of choices again for quite some time. However, close analysis of student needs, course content, and educational effectiveness has led us to believe that hybrid technologies evolved over time and respondent to individual courses and student audiences produce superior educational results. Educational needs and goals should drive technology, not vice versa.

Wrong Turn Three: Don't worry about student satisfaction; the learning is fine

Indeed, much past research on distance learning using all kinds of different delivery modalities from correspondence courses to web has indicated that students seem to learn as much from distance courses as they do from face-to-face instruction (Russell 1996). However, we cannot ignore that cybercourses vary enormously in learner-satisfaction and quality. In an ideal educational cyber-marketplace, learner-centered course design will eventually prevail. Courses which use technology well and flexibly to deliver their course content and achieve course goals, and courses which attend to a wide variation in student learning styles will have better success. Convenience of access is not enough; quality matters, too.

Wrong Turn Four: Move everything onto the cyber-track.

With the emergence of virtual universities and entire degree plans available by remote technology, the instinct of many institutions is to think of distance learning offerings as a substitute for face-to-face instruction, rather than an adjunct to it. However, a closer look shows quite clearly that cyberlearning has, thus far, leaned heavily in the direction of engineering, business, computer science and health sciences. (Miller 1998). According to Miller, all other subject matters account for only 10% of cybercourses. In spite of the pronouncement of Peter Drucker (1997) that "Universities, as we know them, won't survive," almost all lower-division and humanities courses continue to be offered in traditional fashion. One reason for this, we believe, is the need for greater flexibility in adapting to the goals of such courses and the needs of students. Cyberlearning should, we believe, offer additional choices to students and teachers--not force them into a course-delivery system alien to them. In fact, we go so far as to argue that cyber courses should, in most cases, have live, face-to-face versions running, too.

Wrong Turn Five: Just market the courses and the students will come

Certainly convenience, accessibility, and low cost are strong incentives for students to engage in cyberlearning. However, issues of equity and market penetration will become ever more pressing as institutions seek to draw increasing numbers of students. Access to computers is increasing daily, as is internet access; however individuals without home computers or internet access may be precisely the ones who most need access to "anytime, anywhere" post-secondary education. Institutions must attend to insuring access at public libraries, K-12 schools and community centers in order to insure equity for all ranks of society and to avoid widening the digital divide. Moreover, some segments of the market will need additional technology training in order to effectively use the access which is available to them, and institutions must provide appropriate training in technology if they are to draw high-school dropouts and retired persons into cyberlearning.

In a dynamic growth period such as we face now, the drive to implement cyberlearning will benefit many students and institutions, but only if decision-makers tread the path thoughtfully and with their eyes open for wrong turns.

Dynamic Learning Patterns: Temporal Characteristics Demonstrated by the Learner

L. Roger Yin
LEARN Center/Graduate Studies and Continuing Education
University of Wisconsin-Whitewater
United States
yinl@mail.uww.edu

Abstract: This paper sought to identify learner-demonstrated learning patterns when undergraduate students were learning to use a computer-based presentation program in a multimedia learning environment without time constraints. Using analysis of patterns in time (APT), a methodology that can code event changes over time, the frequencies and the amounts of time of the five learning patterns were calculated. The data derived from the APT scores indicated two major findings: (1) The amount of time used by the participants ranged from 20 to 87 minutes. The amount of time spent did not predict mastery of the post test. (2) 'Following through error corrections', 'confirming actions', and 'trying new steps' were the patterns that did appear to predict mastery, and 'hand on mouse' and 'keeping up step-by-step with the video instruction' were indicators of learners' task engagement. The findings suggest that it is important to design flexible instruction to facilitate repeated, persistent, and successful practice in order to achieve mastery in a self-paced, computer-based learning environment, regardless of the amount of time spent.

Iotroduction

This study sought to investigate the existence of any significant temporal patterns of learner-demonstrated sequencing as learning styles that are related to the mastery of learning a procedural computer-based multimedia task.

The impact of how different learning styles affect human learning has concerned educational researchers for decades (Bruner, 1966; Gagné, 1967; Kolb, 1984; Wang and Walberg, 1985; Tobias, 1981, 1987). According to Cronbach and Snow (1977), learning style can be used to predict what kind of instructional methods or strategies would be most effective for a given individual and learning task. Such attempts to discover the predictors for content mastery were typified in Aptitude Treatment Interaction (ATI) research. In ATI studies, aptitude was defined as any learner characteristic related to instructional outcome, and treatment was defined as any variation in instruction to the learner (Cronbach and Snow, 1969). However, research to date on this problem has not identified many robust relationships between learning style and instructional method that are needed in order to generalize the assignment of instruction to different learners (Snow, 1989). Could this lack of robustness be caused by overlooking the means in favor of the ends of learning? Or perhaps the notion of aptitude needs to be defined differently when the means of learning (or learning process) is considered as a critical component in a learning experience.

Frick (1990; 1992) indicates that one of the fundamental problems of ATI is that the linear model approach (LMA) employed by ATI cannot explicitly demonstrate the different means of learning because the LMA was designed to estimate parameters of mathematical models and is not adequate in dealing with occurrences and relative frequency of temporal events. LMA is best for explaining the relation between two or more independently measured variables, but it cannot measure the frequency or duration of occurrences of a temporal path (Frick, 1983). This observation directly implies that there is a need for a methodology other than LMA when we investigate the temporal patterns in a learning process, especially with a concurrent attempt to examine aptitude in a different way.

Learning takes time. Learners take different amounts of time to perceive information in order to acquire knowledge. Knowledge is actively constructed through temporal sequencing of meaningful interactions between the individual and the learning context (Piaget, 1973; Dewey, 1916; Bruner, 1973; von Glasersfeld, 1991). But how can we move the learning-styles research away from the instruction-centered "how one should learn" to the learner-centered "how one does learn"? In order to make instructional systems more adaptive, researchers need to put more emphasis on learner-demonstrated learning styles, where the relationships between the sequencing, time duration, and nature of the media should be carefully examined. This need is especially important now that multimedia, productivity software programs, and the explosive growth of the Internet have entered our educational settings and homes (Nielsen, 1995), and the technological capabilities have caused us to reconceptualize the learning process and to design new instructional approaches (Duffy and Jonassen, 1992).

To understand the need to redefine learning styles, it is necessary to comprehend the nature and limitations of conventional learning styles. Sewall (1986) compares four popular instruments to measure learning styles: the Myers-Briggs Type Indicator (Myers, 1962), the Kolb Learning Style Inventory (Kolb, 1976), Canfield's Learning Style Inventory (Canfield, 1980), and Gregorc's Type Indicator (Gregorc, 1984). He finds that all of these instruments fall short generally in four areas: (1) no appropriate normative base for the valid interpretation of scores; (2) limited validity due to construction problem with the instruments; (3) reliability estimates are unstable, though one can argue that the dynamic nature of learning style makes high test-retest reliability unnecessary; (4) the normative frame of reference makes the interpretation of scores very difficult. Among his suggestions for future research, one suggestion particularly interests the present writer:

"Future research could also explore the issue of whether an individual's preferred learning style is modified by the educational environment. For example, do adult students learn better when instruction is adapted to their learning style preferences? Can people be trained to adopt a particular learning style? Do learning styles remain stable over time in the adult population? Does a significant change in life situations result in changes in learning styles?" (p.61.)

It is interesting to notice that all four of the above-mentioned learning-style instruments use lists of verbal statements or different visual forms prepared for people to choose or rank. This isolated "one size fits all" approach is decontextualized and artificial, and apparently biased on language skills and cultural backgrounds. The predefined assessment tools require people to fit in the limited and selective choices with "I think this is who I am" or "I think this is what I will do or how I will react," which may not predict how one actually reacts to or interacts with a problem in a specific learning situation. This predetermined and convergent assessment approach may be the fundamental reason that only limited reliability and construct validity have been found in existing learning-style studies.

Maybe, as Sewall suggested, human learning styles are constantly modified by the educational environment and social context and are too dynamic to measure on a predetermined and predictable scale. This notion leads the present writer to believe that to survey fully the dynamic nature of learning styles, rather than using artificial instruments, we can observe and faithfully record the event changes of a learner-demonstrated process over time. In other words, the result of this study may not verify that learning style is a stable trait (Bateson, 1979).

Researcb Questions

1. In the midst of the information explosion, multimedia has become the new learning environment. Learning how to interact with multimedia-based information or instructions has become our daily experience. It is important to note that multimedia is a combination of three forms of content: (1) abstract (e.g., verbal -- either text or audio -- explanation in a computer program window), (2) iconic (e.g., the screen capture of a computer program window printed on paper), and (3) concrete (e.g., the actual computer program windows displayed on a monitor screen). The main questions addressed in this study were as follows:Given the choice of instructional materials in different forms of content, what learning sequences are selected by the learners?

1.1. If the sequences differ, how do they differ?

1.2. Are any of these sequences especially likely to result in overall mastery?

1.3. Is there a difference in the amount of time spent learning for those learners who achieved mastery and those who did not?

In order to increase both reliability and validity in identifying the learning patterns (Denzin, 1970; Foreman, 1948), a triangulation method was used that involved observation of the learning process and think-aloud interview. "Triangulation" is to use multiple methods in data collection (Denzin, 1970). Merriam (1988) indicates that "methodological triangulation combines dissimilar methods such as interviews, observations, and physical evidence to study the same unit." An observation system designed and based on the analysis of patterns in time (APT) approach was used to code how and how long students use and switch the instructional materials, and their engagement during the processes of learning. Both the learning processes and the think-aloud interviews were recorded on videotapes for examination and analysis.

Twelve participating students from a midwest regional university were selected through a screening process using Kolb's Learning Style Inventory (Kolb, 1976) where three students were selected extreme cases in each of the four learning styles identified by Kolb (converger, accomodator , diverger, and assimilator). The participants were expected to create three electronic slides using Astound, a multimedia presentation software, during the learning process. They were told that there was no time constraint and that they could freely use the printed jumpstart instructions, the video demonstration parallel to the printed instructions, and the user manual and tutorial. They then created a fourth slide without instruction as the post test. Learning sessions were recorded on video, and participants subsequently watched their own videos and were interviewed using think-aloud methodology. Multiple observers watched the videotapes of the learning performances for patterns of interaction, which were illuminated by the think-aloud interviews.

In this study, the interview was semistructured. The interviews followed the observations, hence the interviews supplement and complement the outcomes of the observations, rather than forming a different set of data not related to that from the observations. The questions asked were open-ended so the students could explain fully and interpret any specific events that occurred in their learning performance.

As soon as the raw data from the interviews were collected, the data gathered from both the observation and the interview on each student were arranged into one case for analysis. As Merriam (1988) suggests, the "simultaneous analysis and data collection allows the researcher to . . . develop a data base that is both relevant and parsimonious."

Next, the data collected from both the observation and the interview were sorted into any repeated patterns that are common to more than one person or identifiable categories or themes. Some patterns and their variations were spotted faster than others. Some unexplainable events or sequences from the observation were explained when data from the interview were reviewed and compared. This step was repeated until all 12 cases were analyzed. Then, an analysis to reduce and refine the categories or patterns among the cases was conducted.

Result

The narrative temporal descriptions of each of the 12 cases were compiled. The descriptions included answers to the following questions: Who was the person (age, gender, race, academic major, Kolb's learning style, mastery of the post test, prior computer experience). What did s/he do with the instructional materials during different parts of the learning session? What comments (direct quotes from the think-aloud videos) did the person make about what s/he was doing? These thick descriptions (Lincoln and Guba, 1985) illustrated how the participants actually interacted with the instructional materials during the learning sessions. These thick descriptions (Lincoln and Guba, 1985) illustrated how the participants actually interacted with the instructional materials during the learning sessions. To demonstrate the uniqueness of these participants, the following is a complete set of descriptions recorded from one of the 12 students.

Student F

Student F was a twenty-two-year old white male. He majored in Secondary Education and had had four years of computer experience. He was a converger (with a tendency toward active experimentation and abstract conceptualization), according to Kolb's learning style. He was judged a master of the post test. He spent a total of 42.5 minutes in completing the learning tasks and the post test.

Student F spent nine minutes on Task #1. He began his learning session by playing the video demonstration while reading the instructions. Student F is rather reserved but well-mannered. Of his choices of instructional materials, he said, "I didn't mind it. I like to have something to follow along with [the printed instructions], and I can stop [the video] whenever I want, so that makes it a lot easier for me." When asked how he used the instructional materials, he answered, "I started by reading the [printed] instructions and watching the videotape step-by-step. But after a while, I was not even watching it, 'cause I know pretty much what to do by listening to it." He said of his reading strategy, "After a while, I was just reading ahead, and make sure that I wa instructions, "I could have gone faster", he said, "but I just wanted to cover all three [video, computer, and printed instructions] to make sure I am not doing anything wrong."

Student F spent eight minutes on Task #2. He continued to follow the video demonstration while reading the instructions. He noted that he did not use the manual, "I didn't use the book [the user manual]. It was kind of complicated. Your language may not add up to the technical language they use. It is better to have these kind of materials [the printed instructions] that are more specific." He said of recovering from a mistake, "When I made that mistake, I was not watching the video. I just remember how to put a 'Next' button and I just did it." On how he checked with the instructional materials, he noted "After a while, I was just checking [with the instructions], though I wouldn't go word for word."

Student F spent nine minutes on Task #3. He continued to follow the video demonstration while reading the instructions. He said he had his hand on the mouse because "I think I was just getting ready for the next step." When asked what if he were not given the printed instructions, he replied "I wouldn't have read the instructions if I didn't have it. Since I had it, I used it anyway for checking." When asked which instructional format he liked better, he answered, "I would recommend the video because you can see the actual mouse movement, for example, to click on a certain push button or menu

Student F spent 16.5 minutes on the post test. He explained how he created the forth slide without the instructions, "Now without the video I am going a little quicker. Basically when I use the computer I just do it; if I mess up, I can always go back." On trying new things and recovering from error, he said "There I picked the frog [an animation object] and made the frog box too small, but I know how to make a box bigger so I made the frog the size I want."

When Student F was asked to describe his own learning style, he answered, "I like it being hands-on, and being able to see what I am doing. I don't like just to 'sponge in' and dump it on paper

In a careful review of all the think-aloud interviews in which the learners answered open-ended questions to explain their learning performances while watching the video recording of their learning Astound, five learning patterns emerged: (1) following through error correction, (2) confirming actions, (3) hand on mouse, (4) keeping up step-by-step with the video instruction, and (5) trying new steps. Using analysis of patterns in time (APT), a methodology that can code event changes over time, the frequencies and the amounts of time of the five learning patterns were calculated. The data derived from the APT scores indicated two major findings: (1) The amount of time used by the participants ranged from 20 to 87 minutes. The amount of time spent did not predict mastery of the post test. (2) 'Following through error corrections', 'confirming actions', and 'trying new steps' were the patterns that did appear to predict mastery, and the other two patterns were indicators of learners' task engagement. The findings suggest that it is important to design flexible instruction to facilitate repeated, persistent, and successful practice in order to achieve mastery in a self-paced, computer-based learning environment, regardless of the amount of time spent.

Suggestions to Practitioners

First and foremost, the implications these dynamic learning patterns brought to the instructional designers and teachers are:

(1) Ideally, there should not be any time constraints in a self-paced computer-based learning environment. However, in classroom settings and even in corporate training settings, there are time limitations. As teachers and instructional designers, we should try to mitigate the way the timed classroom hour shapes learning. For example, in a traditional classroom hour, Student H, a master who took 87 minutes to finish the task, would have failed to master the task if she had had to stop after 50 minutes. We need to develop new ways of structuring the time of the class so that such failures would not be built into the classroom framework. Nevertheless, the immediate value of self-paced learning will be outside of the classroom where the learners or trainees can determine or have control over the time they use to learn the tasks.

(2) Those learners who have difficulty with following through error correction may have problems with a lack of lower-level computer skills. The present writer recommends that under such circumstances that the instructional designer needs to develop a mechanism to detect the problem quickly and refer the learner to simple optional lessons on the conventions of the operating system (e.g., Windows 95 in this study) and the basic features of the application software program (e.g., the tools featured in Astound in this study).

(3) If those learners who choose to use exclusively the text-only printed instructions and have difficulty finding the features, tools, push buttons, or have difficulty finding "where they are" from just a verbal description, then if space and format allow, the related graphical icons of the tools and the appropriate screen captures should be added to the printed instructions.

(4) Making the printed (verbal) and the video versions of the instructions as well as the computer with the software program available as options *at the same location* can accommodate most learners' preference in terms of forms of content and sensory modalities.

(5) For those learners who like to try new steps, the learning lessons should be flexible. However, for those who do not like to explore new things, more structured jumpstart lessons at the same or at different levels of complexity should be provided.

(6) Many participants in this study strongly suggested that more "context sensitive" hints or notes should be made available on both the printed and video instructions because the just-in-time hints or notes given immediately before or after the "problematic spots" helped some learners recover from errors quickly without getting frustrated. Therefore, it is important to observe where in the lesson learners tend to have problems with something, then design and position the "anticipatory fee

Discussion

In this study, there were five learner-demonstrated patterns identified in a self-paced environment in learning to take part in a computer software program. Although generalizations cannot be made for all people in all kinds of learning because of the relatively small and selected sample, the trends found in the data do suggest that a number of these learning patterns would be predictive of mastery in procedural learning. Future studies with a larger randomly-selected sample size will further test the character of these trends.

This present study used Kolb's Learning Style Inventory (LSI) as the screening tool to select samples because the LSI is a popular instrume
weaknesses as a learner" (Kolb, 1976) and used widely for career predictions. Comparing the activities from the emerging learning patterns identified in this study with Kolb's four learning abilities, we can draw some parallel relations between them: reading printed instructions is an example of abstract conceptualization (AC); watching a video demonstration, an example of reflective observation (RO); doing the steps as described in the instructions, an example of concrete experience (CE); and trying new steps, an example of active experimentation (AE).

Kolb's learning styles are generated from two combination scores (AC - CE and AE - RO) that indicate the extent to which an individual emphasizes abstractness over concreteness and action over reflection. However, the similarities between Kolb's learning styles and the identified learning patterns end here. One fundamental difference between these two is that Kolb assumes the learning styles are stable personality traits, whereas the learning patterns identified in this study are dynamic in nature. For example, while student F was designated as a converger with tendency to be abstract and active, according to Kolb, he actually demonstrated in his learning performance that he engaged in all four learning abilities over time. Student F was watching the video demonstration (reflection) and following each step as it was described on the video (concreteness). He also frequently checked with the printed instructions to see if he did the steps right (abstractness). After getting more familiar with the computer program, he started to try new steps that were not included in the instructions (action). Over all, Student F showed a dynamic learning sequence that involves several learning patterns that even he himself could not have predicted or repeated.

In the present study, the major finding is that regardless of the amount of time spent, repeated, persistent, and successful practice tends to lead to the mastery of the post test. This finding echoes the result found by Sze (1988) that repeated masteries during practice strongly affect student learning achievement and attitude in an adaptive computer-guided practice environment. Also, it concurs with the Academic Learning Time (ALT) research reported by Berliner (1979) that when students spend more time engaging in a particular curriculum content area, they are more likely to attain higher academic achievement. It is important to note that the above-mentioned findings strongly support Carroll's (1989) argument that aptitude is primarily a measure of time required to learn. This argument is in contrast with the classic models (based upon theories of intelligence) in which all learners are given the same amount of time to learn, and the focus is on differences in ability.

Does the labeling of links assist user orientation?

Rolf Zajonc & Lutz Schön
Humboldt-University

10115 Berlin, Germany
zajonc@physik.hu-berlin.de
www.physik.hu-berlin.de/ger/gruppen/didaktik/a06.htm

Abstract: Hypermedia learning material often makes broad use of links to information which goes beyond the learning objectives. But instead of being additionally motivated some students rather feel too much asked of. Within the Lilienthal project (www.pilotschool.net) links that don't follow the linear navigation are labeled with respect to their relevance for the learning objectives. First evaluations prove that the students welcome this assistance.

Introduction

"Information overflow" or "lost in hyperspace" are keywords, which also are frequently used to describe the difficulties of students using hypermedia for learning purposes. Indeed they give a good impression of what may hinder students from enjoying the new technical possibilities offered by the internet in contrast to their teachers expectations. When creating webpages instructors believe they can motivate their students by offering many links to further interesting or related aspects on the specific subject matter. But e.g. many lecturers report, that rather the opposite effect is shown by their students: learners tend to complain about the number of webpages they are supposed to visit (Dunlap 1999).

The problem faced is, that while the lecturer wants to offer the students the best chances to learn the subject matter as well as possible, the student also has in mind, that he needs to achieve certain learning objectives within a certain amount of time, e.g. to be prepared on time for an examination. Consequently students feel overwhelmed and frustrated by the amount of information, because they cannot differentiate between more and less important links as their teachers can. One possible solution to this problem might be the labeling of the links according to their relevance for the required learning objectives, e.g. by the use of small icons in front of links.

Labeling of links according to relevance

This directly leads to the first question: How to decide on the relevance of a link? The answer can be easy, if the creator of the webpages and the corresponding examination responsible are the same person. But in many cases the learning material is programmed by a team whose members can have different opinions on this question. As this also affects the pages' content in general, it is necessary, that the complete team agrees on a set of well formulated (e.g. Mager 1978) detailed learning objectives before the actual programming takes place. Afterwards the links can be labeled with respect to these detailed learning objectives.

In order not to confuse the students within Lilienthal it has been decided to restrict the labeling to three icons:

-***mandatory***, e.g. a link leading to a formula which the student must know by heart;

-***recommended***, e.g. a link leading to an interesting example which illustrates the effects of the formula in a certain context; or

-***nice to know***, e.g. a link leading to an abstract about how this formula had been discovered historically.

Of course it still remains the student's decision whether he follows a link and for how long he stays on the corresponding pages.

Research

Hypermedia material for roughly 80 hours of learning time has been distributed to pilot students of four European flightschools. The material had been programmed after a Delphi-process (Linstone & Turoff 1978) which lasted one year, during which several subject matter experts of all involved flightschools had discussed and finally agreed on a set of detailed learning objectives, each describing 5 minutes of learning time. On this basis, the links within the material have been labeled as described above. The number of links vary per module (9 DLO in average).

At this point in time (March 2000) evaluation of the various data (tests, questionnaires, protoquols) has just started. A first evaluation of 208 questionnaires on 11 different modules (average 45 minutes) not only proved that the big majority of students found the labeling of links useful (compare figure 1), but also that there is a strong correlation ($p < 0.01$) to the statement "the module is easy to operate". A reasonable interpretation of this correlation is that those students who made use of the additional info of the labeling icons, also felt they had a better control in general.

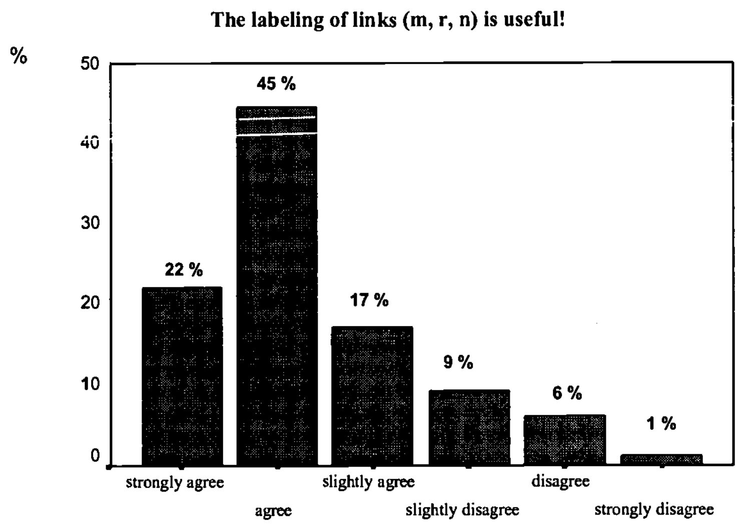

Figure 1: Evaluation of 208 student questionnaires on 11 different modules for the statement *The labeling of links is useful!*

Nevertheless further investigations are required, e.g. because in the pre-evaluation (in total 19 students) 14 out of all 17 students who marked "(strongly) agree" almost immediately added "...but still you click on every link anyway". This shows a well known behavior of hypermedia users, who only have little navigation experience. The assumption is, that the labeling will have a stronger influence on the 'click or no click'-decision in the long run.

In this context, although in our case the pilot students certainly form a rather homogenous group (typically male, age 19-23, open-minded for technically related matters, good marks in physics and mathematics), it is still expected, that students are influenced differently by this labeling. E.g.

A students still click on every link,

B students select recommended and in particular nice-to-know links according to the indicated topics,

C students avoid most recommended and all nice-to-know links.

In addition it might well be possible, that a student changes his attitude in the courses process. As has been mentioned before, in particular novices might rather show A behavior, but after a while they are expected to realize, that they need to work more efficiently and become B or C students.

But the labeling should not only influence the decision whether to click but also the navigation on the following pages. A student should be more likely to really *explore* a webpage if he knows its content belongs to the mandatory level. In contrast he might show *scanning* navigation (Canter, Rivers et al, 1985) if he knows that he needn't follow the link before at all. Since so far almost no experiences are reported in this context, these are just reasonable assumptions, which need to be investigated.

SHORT PAPERS (Work in Progress)

When is an Interactive Learning Scenario a Matter of Interface Design?

Christian M. Adriano, Adriane M. Adriano, Ivan L. M. Ricarte
State University of Campinas, Brazil

Interaction is an important feature a learning activity must promote. Parker (1999) outlines benefits provided by interaction: "Understanding and long-term internalization can only be acquired by communication, reconstruction and reconciliation of information; interaction enables socialization, promotes motivation, and learning commitment; interactive processes foster comprehension and consensus on universal truths".

In previous research (Adriano et al.1999), we implemented a computer supported learning scenario by producing content, modeling evaluation, and choosing a proper pedagogical orientation. Our effort resulted in the first version of the CALM platform, which implements a learning scenario inspired by the Goal Based Scenario approach, provides an intelligent tutor, and hosts material for learning Java. In order to guide further effort on interaction, the following problem was posed: When is an interactive learning scenario a matter of interface design? We propose two situations in which developing interactive learning scenarios incurs in interface design. First, when concern fits on one of the items proposed by Marcus (1994): Mental and Navigation Models, Appearance, Interaction, or Metaphor. Second, when the learning scenario, implemented by the resulting interface design, must accomplish complementary definitions for the concept of "interaction".

Metaphors are fundamental concepts communicated through words, images, and sound. Mental models are data structures, functions, tasks, roles, jobs, and people in organizations of work. Navigation is the process of moving through the mental models. Interaction is all input-output sequences and means for conveying feedback. Appearance relates to visual, verbal and acoustic information.

The designed metaphors (Adriano et al. 2000) were annotation, document, and annotation-place. The design of the interaction item resulted in three annotating paradigms represented by specific annotation-places: Bridge, Inline, and Tree. The Bridge place represents the idea of annotating as adding links. The Inline place supports the paradigm of writing over the text and having the annotation content visible. The Tree place organizes annotations in a newsgroup-like fashion. The mental model comprises the annotation-place model and organization of roles. In the former, a document may contain many annotation-places and an annotation-place may contain many annotations. The organization of roles depends on each learning scenario specification. The navigation model comprises resources to manipulate metaphors. Such resources correspond to: annotation editing interfaces, a search tool, a document composition tool (annotation-places are implemented as applets within Web pages), a tool for repositioning annotation-places due to changes in the original Web page, and a tool to generate workbook-like compilation of annotations. The appearance item relates to types of annotations and annotation-places. The annotation metaphor has four visually different types: doubt, suggestion, commentary and mark.

The discussion scenario comprises theme presentation, individual annotation, group annotation, and discussion summarization. Roles are "moderator" and "commenter". The theme presentation is a notification that the Web page hosting the text for discussion is available for commenting. After notification, starts the individual annotation phase in which commenters read and make personal annotations on the text. In the next phase commenters may request the annotations of their peers and discuss opinions and acknowledgements, which involves commenting on each other annotations. When discussion is finished, due to a deadline or a common agreement, the moderator compiles annotations into a second text elaborating a summary of the discussion.

The co-authoring scenario includes goal definition, authoring, reviewing, voting, and consolidation. Roles are "co-author", "reviewer", and "author". Co-authors annotate using inline annotation-places and may define when an annotation is ready to be seen by others. Reviewers may comment on annotations made by co-authors. As a co-author decides that an annotation should become part of the underlying text, he/she requires the author to consolidate the annotation. If the author agrees, the annotation is incorporated to the text. The author can also ask for co-authors to vote whether an annotation should be consolidated. An annotation has states such as ready, removed, in consolidation, being voted, and not available.

Some interaction definitions were collected from Vigotsky, Habermas, de Certeau, and Chartier. Vigotsky (1978) deals with the cultural dimension of learning. Apprenticeship is result of interactions among historical subjects and the world. Signs and symbols are the condition for these interactions. People, instruments and signs mediate relations between a subject and physical/social environment. Signs correspond to a representation of reality and refer to remote times and spaces. Interaction is conceptualized as relations among historical individuals, signs, and instruments. Such definition is satisfied by interfaces that relate individuals as role players, signs as metaphor representations and instruments as tools of the navigation model.

Certeau (1974) states that interaction is based on a metaphor of landmark and on distinctions between place and space. In short, place is static and permanent, while space is dynamic and transient. Landmarks delimit regions (spaces or places), being also classified as dynamic or static. Static landmarks are frontiers, like rivers and fences, delimitating places. Dynamic landmarks are bridges, like doors and windows, delimitating spaces. Bridge-like landmarks represent encounters of action. Moreover, there will be so many bridges as the number of "interactions". Interaction is defined as a bridge separating spaces of action. Such concern inspired the design of annotation-places, whose types provide different bridging between the document space and the annotation space.

As quoted by Prestes (1997), Habermas argues that the communicative action has a kind of anchor constituting background knowledge. Such knowledge fosters interpretations for participants of an interaction. The background knowledge relates to a world of life (*Lebenswelt*), the horizon on which we move. It is pre-scientific, intuitive, not expressed and not questionable. It constitutes itself not only by cultural convictions, but also by institutional organizations and structures of personality. Habermas uses the daily communicative praxis to guarantee the symbolic reproduction of three spheres; culture, society, and personality. Culture refers to knowledge acervus, over which we formulate interpretations to understand the world. Society refers to legitimated organizations that regulate our bindings with social groups. Personality refers to competencies that enable subjects, capable of language and action, to take part in an understanding process. The following citation of Habermas clarifies these three aspects: "In respect to the functional aspect of understanding, the communicative action promotes tradition and cultural renovation. In respect to coordination aspects, the communicative action promotes social integration and creation of solidarity. In respect to socialization, the communicative action promotes formation of individual identities". Interaction is a space of conflict between a pre-comprehension of world of life and the communicative action. Therefore, when and where interaction happens, the stability of the world of life is disturbed by arguments of the communicative action. Annotation interfaces enabling discussion was a mean to accomplish such vision.

Following a historical point-of-view, Chartier (1997) provides a study of how mankind has been interacting with and by means of the written letter. Medium has changed from papyrus, to codex, to Gutenberg press, and, nowadays, to digital text. Each medium required a proper interaction paradigm suggesting that interaction be also defined by the enabling technological support. In other words, medium defines interaction. Such concept for interaction was accomplished by supporting audio and written media for annotation.

In addition to the five components proposed in Marcus (1994), we suggest a careful study of the interaction concept. The presented discussion stems from project meetings between educators and software developers. A recurring problem faced was the lack of consensus on concepts, accompanied by concerns of presupposing things that needed better understanding before implementation. Interaction conceptualization is one these concerns. We hope the ongoing research will collect further insights to the design of interactive learning scenarios as a cooperative entrepreneurship of educational and computer scientists.

An Interactive System Model of an Online System for Teaching & Learning Developed as a Scoping / Costing Instrument

Anne A'Herran, Educational Development Adviser (WWW), Teaching and Learning Development,
James Cook University, North Queensland 4811, Australia.
anne.aherran@jcu.edu.au

Abstract

Although there are strong reasons for purchase of an off-the-shelf system for online course delivery (including the competitive advantages of reliability, the comfort of a large client base and scalability), many universities develop a system themselves. These home-grown systems are often more responsive to specific needs. When James Cook University undertook to investigate available systems for university wide online course delivery it was important to explore costs of building a system using university resources. To this end a system model was designed as an interactive diagram reflecting each part of the system in prototype http://www.tsd.jcu.edu.au/jcudevelop/jcuproto/jcuonline The model is both an innovative example of organisational design method and a useful means of testing user pathways through the system, (use-case), which can assist costing and project management of the development of such a system.

As part of the search for the most suitable system for use at JCU we set out to determine the costs of building a system using university resources:

- there was a high level of interest in the JCU community;
- the possibility of economies of production;
- a collaborative venture of this kind with the potential for cross-institution partnerships could be of value to the university in the future.

To this end a system model was designed as an interactive diagram reflecting each part of the system, in prototype (at http://www.tsd.jcu.edu.au/jcudevelop/jcuproto/jcuonline).

The model is both an innovative example of organisational design method and a useful means of testing user pathways through the system, (use-case), which can assist costing and project management of the development of such a system.

Discussions were held with the schools of IT and Computing Science. The interactive system model was felt to be helpful in this process in that it provided, by visible and testable means, a common understanding of the scope and direction of the exercise. Costing was based in staged development from base level, adding functionality as we saw a need.

There was found to be no case for developing DIY for immediate implementation:

- the real costs of DIY infrastructure are high for a one-off development which is not amortised over other products;
- time of development has to be compressed to keep pace with user needs and technical innovation: to compress time requires commitment of personnel which increases costs;
- when a university implements its own system, support for users becomes an internal budget decision not externally (market) driven: support is therefore subject to internal budgetary pressures rather than the wider driving client base.

Validating a Theory-Based Design for Online Instruction: Aligning Tool Use and Learning Outcomes

Arshad Ahmad
McGill University
1455 DeMaisonneuve
Montreal, Quebec. H3G 1M8
arshad@mercato.concordia.ca

Abstract: This paper provides a theoretical framework for the design of a successful web-based course in Personal Finance. Using an open learning model based on constructivist principles that draw from the literature in cognition and the social sciences, this paper sketches an instructional design model and specifies online tools that mediate between course objectives and desired learning outcomes. In order to validate the model, data generated from tool use and from student performance will be analyzed using confirmatory factor analysis.

Mixed Messages with Multimedia

A growing body of research is exploring the learning effects of multimedia designed environments. Some of this research has attempted to incorporate educational concepts in the design, process and implementation of course production in technology-rich platforms. However, the results are mixed. According to *The No Significant Difference Phenomenon* (Russell, 1999) which is based on 355 research reports, summaries and papers, the conclusions mainly indicate that the learning outcomes of students using technology enriched courseware are similar to those of students who participate in conventional classroom instruction. Yet, universities are allocating substantial resources towards the development of distance education courses and programs (Brahler, Peterson et al., 1999) to increase access to learning, with the hope that the quality of education will be damaged little, if at all (Ehrmann, 1999) Questions and concerns relating to technology integration are being raised, but as yet have had little systematic impact on the policies that guide educators, administrators and practitioners (Merisotis and Phipps, 1999; Welte, 1997)). Faculty realize that there are certain benefits of technology-based distributed learning environments, but put up considerable resistance to the development of such environments (Rickard, 1999).

Mixing Cognitive and Social Science Approaches

This working paper presents a theory-based design of an undergraduate web-based course in Personal Finance with the aim of addressing some of the issues addressed above in the context of better understanding student learning. Concerns relating to technology integration in educational practice, and technology's intersection with learning theory are addressed in a design framework that aligns learning objectives, course activities and assessment methods. This alignment simultaneously considers the selection of online learning tools that mediate between design components for Personal Finance. The selection of learning tools also plays an important role in terms of how they will be meaningfully used by students, and how they will affect student performance.

Web-based instruction that is designed on accepted theoretical principles in cognitive psychology opens new doors to designers, learners and practitioners. This is simply because we know very little about best practices arising from the design of courseware that primarily uses this medium. However, in contrast, there is an abundance of theoretical studies in the cognition literature that have increased our understanding of competence in understanding a given discipline (See for example, Anderson, Corbett et al., 1995; Ausubel, 1968; Hatano, 1996; Means, 1993; VanLehn, 1996; and Winn, 1990). Similarly, studies from the literature in social sciences have proposed interactive socio-cultural contexts as a basis for understanding how learning can be constructed, scaffolded and facilitated (See for example, Bandura, 1986; Brown, Collins et al., 1989; Derry and Lesgold, 1996; Lave and Wenger, 1991; Moore, 1994; Shuell, 1993; and Richey, 1994. In his 1999 AERA Presidential Address, Alan Schoenfeld describes the split between cognitive and social science research with references to studies in cognition that excel in fine-grained data analysis but suffer from tunnel vision and points to as many sociological studies that are rich in scope but are weak with respect to validity and reliability constructs. His suggestion to bridge the gap was to "build something to see if it works and then study the hell out of it".

This study seeks to validate a non-traditional design based on theoretical findings from the cognitive and social sciences literature. The world-wide-web is an obvious choice as the platform for building a design prototype because learners recognize that it is more accessible and convenient than traditional opportunities afforded in the classroom. Combining the web platform and a theoretical basis into a prototype design becomes meaningful when specific learning goals arc specified with evidence to link these goals with performance outcomes that are assessed. These links are critically explored and are the focus of this study.

Challenges in the Design Process

The term technology is used broadly to refer not only to tools but also processes and is closely identified with the Greek form *techne* (art, craft, or skill), which was closely associated with *episteme* (systematic or scientific knowledge). Its educational meaning is historically derived, bound by specific psychological theories and philosophical underpinnings (Saettler, 1990). Visions of technology look very different depending on the explicit theories of learning that guide their design and implementation. According to The Cognition and Technology Group at Vanderbilt (1996), the challenge for instructional design based on significant technology integration is that learning theory, educational practice and technology interact with each other. To understand the role of technology, one must examine a simultaneous intersection with student learning and educational practice. This challenge is increased since all three areas have seen dramatic change in the past ten years. Thus, changes in theories of learning affect uses of technology, but new technologies such as the world wide web also make new kinds of interactions possible and hence affect theories of learning (Kozma, 1994; Saloman, 1993). Knowledge acquisition in constructivist environments engages learners in drawing meaning from multiple perspectives and through collaborative efforts. Engagement in real world or authentic tasks provides a context for the learner to construct meaning from his/her experiences. Thus, learning is situated in a community of learners who construct personal meaning through dialogue and socialization (See Brown, Collins et al., 1989; Jonassen, 1998; & Wilson, 1995).

Sketching the Design Components

Given these perspectives, different views of how humans learn and how designers approach instruction are incorporated under the umbrella of knowledge acquisition and knowledge construction. In addition, aspects of situated cognition, which emphasizes social and ecological interactions is also included. Parts of the design relies on an information processing view emphasizing course content that hierarchically structures the sequence of information. Using Hannafin, Land et al.'s (1999) open learning model which emphasizes diversity and choice, course material was selected to reflect a variety of print-based, multimedia and interactive web-based tools that could best enable the learner to attain the learning goals set for the course. The importance of constructive alignment between different design components is emphasised by Biggs (1999); they become inextricably linked, so that the course becomes greater than the sum of its parts. These components include a *textbook*, *short vignettes* with practionners who introduce each topic, *simulations* that forecast your net worth, or your tax bill, *interactive practice tests* including pre-tests, review exercises, short cases, etc and *communication software* that allows for threaded discussion, chats, critiquing, posting and other activities consistent with best practices in effective learning communities. Technology has been nested within a constructivist framework to raise the intellectual, social and ethical standards of learners, by empowering them to question, participate, and practice authentic issues in personal finance. Jonassen, Davidson et al. (1995) summarize this approach:"...learning is necessarily a social dialogical process in which the communities of practitioners socially negotiate the meaning of phenomena" (p.9).In addition, feedback opportunities are provided by experts (the instructor as well as practionners) to ensure accurate knowledge acquisition. Finally, communication strategies are designed to facilitate elaboration of content and solicitation of responses that reflect what students are thinking. Here, the tools employed include interactive tests, e-mail and bulletin boards, as well as audio conferencing.

Data reflecting student use of designed tools and their performance on assigned tasks will be collected to confirm the validity of the design model. Evidence of learning using Bloom's (1956) taxonomy will reveal the general factors associated with the model. Path analysis will be used to confirm the relationship amongst the design components as they fit within the instructional design model.

Learning Strategies for Multi-Media Instruction

Mohamed Ally, Ph.D.
Athabasca University
1 University Drive
Athabasca, Alberta,
Canada, T9S 3A3
mohamcda@athabascau.ca

Abstract: Multimedia instruction must follow instructional design principles that are based on learning theories. This session will share an effective model for designing learning materials and will describe the strategies that should be used when designing multi-media learning materials.

Pre-instructional Activities

Before teaching new materials to students, the lesson must overview the materials so that students can form a mental set for the materials and become motivated to learn the materials. The different types of pre-instructional activities include content map, advance organizer, pre-test, learning objectives, and rationale.

Prepare Learning Activities

Conventional instructional methods tend to use passive instructional strategies. It is important to use strategies that will keep students active so that they will be motivated and will process the information in greater depth. To encourage active learning, it is important to use discovery strategies so that students can find out things for themselves. Instead of teaching a large amount of information to students, we should give students the task and then guide them to find and apply the information. Multi-media and on-line instruction are excellent methods to promote active learning.

Elaborative Strategies

To make the instructional process more effective and efficient, the lesson must provide activities for students to process the content at a deep level. The deeper the information is processed, the better it is learned or remembered. As a result, the instruction should contain elaborative strategies to help facilitate deep processing. Some common elaborative strategies are asking questions during the instruction, ask students to summarize segments of the instruction, requesting students to make their own notes, and asking students to underline or highlight important information. The elaboration process facilitates efficient storage in long-term memory. This is important since the ease of retrieval will depend on the way the information is stored in long-term memory.

It is known that when new learning materials are encountered, they are attended to and transfer to short-term memory storage. After entry into short-term memory, the information must be transferred to long-term memory immediately since short-term memory has limited capacity. As a result, students should be given the opportunity to elaborate on small segments of instruction so that the materials can be transferred to long-term memory immediately.

Presentation Strategies

Most instruction is done in an expository fashion where the learning material is presented in its final form to students. The most common expository methods are rote, inductive, and deductive learning.

The rote method consists of presenting the materials to students and then asking them to recall the materials as presented. For example, the lesson may present a rule and then ask students to recall it. The deductive method occurs when students are given a rule followed by examples to explain the rule. The inductive method involves giving examples on a certain rule followed by the rule. However, to make learning more efficient and effective, discovery strategies must be used. With the introduction of new instructional technologies and multi-media, it is possible to design instruction that contains discovery strategies.

Practice Exercises

Another important component of instruction is practice with feedback. After the presentation of the materials, students should be given the opportunity to practice what they have learned so that they can get feedback on how they are performing and at the same time prepare them for the final test in the lesson. In addition, the practice test acts as a good learning strategy since test questions usually consist of general ideas which act as cues to recall specific details and skills.

Summarize the Lesson

After the lesson is presented to students, they should be given a summary so that they can get a sense of closure for the lesson and gives a general review of the lesson.

Web-Based: Instructional Effectiveness

Nella B. Anderson
Western State College of Colorado
112 Kelley Hall
Gunnison, CO 81231
nanderson@western.edu

Abstract: Training preservice education students on the Internet requires the course to be more structured than would be required to teach the same course without an electronic component (Gillette, 1996). Education students have consistently expressed the need to see technology used by their university instructors if they are to use these tools effectively in their own teaching (Larson & Clift, 1996). Due to both a lack of suitable instruments and the importance of being able to assess web-course effectiveness, the authors developed the Web-Based Survey of Instructional Effectiveness (WebSIE) to meet this need. Forty-one students enrolled in a web-based course were given the WeBSIE prior to and after the completion of the course. Pretest to posttest comparisons showed students improved in their self-reported web-based skills and attitudes in the use of the internet, integration of the internet into instruction, general computer use/attitude and using a computer for communication. Future studies need to replicate these findings and investigate the effects of the integration of technology into more and varied teacher training courses.

The effective use of technology includes rethinking traditional forms of instruction. Instructors teaching online need to maintain the perspective that we learn best "with" technology rather than "from" it (Johnson, 1996). This perspective allows instructors to engage students in active (Copley, 1992; Reeves, 1996; Yakimovicz & Murphy, 1995), authentic (Copley, 1992), challenging tasks (Copley, 1992; Reeves, 1996), and collaborative efforts (Reeves, 1996; Yakimovicz & Murphy, 1995).

A computer-specific introductory course is usually insufficient in modeling for preservice teachers the use of technology as a tool for teaching and learning (Topp et al., 1994). Education professors from various disciplines must begin to use technology as a cognitive tool to mediate and transform the training experiences of teacher education students (Larson & Clift, 1996).

Instructional Design

Training preservice education students on the Internet requires the course to be more structured than would be required to teach the same course without an electronic component (Gillette, 1996). The structure that is embedded and remains consistent throughout each unit of study. The structure of an introductory special education course taught online will be elaborated on in this section by clustering the components into categories and providing a brief description of each.

1. Instructional Design Framework
   (a) Each unit of study is divided into six instructional steps.
   (b) Each of the six steps are divided into instructional components.
   (c) Reference numbers are assigned to each of the instructional components. The reference numbers are depicted using three digits separated by decimals (e.g., 2.3.4 represents Unit 2.Step3.Activity4). The reference numbers are used when discussing activities via e-mail, newsgroup, and/or chat.
   (d) Buttons are located at the bottom of each of the six instructional step pages so that students can go to the "next step" or return to the "unit index", which provides links to all six steps.
2. Curriculum Development
   (a) The curriculum is built upon the principles of active learning, cooperative groups, peer-mediated instruction, and content experts

(i) Active learning is integrated into the course through the use of interactive forms and case studies found on the Internet.

(ii) The class is divided into cooperative groups of two based on where students live and their educational major.

(iii) Peer-mediated instruction is used through the creation of student homepages and peer expertise pages. These pages allow students to share their work and ideas with each other.

(iv) Content experts are utilized by incorporating parents of students with disabilities and personnel in special education field in local public schools into the class discussions (e.g., e-mail, chat, and newsgroup).

(b) All activities taught in the traditional course on campus are incorporated into this online course through the use of e-mail, chat, newsgroup, electronic handouts, forms, and web sites.

Teaching in this virtual classroom in comparison with teaching in the traditional classroom requires much more learning and much less teaching (Peterson & Facemyer, 1996). The dynamic learning environment available online, which is expanding at exponential rates, provides opportunities for students to become explorers and discoverers (Gates, 1996).

Education students have consistently expressed the need to see technology used by their university instructors if they are to use these tools effectively in their own teaching (Larson & Clift, 1996). All students enrolled in this online course had completed at least one required computer-specific course prior to the beginning of this online course. The development of a survey of instructional effectiveness was developed by the authors to measure the effects of learning educational content through the use of web-based technology.

Web-Based Survey of Instructional Effectiveness

Due to both a lack of suitable instruments and the importance of being able to assess web-course effectiveness, the authors developed the Web-Based Survey of Instructional Effectiveness (WebSIE) to meet this need. Expert opinion from individuals with both academic credentials (Ed.D. or Ph.D.) and web-based course experience were sought to develop an original pool of 58 items. This pool of items was subjected to factor analysis. A five-factor model was adopted retaining 30 items: Use of the Internet (8 items); Integration of the Internet into Instruction (8 items); General Computer Use/Attitude (4 items); Using a Computer for Communication (5 items); and web-based Course Effectiveness (5 items).

Using this 30 item survey authors administered 313 to preservice education students and practicing teachers. Cronbach's alpha and split-half reliabilities were calculated for the five scales. Alpha for the whole 30 item instrument was .803, and the five scales were Use = .557; Instruction = .531; Computer Use/Attitude = .415; Communication = .653; and Course Effectiveness = .419. Split-half reliabilities for the five scales were Use = .762; Instruction = .750; Computer Use/Attitude = .726; Communication = .823; and Course Effectiveness = .672.

Forty-one students enrolled in a web-based course were given the WeBSIE prior to and after the completion of the course. Single-sample Dependent T-tests were performed on all five scales. An alpha level of .05 was used for all statistical tests. Four of the five scales were significant: Use, $t_{41} = 4.873$, $p < .001$; Instruction, $t_{41} = 4.143$, $p < .001$; Computer Use/Attitude, $t_{41} = 3.797$, $p < .001$; and Communication, $t_{41} = 2.401$, $p < .02$.

Pretest to posttest comparisons showed students improved in their self-reported web-based skills and attitudes in the use of the internet, integration of the internet into instruction, general computer use/attitude and using a computer for communication. These statistically significant gains in web-based skills and attitudes were noted after one education methods course that modeled the use of the Internet in instruction. Future studies need to replicate these findings and investigate the effects of the integration of technology into more and varied teacher training courses. Additional effects of the integration of technology into teacher training programs needs be studied after these preservice teachers become practicing teachers, focusing on how often and in what ways they integrate technology into their own teaching.

The Interaction and Psychological Distance in Educational Situations: Experimental View

Shaker Hasan Aradi
Institute of Education, University of Tsukuba, Japan
shaker@human.tsukuba.ac.jp

Abstract: This paper reports the findings of a study conducted with an experimental undergraduate-level class. It investigated the differences between learners studying with the teacher face-to-face and learners studying at distance in terms of three dimensions; ① learners' sense of distance, ② interaction, and ③ achievement.

Introduction

One of the most important innovations resulting from the remarkable advances in communication and Internet technologies is *'face-to-face at distance education'*, which is forcing us to adapt new definitions, theories and practices. Physical distance is no longer the limiting factor; *"psychological distance"* is. Drawing on Moore's work redefining "distance", "interaction" and "transactional distance" (Sewart, 1988 & Moore 1991), the concept of psychological distance (PSD) refers to how close the participants within the educational environment feel to each other in terms of emotional comfort and satisfaction.

As Holmberg (1988) observes "real learning is primarily an individual activity and attained through an internalization process;" thus, learning is the product of internal interaction between the learner's previous experiences and new information obtained from external interaction with the other components of the educational situation, including contents/media, other learners and the teacher/instructor/coach.

The present study focuses on this interaction within the educational environment, in terms of the *learners' sense of distance*" (SoD)[1], as a direct indicator of PSD. Specifically, the main objective of the experiment is to examine the relationships that exist between: a) "the learner's sense of distance", b) "interaction within the educational environment" and c) "learners' achievement".

The Study

Twenty-two (only the data from 19 participants was usable) Japanese undergraduate-student volunteers, from a women's university attended four seminars entitled "Introduction to Public Speaking" during spring, 2000. The participants were divided into two equal groups, matched for age and scores for English and Japanese language; a "*local group*" (LG), which studied with the teacher face-to-face and a "*distant group*" (DG), which studied with the same teacher at distance. An ISDN-based TV conferencing system was used to mediate communication between the two groups, so that they can study in different places at the same time. Achievement was evaluated by pre-tests and post-tests. The participants were asked to evaluate their "sense of distance" from others (i.e., the teacher, other learners in the same group and other learners in the other group) on a 5-point scale, with 1 indicating very close and 5 very far. The participants also recorded both how often they actually interacted with others, and how often they wanted to, as an indication of the interaction within the educational environment. The classes, as well as short interviews after each class to regarding technical aspects such as sound and picture quality, were also videotaped for further analysis and to improve the seminar contents.

[1] Sense of distance is contrasted with "real distance," as a measure of the distance learners feel to exist between themselves and other components of the educational setting, irrespective of the actual distance.

Findings

The differences between pre-test scores concerning the participant's knowledge of public speaking for the two groups were not significant (average scores were 4.5 and 5.22 for the LG and DG conditions respectively). The scores for the post-test were 16.4 for the LG and 18.66 for the DG, indicating significant improvements in knowledge concerning public speaking for both groups ($p < 0.0001$). The average scores for both groups also indicate that there were no significant differences between the two groups in terms of achievement at the end of the experiment.

In terms of learners' SoD to the teacher, the average evaluation rating for the LG condition fell from 3.166 after the first class to 1.7 after the last class. In the DG condition, this fell from 4.7 to 3.00. Although analyses (Wilcoxon Signed Ranks tests) indicated that these changes were significant ($p < 0.025$ and 0.015 for LG and DG respectively), further analyses (Mann-Whitney U test) also indicated that there were significant differences between the two groups after both the first and last classes. In other words, although the learners' sense of distance to their teacher declined significantly for both groups, those in the LG condition felt much closer to the teacher then those in the DG. Reviewing the videos for both sites, we found that although the teacher almost had the same amount of interaction with both groups during the class, he did spend more time talking and explaining to the LG both before and after the classes, and that he was able to give more individualized attention to the learners in the LG condition, which may have contributed in making them feel closer to him.

The data indicated no significant changes in the learners' sense of distance to other learners in the same groups at both sites, which might be due to the fact that the students came from the same university. Examining the learners' sense of distance to the learners in the other group, the evaluation rating fell from 4.62 after the first class to 3.00 after the last class for the DG condition (significant at 4.6% level). However, there were no significant changes in the SoD for learners in the LG condition. This might be due to the initial setting at the LG site, which did not allow learners at the DG site to see their counterparts at the LG site during the first class, which was adjusted for later classes.

The correlation between the learners' SoD to their teacher and the records of interactions was –0.287 (sig. at the .05 level). Although no significant correlation was found between the learners' SoD to their teacher and achievement, the learners' SoD was highly correlated (0.636 sign. at the .01 level) to how important the learners regarded the contents, and how much they felt they had learnt (0.496 sign. at .1 level).

Conclusions

The results of this study suggest that it might be very difficult to acquire the same quality of interaction with physically-distant learners, and that it, therefore, takes more effort in order to reduce their SoD compared to learners studying face-to-face. Despite this, however, the more learners interact with their teachers the closer they feel to them regardless actual physical distances. Moreover, as learners feel closer to their teachers, they tend to regard the study as more important and to feel that they understand it.

This study owes its completion to the support and assistance provided by several generous people. I am indebted to Dr. Morio Yoshie and Dr. Ichiko, Shoj from Institute of Education- University of Tsukuba and Noriko Kanakubo from Tsukuba Women's University for their valuable comments, kind considerations, supportive advices and guidance and more for there continuous encouragements.

I also wish to express my sincerest gratitude to all the people and organization that helped me in completing this experiment. Especially, my friends Josh Kirby who kindly taught and prepared all the materials for the classes and Vikash Chandra who help in the experiment's setting and speared no effort to make it happen.

A Generic Pedagogical Agent Architecture That Supports Conversational Authoring

Jeremy W. Baer and Steven L. Tanimoto
Department of Computer Science and Engineering

Abstract: Pedagogical agents offer great promise to improve the learning experience of students interacting with educational software systems. This paper describes work in progress on a generic pedagogical agent architecture and an authoring system to support the creation of custom agents by teachers and other domain experts using a natural, conversational metaphor.

The field of pedagogical agents is a recently emergent one which draws from previous work done in intelligent tutoring systems, autonomous agents, and educational theory (Johnson et al. 2000). Pedagogical agents have the potential to offer a wide spectrum of educational interactions with students, including opportunistic instruction, and have been shown to have positive affective as well as cognitive influences on students (Lester et al. 1997).

Several successful pedagogical agents have been designed for a variety of learning environments, ranging from skill-based training systems to more open-ended constructionist environments (Johnson et al. 2000). Currently, however, the task of building pedagogical agents is a non-trivial one which falls within the domains of researchers and professional programmers -- not those of teachers, curriculum designers, and other non-programmers. Authoring tools designed for non-programmers to create customized content for particular agents are under way, but little attention has been devoted to the question of authoring tools for creating customized agents, given a particular computer-based learning environment. It is to this question that we turn our attention in this paper. We will describe work in progress on a project which aims to allow teachers and other non-programmers to author customized pedagogical agents for interactive learning environments. We first discuss the design of a generic pedagogical agent architecture, suitable for use in constructionist learning environments. Secondly we discuss techniques we are developing to allow teachers to author agents based upon this architecture. We require that the architecture be suitable for constructionist learning environments due to their open-ended nature, which raises a greater challenge for the agent designer.

Our generic agent architecture (see figure at http://www.cs.washington.edu/homes/jbaer/pedagent/agentarch.jpg) is built around the Agent Control Module. This module is responsible for processing events received from the learning environment, updating its student and session models based on those events, initiating interactions with the student, and potentially sending commands back to the learning environment. The appearance and user interface aspects of the agent have been separated out into a distinct module. This allows for maximum flexibility in the appearance of the agent. Either the agent can appear in its own window, or the learning environment itself can implement this module, allowing the agent to appear within the main window of the environment, as do many of the existing pedagogical agents described by Johnson and Lester (Johnson et al. 2000) do.

The interaction between the agent and the learning environment consists of the agent receiving events from the environment and requesting state information from the environment or sending commands to the environment. It is up to the environment to define the set of events that will be sent to the agent, as well as the state and control commands that it wishes to expose. A distinguishing feature of this agent model is that we do not require the agent to have complete access to the state of the learning environment. While this can limit the information which the agent has to work with, it allows for interoperation with a wider variety of learning environments, all of which may represent their state in different ways.

While the Agent Control Module is the center of operations for the agent, it does not contain any built-in intelligence pertaining to any specific learning environment. Instead, it relies on the Agent Behavioral Control Description (ABCD) for this information. The ABCD is divided into four types of objects: potential student actions, agent interventions, pedagogical goals, and student concepts. Potential student actions are actions or classes of actions which the student might take within the environment, and which the agent should recognize. These actions are comprised of a series of events, each of which may contain a parameter sent from the learning environment to the agent. The sequence of events and their parameters can be generalized using regular expressions. Agent interventions may be of three distinct types - information presentation using text and images, agent-initiated dialog with the student, or agent-initiated intervention of arbitrary complexity by loading and executing an externally authored program. Pedagogical goals represent general learning objectives, for example, what the most important concepts are for a student to learn, what interaction styles to prefer, etc. Student concepts represent correct or incorrect conceptions that students may hold. Our notion of student modeling is based upon the work of Minstrell et al on educational facets (Minstrell 1992), and our student concept database is a facet base, in their terminology. The student model the agent constructs consists of a collection of student concepts; the agent infers these, and each is weighted with a confidence factor.

Since it is the Agent Behavioral Control Description (ABCD) which makes a particular agent unique, we must allow non-programmers to author it. Its rules are similar to rules in a declarative programming language. However, we do not want to require teachers to think like programmers. Our solution is to have the agent guide the author through the process in a natural, conversational manner. The agent directs the authoring process by asking a series of questions. As the author responds to these questions, the agent modifies the conversational flow and builds components of its ABCD, based on the author's input. In addition to direct question and answer, the agent utilizes generalization techniques from machine learning to allow for authoring by demonstration in some circumstances.

This authoring technique, which we call "conversational authoring", bears a resemblance to the command "wizards" which are found in a variety of applications. However, there are a number of factors that distinguish this authoring paradigm from application command wizards. One factor is that the interaction between the author and the system may be long-lived and span multiple authoring sessions. Because of this, a need exists for the agent to maintain continuity between sessions by being able to summarize the previous session and describe its current state to the author in a conversational manner. This self-description is also important for purposes of agent validation. The conversational authoring tool runs concurrently with the agent and learning environment, so the author can test the behavior of the agent at any point in the authoring process by using the environment from the perspective of a student. However, simply testing the agent may not provide enough validation that the desired ABCD structure has been created. The ability of the agent to conversationally summarize its state at any given point in the authoring process adds another tool that the author can use to validate the authoring outcome.

The work described in this paper is currently in progress. The generic agent architecture has been implemented in Java and integrated into a constructionist learning environment called PixelMath. PixelMath is a recent outgrowth of research at the University of Washington designed to teach mathematical concepts through digital image processing. Additionally, a custom agent has been built on top of the generic architecture by hard coding the ABCD in Java. We are currently in the process of implementing the conversational authoring tool, which will be tested for effectiveness by teachers familiar with the classroom use of tools like PixelMath. A complete description of this project, including current status, is available at http://www.cs.washington.edu/homes/jbaer/pedagent/index.html.

From "Learning-by-Viewing" to "Learning-by-Doing": A Video Annotation Educational Technology Tool

Ofer Bergman, Ruth Beyth-Marom, Ahuva Leopold, The Open University of Israel
Doron Hadar, Ben Gurion University, Israel
Amnon Dekel, Interdisciplinary Center, Herzliya, Israel
Synopsus@netvision.net.il

Abstract: Video films are particularly suitable as a way of experiencing the world because they provide a dynamic, although vicarious, encounter through sound and vision. However, the use of video films in their present, mostly passive, form, do not succeed in contributing enough to the learning process. SYNOPSUS was designed to cause a shift from the passive "learning-by-viewing" model to the "learning-by-doing" model while studying with educational films. By utilizing a simple user-friendly interface, the tool allows students to engage, on a computer, in active, reflective, and interactive learning with existing video films. The tool and some preliminary results of an evaluation study will be presented.

Introduction

Video films are particularly suitable as a way of experiencing the world because they provide a dynamic, although vicarious, encounter through sound and vision (Collis, 1996). Moreover, they use a number of technical devices to manipulate that experience. Salomon (1979) called these devices "supplantations", in the sense that they supplant a cognitive process.

However, the use of video films in their present, mostly passive, form, do not succeed in contributing enough to the learning process (Clark & Craig, 1992). In active learning situations students are able to reflect, construct and interact (Laurillard, 1993, Bates, 1997). In such learning environments, students are expected to comprehend the structure of the lesson, integrate its parts and construct their knowledge through experienc-based actions. Present video-film learning environments do not succeed in providing such a model.

SYNOPSUS was designed to improve the passive "learning-by-viewing" model by reinforcing a shift to "learning-by-doing" while studying with educational films.

SYNOPSUS - An Educational Tool

By utilizing a user-friendly interface, the tool allows students to engage, on a computer, in active, reflective, and interactive learning with existing video films. By allowing students to actively summarize a video film, the tool encourages them to engage in active learning. While summarizing the film, students are creating their own personal model of the movie, its structure, and its contents.

When the observer decides to summarize the film (which is seen on the left side of a computer screen), he/she begins typing the summary. Immediately, the film stops running; the written summary appears at the right side of the screen and the last video frame is attached as an icon to the beginning of the text. Pressing the Esc function resumes the film, and the summary with its icon are framed in a box. Each time the observer begins typing, the film stops running and another summary appears with its relevant icon on the right side of the screen. At the end, the student has a list of blocks in each of which there is an icon representing the place of summary in the film, and a written text which can be printed. This list of blocks can be arranged according to their order in the film, or according to the order in which they were created.

By automatically attaching relevant video icons next to a summary block, the tool provides an easy way of visually remembering and keeping track of, and returning to, important points in the film. This capability encourages students to engage in reflective thinking since relevant sections of the film can be found and seen by clicking on an associated video icon that immediately moves the film to the intended section. Reflection is also aided by allowing immediate access to relevant sections in the film via simple word searches on the textual summaries.

The tool also allows instructors to prepare interactive questions and assignments pertaining to the film watched. The questions and assignments pop up when the student reaches a pre-specified point in a the film.

SYNOPSUS can be used for distance learners and for face-to-face teaching during frontal teaching sessions. By using the presentation mode of the tool, instructors can show predefined segments of a film along with their own headers and annotations.

An Evaluation Study

The Open University of Israel (OUI) is a distance learning institution. Some of the courses offered to students are telecourses which include as learning material a textbook, 26 video films and a student guidebook. A telecourse in psychology was chosen for a study of the new tool. Out of 400 registered students, 100 volunteered to try the software. They received two CDs: one contained the software and the other contained a thirty-minute educational film. The first 60 students who were willing to participate in the study (after experimenting successfully with the software), were divided into two groups of 30 students: In group 1 students received films 1 to 6 on CDs, and in group 2 students received films 7 to 12 on CDs. Both groups received all other films on video cassettes. The two groups were similar in average age, percentage of males and number of previous course credits. This design allows for between and within comparisons regarding the experience with the software and CDs on the one hand and video films on the other hand. A third group of eight students with learning disabilities served for an exploratory investigation into the possible advantages of the software for students with such difficulties. They received the same material as group 1.

A questionnaire will be sent to all three groups at three points in time: (a) after the allocated learning period for the first six films (CDs for groups 1 and 3 and videos for group 2); (b) after the allocated learning period for films 7-12 (CDs for group 2 and videos for groups 1 and 3) and (c) after the allocated learning period for films 13-18 (videos for groups 1, 2 and 3). Group 3 subjects will be interviewed individually regarding their experience with the software and its possible help in overcoming some of their special learning difficulties. At the end of the semester students will be asked to send their summaries to the research team.

The purpose of the experiment was to test learners' attitudes towards the learning tool as well as their learning processes while using it. The design of the experiment permits absolute evaluations as well as comparisons with learners who watch the films on the TV screen without the tool. The following hypotheses will be tested:

1. SYNOPSUS facilitates the process of summarizing the film.
2. Subjects summarize more and better with SYNOPSUS than without it.
3. SYNOPSUS facilitates concentration while watching the film.
4. SYNOPSUS facilitates the process of locating a specific subject in the film.
5. Subjects go backward and forward in the film in order to access specific segments of it more often while learning with SYNOPSUS than while learning without it.
6. Subjects enjoy the film more on a television screen without SYNOPSUS than on the PC screen with SYNOPSUS.
7. Subjects feel they learn more from a film they watched on a PC screen with SYNOPSUS than from one they watched on a TV screen without it.

SYNOPSUS will be presented along with some of the experiment's results that will be available at the time of the conference.

Censorship or self-discipline on the Internet?
Strategies for limiting access to morally undesirable Internet resources.

John Boatright, MA
University of Minnesota
1283 Goodrich Avenue
Saint Paul, MN
boat0011@tc.umn.edu

Abstract: The purposes of the Internet are many; commercial, recreational, informational, educational, communicational, relational. The Internet is a paradoxical universe of structure and anarchy: producing some good and some bad, some beautiful, and some ghastly. There are many, educationally relevant Internet resources. "by the year 2000, anyone in western civilization will be able to get the answer to any question that has an answer" according to influential *Byte* columnist, Jerry Pournelle. In the 1997 Current Population Survey by the US Census Bureau computer use was surveyed. The study showed that three quarters of the children in the USA have access to computers at home or school - significantly more at school than at home. Children most frequently used home computers for educational purposes (93.3%) and games (83%). One fifth of the children who have home computers used them to access the Internet. For adults, 18 and over, 92 million people used the computer at home or work. More than half these adults accessed the Internet from home, with 80% of them using the web to access government, business, health or educational information. Significant increases on the order of 5-15% were recorded for every category of questioning over the 5 years span between surveys. In all, one of five Americans (ages 3 and higher) used the Internet in 1997[8].

This presentation/essay concerns controlling a kid's access to "morally undesirable" information. But before we can get to that, it is important to consider the need for such control. In the schools of our nation, our children are using the Internet to reach out of the walls and experience the universe. Free ranging access to the wonders of science and humanity can be had through simply searching the Internet using search programs. Any teacher or student deserves these resources and they deserve to follow the curiosities that are a contingent element of human intelligence. The question that arises involves the various interests of the purveyors of these archives. Some of these interests are illegal and even more are morally undesirable.

Introduction

The purposes of the Internet are many; commercial, recreational, informational, educational, communicational, relational. The Internet is a universe of anarchy and chaos: producing some good and some bad, some beautiful, and some ghastly. There are many, educationally relevant Internet resources. "by the year 2000, anyone in western civilization will be able to get the answer to any question that has an answer" according to influential *Byte* columnist, Jerry Pournelle. In the 1997 Current Population Survey by the US Census Bureau computer use was surveyed. The study showed that three quarters of the children in the USA have access to computers at home or school - significantly more at school than at home. Children most frequently used home computers for educational purposes (93.3%) and games (83%). One fifth of the children who have home computers used them to access the Internet. For adults, 18 and over, 92 million people used the computer at home or work. More than half these adults accessed the Internet from home, with 80% of them using the web to access government, business, health or educational information. Significant increases on the order of 5-15% were recorded for every category of questioning over the 5 years span between surveys. In all, one of five Americans (ages 3 and higher) used the Internet in 1997[8].

This essay concerns controlling a kid's access to "morally undesirable" information. But before we can get to that, it is important to consider the need for such control. In the schools of our nation, our children are using the Internet to reach out of the walls and experience the universe. Free ranging access to the wonders of science and humanity can be had through simply searching the Internet using search programs. Any teacher or student deserves these resources and they deserve to follow the curiosities that are a contingent element of human intelligence. The question that arises involves the various interests of the purveyors of these archives. Some of these interests are illegal and even more are morally undesirable.

Illegal interests are pursued and prosecuted in the United States by state and local law enforcement, the FBI, the US Marshall or the Federal Trade Commission depending on which jurisdiction the activity entails. The international nature of the Internet may bring other law enforcement agencies into the investigation and prosecution. In the US there are specific police resources devoted to cyber-crime.

On the morally undesirable side, there is no such concerted effort – in fact there seems to be a fair level of disagreement. While there is much media attention given to (thus far ineffective) efforts aimed at outlawing these undesirable Internet activities, there is a strange avoidance of discussion into exactly which information should be restricted. Consensus has arisen around some pseudo-illegal activities such as distribution of child pornography. But aside from that...almost certainly the literature simply starts off with the assumption that children need to be protected from whatever morally reprehensible activity the writer is imaging but not really describing. And, honestly, aside from acknowledging this vagueness, this writer is not much different.

The generally agreed philosophical rationale is that children from ages 5 to 18 must be protected from this information because they are not ready to contextually understand these darker fantasies and features of our culture. (In extreme cases -- I am wondering who is?) Kids are ignorant to the dangers that may be encountered through their venturing into knowledge unconditioned by experience. A loud debate rages about "how to stop access" to these dark media resources. When the next kids-killing-kids, school shooting incident occurs, our attention will be brought sharply back to the studies that widely implicate media's influence on a child's moral development. This research is not clear on the nature of the developmental harm associated with a premature familiarity of the darker side of humanity. We could wish for more specifics as to which type of media, how it specifically affects development and when in the child's development are they vulnerable to such influence.

For purposes of this essay, it will be assumed that *kids* need protection from morally undesirable elements of our culture even if adults do not. That further, the special media circumstance of Internet delivery of these morally undesirable archives directly into our schools and homes deserves our special attention. We will assume, as do many others, that an inadvertent curriculum can formulate around these dark and undesirable interests.

Since these fascinations with the darker elements exist in our culture, there is necessarily a developmental time when youth should gain controlled experiences in them. The school however is excluded from that objective – it is left to parents to control this curriculum. There are logical flaws in this plan (e.g. that parents often do not address these legitimate needs) will also be excluded from this essay.

This essay will assume that someday these "morally undesirable" graphical and information archives can be identified through public discourse and reasoning. Something beyond the "we will know them when we see them" criteria. Though there is no theory on whether it really is undesirable for children to be exposed to any of the following areas...and though there is no sharp delineation of the level at which information becomes damaging...the general content areas are well elaborated in the literature and involve concern about the following issues.

Inappropriate sexual displays.

There is a well-publicized and very active pornographic sector accessible through the Internet[7]. These resources may involve text or graphical displays that are developmentally inappropriate for children (and frankly adults!). This area receives much attention by the naysayers of open Internet access. It is said to represent a significant but small proportion of Internet informational traffic (I have seen figures of less than 10% - I cannot seem to find the source right at this moment though) Additionally, these sites often involve unscrupulous schemes to charge the viewer -- while claiming to be free of charge. It is a common family dilemma to have a surprise encounter with the financial consequences of a child's experimenting with Internet sex sites. Again, research is disappointing here, but in my circle of friends and family, children have spent thousands of dollars in this way. Anecdotally, costs associated with these episodes are confabulated with similar costs charged by cable and phone sex experimentation.

Predatory persons

There is a danger that children may be lured into meeting some predatory person, whose desire is to do them physical harm. While this danger is theoretically real, there is no frequency data available in the literature. It can be assumed though from reports of *adults* being lured out to meet predatory persons, that children would be also similarly vulnerable to such risks[22].

Financial Scams

There are a number of financial schemes communicated through the Internet. Pyramid schemes are popular -- so are offers "too good to be possible." Low interest, poor credit credit card offers are also frequently offered on the Internet. It can be assumed that the limited experience of kids would make them targets for these deceptive or illegal activities. Again, there is no data readily available on the incidence of children being victims. It is sufficient to say, that there are many adults that get scammed. We can be sure that if there were unlimited access to children for the scam artists and a source of credit for the children, there would be a significant level of risk to the financial well being of families and children[27].

Privacy concerns

The issue here is that children might give out information that could physically target them for predators. Another concern may be that the child, not being aware of the risks, may innocently or out of bravado arrange a connection with an unsavory character[21,22].

System integrity and security issues

There might be risks to the stability of the network due to downloading programs that originate from certain Internet sites. There is a fair amount of Internet traffic visible on lists associated with "hacking." (search keyword "crackers") The substance of these messages often reflects an interest in illegally obtained software and passwords to various nefarious sites. An easy and more popular invasion of networks involves reflecting junk e-mail ("spam") from the users domain so that it will appear to be from your computer system. I work for a women's college in the upper Midwest and we discovered that advertising for a pornographic site was using our domain as a reflector...to the extent that in one night 60,000 emails had been distributed! This, of course, was unacceptable to our network administrators. Protection from this type of hacking has been installed. Another concern is viruses and virus hoaxes. Aside from the damage an actual virus can do to networks, the volume of messages that virus hoaxes can generate is in itself, a plague.

Harassment

It is possible for a predatory person to stalk and harass a person via the Internet. Especially if used in combination with other modes of information accessible through the Internet or other information providers. Phone numbers, addresses, maps may assist the stalker to find their target repeatedly. It is more and more difficult to "disappear" if one needs to. One source listed the costs for information on the a person as $15 for social security number, to $150 for a complete background check.

Internet "addiction"

While dubious as a real disorder, some people spend inordinate, obsessive amounts of time on the Internet[3,4,11,12,13,14,15]. Sometimes this interferes with normal activities of daily living. The fear is, that introducing Internet use in schools give tacit approval for obsessive use of the Internet. There is no empirical data available in the literature, but based on anecdotal evidence (again from families and friends) teenagers are known to sacrifice duties and sometimes sleeping in order to use the Internet. Recently, the American Psychological Association gave some context to the question during a symposia on the topic. They concluded that pathological internet use was possibly an addiction, a disorder or a symptom of depression.

Abuse of credit

A problem not exclusive to the Internet, there cannot be any doubt that the Internet is a good place to spend a lot of money. Many Internet retail and service sites exist and accept credit cards. It is easy to rack up an impressive bill in a few hours of Internet shopping. Amazon.com for books, records, presents; Quill for office supplies; LandsEnd for clothing; EggHead for software; Dell for a computer; Auto.com for a car; ebay for a boat; pretty soon you've spent some bucks!

Depression

There have been articles in the psychology literature about a relationship between Internet use and depression[5,6]. The debate rages on with both side positing credible pros and cons. The crux of the issue here is the chicken/egg problem. That is did the depression precede the use of the Internet or was depression a result of Internet use? Currently the theory that seems most favored is that use of the Internet is more a symptom than a cause of depression.

Academic integrity

A virtual industry has evolved selling term papers to students. Keyword search on "term papers" revealed 100s of sites devoted to free and for sale papers. Many services offered custom services. According to "Paper-Masters" their custom written term papers are meant to be research to assist you writing your own paper. They conclude that it is not in any way unethical to use their services.

Identity

The relative anonymity provided by the Internet is a challenge to individual identity. This feature also allows people to fabricate an identity that is quite different from their own. The concern is that this fantasy identity may interfere with the identity forming process that is an important in the child[34].

Community

There are fears that rather than encouraging community and multicultural exchange the Internet actually encourages isolation.[2]

Intellectual property

Many teachers report a cut and paste form of writing where the students simply search out information on the Internet and then copy it directly into their papers without quotation. Additionally copyright infringement rules are very difficult to understand within the context of the Internet.

Social accountability

The anonymity and 2 dimensionality of the Internet does not foster authentic relationships. This issue is the converse of the safety afforded by the electronic distance of the Internet. One concern for kids is the negative role model that this demonstrates. The superficiality of complex individuals as represented on the Internet is also an impression that is unrealistic. On the Internet, as with other media, the distinction between real an imaginary is difficult to detect.[36]

Review of the literature

While it this essay is focused on educational issues in American schools, it is interesting to observe that in Europe several countries (GDR, GB and others) have also sought to control certain types of Internet communications. Great Britain actually has a complaint bureau, The Internet Watch Foundation[1], where consumers can expect to see prosecution of child pornography, and other harmful activities. The bureau expressly stays clear of controversies into items of political or social question though. Internet access is severely limited at the source - the Internet access hub, in several Middle Eastern countries (Saudi and Egypt). All accessible sites are government approved even email is scrutinized.

In the United States, a first Amendment disagreement has arisen over Internet control. The US Supreme Court has made four determinations in favor of free Internet access for anyone able to get there. Though there are plenty of details left to interpretation, the court has made sweeping statements about the freedom of the Internet. Congress continues to contemplate legislative action, intended to circumvent the Supreme Court's First Amendment rulings and control some types of Internet communications. As stated before, illegal activities are prohibited and prosecuted in multiple ways, the debate concerns pseudo-legal and legal but controversial Internet resources such as child pornography, bomb-building directions, racism, slander, misinformation.

Strategies for limiting the access of kids to morally undesirable Internet archives

Free access to all:

It would seem that this is what we have. This is a common misconception of the Internet. Certain types of information cannot (currently) be transmitted via the Internet. The interface is restricted to materials that are comprised of an audio, visual and/or digital nature. Certainly this covers a lot of ground, but in reality this is a significant limitation from the start. Not everything the human has a capacity to sense can be transmitted by the Internet.

Additionally, and of more relevance to the theme of this essay; illegal activities are prohibited on the Internet. As stated above, several governmental policing agencies monitor and in fact utilize the Internet to investigate and prosecute criminal activities[1]. Email threats are taken quite seriously – the appearance of treasury, secret service officers at a local high school last year to arrest a student for having sent a death threat to President Clinton is lesson enough to prove this point. Drug and firearm enforcement agencies also monitor the Internet for signs of criminal activity.

Direct adult supervision:

There is a tacit rejection of direct adult supervision as a control strategy in almost all the literature[30]. It is felt unrealistic that an adult mentor could monitor a kids Internet adventures, or help them gain context if they bump into something morally undesirable. The literature in this area occasionally mentions that this is an option, but that then goes no further than to state it is simply not feasible for presumably practical reasons. There is, however, agreement that this method of control would be desirable and effective. This writer is not so sure that this is the contingent difficulty with the idea. Challenges here may be more associated with the problems of communicating with our youth. Adults are really hesitant to talk about morally challenging topics – a sudden view of human sexual interaction might initiate questions – and that would lead to a difficult conversation. Teachers should be allowed to have this kind of conversation with our youths, but the onus of responsibility is on the family where it <dismay> rarely occurs.

User Self Policing - Moral development and the Internet

It could be left to the user to restrict their own access by virtue of their own experiences[35,36]. This highly improbable suggestion centers on development of a personally held and derived dislike for morally undesirable Internet resources. It can happen, and most probably does, after the thrill is gone so to speak. The impractical part of this suggestion is not the philosophically sound grounding that exists in allowing people to morally develop, but rather the political impossibility of implementing such a plan in a country founded by the Puritans. Additionally, there is much to be said for the idea that a staged approach with contextulization would need to be implemented to coincide with the developmental capacity of each individual kid. Given the performance record of our public schools…it is utopian to imagine such a strategy could be harmlessly implemented.

Legislation:

Communication Decency Act (CDA) and Son of CDA – overturned by the US Supreme Courts. Ruled as unconstitutional by virtue of their violation of First Amendment rights[10]. Politicians continue to bring up legislation that the American Civil Liberties Union defeats in court challenges. Literally millions of dollars have been expended in the quest for legislation that can get through the first amendment tests. Often the problem is that the definitions for morally undesirable materials cannot be specifically measured, and could thus be applied too widely.

Acceptable Use Policies (AUP):

As an aide to self control, a signed statement of appropriate internet use AND the consequences of abuse of privileges is used. Samples of AUPs are available on the Internet. AUPs are used in nearly all networked computer labs. It is necessary that some person observe the Internet use in such situations. This can be done by walking around the lab or by looking at the log of Internet addresses that has been accessed on a particular computer. It would seem very possible to automate this observation of a lab by sharing the log with a central teachers workstation, but there was no mention of this strategy in the literature. See references[31] for a link to an example provided by Rice University.

Rating Systems:

A strategy familiar to moviegoers is common of the Internet – warning the consumer of adult content. Most commercial (even free) adult sites require the user to physically confirm select their intent to utilize the morally undesirable archives. Some Internet businesses have arisen that claim to restrict the access of minors to their sites by virtue of credit card credentials. Of course, a credit card has little to do with verifying age – these sites are more interested in connecting interested parties (and their credit cards) with their cadre of pornographic vendors. The intent is to protect the inadvertent viewing of these resources, but of course, many curious 15 year olds are undeterred by these warning and click right through.

Screening Software:

It would be nice if software could be developed to filter morally undesirable Internet content, but thus far efforts have been only partially successful.[26,27,28,29,30] Current filtering software can be grouped based on the strategy used to filter. One group uses keywords, taken from a ready made list of dirty words, to eliminate access to undesirable Internet archives. Often the list can be modified by the administrator to add new words or to add in a miss spelling of the particular dirty word of concern. This is effective but suffers from the problem that sometime dirty words also have morally desirable alternative uses. For instance "breast" as a keyword will also eliminate sites concerned with breast cancer. Another approach is to keep a list of either acceptable and unacceptable sites. For instance sites ending with the ".gov" suffix are approved, Disney.com is approved, a list of sites that are not approved is provided and updated by the software company and can be modified by the administrator. Unfortunately, the undesirable element of the Internet moves around a lot, and new morally undesirable sites are launched every day, so it is easy to imagine that something will get past the filter.

Network Filter programs:

Similar to screening software, more sophisticated filters can be installed at the network hub[30]. This is the strategy used by those Middle Eastern countries to prevent access to certain internet resources.

Intranet strategies:

One strategy taken by some schools has been to simply offer only internal versions of Internet available resources. It's a sort of smaller, internally stored version of the Internet. WebWhacker[30] whacks entire sites out of the Internet and stores them on your computer network. This strategy is fine as long as the learner only asks questions available within the limits of the stored information. An encyclopedic resource, and other informative resources are made available. Often access to the external Internet is possible for special situations, and can be more effectively monitored.

Internet watch groups:

Another way used in concert with screening software is to have a group of evaluators monitor the moral permissibility of Internet sites[30,33]. What happens is that a software company or a school enlists the help of a screening committee. Their function is to expand the list of forbidden and permitted Internet resources.

Free market pressure and industry self regulation:

Especially during the legislative debate on CDA, many Internet Service Provider companies became concerned over the trouble it might be if they could be held responsible for Internet content. America Online, the largest Internet Service provider, initiated a program of parental controls that allow various levels of access control over the Internet and AOL network resources[1,17,18]. Also, they developed a system of "moderators" to monitor kid chatrooms, as well as a responsive complaint system. In other words, they felt it was good for their business interests to allow the user to determine limits on access.

Conclusions

So what is the big picture here? First, this is a new experience to all of us, second the Internet needs to be a vital part of the learning experience for kids, Third we will not be able to bring ourselves to restrict anything but illegal activities from the Internet – and even here it's a post hoc analysis.

Clearly the best choice is to design a system where Internet use is closely monitored, but not for punitive purposes, but for contextualizing by adults who are skilled and vested in helping kids see our world, all of it at the right time. Since this is so impossible given our current factory model schools, I would recommend the strategy where much of the information needed by students is anticipated and locally stored on school friendily servers – a second network soto speak. When kids need to venture onto the Internet let them, and be there for them.

There is much research that needs to be done, but some of the important questions IMHO (in my humble opinion) have to do with cultural changes that will come as a result of this new dimension. Questions about moral development, community and diversity seem largely unstudied. Philosophical and psychological issues such as what really is inappropriate and at what developmental age are barely disturbed. Finally, I wonder what the future will hold for new ways to communicate human sensations and feeling will be.

Using Speech Recognition to Support Online Learning of Second/Foreign Languages

Francis Bonkowski, IC Education, Inc., Canada
Quinn Cheung, IC Education, Inc., Canada
Liam Cheung, IC Education, Inc., Canada

This paper presents IC Education's state-of-the-art pedagogy and technology to support online language learning. IC Education has developed speech recognition over the Internet using a new client/server application that recognizes the voice of user's without having to install complicated software on a personal computer. The system entails minimal software installation by the user and provides centralization of the speech recognition engine. This innovative technology is a powerful, albeit simple tool used to teach learners proper pronunciation and new vocabulary.

A BUILDING-BLOCK METHOD FOR COURSEWARE DEVELOPMENT FOR LESS-EXPERIENCED DEVELOPERS

Eddy Boot & Yvonne Barnard
TNO-Human Factors, Soesterberg, The Netherlands
Kampweg 5, P.O. box 23, 3769 ZG Soesterberg
Email: boot@tm.tno.nl, ybarnard@tm.tno.nl

Abstract: *Although courseware has the potential to increase the efficiency and effectiveness of courses, until now the results of its application is often disappointing. In our research concerning courseware development within the Royal Netherlands Army (RNLA), we investigated some of the underlying reasons for this, and specified an approach to promote its applicability. One of the main problems is the high cost of courseware development, resulting from the long development time and the specific expertise required. We constructed a 'building-block' approach, which enables instructors with limited multi-media expertise to rapidly develop courseware for simple learning objectives, but with the use of advanced multi-media technology,. This approach consists of templates that incorporate sound didactical principles, lower the technological complexity of courseware development, and can be used within modern authoring tools. Currently we are implementing the method and are studying how to enlarge the scope of the method towards more advanced learning goals.*

The use of courseware

Recently, the interest for the use of courseware within many educational and corporate organizations is increasing in a rapid pace, as it has the potential to increase the efficiency and effectiveness of courses significantly. Organizations want to develop courseware in-house, as in most settings Commercial Of The Shelf (COTS) courseware is not specific enough and currently modern, powerful authoring tools are available. However, in many cases such attempts have been disappointing in terms of contributing to efficiency and effectiveness of (the development of) training programs. For instance, in the last few years, the Royal Netherlands Army (RNLA) has spent considerable time and effort in developing courseware for its Training Centers. This courseware mainly directed at concept learning and procedural tasks. However, the application of courseware has not yet lived up to its expectations. It has never been very cost-effective and (therefore) organizational acceptation or broad adaptation of courseware within training programs is still not accomplished.

Bottlenecks in developing courseware

TNO-HF has been asked to investigate this problem and to formulate, implement and test solutions for it. We found a number of problems concerning courseware development (Boot & Van Rooij, 1999). The development of courseware is mostly done by Subject Matter Experts (SME's) and instructors, using modern authoring tools. Despite the efforts and promises of these tools to reduce development time and the level of required expertise (e.g. Asymetrix, 1998), it still takes considerable time (and therefore costs) to produce courseware. We found that considerable programming knowledge is required for anything more that very simple courseware. Also, much time is required to familiarize with the tools and its many features and the translation of didactical models into courseware is complicated. In the RNLA, the SME's and instructors lack the didactical-, multi-medial- and programming expertise to make optimal and efficient usage of these tools. One can conclude that the development of anything more advanced than very simple courseware programs, remains costly and will be only cost-effective for large target groups.

The building-block approach

If one aims at courseware with advanced technological features (in terms of multi-media usage and interactivity), developed by people with limited programming expertise, a so-called 'building-block' approach can be a solution. This approach pre-structures the development-process by offering templates within authoring tools. Templates consist of empty courseware-structures to be filled with content. These structures incorporate sound didactical principles and advanced technological features. Once connected to each other (hence the name building-block approach) and filled with content (the learning materials), they constitute a complete courseware program. We investigated some build-in pre-structuring features of modern authoring tools that make the same claims, but they are too limited for our purposes. Therefore, our templates should be more advanced and comprehensive, in order to promote proper implementation of didactical models and lower the technological complexity. As standardization, re-usability and exchangeability of courseware(elements) is a key issue, these templates should be embedded within COTS authoring tools.

Specification and implementation of the approach

We specified a building block approach for the RNLA, with templates for four levels of courseware-structure (Boot & Van Rooij, 2000);

1. At the top level, templates provide different kinds of navigation through a number of lessons.
2. At the second level, templates provide different kinds of navigation of learning activities within lessons.
3. At the third level, templates provide interactivity within learning activities.
4. At the bottom level, templates provide the presentation of multi-media elements within learning activities.

Altogether, they contribute with standardized screen-elements to the complete user-interface of the program. The didactical functionality, embedded in the templates, is directed at relative simple learning goals; learning facts, concepts, procedures and principles. The instructional strategies that are embedded are based on theories like Gagné's Nine Events and Merrill's Component Display Theory as found in Reigeluth (1983). Technically, the templates are build using Knowledge Objects® within the authoring tool Authorware® Version 5, and are provided with Wizards for guiding the interaction with the developers. For reasons of acceptance and commitment of the future developers, we have involved them during the specification process of the building-block approach. We found that it is important and difficult to balance well between how much templates should prescribe and which freedom remains for the developers.

Currently, we are in the implementation phase; external software developers are building the templates, after which they will be used by some developers within the RNLA. We will start a number of pilot projects to evaluate the application of the approach and the resulting courseware. Based on these results, the templates can be improved and the building block approach will be applied on a wider scale.

Future developments

One important aspect of our research is yet unresolved; how to specify a building-block approach that is also directed to more complex courseware? During specifying the described approach, we found that finding a sound theoretical basis is troublesome. It is a challenge to embed didactical models and instructional principles into software-templates that are content-empty. Our future research will be directed at embedding didactical models for advanced learning goals, using principles from learning theories like constructivism and situated cognition. Our goal is to formulate concrete guidelines for the problem-based or case-based approaches from such theories, and implement and test these within an advanced version of our current building-block approach.

Collaborative University Teaching over the Internet

Jacqueline Bourdeau, Department of Education
Université du Québec à Chicoutimi, Chicoutimi, Québec, CANADA G7H 2B1
jbourdea@uqac.uquebec.ca

Abstract: A concept has been developed to achieve various forms of collaborative teleteaching, such as sharing ideas about teaching, using learning scenarios, and engaging in joint teaching actions. Professors play a key role, since they are instrumental in integrating new technologies into teaching. An environment is being developed to encapsulate an instructional design technique to facilitate sharing processes. A database technology provides distributed services over the Internet.

From Teaching to Teleteaching

University teaching has traditionally been defined as an on-campus activity where all players (1 professor and X students) are in the same place at the same time, with or without any media. In fact, all teaching has been based on these parameters. New technology (NT) brings many potential changes to these parameters, since it creates an opportunity for innovative distributed teaching modes. This potential has increased the need for instructional design, and consequently the progressive transformation of traditional teaching modes into instructional design-based teaching. Integrating NT into teaching implies changing teaching practices. Integration has taken various forms in higher education, such as: Web-based instruction, online education (www.telelearn.ca); videoconference-based teaching (Bourdeau & al., 1998); the virtual campus (www.tecfa.unige.ch), or integrative distance learning environments (www.licef.teluq.uquebec.ca). Satisfaction levels in students and faculty vary from enthusiastic to negative. Faculty is being pressured to digitize material in the form of electronic books, or add electronic communication to their classroom teaching. However, teaching continues to be based on the synchronization of professor and students in a given space. There is room for integration modes, which could be better anchored in current practices, while simultaneously fostering greater faculty involvement.

PETRUS: The Concept

Petrus is a new concept developed to integrate new technology into university teaching. The fundamental characteristic underlying the idea is to consider professors the driving force behind educational integration, since they are the agents who design teaching specifically for their own students. The integration of new technology derives its meaning (direction and semantics) from their teaching and personal interpretation. The second one is to consider new technology a catalyst rather than a tool: the spirit of the Internet is all about sharing and cooperation. A good number of professors are clearly prepared to integrate this spirit into their teaching. And lastly, the third characteristic of Petrus is to provide professors with a computerized environment where the groundwork for an instructional design technique has already been laid through scenario-building. Depending on their preferences or needs, professors can use the ScenarioBuilder in Petrus to: 1) assemble dynamic instructional scenarios, 2) gain shared access to comprehensive, validated scenarios, 3) select individual components from scenarios.

Implementation Plan and Work in Progress

Implementing sharing practices requires sharing processes and an environment designed to support these processes. Scenario-building skills can be acquired through a high-quality system where instructional principles have been built into an expert environment. Professors can access, consult, edit or assemble scenarios in the most flexible ways. They also have the option of designing their own teaching environment and learning interface for students. Teleteaching services naturally have to be anchored in current teaching practices and jointly designed with professors. The following plan was designed for a course on learning theories: 1) Collect and analyze a series of syllabi on learning theories; 2) Extract and classify items according to objectives, content, learning/evaluation activities and material; 3) Conduct a needs assessment of useful teleteaching services; 4) Choose software engineering solutions; 5) Develop and test a prototype for one course; 6) Develop and test a prototype for five courses on distributed sites; 7) Develop a full environment including rights and privileges. The plan is currently under way after a team of professors agreed to jointly design and test the scenario-builder. Steps 1 through 5 have been completed, and a Web-based prototype environment is being developed. The environment will be served by a database that dynamically feeds information into the system. First results will provide information on the quality and level of interest in collaborative teleteaching for a course on learning theories in teacher education programs.

Related Projects

To the best of our knowledge, the concept that comes closest to Petrus is ARIADNE, which stands for Alliance of Remote Instructional Authoring Distribution Networks for Europe (http://ariadne.unil.ch/). The project focuses on the development of tools and methodologies for producing, managing and re-using computer-based educational components and curricula. Collaborative approaches are encouraged, as is the share-and-reuse principle (Duval, 1999). Petrus is radically different in that professors are at the centre of all processes; they are the agents through whom everything passes, and both their personality and teaching style are incorporated into the design. Petrus is not looking to set standards, but seeks diversity instead in terms of intellectual perspectives and teaching styles. Secondly, Petrus contains a scenario-builder that incorporates teaching strategies which can also be shared. The STAR.Legacy project (http://peabody.vanderbilt.edu/ctrs/ltc/) at Vanderbilt University has some features similar to those of Petrus: the learning cycle resembles the Petrus Scenario-Builder and, and the "multiple perspectives" activity in the STAR Legacy learning cycle is characteristic of a team-teaching situation. The working hypothesis underlying the Petrus project is as follows: the successful integration of digital technologies into university teaching must go through the professor – an expert in a particular domain who is responsible for conveying information, inspiring and coaching students to help them achieve their personal, academic and career goals. Professors need to customize the learning environment for their students, and change it as needed. Professors would ultimately be engaging in team teleteaching. Videoconferencing and video servers would provide a multitude of perspectives for students, thus enabling them to acquire greater discernment and critical skills.

Sharing, Collaboration and Teleteaching

In the context of computer-supported collaborative work, sharing is seen as a sub-process of collaboration, which is itself a combination of communication and coordination. Coordination science defines coordination as managing interdependencies, and this concept can be extended to the management of interdependencies among actors (Bourdeau & Wasson, 1997). In the Petrus project, sharing processes can be identified together with their associated interdependencies. The software environment would be built around these interdependencies and provide the means to manage them. Examples of sharing processes include: sharing ideas, scenarios, teaching or coaching activities and lessons learned. Mentoring (at the novice or expert level) can also be considered a sharing process. Examples of sharing principles include: reciprocity, privileges, task distribution, resource allocation, and so on. Software to manage and support sharing processes will be designed when sharing processes are identified and validated, and means for managing interdependencies are developed. Ethical and legal issues will also be taken into account.

Abstract: This paper describes the work of the Carlos III University in the project SEBASTIAN (Educational System based on Internet Technology). The aim is to develop a tele-educational tool, providing to educators/trainers with a simple mechanism that makes possible the use of the network for the broadcast of educational content and enabling the creation of multilingual courses based on XML (Bray, 1998) and SMIL (Stephan, 1998) technologies.

Introduction

As soon as web technologies first became available, they were adopted for educational purposes. Hypertext technologies had already been used in learning systems, and the Internet facilitated the overcoming of distance. Higher education is now undergoing structural changes in terms of the composition of student populations, learning paradigms and curricula. As distance education becomes an integral part of higher education, student bodies are expanding to include more non-traditional students and the contents of courses are richer than before, and incorporate more interactivity.

In this new world, students participate more actively in class and collaboration becomes a more important component of the learning process. These changes have stimulated the development of new ways to represent information (for example: animations, simulation, hypertextual navigation and so on). In particular, multimedia content has been introduced via the medium of the WWW. However, there are problems associated with the variety in present day formats. Facing up to this situation, The Carlos III University of Madrid is working on a project named SEBASTIAN.

System Architecture

The system serves to integrate multimedia learning experiences into the network enabling it to be visualized according to the preferences and characteristics of the student. The courses generated are described in EML 2.0 (Educational Markup Language 2.0). This language is based on XML and includes spatial information (multimedia objects place, presentation size, etc.), temporal information (duration of multimedia objects, scenes, etc.), and information about students profiles (learning styles). The professor will eventually have one tool with three integrated functionalities for the creation of courses, see [Figure 1]. The functions are:

- **LG (Layout Generation):** Allowing the description of the spatial distribution of multimedia elements that comprise each scene of the presentation. A description language, SLML: Space Layout Markup Language (based on XML), has been designed for this purpose. This functionality will provide the creation of multimedia templates. Initially, some predefine templates will exist, but the object is that professor generated its own templates.

- **STG (Synchronous Text Generation):** The files generated are based on a new language STML: Synchronization Text Markup Language, and provide textual content in several languages. These files contain synchronization labels which synchronize the text with audio or video, as in a karaoke session.

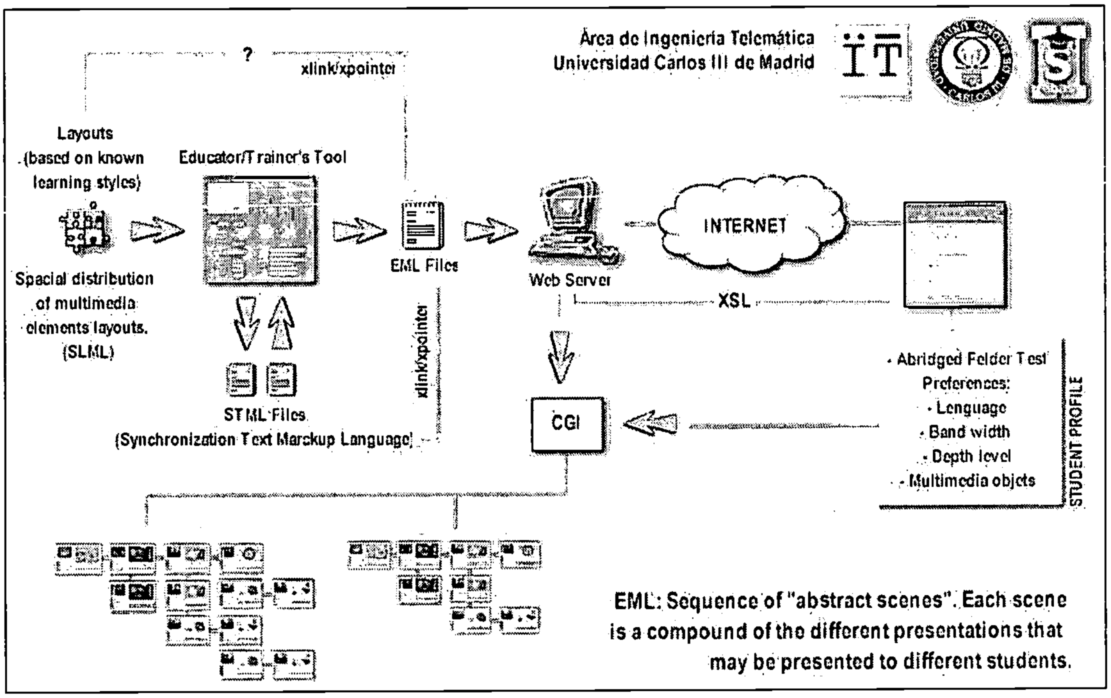

Figure 1: Contents generation, distribution and visualization process.

- **CG (Course Generator):** Integrates multimedia files and files generated by the two previous applications. The result is a presentation composed of a sequence of "abstract scenes". Each scene is a compound of the different presentations that may be presented to different students. The view presented to each student depends on their preferences and pedagogic profile. These profiles are generated automatically in accordance with the Learning Style Model (Richard Felder, 1996), the PAPI (Public and Private Information, 2000) and the LOM (learning Object Metadata 1999) specifications.

Acknowledgments

The work reported in this paper has been partially funded by the project SEBASTIAN 07T/0015/1997 of the Spanish CAM and the project INFOMEDIA CICYT TEL 1999-0207. We wish to acknowledge fruitful discussions with our colleagues in the Department of Telematics Engineering in the Carlos III University of Madrid.

TScott@Education.concordia.ca

Abstract: This paper describes an on-going project that involves the construction and evaluation of an Internet-based Knowledge Integration System (IKIS) developed to support a Computer-assisted Instruction (CAI) graduate course. The IKIS integrates cognitive theories of learning and instruction, computer networking technologies, and face-to-face classroom teaching in order to (a) help students build coherent knowledge representations of a great variety of knowledge and skills that are required to design and produce instructional software prototypes and, (b) create a community of practice to aid students in making the decisions concerning the design and production. Our discussion will be focused on two important system features of the IKIS (i.e., the information architecture and communication facilities) that enable us to achieve such goals. A plan for evaluating the IKIS will also be briefly described.

In this paper, we will describe an on-going project that involves the construction and evaluation of an Internet-based Knowledge Integration System (IKIS) developed to support a Computer-assisted Instruction (CAI) graduate course in which students will develop knowledge and skills for designing and producing instructional software prototypes. Understanding of various design concepts and approaches, specification techniques, authoring tools, and development methods is emphasized within this course. Whereas the instructor of the course provides face-to-face lectures, demonstrations, discussions, and laboratory work, the complex nature of the subject can still pose a challenge for students to assimilate and integrate such knowledge. Furthermore, traditional classroom instruction remains an inadequate method in providing timely instruction to each individual student. The IKIS for (CAI) was constructed to (a) provide students with a rich, well-structured knowledge base in order to ensure their active assimilation and integration of a variety of knowledge and skills to be learned, and (b) create a community of practice to aid students in making the decisions concerning the design and production of software prototypes.

The Design of the IKIS

The IKIS integrates cognitive theories of learning and instruction, computer networking technologies, and face-to-face classroom teaching to enable students to use the well-structured knowledge base and diverse tutorial resources to build coherent knowledge representations of the subject-matter knowledge to be learned. The design of the IKIS is based on the cognitive theories of text comprehension that emphasizes the importance of structured knowledge presentations in the construction of coherent knowledge representations (Kintsch, 1988; 1998; Mayer, 1999; 1997), and on situated theory that views social interaction and collaboration as crucial factors in the development of scientific understanding (Lave & Wenger, 1991; Resnick, Levine, & Teasley, 1991). In addition, the *cognitive apprenticeship* model proposed by Collins, Brown, and Newman (1989) also informed the design of the IKIS. Five principles are articulated to guide the design of the IKIS: (a) providing a rich knowledge base to reflect expertise in the domain of instructional software design; (b) providing a well-organized and transparent knowledge structure to help students construct a coherent conceptual representation of the subject-matter knowledge, (c) employing an effective model of instruction, (d) building a community of expert practice and providing multiple perspectives towards the solutions and, (e) facilitating collaborative learning among students. The theoretical foundation and design principles of the IKIS have been described in details elsewhere (Chen, 1999; Chen, 2000). In this paper, our discussion will be focused on two important system features of the IKIS, namely the information architecture and communication facilities that reflect the principles described above. In addition, an evaluation that we will conduct in the near future will also be proposed.

The information architecture incorporated into the IKIS

The CAI graduate course is focused on the user-centered design for Computer-supported Collaborative Learning (CSCL). A series of topics were identified as important for successful design and implementation of instructional software prototypes. In order to help students construct coherent knowledge representations, the IKIS incorporates an information architecture (i.e., a hierarchical organizational scheme) to represent two "layers" of the knowledge to be learned: the first layer consists of various topics, which range from learning theories to web authoring techniques whereas the second layer is a breakdown of knowledge on each topic which includes concept, rationale, goals, methods, example, related issues, trouble shooting and tips, and reflective questions and exercises. Such a knowledge base is expected to enable the students to answer questions concerning what, why, how, to evoke reflective thinking, and ultimately, to create a rich context for students to engage in productive group discussions on the topics via computer-mediated conferencing. Furthermore, some Internet resources and lab tutorials that are relevant to specific topics are also provided to extend the knowledge base of the IKIS. Students can also access a perquisite-course website to acquire background knowledge if they wish. The information architecture of the IKIS enables the students to learn the topics in a logical manner, meanwhile this architecture is flexible enough to allow each individual to take a different navigation path based on his or her own selection. There is a navigation bar located on the top of the screen that allows students to maneuver through the course topics and breakdown by following either a pre-determined sequence or a selected path. In addition, a bottom navigation bar is available all time to enable the students to access a computer-mediated conferencing facility, newsgroup discussions, and e-mail addresses in the context of reviewing the course topics and breakdown. This bottom navigation bar also provides accesses to the resources and lab tutorials outside of the instructional content that is defined in the IKIS. An on-line help, site map, and search facility are also provided by the bottom navigation bar to enable students to navigate efficiently through the site.

The communication facilities utilized in the IKIS

There are numerous decisions that one must make in the processes of designing and producing instructional software prototypes. No matter how rich the knowledge base is and how well such knowledge base is structured, students may still have unanswered questions. The purpose of proving the accesses to a computer-mediated conferencing facility, newsgroup discussions, and e-mail addresses is to enable students to discuss such unanswered questions with their peers or experts outside of their physical environments. Three communication channels are established to support students' knowledge construction and decision-making: (a) *a channel for integrating with the peers*: the FirstClass™ software program is used to provide computer-mediated conferencing and chat facilities to facilitate the discussions among students. Each student is required to provide answers to the reflective questions that are proposed at the end of each topic. Students are also encouraged to bring up issues that they wish to clarify and respond to each other's questions. Students can also the FirstClass™ to exchange electronic files that they produced for their group work. The instructor and teaching assistant will monitor the discussion and provide directions and clarifications if needed; (b) *a channel for participating in the communities of practice*: The IKIS provides students with access to the Internet newsgroups that are most relevant to the topics discussed in the course. These newgroups are organized in a way that is sensitive to the course topics so that the students can be exposed to multiple perspectives on a given issue. Students will also have the opportunities to share their experience and expertise with people who face similar problems and understand the concerns of the practitioners in the community; (c) *a channel for* communicating with experts: In addition to the communication with the instructor of the course, students can ask questions to some design experts who will serve as the mentors during the course of the semester. These experts will help the students diagnose some "unsolvable" problems and provide suggestions via e-mail. In addition, a list of e-mail addresses of the experts in the fields relevant to CAI design will also be provided to allow students to contact these experts. The communication with these experts may provide students with insights into how experts think and practice. Thus, The communication facilities offered by the IKIS will break the boundary of time and location that is inherited in traditional teaching.

The Evaluation of the IKIS

The IKIS will be evaluated both formatively and summatively. In the formative evaluation phase, a few representative students will be asked to "walk through" the environment and provide "think aloud" protocols for making diagnosis of the system in terms of its usability and learnability. Following the necessary modifications, a summative evaluation will be conducted to determine the effectiveness of the IKIS. Two groups of students will be compared: one that use the IKIS and another that use a print-based version of the same material. An attitude questionnaire will be administered before and after the course to determine the changes in student attitudes. In addition, students' on-line discussions and course work will also be analyzed to determine the levels of expertise developed. The ultimate goal of the project presented here is to understand the ways that computer technologies can be used to enhance student learning of complex subject-matter knowledge and to develop a model of successfully integrating technology into the classroom teaching.

Design decisions in the development of modular instructional content: Describing the transition from local to global learning systems

Paul Cholmsky
Concordia University, Montréal, Québec, Canada
cholmsky@videotron.ca

1. Introduction

Although the increasing sophistication of computer-based learning systems has enabled gains to be made in terms of their pedagogical effectiveness, an undesirable consequence of this sophistication has been a significant increase in development cost. The high cost of these systems has been identified as a principal barrier to their widespread deployment. Increased complexity in learning systems has also led to lengthier development cycles, which has constrained the rate of design evolution and innovation. As a result, there is a pressing need for instructional designers to focus on the efficiency of their development processes as well as the effectiveness of the outputs that are produced by them.

A possible strategy for reducing the time and cost of system development is to create a context wherein whole systems would not have to be designed largely from scratch. A key aspect of such a strategy could be the establishment of cross-organizational standards that would allow developers to reuse content components from other systems, both from within their own organization and from external sources. In essence, this would represent an attempt to leverage the productivity gains from reusability that have been achieved in software engineering into the domain of instructional content development. Over the past year, coordinated proposals have rapidly emerged from several bodies (e.g., Advanced Distributed Learning Initiative, 2000; Anderson, T., McArthur, D., Griffen, S. & Wason, T., 1999) as candidate standards for this purpose. As these proposals are vetted through their initial trials in actual learning systems, it will be important to observe how standards for content reusability affect instructional content development methodologies. Will processes primarily developed in the context of authoring content in small-scale closed systems evolve smoothly into processes for architecting large-scale distributed learning environments where the number of distinct content components may be in the hundreds or thousands? Conversely, if new processes must be developed, which ones will be required, and on what basis do we start their development?

A fundamental issue that needs to be addressed in this regard is the broad function of instructional design (ID) in the development of systems that have a substantial information technology (IT) component. Where does ID stop and IT start? Consider the development of a set of interactive practice exercises that include variable remedial feedback based on learner response patterns. A design decision could be made to use a database-driven approach wherein feedback is assembled from low-level content components that are sourced from a database. If these low-level components include subject-matter terms and their definitions, the same database might be used to drive a glossary function in the learning environment, serving the objective of content reusability. In designing such a system, we would likely not expect an IT professional to author the subject-matter definitions that lie within the database, just as we would not expect the ID professional to design the software that allows the database to communicate within a client-server environment. Appropriate allocation of responsibility for many other design issues, however, is not as clear-cut. For example, is one of these professionals primarily responsible for decomposing the feedback into suitable lower-level components, or is this a joint responsibility - and, if so, how do these professionals collaborate on this task effectively? Of specific concern are the pedagogical implications of successful technical convergence (e.g., the use of database-driven content systems, or the adoption of XML as a markup language): does this form of standardization support research on and development of pedagogical strategy, or does it sacrifice flexibility at this level to achieve the goal of technical convergence? The absence of a clear articulation of the interface between pedagogy and technology in practical terms may prove problematic.

2. Common architectural issues in the design of computer-based learning systems using modular content

To begin assessing the viability of current content development process models in the context of large-scale distributed learning environments, we can examine common categories of design decisions that occur in smaller-scale development projects and assess the possible ramifications of a significant change in scale on them:

- Modularity: What is a module, in terms of instructional content? What are the quality criteria for the definition of 'good' modules? Do these criteria change as scale increases? How do we use partitions between modules to manage risk in content development? For example, how do we partition a system in order to increase our ability to test numerous content components as they are being developed?
- Communication and information flow: What types of information get communicated between modules in a single system? Where are the architectural boundaries in an open content system? How does the information flow in a learning environment instantiate a pedagogical theory of control?
- Object- and component-based approaches to the development of instructional materials: How do we determine the right grain sizes for content development? What is the relationship between grain sizes for authoring and the units of analysis employed during front-end analysis? How can the choice of content units facilitate collaboration with software developers during design and production?
- Reusability: How is the design of a single reusable content component different from the design of an instructional product out of reusable components? What parts of a learning environment can be reused? How do we move from ad-hoc, opportunistic reuse to systematic re-use? What are the tradeoffs involved? Can there be too much reuse?
- Interoperability: At what levels is it feasible to make content interoperable? What goals are achieved by making content interoperable? What is the relationship between reusability and interoperability?
- System maintenance and evolution: How do we design system architecture so that it can survive, and indeed facilitate, bottom-up evolution of the system? What kind of evaluation data should the system collect, and how? How do we document system architecture so that it is understandable by those who will be responsible for its maintenance and evolution?
- Coordination: What happens when we move from managing individual content development projects in relative isolation to managing integrated content development programs? Which design assumptions are challenged when discrete learning products become parts of continuous learning systems?

3. The identification and categorization of design decisions

When a design domain is relatively stable, the explicit articulation of design decisions is less important, since decisions and their consequences are reasonably predictable based on past experience. Process-level issues can generally be resolved on a case-by-case basis in such circumstances. As the transition is made to developing instructional content components for use in distributed learning systems, instructional designers may face a period of domain instability where novel and complex interactions force many tradeoffs to be made unwittingly. Reassessing and evolving processes in light of these challenges will require an understanding of the new design space that instructional content developers are working within. In part, the opportunities and constraints associated with this new context will have to emerge through hard experience. A viable approach for articulating the boundaries and substance of this space in advance, however, is to identify and categorize the macro- and micro-decisions that are made in developing small-scale modular content, and examine these decisions in terms of their scalability to larger, more integrated systems. This is the subject of my current work-in-progress. By examining the development process from the perspective of decisions that are made during design, a top-down, principle-based approach to learning system architecture can be combined with a bottom-up awareness of the individual decisions designers make on actual projects. This is a key stepping-stone in the analysis of the cohesiveness and comprehensiveness of a given set of instructional development processes. The design decisions can also serve to frame, in tangible terms, the relationship between a given pedagogical strategy and its technical implementation.

Abstract: Concerned with the relationship between interaction and learning, this paper aims at exploring relations between interactive flows in an EFL course offered on the Internet and language learning. The course was produced and is run by the research team of EDULANG, an ongoing research project in language learning on the Web and teacher development for the Web. In this research context, interactive flows are being used to record and analyze the rate and type of interaction in the course, identify units, tasks and course spaces that do not promote expected levels of interaction and plan and promote improvement in course structure, course content and teaching strategies.

Aims and Context

This paper derives from ongoing research in the context of EDULANG, a team project that aims at investigating multiple aspects of language learning and teaching in courses on the Internet. The paper is more specifically concerned with the relationship between interaction and learning and aims at exploring relations between interactive flows and language learning. An interactive flow is here defined as a longitudinal profile depicting amount (no. of messages or interactive turns) and direction (sender and recipient) of synchronous and/or asynchronous participation in an online course. The context of the research is an EFL course offered on the Internet (www.cogeae.uol.com/sal). The course was produced and is run by the research team of EDULANG. Aimed at adults with a basic command of English, its general social aim is to offer students the opportunity to make new acquaintances on the Internet. This general aim unfolds into specific social and language-specific, communicative functions. The course officially lasts 8 weeks but can in fact reach 12 to 13 weeks. The interactive spaces make it possible for participants to a) communicate through messages posted to a virtual Bulletin Board (BB) subdivided into three forums (Classroom, Café and Technical Support), b) display (and re-edit) their interactive production to course peers in a Production Panel, c) send progress tasks and tutorial exercises to the teacher through mail-to devices on the course pages and d) participate in online Chats. All communication is carried on in English, except for messages left in the Technical Support forum. As an essential element of learning and knowledge construction, interaction must be evaluated for type, effect and efficiency in courses on the Internet. In this research context, interactive flows are being used to record and analyse the rate and type of interaction in the course, identify units, tasks and course spaces that do not promote expected levels of interaction and plan and promote improvement in course structure, course content and teaching strategies.

Method

Data was collected from indicators about sender, recipient, date and subject of 6 groups of students and their respective teachers, in 1998 and 1999, and include a) messages posted in the Bulletin Board, b) messages with ongoing tasks sent to the teacher, c) texts displayed in the Production Panel and d) participation in online chat sessions. All indicators were available within the course system.

Some Findings

Results were organized in order to reveal graphic flows of interaction involving students and peers, students and teacher, teacher and students. These flows reveal trends within each group as well as across groups. Interpreted in the light of the course context, the graphic flows below have offered support for pedagogical and managerial decisions, as well as for changes in design. Figure 1 indicates that in this course, the amount of student talk tends to be equivalent to or higher than teacher talk. This may mean that in an interactive internet course, students engage in more interaction than students in traditional face-to-face EFL courses. Figure 2 shows that different groups present different types of flows, either with a focus on teacher-student and student-teacher interaction or with a focus on communication among students. In groups where the teacher talks less, interaction among students tends to be higher. In this sense, the amount of teacher interaction with students influences the amount of students' interaction with their peers. Additionally, Figure 2 shows that groups A, B, C and D (taught in 1998) communicate a lot less in the BB than groups C and D (taught in 1999). This suggests a development of familiarity and comfort with educational contexts on the Web for both students and teachers. However, relatively close averages of participation in the 1998 groups (11.07, 5.53, 8.45 and 11.95) and equivalent participation in the 1999 groups (28.28 and 28.38), suggest that students seem to have a *quantitative communicative quota*, that they strive to use, regardless of the interlocutors they choose to have (the teacher or a peer). Figure 3 allows an interpretation of the interactive flows in the BB in the light of course content distribution (weeks 1-3 for unit 1, weeks 4-5 for unit 2 and weeks 6-8 for unit 3). A higher state of motivation seems to be associated to specific phases of the course when participants are all getting to know each other (the beginning) or students are trying to close their participation successfully (the official end, the 8th week). Mid course activities have not been able to sustain adequate levels of interaction (notice the relative drop both in the 98 and 99 groups) and are now being thoroughly reformulated. Figures 4 and 5 offer data for interesting observations. Groups A and B seem to reinforce the *quantitative communicative quota* hypothesis, with task completion and BB message flows in a complementary relationship (lower averages in one flow type complement higher averages in the other). Groups C and D, on the other hand, present opposite results in both types of flows and suggest that teacher management has a big influence on task completion and student participation in the BB. Figure 6 reveals that among students who completed at least 50% of tasks there are more poor "chatters" (23) than good "chatters" (13). However, among the best "chatters" (more than 30 turns) were the best task completion rates. This suggests that completing tasks (a traditional activity) is still favored over other web-typical types of participation and that an intensive participation in chat sessions is usually associated to intensive task completion.

The effects of collaborative, online learning on broadcast journalism students: Perception and understanding of undergraduates at linked universities worldwide.

Marion Coomey
International Centre for Learner Managed learning
Middlesex University
United Kingdom
m.coomey@mdx.ac.uk
marioncoomey@hotmail.com

Abstract: This paper describes a study that is being developed to explore online collaboration between undergraduate journalism students at universities in Australia, Canada, New Zealand, the United Kingdom and the United States. The premise of the study is that by bringing students, instructors and experts together to examine different perspectives of international news stories, learners will develop a stronger understanding of stories that get international coverage. The goal of the research is to develop a consensual and collaborative module that explores international perspectives on global news and to present this module, online ,to teams of students at the partner universities. Data will be gathered from online interviews and questionnaires given before and after the module.

Introduction

In the past decade there has been a growing amount of research in journals, books and conference papers in the area of online learning. Online learning, for the purpose of this research, refers to study that is done using computer technologies with the learner at the same location or at a distance from the instructor.

Many established universities, such as Stanford in the United States, Deakin in Australia, University of Twente in the Netherlands, offer online classes to students who live at a distance from campus, to learners studying part-time and to professionals engaged in life long learning. These classes may have an international reach but are run and controlled entirely by individual universities. The Open University in the United Kingdom and the University of Phoenix in the United States are two examples of universities that are completely online. All students study from a distance but students are still studying at one university and working within the structure and policies of that system.

Most of the online classes described above, involve students working alone online with some support from instructors or tutors via e-mail but with little collaboration amongst students themselves. Collaborative learning, as defined for this study is: learning in an educational program created by a group of partner universities and in which students and instructors get together to examine course content issues. This sort of interactive, online learning is becoming more widely practised. Medical schools throughout Germany (Friedl, 99) share online resources to study cardiac surgery. An online training for trainers course involved learners in 22 European countries (Leino, 99). Organizations such as the United Nations are using online modules to give professionals around the world a chance to study copyright law (Durant, 99).

So far, in this researcher's literature search, most examples of online collaboration involve engineering, science, medical and business programs and most of the collaborations are developed at one university. Telg (96) noted that in the United States "few collaborative distance education efforts have taken place between American universities and universities in other countries".

In this researcher's area of interest, broadcast journalism, there is little documentation in the literature of any programs using online collaboration as a learning tool.

Study

It is becoming easier and easier for journalists to quickly gather information from any part of the world and disseminate it to any other part of the world but McGregor (98) asks is "the news is better reported with more understanding as a result of the new technologies". We are sending young broadcasters into a world of instant information, instant analysis and instant conclusions about global news issues. One of the questions raised by this study is: do those young journalists, and the experienced story tellers for that matter, have the enough understanding of global issues to provide clear, non-biased reports?

The premise of this study is that by linking students, instructors and broadcast experts in online discussion and by working in international teams on assignments and presentations concerning global news, the learners will develop a stronger understanding about stories that gain international media attention. The researcher is working in consensus with partner instructors in Australia, Canada, New Zealand, the United Kingdom and the United States to develop a collaborative module that will allow students to examine and discuss international perspectives on global news stories. Students will gather at the module web site that includes: structured and unstructured forums for discussion and debate, a location for students, instructors and industry professionals to interact, links to broadcast networks worldwide plus visual and written content that takes the learner through the module and its assignments step by step.

Data will be gathered using a quiz to examine students' knowledge of global news issues, before and after the module is run. Learners and instructors will respond to questionnaires online before and after the module and will participate in structured and informal taped interviews to elicit personal and anecdotal information. At least ten students from each partner university will participate in the first run of the module in April 2001.

The result of this study will be to establish an international circle bringing learners with different backgrounds and understandings of international news, into an ongoing discussion. The timing is right to examine how online collaborative learning functions within the untested area of broadcast journalism and to determine if there is a benefit for students in using this new teaching/learning method. This study aims to bring issues of online learner effectiveness to light to provoke further discussion research and practise in this area.

Over the next decade, there will be an increasing digital gap between higher education institutions offering and not offering online courses. This will result from the lack of planning by offline institutions in information technology policies, networking and technical infrastructure, and access to remote electronic library resources. This is not an all or nothing situation. Some offline institutions have laid plans for a digital learning future. But compared to online institutions, they have less extensive plans. It takes several years of laying down the technical infrastructure before we see the results in suites of online courses. An institution cannot decide one year to start putting in place such an infrastructure, and then expect to see the results the following year in a dramatically increased online learning.

We mailed 8 questionnaires to 310 colleges, CGEPS, and universities in English and French Canada. 134 institutions returned at least one questionnaire from June, 1999 to April, 2000, for a response rate of 43%. The response rate was good among the 60 universities (89%), but poorer among colleges (35%) and CGEPS (25%). This is due to the inclusion of many very small colleges and CGEPS that had difficulty filling out complex questionnaires. The questionnaires were completed by 8 senior officials responsible for policy and implementation of information, communication, and learning technologies (questionnaires returned are in parentheses): VP or most senior officer responsible for information and communication technology policy (82/134 =61%); manager or director of networking and technical infrastructure (72/134 = 54%); head of computer support (84/134 = 62%); director of audio-visual services (68/134 = 51%); head librarian (68/134 = 51%); head registrar (69/134 = 52%); director of instructional development or academic or teaching technologies center (75/134 = 56%); and, president of the faculty or teachers' association (47/134 = 35%). The following comments and analyses are based on these data.

INFORMATION TECHNOLOGY POLICIES

VPs of Information Technologies at institutions offering online courses, compared to those not offering online courses, placed more emphasis over the next 3 years in: instructor training in teaching technologies; recruitment of more technical staff; cooperation with other institutions in software licensing; encouragement or requirement of student computer ownership, and provision of open access computers to students. If we expect the information technology gap to close between online and offline institutions, institutions not offering online learning should emphasize these policies at least to the same degree, if not more, than institutions offering online courses. But this is not so. Over the long term this will lead to a growing gap between online and offline institutions.

NETWORKING AND TECHNICAL INFRASTRUCTURE

We asked Managers of Networking and Technical Infrastructure how much they emphasize servers, networking, student computers, and wireless devices in their plans. The data on servers reflects the declining use of UNIX (despite its history and stability), and the rise of Linux and Microsoft NT servers. But institutions offering online courses are more likely to have all three server types in their plans than institutions not offering online courses. This may reflect the greater demand on servers among institutions that offer online learning. However, online courses are not the only demand for servers; they are used for a wide variety of administrative and educational functions. Our question did not tie the server type to a particular online learning use. The data probably reflect a more general difference in information technology configurations between online and offline institutions. Online institutions are also much more likely to expand wired and wireless networking, fast ethnernet connections, notebook and other mobile computing devices, and student computer lab capacity. The differences are so large that this kind of weak infrastructure in offline institutions will likely undermine their inability to offer future online learning.

DIGITAL LIBRARY RESOURCES

If institutions not offering online courses expect to catch up to institutions offering online courses, they should reduce their expenditures on hard copy print library resources as much as or more than institutions that are heavily into online learning. In fact, that is not the case. Offline higher education institutions plan to spend more on hard copy print library resources. A greater percentage of head librarians of institutions offering online courses plan to expand electronic library resources over the next three years in contrast to offline institutions. This reinforces the view that institutions already offering online learning are forging ahead with additional plans to develop and extend their information technology infrastructure, in this case the library infrastructure, in contrast to institutions not offering online learning. Our data also suggest that most libraries are moving quickly into the electronic age on almost any information technology question we asked. But only about one-third of head librarians plan to emphasize student e-mail access over the next three years. Libraries do not view themselves as centers for providing students with e-mail access; such services and access are available elsewhere on campus and from off-campus.

SUPPORT FOR ELECTRONIC COURSEWARE

Directors of Academic Technology and Instructional Development Centers at institutions offering online courses plan to emphasize the following between 2000 to 2003 in contrast to institutions not offering online courses: funding for teaching support and teaching technology support units; funding for free instructor workshops in academic technologies; training instructors in computer literacy and web design; funding for instructional technology projects proposed by instructors, academic programs, and departments; web course outlines; interactive multimedia web courseware with full instructor participation to teach the courses; standalone interactive web courseware with minimal instructor intervention; e-mail in courses; computer conferencing in courses; and, computer-supported collaborative learning (CSCL) in courses. However, those items receiving the greatest endorsement over the next three years among institutions offering online courses are: course outlines on the web; computer conferencing in courses; computer supported collaborative learning in courses; and, training instructors in web design. The least emphasis in plans over the next three years are in user-pay instructor workshops in academic technologies, and funding for instructor release time to work on teaching technologies.

REGISTRAR PLANS FOR SUPPORTING ONLINE LEARNING

Among head registrars at Canadian higher education institutions, there is a moderately positive association between the number of online courses offered and plans over the next three years in: student web registration; electronic delivery of student academic counseling; web course evaluations and course outlines; courses geared to job skills; distance education courses; computer conferencing, video-conferencing and e-mail in courses; computer-based training; and, linking electronic classrooms between institutions. There are no plans among registrars in institutions with many online courses to move into general paperless office procedures and web calendars over print versions (already done); student computer competencies (these skills are assumed or picked up as students take online courses); instructor online access to class lists and online submission of student grades; and, information technology in face-to-face courses . There are three areas in which registrars with low numbers of online courses plan to emphasize over the next three years, while registrars at institutions with many online courses will definitely not emphasize: part-time student enrollment; continuing education; and, instructor access to student academic records. It is often assumed that distance online learning goes hand-in-hand with continuing education and part-time studies. This may have been the world of traditional distance education. Online learning has moved out of continuing and part-time studies into full-time studies. We are probably witnessing here a transition in the academic programming of distance education as it moves from offline print correspondence to online learning.

DEVELOPMENT AND DELIVERY TOOLS OVER NEXT THREE YEARS

We asked directors of Instructional Development and Teaching Technology Centers the emphasis that their institutions will place on development and delivery software over the next three years. Institutions offering online courses indicate that they will move more strongly in the direction of the top software in the market. Over three quarters (78%) of institutions offering online courses indicated that they will move even more strongly in the adoption and implementation of courses using Web CT. Even among institutions not offering online courses, almost one-third (30%) plan to adopt WebCT. No other software comes close to WebCT in the future plans of institutions. However, there is significant growth potential in Lotus Notes, Centrinity's FirstClass, Macromedia Director and Authorware, Asymmetrix's Toolbook, and the Web Board. There does not seem to be much growth potential in Virtual-U, Question Mark, Allaire Forum, Norton Connect, and Web Course in a Box.

CONCLUSION

There is little evidence to suggest that institutions not offering online courses will soon catch up to institutions currently offering online learning. They have not prepared their technical infrastructure for offering online courses. Their main hope might be closer collaboration with neighboring institutions that have prepared their own infrastructure for a digital future in online learning.

SUPPORTING A COMMUNITY OF PRACTICE: THE ROLE OF WORKERS AS LEARNERS

Maarten de Laat, Frank de Jong and Julian ter Huurne
University of Nijmegen and the Education and Knowledge Center (LSOP) of the Dutch Police
m.delaat@ped.kun.nl

Abstract: In this paper we focus on the use of computer supported collaborative learning (CSCL) in an organizational setting. The program we use is Web-Knowledge Forum. Although there is a lot of experience in using Knowledge Forum in a classroom setting, little is known about how to implement and work with this program in an organization other than schools. The problem investigated in this pilot study is how a community of practice uses Web-Knowledge Forum as an online learning environment to discuss work-related problems. This study focuses on role of the worker as a learner in an unstructured process of negotiation of meaning in a community of practice. In the study eight police officers participated by forming a heterogeneous group initiated by the Information Management Approach of Criminal Investigation in Police Education (ABRIO) a subdivision of the Dutch police force.

Introduction

A learning organization stimulates the ability to learn individually, in groups and to learn by the organization as a whole. The aim in this is to support continuous learning to combine and develop knowledge in the organization in order to respond flexible to changes that occur in the market (Bolhuis and Simons, 1999). There is a tendency to organize this learning as close to the workplace as possible instead of sending people to courses given outside the workplace (Van der Krogt, 1995; Nonaka & Takeuchi, 1997; Bolhuis & Simons, 1999). Revans argued for action learning. He formed learning teams to work on real organizational problems and to structure their experience in such a way that both useful solutions to these problems emerge and substantial learning occurs for participants (Vaill, 1996). So the employees are recognized as an important resource to the organization. According to Wenger (1999) people in organizations form communities of practice by helping out each other and discussing the latest developments. These communities of practice are bound by a shared practice related to a set of problems. In these communities they share and create knowledge; they learn through participation (Wenger, 1998). Membership to these communities of practice is voluntary, these communities are not bound by organizational affiliations.

In large organizations like the Dutch police force online communities have an advantage in bringing people together independent of time, space and local cultures. CSCL makes it possible for people to participate in communities of practice and work at their own pace and time. One of the programs that support this kind of collaboration is Web-Knowledge Forum. Web-Knowledge Forum is a discussion program designed to form a learning community over the Internet. It's a product of the Computer Supported Intentional Learning Environments (CSILE) family, developed at the Ontario Institute for Studies in Education (OISE) to support the collaborative construction of knowledge (Scardamalia & Bereiter, 1992). The participants operate in a shared workspace in which they read and write notes. A note is a contribution that can contain text, pictures and links to documents, html pages or other notes in the shared knowledge workspace. Working with this program stimulates the participants to talk about the subject, read relevant resource materials, pose questions, offer theories, conduct experiments, and work together to make sense of new ideas. By working together participants develop greater competence in a particular subject area, using what group members already know as an important component and co-constructing plans of action to extend that knowledge (Hewitt & Scardamalia, 1998). The creation of knowledge therefore is seen as a social product.

Originally this program was designed for use in the classroom to support the construction of knowledge in a social context. The aim in the development was to support an environment that will make it possible for schools to function as knowledge building communities (Scardamalia & Bereiter, 1992). Within knowledge building communities the focus is on knowledge construction. It's a knowledge-centered community of practice.

The problem we face is how to facilitate the creation and support of communities of practice in organizations that work in a Web based environment and make knowledge building the core of their activity. In the first place there has to be identified a 'real' and meaningful problem that exists in the organization. A problem that is owned by the participants and in which solution they are willing to put effort. Second the members of the organization who feel affiliated by this problem have to form a community in which they can participate on a voluntary and functional basis. In this paper we focus on the possibilities of Web-Knowledge

Forum to serve as a meeting place for such communities. A place where participants can work together, undertake collaborative learning activities, sharing their knowledge, aimed at deepening their expertise in the problem to be solved.

Our question is: Can groupware, e.g. Web-Knowledge Forum, support the negotiation of knowledge and understanding in communities of practice in an organization?

We focus on the role of the worker as a learner in an unstructured process of negotiation of meaning in an online community of practice.

The study

This study was conducted to gain experience with participants who were engaged in an online learning community. The community consisted of eight participants who voluntary joined in the community. They responded to a letter that was sent by the ABRIO to several police departments explaining the problem that has to be solved. The problem was about how to identify and describe general work-processes used in the field of criminal investigation. As a whole the participants formed a heterogeneous group (policy makers, criminal investigators and experts).

During a period of two months they worked together using Web-Knowledge Forum. There was much uncertainty about how to identify work-processes, therefore the participants agreed to start with an open discussion on the subject 'work-processes', instead of following a structured plan of action to tackle the problem. Web-Knowledge Forum played a central role in supporting the discussion because all the written contributions are stored as notes in a shared database available to all the participants. The discussion was divided into certain subjects called views in which the participants contributed a note or comment on a note they had read, by writing a build-on note.

Instruments

The way people participated and interacted with each other provides information about the activities of such a community. Web-Knowledge Forum is provided with an analytic toolkit (ATK) that analyses the activities of the members of the community in the database. It creates log files of all the users about how many times they have read, write or edited a note. How many notes are linked to each other and how many 'build-on's there are made.

Web-Knowledge Forum is designed to facilitate cognitive and metacognitive activities by providing opportunities to give your opinion, to give a comment, or by making suggestions or providing new information. Because of these possibilities it is important to know more about the nature of the content of the material the community has created together and what kind of activities the participant undertake. Are they trying to advance their knowledge? Veldhuis-Diermanse (1999) developed a coding scheme to gain information about the content of the written notes based on the constructivist view of learning in an educational setting. This coding scheme is still in a design stage and it is the first time this scheme is applied to an organizational community. This coding scheme consists of three main categories: 1 Cognitive activities, 2 Metacognitive activities, and 3 Affective activities.

1 Cognitive activity: Cognitive activities are used to process and acquire insight in the information being discussed. Veldhuis-Diermanse recognized three subcategories of cognitive activities: 1 debating, the accent is on arguing, presenting new ideas or thoughts about the subject; 2 using external information, the accent is on referring to information found in other sources than the database; and 3 linking or repeating internal information, the accent is on referring to information found in the shared database.

2 Metacognitive activities: Veldhuis-Diermanse (1999) describes metacognitive activities as activities undertaken to regulate each other's learning process or to regulate the goals and direction of the discussion.

3 Affective activities are used to cope with feelings occurring during the discussion among the participants (Veldhuis-Diermanse, 1999).

At the end of the pilot-study we gave the participants a questionnaire to gain information about their experiences working with Knowledge Forum.

Results

The log files generated by ATK gives a description of the activities that has taken place in the database (Tab. 1). The participants contributed 98 notes in the database. That's an average of 12,25 notes per participant. 56% percent of the notes have been read. This means the amount of notes that have been opened by the participants. So this might exaggerate the actual reading that has been done. 83% percent of these notes are linked, also called build-on. The log-file only records the activities of the participants, a build-on activity therefore does not have to be content related. Table 1 shows that there are substantial differences between the participants, both in writing and reading. Notice that build-on notes are also a part of the written notes.

	Written	Build-on	Read
N	8	8	8
N	8	8	8
Mean	12,25	10,75	232,62
Mean	12,25	10,75	232,62
Std. Deviation	9,54	8,80	147,51
Std. Deviation	9,54	8,80	147,51
Minimum	1,00	1,00	113,00
Minimum	1,00	1,00	113,00
Maximum	30,00	26,00	552,00
Maximum	30,00	26,00	552,00

Table 1. Participation in the database

The content analysis of the notes reflects the following cognitive and metacognitive activities (Fig. 1).

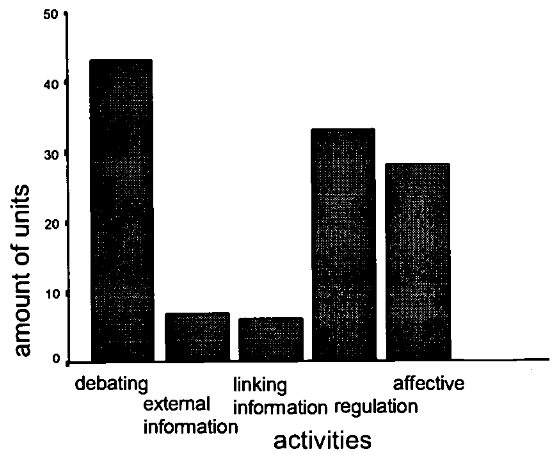

Figure1. Activities in the database

These results indicate that the participants discuss a lot about the subject. The participants present a lot of ideas of there own and start discussing about that in the community. The participants do not bring in much new information; only seven times they referred to information that can be found outside the database (e.g. book pages). Also they did not make many content related references to the contributions of other participants in the database. Although according to the ATK 83 % of the notes are linked. This difference is explained by the fact that the coding scheme only refers to written comments to other contributions in the database. The participants show quite a lot of regulative activities, but in fact two participants are responsible for 66% of the regulative activities. There are quite a lot of affective contributions in the database. The explanation for it is that this way of working was new to them and therefore they were regularly asking for feedback and gave a lot of general reactions to the other participants. This category shows that they did not use this medium for chatting or sending 'e-mails' to each other, that are not related to the discussion. Most contributions even the affective ones were subject related.

The questionnaire provided information about the way participants worked with Web-Knowledge Forum, five out of eight were returned. 60% of the participants agreed on the question if they were collaboratively building new knowledge about 'work-processes', but they pointed out that they need to grow more into building upon the ideas of others. Also they mentioned that there was a lot of confusion about the concepts being used and that they need to clarify the goal of their study, to give more direction to the discussion. 80% of the participants indicated that they were satisfied with the opportunities, provided by the program, to discuss the subject together. The participants (80%) notified to have enough information to be able to take part in the discussion. Answers to the question, what they do if they lack certain information, are searching for relevant information, consulting colleagues at work, and trying to stimulate the other participants to explain certain issues. Results of the question about what they thought of the quality of the written notes, varies from good to reasonable. In general the quality is good but the discussion became more silent later on. "There is to little structure to guide our discussion, the notes contain valuable information but what does it bring to us?" 40% of the participants indicated that there was to less coordination during the discussion. 60% of the participants pointed out that a more structured or goal directed approach is necessary. They argue that this will help them to achieve agreement and build on to that.

Conclusion and Discussion

Summarizing the results it can be seen that the participants show a lot of activity in the database although they read much more than they contribute. Related to the content analysis of the contributions. It seems that the activities the participants undertook are more discussion oriented than building knowledge upon already contributed or new information. However in their perception of working with groupware they appreciate the possibility of knowledge sharing. On the first glance people are willing to work in a groupware environment and share knowledge together. This is promising for the support of working in communities of practice in organizations. The analysis also shows that sharing of knowledge does not happen automatically. Although there are a lot of regulation activities, it turns out that they were mostly carried out by two participants. The questionnaire reveals that the community members desire more structure and support to direct the knowledge building activities of the community as a whole. The use of groupware in communities of practice in organizations seems promising. The participants report that this tool is useful for knowledge sharing but that the actual knowledge building activities needs to increase. They had trouble clarifying the goals and direction of the discussion. Also they discovered that there was quite a lot of confusion about the concepts used by the participants. The main concern was lack of coordination during the discussion. In an unstructured process of negotiation nobody feels direct responsibility to organize and structure the content of the problem studied. The lack of the learning ability in the sense of regulating the content and community processes seems to be crucial for people to become used to share knowledge, deepening their own and common understanding and creating further insights. To compensate this lack one can structure the negotiation of meaning by making a learning agenda. By which participant express their goals, divide certain tasks, and divide responsibilities (e.g. coordinator of the content, someone who keeps the community together or invites new participants when needed, technical assistance). One can also introduce a didactic approach of inquiry analogue to phases of the scientific enquiry process or problem solving.

Abstract: Federal mandates enacted on August 7, 1998 revealed that "Effective 2 years after the date of enactment...any individual with a disability may file a complaint alleging that a Federal department or agency fails to comply with subsection (a)(1) in providing electronic and information technology. (Section 508. "Electronic and Information Technology) "The new rules will apply within a few months to all web sites operated by government agencies...By August 7, 2000, they will extend to vendors doing business with the federal government. "Possibility soon afterward they may extend to every Web site posted in the U.S." (Adam Clayton Powell III). Are ready for August 7, 2000? If not, this paper can provide ideas to help you get started.

Introduction

In PC Week Online, Vaas (2000) notes that between 95 and 99 percent of web sites are inaccessible to the visually, hearing -and/or mobility impaired. Many web developers are ignoring the accessibility issue or just do not know how to making their sites universally accessible. They are bewildered in the face of the vast information available in terms of how to make it applicable to their situation. Three areas can help focus the journey to understanding.

What's What

The law is the driving force behind the need to have universal web sites. There are already been law suits against AOL and Universities for not providing accessible web access. Equally access to information is the key reason that the focus is on web sites. Individuals cannot fully participate in today's complex society based on technology-based information if they do have access to the same information. There are several references to the law at the following web site:
http://www.swt.edu/~df12/summit/LAW.HTM

Who's Who?

This paper will mention just a few of the leaders in the field who are trying to make electronic information globally accessible. **The first is W3C.** Their mission states "The W3C's commitment to lead the Web to its full potential includes promoting a high degree of usability for people with disabilities. The Web Accessibility Initiative (WAI), in coordination with organizations around the world, is pursuing accessibility of the Web through five primary areas of work: technology, guidelines, tools, education & outreach, and research & development."
(http://www.w3.org/WAI/) W3C focus is for experienced programmers and guidelines can be found at the following address:

http://www.w3.org/TR/1999/WAI-WEBCONTENT-19990505/

Accessible Web Authoring Resources and Education **(AWARE)**, mission is to serve as a central resource for web authors for learning about web accessibility. The AWARE Center was launched in April 1999 as part of the HTML Writers Guild's (HWG) annual Web Accessibility Month, a special focus on the importance of designing for universal accessibility. The Center is supported by the Guild's staff and volunteers, and is designed as a resource for all web authors. Ken Barlett co-founded the HTML Writer's Guild with Martin Bayne. The HWG is the world's largest international organization of Web authors with over 130,000 members in more than 130 nations worldwide. The HGW exists to assist its members in developing and enhancing their capabilities as web authors, to compile and publicize information about standards, practices, techniques, competency, and ethics as applied to web authoring, and to contribute to the development of the web and web technical standards and guidelines.

Disability Access Information and Support **(DAIS).** Jane Jarrows, President, states, " But after we got the ramps and elevators installed, we could think about how to make the teaching that had always gone on in those classrooms fully available to all students. The parallel ends here. While we are scrambling to get the technological "ramps and elevators" in place, we are actively creating new barriers to access on a regular basis. At the risk of stretching the analogy a little too thin, if we don't be careful we will find that when those technological ramps and elevators we installed are finally in place, they only allow for a better view of the opportunities passing by us. We cannot wait to get the technology in place before we start trying to impact on the application of that technology

Microsoft. The Microsoft Senior Initiative is a program aimed at bridging the digital and generational divides and ensuring that seniors are not left behind on the information superhighway. By providing access to information technology and PC literacy training, the Microsoft Senior Initiative introduces the exciting possibilities of technology to senior citizens. The Seniors and Technology Web site (http://www.microsoft.com/seniors/) is a resource for seniors, their families and communities about the exciting possibilities that can be realized through the use of technology.

How to? For people who are just learning how to develop web pages, the easiest way is make a page using a "what you see, what you get editor," then save the web page as text and htm. The problem with this method is that that many people do not do an adequate job of keeping both pages updated. Software companies are starting to make it easier to make web pages accessible through what is called, style sheets, which control the presentation of a document. It is often easier to work in pairs or teems of two to learn this process. There are often many free workshops on the web and in your local area. Perhaps partner with someone who can pay to have a consultant.

Design is the first part of "how to." The second part is getting your page validated by a reliable source. Sites can be easily validated using on-line features which require that you paste your URL name in the box and almost immediately you will learn if you have accessibility problems. The top two sources of validation are:
Bobby Accessibility Validator
http://www.cast.org/bobby/

W3C HTML 4.0 Validator
http://validator.w3.org/

The complexity of implementation of this mandate can not be fully address with this in progress paper; however, there will a much greater discourse at the Universal Web Accessibility Symposium 2000 (at WebNet 2000) -- San Antonio, Texas, October 31, 2000.

Introduction

Many educators are experimenting with flexible on-line learning; consequently academics have to adapt their delivery, preparation and course administration. This study shares staff and student experiences of participating in a completely remote on-line course, compared to a flexible on-line course where students can attend classroom sessions.

The issues we encountered included ones related to hardware and software, submission of assessments, student communication with each other and the lecturers, as well as student and staff motivation over the holidays.

Existing research documents the pitfalls of teaching on-line and we used these lessons to anticipate problems as we planned our on-line course. This study documents the problems we encountered but hadn't anticipated.

THE COURSE

Internet and Web Design (IWD) is a popular first year introductory course in the Bachelor of Computing Systems degree. It is normally taught flexibly with lectures and practical classes as well as a self-paced on-line course comprised of notes, exercises, self-assessment questions and a discussion forum (1). In the 1999-2000 Summer School, the course was offered completely remotely and condensed from 14 to 11 weeks. There were no face-to-face sessions except an orientation session, the project presentations and final exam. If students had problems they were requested to post their question on a discussion forum and had no option to ask the lecturers face-to-face.

DISCUSSION

Student issues

No time for a Summer break, condensed time frame, lack of personal tutor-student contact, no option of attending classroom sessions for personal contact with other students and no opportunity to take on a vacation job. Perhaps because of the above issues, there was a higher level of drop outs than normal. Reasons for students dropping out included: getting a job, workload too heavy and no computer access at home

Staff issues

Lack of a gap between semesters to attend to the course administration for the previous course. We undertook the course as an extra to our workload, meaning no summer break to recharge and prepare for the next semester. Most of the workload consisted of administration and marking and we felt the remuneration we received did not reflect the associated workload.

Bulletin board issues

If students had problems they were requested to post their question on the discussion forum rather than e-mail the lecturers, (so that we could avoid duplication of lecturer responses and attempt to mirror classroom communication by allowing students to answer each others' questions when lecturers were not around). Despite our attempts to encourage participation, the use of the bulletin board was fairly low, with only 140 posts over the whole Summer School. Many students continued to email the lecturers rather than use the bulletin board for questions. Perhaps this was because they didn't want to look unknowledgeable in front of their peers, or because we didn't assess the students' contributions (2,3). Lecturers accessed the bulletin board every other day to check for questions to answer. The lecturer's often interrupted their vacations to make special trips to cyber-cafes, only to find that no students were seeking help.

Assignment submission issues

Students didn't email their assignments to the correct address, often sending them to our home email addresses and multiple addresses. Issues resulting from this included: lack of software at lecturer's home; lecturer's vulnerable to the risk of virus infection; and duplication of administration effort. There was a significant administrative burden for the lecturers who had to confirm receipt by email and print out the assignments. This was exacerbated by the often inappropriately large file sizes of the email attachments, (e.g. one Storyboard Word document was 3.5Mb).

Group work issues

Generally, students find it difficult to work in groups. This is exacerbated in an on-line course by having to use the printed word rather than face-to-face interaction. The condensed timescale of the course made this even more of an issue and one of our groups suffered a complete breakdown in communication. During a Semester course it is easier to identify problems with group dynamics and deal with them before they escalate.

CONCLUSIONS

The students had a generally favourable impression of on-line learning, but with reservations about the lack of personal contact and the high workload due to the collapsed course time-scale. Reasons for the course's success included: anticipating possible problems and devising strategies to deal with them; and the considerable amount of user-testing that took place in the prior flexible on-line versions of the course, when semantic problems could be cleared up easily.

However unexpected problems were: inter-group conflicts; a higher than normal drop-out rate that impacted on other group members; higher than normal administrative burden on the lecturers; and serious practical problems with the publishing of student web-sites using FTP (4).

It is important to spend time forming project groups, to let the students get to know each other's skill-set and interests thereby avoiding problems. This is perhaps even more important in a fully on-line course.

Abstract: Offering video and other rich media content over the Internet is an emerging growth area and represents a new model and opportunity for education. As broadband access increases and advances are made in network caching, streaming servers, video and audio compression, and multimedia databases, delivering streaming video claims unprecedented potential for education. Universities and corporations will continue to look to technology to deliver distance education and web based courses. Determining the pedagogical applications of streaming video is an important area of research. Identifying the strengths and weaknesses from an educational point of view provides an important context to the practical matters of technical implementation. This research intends to investigate both the pedagogical implications and the technical implementation of streaming video.

Overview

Offering video and other rich media content over the Internet is an emerging growth area and represents a new model and opportunity for education. As broadband access increases and advances are made in network caching, streaming servers, video and audio compression, and multimedia databases, delivering streaming video claims unprecedented potential for education. Universities and corporations will continue to look to technology to deliver distance education and web based courses. Determining the pedagogical applications of streaming video is an important area of research. Identifying the strengths and weaknesses from an educational point of view provides an important context to the practical matters of technical implementation. This research intends to investigate both the pedagogical implications and the technical implementation of streaming video.

Often when new technologies, like video, are applied to education they are seen as having the ability to make us all learn better and faster. Some of the questions that need to be answered regarding pedagogy include:

- Does streaming video over the web offer any more promise than standard videotape, the Laser Disc, or the CD-ROM?
- Can the metadata applied to streaming video offer learning strategies and information that was previously unavailable?
- Does the distribution medium, the Internet and a computer, improve the quality or access to instruction?
- What are the ideal tools and methods to develop content and sufficient metadata that make streaming video effective in teaching and learning?

In addition to the pedagogical perspective, there is a highly technical aspect of streaming video that affects price, availability, usability, performance, and quality. The following technical components will be investigated:

- Copyright, Security, and Intellectual Property
- Multimedia Databases
- Servers
- Clients
- Compression
- Network Caching and Bandwidth Issues

Finally, partnerships with industry suppliers, distributors, faculty, and technology solutions will be investigated in an effort to provide business models that can recover the costs of implementing and delivering streaming video content for universities.

Currently, the pedagogical potential of streaming video has not been demonstrated, the technology is so new that it remains largely untested in a learning environment, and content development tools are crude or non-existent. Answering the various pedagogical and technical questions are important outcomes of this research project. Performance indicators of this research will include the application of streaming video technologies to multiple content areas - including campus and off-campus users. In addition, the partnerships developed with industry, such as Akamai or other industry partners, will be measured against the benefits to the institution.

Detailed Description

Applications for streaming video are various. They include: webcasts of special lectures; access to a rich educational video library; video and audio conferencing; the integration of video into course web pages; and the creation of video-based educational objects. The effectiveness of this technology to teaching and learning is largely untested, but none the less the demands to incorporate it into teaching and learning are starting to be met by the technology. Only recently has a distribution medium become available that allows full text searching of video, the application of metadata, interactivity, and other media in ways that make the use of video in education more flexible than ever before. Research into the tools, usability, educational effectiveness, and various solutions benefit current and future teaching and learning at our post-secondary institutions.

The focus is on three main aspects of streaming video. These are quality and performance, pedagogy, and business models. Compression algorithms, the end user software, or client, networking technologies and server solutions impact quality and performance. In order to study quality and performance, various partners around the world are providing and testing content. Other partners, that can provide performance enhancements to streaming video including, cable companies, phone companies, and broadband access providers is under investigation. Various solutions' quality and performance will be compared by individual reviewers and focus groups in several locations. Quality and performance will be tested given different conditions, including connection speed, time of day, distance from server, end-user platform, server characteristics, compression algorithm, and client. Akamai's Free Flow server technology will be tested to compare performance enhancements at a regional and international level. Campus and off-campus user tests will determine quality and performance standards for the main streaming video solutions.

Streaming video, in itself, is like any other video format from a pedagogical point of view. Video, in general, is considered linear and lacking interactivity. If putting learners in front of a video feed was effective, we would learn from home, in front of our televisions, watching a video taped lecture. Clearly, streaming video of lectures over the web does not represent any educational advantage over distributing VHS copies of lectures. However, the potential for the video and audio to contain additional information may provide an educational advantage. Using video taped scenarios that demonstrate procedures and principles can be an effective use of video. Marking up that scenario with additional information, or metadata, may demonstrate clear advantages for teaching and learning. Creating interactivity, allowing the learner to make decisions, search text, navigate non-linearly , and interact with the video may allow a learner more effective access to learning using video than previously possible. Demonstrating the possibilities is not simple. Tools that develop the metadata, and procedures that accommodate advanced content development for video are crude and difficult to use. In fact, although the need and technology exist, there no cost effective methods for creating a transcript of a video without the use of an individual typing what they hear into a computer. The expense of adding this metadata discourages its inclusion. The goals here are to demonstrate its potential and to discover processes and tools that permit the inclusion of metadata for streaming video. It is anticipated that this research will more clearly specify the need for content development software to be developed.

Associated with content development for the metadata of video are the data stores for the video and its metadata. There are several commercial database solutions currently available and establishing the criteria that matches sound pedagogy for the database is an important outcome of this study. One of the issues is extensibility of the database. Scalability, compatibility and reusability are all related to extensibility. The momentum of educational objects and IMS metadata standards for education dictate the need for the open, flexible standards and an object oriented approach. A solution where costs do not prohibit university access to necessary features, while offering security and intellectual property protection will be sought.

The third aspect of this research focuses on the costs, partnerships, infrastructure requirements, and opportunities of streaming video for institutions. In essence, a business model that can sustain the delivery of streaming video for the institution. Costs associated with video production, editing, and compression are high, adding in metadata and storing in it all in large database applications can be very high. Pricing varies widely between suppliers and solutions and an investigation into the details will lead to recommendations for implementation. Other costs associated with streaming video include servers, licensing fees, and Internet infrastructure. A detailed comparison of these costs against the performance and quality testing will lead to additional recommendations.

In addition to the cost/benefit analysis, the opportunities for collaboration with the private sector is being investigated. Opportunities exist that allow the university and its faculty to recover royalties to its intellectual property and charge for access to its servers. Streaming video over the web could prove to become the best distribution medium available for the thousands of hours of video already produced and owned by our institutions. Developing the types of partnerships and business models that could help support delivery, provide new content, build infrastructure, reach broader audiences, and maintain hardware and software is being prototyped at the University of Calgary.

Summary

The various complex issues from network, to compression, multimedia databases and usability require research, development, and testing to determine the best solutions for the institution. Guided by sound pedagogy, the framework suggested above is meant to get to some of the most important and practical issues, enabling the recommendation and adoption of solutions for the use by a post-secondary institution.

The Impact of Visualisation on Chemistry Teaching and Learning

Abstract: The availability of computers, the emergence of new visualisation and authoring tools and techniques, together with the expansion of web based learning environments and CD-based multimedia applications, offer chemistry teachers new possibilities for bridging the gap in students' knowledge and understanding of abstract and concrete chemical concepts and processes. This paper shows by example how the advantages of both the Internet and the interactive CD-ROMs can be used to improve students' learning at both macro- and microscopic level. We present results of a study of the effects of interactive multimedia teaching units on the quality of knowledge.

Introduction

The old Chinese saying, "a picture is worth a thousand words", has been proven many times by modern neuropsychological studies. Human beings can memorize 20% of what they read, and 30% of what they hear, but 40% of what they see, 55% of what they say, and 60% through active involvement; however, when all of the above sensory channels are used simultaneously, this results in the memorization of 90% of the content (Rose, 1993). According to the Gardner theory of multiple intelligences (Veenema & Gardner, 1996), we possess a number of relatively independent types of intelligences: linguistic, logical, musical, kinesthetic, spatial, inter- and intrapersonal. Each individual has the natural ability to use some of his sensory systems better than others. This shows that many different communication channels have to be used to achieve similar objectives with most of the learners. Spatial intelligence is commonly linked to visualisation and can, like all intelligences, be improved by various activities (e.g. in chemistry through use of models of chemical structures), which should be increasingly incorporated in the teaching and learning process.

In chemistry, three levels of visualisation are defined, which we explain by the example of chemical experiments. At the macro level, the real world is representable by photographs, drawings or video clips of the laboratory experiments. The 3D models of chemical structures or animations of chemical changes represent the micro level. At the symbolic level, chemical change is visualised by chemical equations or graphs. In order to achieve the learning objective, all three levels have to be correlated.

In this paper we present our work on the design, development and evaluation of interactive multimedia teaching units and web based teaching resources to be used at the primary and high school level. They can be used either for individual learning or in parallel with the traditional teaching tools in the classroom situation.

Development of multimedia chemistry teaching materials

In the design and implementation phase of the underlying CD-ROM applications of teaching materials all three different levels of visualisation in chemistry are taken into account. By using video, animations, and simulations coupled with interactive questions, games and problem-solving tasks, the users have, e.g. in the case of a chemical reaction, the possibility to observe chemical changes in reactants and products as well as energy changes, to follow them step-by-step, and then evaluate their observations. We try to simultaneously activate as many of their receptor channels as possible, and the use of nonvisual and static elements is kept to the minimum; the learning and testing

segments are tightly interlaced. Through communication - either live discussion with a teacher or via guided online discussion groups - the concepts learned are further clarified and relevant information is shared among the users.
The use of existing multimedia teaching materials in schools is supported by the intensive in-service training seminars for chemistry teachers. Teachers become prepared for active involvement in the development of teaching materials, produced by the University. To facilitate the needs of teachers and students, a specialized chemistry website named KemInfo was established. It includes a module on the visualisation of chemical structures and processes, together with tutorials for existing high quality educational multimedia CD-ROMs. It also provides the users with original interactive teaching materials, prepared either by teachers, through small-scale projects, or by the university lecturers. The teaching materials vary in size and complexity, the emphasis being on the applications using visualisation techniques (e.g. interactive maps of chemical reactions) and interactivity (collections of interactive exercises and games).

Evaluation of multimedia chemistry teaching materials

In spite of the rich assortment of educational CD-ROMs for chemistry, very little has been published regarding the impact of multimedia on the knowledge and motivation of students, let alone the cost-effectiveness of these products. In a research project, our own interactive multimedia CD-ROM, "Light and Chemical Change", was evaluated. The impact of multimedia on cognitive, motivational and motoric development of students was investigated in a qualitative study. The research involved a sample of 50 third-year secondary school students, who were divided into two proportional groups, namely the experimental and the control group. Both groups were pre-tested a week prior to the experiment through multiple-choice and open-answer written tests, so that the initial difference between the groups could be established. The experimental group then worked with the interactive CD-ROM in pairs, and they were given three hours to learn a specific content, presented by video clips, animations and simulations, accompanied by interactive questions with intelligent feedback. This group did not use any other source for knowledge consolidation. Students from the control group were also given three hours, with several course books available, starting with the teacher's explanation of the subject topic. A week after the experiment both groups took a post-test focused on understanding the concepts at the microscopic level of visualisation. The performance of both groups before and after the learning session was compared. Whereas the groups did not significantly differ at the beginning, the results of the post-test show significant difference in favor of the experimental group, which can be largely attributed to the visualisation elements included in the CD-ROM and its interactivity. In our ongoing research project, a study aimed at improving the efficiency of visual elements used in multimedia teaching units is being conducted. We are investigating the correlation between the spatial abilities of the individual students and their ability to correctly interpret different chemical processes visualised by application of the diverse tools.

Conclusion

Active involvement of teachers in developing high quality multimedia teaching materials is the key factor for their regular use in schools. The research on the effects of such materials is needed to provide the developers with the feedback. The use of visualisation elements at all three levels is crucial in chemistry teaching, however the learning process has to be supported by discussion and testing.

University of Wisconsin, Milwaukee
Box 413, Bolton 574J
Milwaukee, WI 53223
jnd@uwm.edu
grozik@uwm.edu

Abstract:
A unique service organization, consisting exclusively of student employees, exists within the University of Wisconsin's Information and Media Technologies Division. Known as Student Technology Services (STS), this student managed organization is tasked with the operation of various computer, media and technology related campus services. STS employees work in all areas of I&MT including the Campus Computer Labs, Classroom Support, Desktop Support, Help Desk, Network Services, Peer Training, Photo Services, Printing Services, Shortcourses, Technical Resources, Video and Multimedia Production Services, TV Engineering, Distance Education Technologies, Visual Design Services, and Web Maintenance Services. More than 300 students are expected to be employed in STS by Fall 2000.

Student Technology Services (STS):
Student Technology Services (STS) is a student staffed, student managed organization responsible for delivering technology and media-related services to the campus community of the University of Wisconsin-Milwaukee. While empowered student IT workers are employed to provide a service, they are at the same time engaged in a learning experience. They are preparing themselves for their future careers through "experiential learning".

Student employees of STS come from virtually every academic major. Whereas many universities employ primarily technical majors under the mistaken belief that only they can satisfy their campus community's technology needs, STS instead looks for interpersonal skills, drive, and willingness to learn. STS has discovered that customer service and management skill sets have become as important as technical skills in the delivery of information and media-related technology services. Because most STS student employees do not have technical backgrounds, a carefully tailored training curriculum was developed and implemented. The purpose of the curriculum is to empower STS student employees by giving them the technical skills they will need to excel in their jobs as well as important professional and life skills they will need to excel in their future careers.

The STS training curriculum becomes an education when the learning is demonstrated through experience (i.e., implemented on the job) and when the experience is reflected upon (i.e., in an extensive oral and written evaluation.) Because completing the multiple levels of the curriculum, using the skill sets on the job and participating in the evaluation process are all mandatory conditions of employment, STS provides the setting for experiential learning at institutions of higher education. Many of the classes in the STS curriculum are developed and taught by STS students themselves. These STS Peer Trainers do not impose upon the institution's academic teaching mission, yet are an integral part of adding value to the learning experience of STS students. STS Peer Trainers are evaluated after each class they teach and are charged with making the necessary adjustments to their lesson plans.

In addition to the experiential learning provided by the curriculum, STS students are encouraged to transfer to other departments each year in order to learn and practice new skills. The exposure they gain in these other areas strengthens their learning experience and enables them to identify their personal and professional strengths and weaknesses. STS students are required to maintain a portfolio of their diverse work experience and training. The portfolio serves as the reflection piece to the classroom and on-the-job experience, thereby further adding value to TS' philosophy of experiential learning.

STS' focus on experiential learning has been met with welcomed enthusiasm at UW-Milwaukee. STS student employees are sought after not just for their learned technical skills, but also for the maturity and professionalism that they acquire through on-the-job experience and reflection pieces. UWM department heads specifically request STS student employees to be placed in their departments to troubleshoot and to maintain department web pages.

STS' example of experiential learning is now being introduced to the 26 other campuses within the University of Wisconsin System. Wisconsin's governor recognized the benefits of experiential learning as a means of preparing a qualified workforce in the state that can remain competitive even in the fluid environment of information technology. The Governor's Office recommended increased funding for training IT student workers throughout the entire University of Wisconsin system. His decision was based solely on the UWM STS model and its success. The biennium budget was signed into law in October, 1999 thus propagating the STS model of experiential learning throughout the state.

The STS program has generated strong interest from many academic and non-academic partners. We are exploring relationships with public school systems and with leaders in private industry to provide:

- A pre-college program to create work experience and training in technology for high school students.
- A similar work program focused on the two year technical college in Milwaukee
- Summer internships and potential scholarships for the STS student employees at UWM
- Meaningful industry relationships for students leading to employment upon graduation.

We have met with enthusiasm and willingness by all participants to work together on these new relationships. We look forward to a greatly enhanced student empowerment program when the new partnerships are in place.

The Effect of Level of Technology Training on Teachers' Attitudes Toward Using and Integrating Technology

Ronald Dugan, Jennifer Richardson, & Dianna L. Newman, Ph.D.
Evaluation Consortium/School of Education
University at Albany/SUNY
United States
rd1872@cnsvax.albany.edu

Abstract: This paper is a report of an ongoing longitudinal evaluation assessing the effect of level of technology training on teachers' attitudes and comfort toward using and integrating technology into the curriculum. Multivariate and univariate analyses were used on an initial sample of 54 K-12 public and private school teachers from a Northeast state undergoing two levels of technology training who participated as part of a Technology Literacy Challenge Grant. Initial findings support and extend previous research that shows teachers become more comfortable with using and integrating technology, and possess more positive attitudes toward technology, as the extent of training increases.

Introduction

Although over 8.5 million computers are being used for instruction in the U.S., and 85% of K-12 teachers have access to computers and other technology (Survey finds…, 1995), only half of all teachers report using computers for instruction (Hunt & Bohlin, 1995). Social learning theory (Bandura, 1977) predicts that failure of teachers to use computers will vicariously teach students not to use computers. This lack of computer use may be related to attitudes (e.g., anxiety) toward technology (Pina & Harris, 1993). Although ¼ of all people who use computers experience some degree of "computerphobia" (Rosen & Maguire, 1990), when teachers experience it, this interferes with their ability to integrate technology into the curriculum (Hunt & Bohlin, 1995). The strongest predictor of computerphobia is experience (Rosen & Weil, 1995). Limited research has shown anxiety towards computers decreases after training and practice (Cambre & Cook, 1987), yet only 29% of teachers report having more than five hours of technology training in the past year (Technology Counts '99, 1999).

The Study

The purpose of this study was to investigate the effect of level of technology training on teachers' attitudes toward, confidence using, and comfort with integrating technology. Attitudes were represented by three constructs: anxiety, avoidance, and fear of stereotyping. Confidence was measured in three areas: software, hardware, and communication tools. Comfort with integration was assessed by participants indicating one of six stages (awareness, learning the process, understanding and application, familiarity and confidence, adaptation to other contexts, and creative application to new contexts). Training occurred at two levels (Level I; 5 days training on using Power Point or Hyperstudio in the classroom: Level II; Level I training plus 3 additional days training in Web page design for curriculum use). Participants were 54 public and private school educators participating in a regional Technology Challenge Grant training program in a Northeast state. Twenty-six educators experienced Level I training while 28 educators experienced Level II training. Over 300 educators are expected to be trained at both levels by the end of this grant year. An end-of-year paper/pencil survey was administered to the first cohorts of educators experiencing both Level I and Level II training so far this school year. Ten items measured attitudes toward technology (anxiety, avoidance, and fear of stereotyping) on a six-point, Likert-type scale (1=strongly agree, 6=strongly disagree). Eighteen items measured confidence in using technology (hardware, software, communication tools) on a six-point scale (1=extremely confident, 6=not at all confident). The Stages of Adoption Scale (Knezek & Christensen, 1999) measured comfort with using and integrating technology into the curriculum.

Findings

A multivariate analysis of variance (MANOVA) was used to analyze the data. The fixed, categorical independent variable was level of technology training (Level I and Level II). The continuous, random dependent variables were confidence with using technology (software, hardware, and communication tools), and attitudes toward technology (anxiety, fear of stereotyping, and avoidance). Findings indicated no significant difference for level of training on confidence in using technology ($F=1.26$; $df=3,37$; $p>.05$). However, a significant difference was found for the effect of level of training on the construct of attitudes toward technology ($F=2.83$; $df=3,50$; $p<.05$). Examination of the univariate Fs indicated a significant portion of the construct was avoidance ($F=6.78$; $df=3,50$; $p<.05$) and anxiety ($F=6.61$; $df=3,50$; $p<.05$), accounting for 15% of the total variance (Wilkes lambda=.85). A univariate analysis of variance (ANOVA) was used to analyze the effect of the fixed, categorical independent variable (level of training) on the continuous, random dependent variable of comfort using and integrating technology (six stages: awareness, learning the process, understanding and application, familiarity and confidence, adaptation to other contexts, and creative application to new contexts). A significant difference was found for level of training ($F=5.00$, $df=1,50$, $p<.05$) on stage of comfort. Strength of association showed that nine percent of the variability in level of comfort could be accounted for by level of training. Those with more training were more comfortable with integration.

Conclusion

These findings support previous research that shows teachers who receive training in using and integrating technology into the curriculum experience less anxiety toward, and more comfort with, that technology. This study adds to existing literature by showing that additional training with more advanced technological software further decreases computer anxiety and increases comfort with integrating technology above and beyond less, and lower-level, training. If teachers are expected to integrate technology into the curriculum and model appropriate technology utilization behavior for their students, they need more training than the levels currently being received by most educators.

LearnScope and the Development of Virtual Learning Communities

Allan Ellis
School of Social and Workplace Development
Southern Cross University, Australia
aellis@scu.edu.au

Robyn Weatherley
Training and Development Directorate
NSW Dept of Education and Training, Australia
rweatherley@cci.net.au

Abstract: The Vocational Education and Training (VET) sector in Australia is coming under increasing pressure, both nationally and internationally, to deliver courses in flexible ways that incorporate the latest in information and communications technologies such as the Internet and the World Wide Web. LearnScope is a national initiative funded by the Australian National Training Authority (ANTA). Its aim is to provide professional development support to individuals and work groups in order to develop skills and capabilities for the online environment

A preliminary study of LearnScope's Virtual Learning Community (VLC) was undertaken using a questionnaire based survey plus analysis of transcripts of forum discussions and published stories. The results highlight the complexity of the role of providing professional development for establishing online learning communities. The major areas of Technical Skills and Computer Literacy, Writing and Communication Skills, issues of Interactivity, and the development of Self-related attributes are identified as important if the VET sector is to build a critical mass of creative, capable instructors to work in the online environment.

The Changing Context of Vocational Education and Training

As the geographical boundaries of Vocational Education and Training (VET) in Australia become blurred, both nationally and internationally, the competitive edge of providers, Registered Training Organisations (RTO's), will not only be the courses and training programs they offer but the quality of instructor support and service provided to the learner. Information and communications technologies (ICT) such as the Internet and the World Wide Web has seen online interactivity emerge as a critical factor in delivering learning materials and supporting learners and instructors. A series of Australian National Training Authority (ANTA) reports (1994, 97 and 98) provide details to developments in this area.

Traditionally VET practitioners, in particular those in Technical and Further Education (TAFE) Colleges, have been provided with professional development to update their skills. In recent years this has been through work based learning using a range of processes such as mentoring, coaching, workshops, discussion groups, conferences and site visits. In the area of ICT, professional development programs have primarily focussed on technical skills development, that is, learning how to use the technology without focusing on the 'deeper' level of critically understanding the benefits and restrictions of using these tools in the learning environment.

LearnScope and its Virtual Learning Community

LearnScope is a national professional development initiative that is available to work teams and individuals within RTO's. It is focussed on the development of skills to deliver training in increasingly flexible ways using new ICT's. The LearnScope home page provides more details: http://www.learnscope.anta.gov.au/cover.html

For the individual instructors it is LearnScope's Virtual Learning Community (VLC) that provides a range of activities in several zones. These activities include:

- *About LearnScope* – an information about the national LearnScope project, guidelines and application forms and contact people within the project.
- *Key Issues* – an information area which provides clustered groupings of key issues relating to flexible delivery. This includes resources, text, access to software, people or web sites.
- *Project Gallery* – the area where LearnScope teams publish their plans, interim and final reports.
- *Expert Spruik* - an area to introduce key people who will contribute to the LearnScope VET community.

- *RantZone* – an area for people to practice their publishing skills, request information or make a statement.
- *Evaluation* – an area for the LearnScope's project evaluator to submit information about evaluation issues
- *What's New* – a frequently changing area which provides a summary of key information for all users.
- *Forums* - an area for both public and private discussions.
- *Chat Room* – an area for planned synchronous discussions.

While the VLC is primarily for the support of LearnScope project teams, anyone interested in the application of new learning technologies to achieve more flexible learning and professional development within the vocational education and training sector is welcome to register and participate.

The Survey: Methodology and Sample

Data was gathered in 1999 during two rounds of LearnScope projects and in two formats: a questionnaire, and forum discussions and published stories (Weathereley, 2000). A total of 58 questionnaires were distributed and 33 were returned giving a response rate of 57%. A total of 153 postings to 5 forums (average 14, range 10 to 21 participants per forum) as well as 336 published stories were also collected. These data was then used to:
(i) Identify the reactions, feelings and thoughts to using a virtual learning community in the context of the national VET system and to gain insight as to the level of experience of users.
(ii) Identify how VET practitioners used an asynchronous forum area set up specifically for learning.

Findings and Recommendations

It is recommended that for instructors or professional development planners who are engaging in developing online learning plans that the following areas of skills development and capabilities must be addressed:
(i) **Technical Skills and Computer Literacy**: To achieve the best possible learning environment it is necessary to go beyond the simplistic operational understanding of ICT. It is important to have the capability to make critical judgements about its appropriateness and to develop ideas about teaching and learning within the environment. The challenge for the national VET system is getting more people involved in a professional community which as Spitzer and Wedding (1995) says "...requires the active and willing participation of teachers in the process of examining, reflecting on, experimenting with, and ultimately changing the way they practice – in the context of a professional community that allows them to enrich their understanding of subject matter and to consider issues about how students learn."
(ii) **Writing Skill and Communication Style:** For online learning communities to be successful, the writing and language skill must be conducive to the audiences ability so that group interaction, sharing and participation can lead to an environment based on relationship development.
(iii) **Interactivity**
(iv) Understanding the range of interactive possibilities and promoting an environment which encourages active interaction online between people is vital. Understanding the significance of the human medium and the levels of interactivity will provide teachers with the potential to make critical judgements about student learning.
(v) **Self-related attributes**: Developing self-related attributes is significant in professional development for the online learning environment. Teachers need to identify, develop and model these attributes. Self-related attributes should also be an important aspect of learner development.
(vi) **Teaching and Learning**: Knowledge building in order to gain maximum benefits of an online community and to provide a quality learning environment, requires a range of strategies. Based on the constructivist model where learning builds on previous professional and personal experiences, the importance of linking practice with discussion, dialogue and debate in this new learning field is critical. Professional development activities need to incorporate pedagogical dimensions. These recommendations must be incorporated into instructor's professional development plans otherwise a quality online learning environment will not be achieved.

Integrating WWW Technology into Classroom Teaching: Students' Perspectives of the Usefulness of their Course Web sites

Manal A. El-Tigi
Syracuse University
330 Huntington Hall
Syracuse, NY 13210
maeltigi@syr.edu

Abstract: The purpose of this study is to explore students' perceptions of the use of World Wide Web (WWW) technology as an instructional resource specifically customized to support teaching and learning practices on campus-based classes. While there are many efforts to design meaningful learning environments there is very little current instructional design literature on fostering and support of Web-based environments. This study examined college students' perspectives on the usefulness of specific Web site functions used for teaching and learning purposes, in an effort to optimize the use of Web-based instructional support resources.

Review of Relevant Literature

The 1999 Campus Computing Project's (CCP) national annual survey of information technology in higher education reported that many higher education institutions are providing more services via the WWW (CCP, 1999). For example, more than half (69.5%) of these institutions provide online undergraduate applications on their Web sites. More than three-fourths (77.3%) make the course catalog available online. A quarter (25%) of the institutions make library-based course reserves readings available online and almost a half (46.5%) offer one or more full college courses online via the Internet and the WWW. Similarly, the percentages of college courses using the WWW in the syllabus rose from 7% in 1995 to 28% in 1999 (CCP 1996). This number quadrupled by 1999 meaning that more than one in every four classes has a Web page. In fact, compared to e-mail and general use of Internet resources, use of Web pages has shown the highest rate of increase over the six-year period. E-mail had already been in use in 1994 rising to 54% by 1999 up from 44% in 1998, and 20% in 1995. Khan (1997) provided a definition of Web-based instruction used for the purpose of this study.

> Web-based instruction (WBI) is a hypermedia-based instructional program which utilizes the attributes and resources of the World Wide Web to create a meaningful learning environment where learning is *fostered* and *supported* [italics added]. (p. 6)

At a university level, the *Syracuse University Faculty Syllabus Web site* available at http://syllabus.syr.edu is an example of a growing list of campus-based course Web sites. For the purposes of this study, a preliminary analysis of 175 Syracuse University Web sites was conducted during the fall 1998 semester.

Theoretical Framework

A conceptual framework was developed to ground and guide the research conducted in this study. There is evidence from research findings that certain principles exist in most successful teaching and learning practices (Chickering and Gamson, 1987, 1991). Second, there is evidence in the literature that the application of instructional design principles to the teaching and learning practices leads to more effective learning (Gagne' 1975, Gagne', Briggs, & Wager, 1992). One of the important measures of effective instruction is how students feel about the instructional process (Dick & Reiser, 1989). Based on the above premises, one can make the assumption that a well-designed instructional Web site can support and facilitate good teaching and learning practices and therefore can be perceived as a valuable instructional resource for both faculty and students.

Purpose of Study and Research Questions

The purpose of this study was to examine the opinions and perceptions of college students' use of the course Web site as an instructional resource for classroom-based teaching at a private university in the northeast of the United States. The focus of the study was on the identification of Web site functions that students' perceived as *supporting* and *enhancing* of their learning experiences by exploring students' perceptions of the usefulness of the various Web site functions. The following question was posited: How useful did students perceive their course Web sites?

Method

142 primarily undergraduate students enrolled in nine courses that employ Web sites as course resources responded to a questionnaire on their use of their respective course Web sites. Initially, all Web sites were first screened using an instrument developed by the researcher to evaluate the Web sites' instructional quality and design based on principles of instructional design. On the student Web site perception questionnaire (SWPS), functions pertaining to the Usefulness dimension were construct validated using confirmatory factor analysis. Two indexes were constructed for the *Usefulness* dimension using items that loaded (>0.60) on these two factors: GUIDE and PREPARE. The first represents practice, elicitation, and feedback functions. The second represents functions that facilitate recall of prior learning and enhance retention and transfer through communication, enrichment and remediation. All functions are derived from Gagne', Briggs, and Wagers' (1992) nine events of instruction and Chickering and Ehrmann's (1996) principles of good teaching and learning practices using technology as lever.

Results

Results showed that most functions were useful with a mean score for the PREPARE index (n=132, M=1.87, SD=0.74, scale 0-4 where 4=highly useful) and a higher one for GUIDE (n=131, M=2.20, SD=0.71, scale 0-4 where 4=highly useful).

The PREPARE index consisted of functions including: (a) the use of pictures, tables, diagrams, etc. to recall or present new information (n= 78, M=2.79, SD=1.00); (b) the additional links and information on the course Web site for further study (n= 96, M=2.43, SD=1.16); (c) the links to review/pre-requisite material to help recall (n=91, M=1.87, SD=0.74), and (d) overall usefulness of the course Web site (n=132, M=2.63, SD=1.13).

The GUIDE index consisted of functions including: (a) the opportunity to ask questions online (e-mail, listservs, hypermail, etc. (n= 112, M=2.74, SD=1.00); (b) posting graded assignments/Home Work on the Web (n=64, M=2.66, SD=1.30); (c) online practice assignments (n=47, M=2.64, SD=0.85); (d) online feedback on various assignments (n= 73, M=2.60, SD=1.00); (e) situations, case studies, formulas, problems, simulations, etc. posted on the course Web site to improve learning (n= 65, M=2.52, SD=0.99); (f) online self-assessment quizzes (n= 49, M=2.51, SD=1.23); and (g) instructions on how to navigate the Web site and download software, get an account, subscribe to a listserv (n= 100, M=2.30, SD=1.10).

Discussion

Key findings from the study are indicated below using Chickering and Ehrmann's (1996) seven principles of good teaching and learning practices for undergraduate education and Gagne', Briggs, and Wager's (1992) nine events of instruction as the framework for discussion. Findings for the PREPARE index related to assisting students to recall information and to transfer new knowledge were supported by functions representing two principles: (a) Good practice gives prompt feedback and (b) Good practice encourages contacts between students and faculty in that the most useful functions were those that enabled students to communicate with their instructors and to receive timely feedback. Electronic mail, computer conferencing, and the WWW increase opportunities for students and faculty to interact and communicate much more efficiently than before. In addition, the nature of communication becomes more thoughtful, deliberate, convenient and safe. Moreover, the negative aspects of face-to face confrontation are lessened. Findings from the GUIDE index indicated that Gagne's et. al. (1992) instructional events pertaining to presentation, practice, feedback, and elicitation of new knowledge and skills were overall most useful functions. The multimedia capabilities of the Web allow for an almost seamless integration of email capabilities, video clips, sound, images, and animation thereby allowing for multiple modes of communication through feedback and assessments. In conclusion, in terms of theoretical implications, the study supported the usability of Gagne's events of instruction in particular the ones related to presentation, practice, elicitation, and feedback, as a viable means of designing course Web sites to support teaching and learning practices. The study also provided empirical findings to support Chickering and Ehrmann's (1996) principles of good teaching and learning practices in particular the ones related to prompt feedback and student-faculty interactions. It is recommended that course Web site design could be optimized to include more instructional functions such as elicitation of responses, practice, feedback, and increased student-faculty interactions using the interactive and visual and auditory display capabilities of the medium.

Evaluating Motivational Aspects of a Web-based English Language Course through the Website Motivational Analysis Checklist (WebMAC)

Anise D'Orange Ferreira
Graduate Program in Applied Linguistics
Catholic University of São Paulo
Brazil
anise@pucsp.br

Abstract: This work in progress short paper is a report on subjects' evaluations of a web-based language course's motivational aspects through WebMAC, *Website Motivational Analysis Checklist*, developed by Small and Arnone (1998). The subjects were 26 adult students who participated in a basic online English course for Internet users, focused on informal asynchronous and synchronous writing and communication skills, called *Surfing and Learning*. This course is designed by teachers and researchers of the EDULANG research group. The instrument measured the level of four motivation factors which provided the results for two dimensions within an Expectancy-Value framework: *Value* and *Expectancy for Success*. The evaluation results showed a high level of *Value* dimension and *Expectancy for Success*, although factors linked to *Expectancy for Success*, such as *Organization* and *Ease of Use* showed more variation in scores than those linked to *Value*, such as *Meaning*. Although WebMAC seems to be sensitive to student motivation, other kinds of data are required to a complete course evaluation. It will continue to be used for the ongoing evaluation of *Surfing and Learning* and other courses offered by EDULANG.

Introduction

Most researchers agree that motivation is a difficult construct to work with (Weiner,1990). Wlodkowski (1999) says that beyond the general understanding of motivation as a concept that explains why people think and behave as they do, "any specific discussion of the meaning of motivation brings in a cornucopia of differing assumptions and terminology"(p.1). According to Dörnyei (1998) motivation is a "process whereby a certain amount of instigation force arises, initiates action, and persists as long as no other force comes into play to weaken it and thereby terminate action, or until the planned outcome has been reached." (p.118). He also agrees with the idea that motivation is a multifaceted factor and no theory has yet been able to represent it in its total complexity. Despite difficulties, instructional designers continue to seek motivational frameworks in order to achieve a better design in tecnology based learning environments such as the WWW (Cornell & Martin, 1997). Duchastel (1997) elects two main models. One is Keller's ARCS model, considering four factors in motivation to learn: (a)ttention, (r)elevance, (c)onfidence, and (s)atisfaction. The other one is Malone's CFC framework for instrinsically motivated inscruction, which involves three factors: (c)hallenge, (f)antasy, and (c)uriosity. ARCS guided interventions reduced the drop out rate, by half, of a Master's degree distance course intended to prepare adult students for careers in the areas of instructional design, job performance improvement, etc. (Chyung, Winiecki and Fenner,1999). Also influenced by the ARCS model, the *Website Motivational Analysis Checklist* - WebMAC (Small & Arnone, 1998, 1999) was designed to assess the motivational quality of a website. Small (1997) claims that, although the ARCS model is rooted in a number of motivational theories, its main basis is the expectancy-value framework in which motivation to behave is the sum of individual's expectancy for success in a given task plus the value attributed to success in the task. Website quality is measured within expectancy-value framework: the user is motivated to remain in the website if it has value and if the user expects to be successful in the website environment. Dörnyei (1998), surveying motivation in second and foreign language learning (L2) research shows that researchers have adopted and empirically validated some concepts originally introduced by motivational approaches in mainstream psychology, such as expectancy-value theories, goal theories and self-determination theory. Therefore, WebMAC was chosen here to evaluate motivational aspects in a L2 web based instructional design. This evaluation is part of a major research project in which the analysis of interactive flow is also considered (see Collins' paper).

Methodology

The subjects were 26 students, male and female, age 29 to 64 , who participated in a web-based language course in 1999. The course, *Surfing and Learning* (http://cogeae.uol.com.br/sal) offers a basic English for adult Internet users, focusing on informal asynchronous and synchronous writing and communication skills. It was designed by English language teachers, members of EDULANG research group, under the coordination of Heloisa Collins, in the Graduate Program in Applied Linguistics of the Catholic University of Sao Paulo (LAEL/PUCSP). WebMAC versions 3.1 and 4.0 were translated into Brazilian Portuguese and edited into a HTML format, so that the students answered the checklist anonymously at the end of the course and submitted it through a CGI implemented web form. The answers were scored according to WebMAC scoring guidelines. Both versions were used and the scores obtained from 3.1 version were adjusted to version 4.0 factors. WebMAC is composed of assertions or list items to be rated by an evaluator on a 4-point level of agreement scale. The 32 items in version 4.0 measured 4 factors: 1) Stimulating ; 2) Meaningful; 3) Organized and 4) Easy to use. The sum of first two equals the *Value* dimension level; the sum of the other two equals the *Expectation for Success* dimension level. Zero to 8 points for a factor means the site needs much improvement on this factor; 9 to 16, it needs some improvement, 17 to 24 means the site is highly motivating. Version 4.0 contains four additional unscored items: two yes/no assertions and two open questions. Most of list items are the same in both versions. However, they are not related to the same factors. In both versions, each subject provides two main scores that are plotted on a bidimensional grid: 1) Low Value to High Value and 2) Low Expectation for Success to High Expectation for Success. The score position reflects the motivational status of the site in terms of *Value* and *Expectation for Success*. (fig.1)[figures at http://www.anise.f2s.com/anise-edmedia.html]

Preliminary findings

The results (fig. 1) show the scores on the average to high-level area of *Expectation for Success* and *Value*. Only two students showed low *Expectation for Success* and only one gave low scores to *Value* dimension factors. The individuals' scores under each of the four factors (fig.2) show less variation for the *Meaning* factor than *Organized* and *Easy to Use* factors. The answers to WebMAC open questions presented in 4.0 version revealed some students' satisfactions and dissatisfactions. Despite high levels of *Value* and *Expectation for Success*, the amplitude of scores in each of the four factors suggests that the course can be improved in *Organization* and *Ease of Use* factors. The interaction in communication areas of the course was pointed out by students as a particularly strong aspect of the course design. The complaints about tools and dictionaries seem to confirm comparatively lower scores of *Organization* and *Ease of Use* factors. Future work should consider the use of WebMAC during the course. These results can be discussed in terms of guidelines for motivating language learners (Dörnyei, 1998). Although the present instrument seems to be sensitive to student motivation, other kinds of data are required to complete the course evaluation, such as the interaction flow analyses. The ongoing evaluation of *Surfing and Learning* and other courses offered by EDULANG, such as *Reading* and *Listening Comprehension* for public high school teachers, will continue to use WebMAC.

Abstract: UWired created the web-based Catalyst initiative to support innovation in teaching through technology. To scale beyond early adopters, Catalyst has developed a new strategy centered on collaborative partnerships with campus teaching practitioners—learning, technology, and teaching research centers, libraries, and departments—to disseminate innovative uses of technology in teaching through the Catalyst website.

The Problem of Supporting Innovative Teaching with Technology

In 1994, three top-level administrators at the University of Washington were charged by the Provost to "do something about technology." Collaborating with faculty, librarians, technologists, and students they quickly moved beyond a small pilot, rounding up partners and gathering resources from wherever they could to focus on bringing technology into the service of teaching and learning. Today the organization they formed—UWired—has a permanent budget, a staff of eight professionals and over 60 students, and has extended services and support to thousands of students and faculty.

As higher education institutions have scrambled to keep pace with rapid changes in information technology, many campuses have established faculty technology centers, offering workshops and training to interested educators and perhaps even supporting faculty technology projects to transform particular courses. These efforts have generally targeted "early adopter" faculty who are eager and willing to teach themselves how to use and implement new technologies. Resources are thus devoted under the assumption that early adopters will play the role of Johnny Apple-Seed, spreading innovation throughout their home departments. Indeed, UWired inaugurated its Center for Teaching, Learning and Technology (CTLT) to foster and support instructional innovation in this manner.

For the most part, however, this strategy has had a negligible impact on educational transformation through technology. Beyond the few early adopters are legions of "wary adopters" who look for easy ways to improve their teaching through technology but are unwilling to match the time commitment of the "early adopters." The classic early adopter is drawn to technology for its own sake, reveling in the "gee whiz factor" of new technologies, but "wary adopters" are pragmatic. Representing the mainstream of higher education faculty, "wary adopters" will use technology only when it can be demonstrated that doing so will add value to their teaching without significantly reducing time already allocated to teaching, research, and service activities. Needless to say, the CTLT found it quite difficult to scale up support services while also ensuring that these services meet the often different needs of "wary adopters."

Creating a Catalyst for Innovative Teaching with Technology

The need to expand support to a much wider audience—and to do so without a major infusion of new staff or relocation to a larger facility—was clear. How to do so was not. In fact, the CTLT faced four major obstacles posed by the needs of "wary adopters": (1) the absence of a coherent framework for faculty Web publishing, (2) the absence of well explained, compelling examples of enhanced teaching and learning through the Web, (3) the absence of convenient, in-person support located in departments, and (4) the absence of a clear incentive for faculty to explore the use of technology in their teaching. After an intense period of reflection and wide ranging conversations with campus stakeholders and faculty focus groups, the CTLT's leadership team developed a new framework for faculty support. The framework depended upon an instructional support Web site that would provide faculty with anytime-anywhere resources and also serve as the foundation for redesigned instructional workshops and one-on-one consulting.

The Web site, Catalyst, was launched in 1999 to provide this support while placing pedagogy and student learning at the center of the discussion about technology. Catalyst is based upon four assumptions: (1) faculty want just-in-time learning and support; (2) they prefer to learn at their own pace, in their local environment; (3) the Web is or will become the vehicle of choice for just-in-time information and learning; and (4) distributed support personnel are best suited to make the critical decisions about local infrastructure and local support. Given this, the key function for Catalyst—the value add—is in capturing, focusing and disseminating ideas, resources, and tools that allow both faculty members and local support personnel to make innovative use of new technologies in teaching and learning with a minimum of duplicative effort.

Scaling Innovation through Partnerships and Collaboration

Through Catalyst[1], UWired can easily identify promising practices from within the campus and then use them to address enterprise-wide educational needs. As an easily navigable clearinghouse for information on the use of the Web in teaching and learning, the site has met faculty needs and drawn repeat visits, creating a center of gravity for innovation in teaching with technology that far exceeds the physical reach of UWired and the CTLT. Catalyst has four basic types of content: (1) profiles of educators and programs that provide a vehicle to share ideas and experiences with technology, humanizing its use and, hopefully diffusing teaching innovation; (2) guides to instructional methods and technology tasks that provide a map to a wide range of individual documents geared towards improving learning; (3) dynamic content and frequently updated information on news and events relevant to teaching with technology; and (4) instructional tools that provide a standard mechanism for faculty to create interactive, Web-based instructional modules in any computing environment using only a Web browser.

As envisioned, departments and college support personnel who have developed materials specific to their local computing environments—for instance how-to documents on a particular Web editor or "one-off" Web-based instructional tools—have been eager to see their work repackaged and made available to a much larger audience. More, through a partnership with a university-wide initiative, the Program for Educational Transformation through Technology (PETTT), UWired now has the capacity to conduct research on the science of learning and disseminate information via Catalyst, thus promoting the thoughtful exploration, development, assessment, and dissemination of next-generation technologies and strategies for teaching and learning.

Catalyst not only extends UWired's reach, but it also improves the overall quality of faculty support, providing department support personnel with a set of resources they can draw upon, freeing them individually tailor services to their faculty. By aggressively profiling the efforts of campus educators, Catalyst makes faculty innovation visible and contributes directly to the vitality of the teaching community on campus. In its first year, the Catalyst Web site logged half a million page views; it now averages 100,000 page views per month.[2] On the UW campus, over 1000 faculty and instructors from departments ranging from Anesthesiology to Urban Horticulture have implemented Catalyst tools.

Abstract: Social pressures are creating the necessity for a system of lifelong learning. Electronic distance education appears to be the optimal system for meeting the educational requirements of learners. While educational needs have shaped the development of the electronic learning environments there has been little attention paid to the physical and psychological health issues for the electronic learner. Athabasca University (AU) has used questionnaire and focus groups to examine the implications for learners using AU's electronic environments for learning.

INTRODUCTION

Distance education is often identified as a panacea for adult learners as it overcomes geographical barriers that often prevent students from attending universities to study. With the advent of the Internet as a readily accessible medium, web-based courses have become immensely popular with providers of distance education around the world. It clear by the enthusiasm with which computer-based distance delivery has been embraced that society is willing to rely on computer technology for learning.

At Athabasca University, where the mandate is distance education , students are distributed not only across Canada where the University is located, but also across North America and the rest of the world. For the past five years Athabasca University's Centre for Computing Information Systems and Mathematics (CCIS) has offered 20 undergraduate Computing Science courses over the World Wide Web (WWW). In 2001 it will be offering a Master of Computing and Information Systems over the WWW. The Center for Nursing and Health Studies (CNHS) has offered a Master of Health Studies (MHS) degree over the WWW since September, 1999 and in less than a year has over 200 graduate students enrolled in the program.

The needs and capabilities of the learners are our first considerations in the development of an electronic learning environment. In our developments we have focussed on involving the learners to optimize the environment for learning (Holt, Stauffer & Jelica, 1999). However, until recently we did not look seriously at health related issues. Marcoulides, Mayes, and Wiseman (1995) have suggested that the use of computers in the workplace can result in anxiety. Similarly, technology-based learning may result in added stress among learners. There are other potentially negative implications for students who rely on computers for learning. According to Faulkner (1998) these may include psychological factors such as alienation, inadequacy, lack of privacy, loss of responsibility and damage to self-image. Furthemore, Dix et all (1998) noted that physical problems include repetitive motion strain, postural fatigue, eye fatigue and less frequently, skin rash, reproductive disorders, and cataracts.

In order to examine health issues related to the use of computers for learning, we decided to survey graduate students in our Master of Health Studies Degree and undergraduate students in Computing Science. Questionnaire data has been collected on general computer-related habits, any health problems encountered, and their ergonomic awareness related to design of workspace, posture, usage, and exercise. This was a large exploratory study with a questionnaire of 19 items distributed to 1310 CCIS Students and 145 CNHS students). More indepth data will be gathered by focus groups which are underway--the results and will be reported more fully at EdMedia 2000. The more interesting questionnaire results analyzed to date are presented in this session.

CNHS students and CCIS students differed on a number of dimensions including graduate versus undergraduate, continuous monthly enrollment versus semester, discipline, and different WWW-based learning platforms. Since the purpose of the study is to consider ergonomic factors in the design of electronic curricula for both CCIS and CNHS students, we have not focussed on inferential statistics and differences between the groups but upon useful descriptive statistics within each group.

The return rate was low for CCIS students (150 of 1310 questionnaires). It was higher for CNHS students (41 of 145 questionnaires). The low return rate makes the results more difficult to interpret as students with health related problems may be more likely to respond giving us a biased sample. Nevertheless, computer usage was reported to be very high among respondents. Both CNHS students (80.5%) and CCIS students (85.3%) had high rates of computer use in general and relatively high use for education other than the current courses (43.9% and 72.3%). The mean time using computers was 24.2 hours per week for CNHS students and 32.2 hours for CCIS students. There was a wide range of usage but it would appear these are high-use groups at risk for computer related health problems.

CNHS students and CCIS students rated themselves respectively as somewhat or informed (75.6% and 63.4%) about ergonomic issues. However, a majority of all students did not make use of special ergonomically sound furniture and at least half of both CNHS students (53.7 %) and CCIS students (50.0%) did not take any regular breaks while working at the computer. As high usage groups these students ought to be more aware of ergonomic issues and in ideal circumstances, practice more ergonomically sound computer usage.

Both CNHS and CCIS students reported some physical problems related to computer use (26.6% and 26.8% respectively). Problems reported include carpal tunnel syndrome, eye strain, and back strain. Ironically, although both groups reported low rates of psychological problems (9.8 % and 6%), they did report considerable levels of anxiety about their use of computers. Interestingly, the most intense anxiety was associated with issues of privacy and security with 70.7% of the CNHS students and 65.1% of the CCIS students reporting slight to high levels of anxiety in this area. Other areas of anxiety included the cost of computer technology (46.3% and 57.7%); keeping current with software (46.3% and 40.3%); loss of data (43.9% and 60.8%); keeping current with technology (34.1% and 40.3%; and keeping up with the information glut on the Internet (36.6 and 47.7). High computer usage does appear to affect these students' social/family life--36.6% of the CNHS students and 34.7% had complaints from family members about their computer usage. This finding is hard to interpret in lack of comparison with students learning by other methods of education but it certainly warrants further attention.

Of the CNHS students 32.5% reported that the electronic courses aggravated old problems, 50.0% said they created new problems, and 51.3% had suggestions for course design. Of the CCIS students 12.7% reported that the electronic courses aggravated old problems, 16.7% said they created new problems, and 30.7% of CCIS had suggestions for course design. When students listed concerns most of them were related to computer use or course design rather than to health related problems explicitly (other than perhaps related to stress). This could be a function of students being so engrossed in their use of computers for learning that they are relatively unaware of health problems. We are conducting further focus groups to further investigate the factors and underlying situations that contribute to students being in undesirable physical and /or psychological danger and other ameliorative approaches they might use. On the basis of findings to date we are implementing a Java/XML based printing utility and highlighting ergonomic tips in the course materials.

DESIGNING SYNCHRONOUS INTERACTIVE LEARNING TELECONFERENCES: Digital Field Experiences at the Columbus Zoo, an Informal Science Contextual Setting

Tamara J. García-Barbosa,
Andrea K. Balas,
Dr. Barbara S. Thomson,

249 Arps Hall, 1945 N. High St.
Columbus, OH
garcia-barbosa.1@osu.edu

Abstract: The Columbus Zoo has a Distance Learning Interactive Field Experience Teleconferencing program (CZDLIFE) to provide a vehicle to enhance standards-based math and science instruction in Ohio's schools. The use of interactive technology in schools can increase the ability to use contextual settings in education which add a level of reality to classroom learning. Making connections through planned partnerships outside the traditional classroom promotes curiosity, creativity, and exploration. Learning in an informal setting helps students connect and transfer their knowledge base as they engage in new learning opportunities. Zoos can provide an excellent informal context to ground distance learning interactive field experiences.

The Project

The goal of the Columbus Zoo Distance Learning Interactive Field Experience (CZDLIFE) is to offer educational and scientific resources to enhance standards-based math and science instruction using two-way audio/video interactive technologies. The CZDLIFE provides an exciting and meaningful curriculum that incorporates a variety of activities for all students at the distant site. The instructional design of the project was grounded in contextual teaching and learning theory and situated learning environments (Brown et al. 1989, Balas, 2000). The design emphasizes the use of several pedagogical strategies blended with contextual experiences that promote real-time problem-solving interaction. These experiential activities are designed to promote knowledge creation through interaction with zoo facilitators and other learners (Thomson, B., et al. 1999). The field experience was constructed using six key areas: 1) considerations to connections to the curriculum, 2) connection to multiple content areas, 3) inclusion of non-formal educators in the design phase, 4) developmentally appropriate activities, 5) professional development activities, and 6) follow-up activities (Francis, 1999).

Research Problem and Question

The Columbus Zoo has experienced a great deal of success implementing on-site and outreach educational programs. The recent advent of the use of two-way audio/video interactive teleconferencing as a means of sharing the zoo resources has added a new and complex medium for educational content delivery. Interactive teleconferencing is a unique medium that requires different and diverse pedagogical approaches than those regularly used with on-site visitors and outreach populations. The main benefit of two-way interactive teleconferences is that the nature of the system provides a level of intimacy in communication that is not apparent in other forms of distance learning. Two-way real time video transmission of information implies a new definition of real-world context, in which the learning environment, although video-mediated, is indeed the actual environment with which the learner interacts (Jonassen et. al. 1995). Another strength of the technology lies in its synchronous nature; the teacher and learners experience parallel delivery and reception of information without a time delay.

In order to add to research based design, the main question of the study is How do you design effective standard-based two-way synchronous teleconferences from an informal education setting?

Research Design and Procedures

Background research in the development of interactive teleconferences in contextual settings such as the zoo is almost non-existent. The study involves the Columbus Zoo, in Columbus Ohio, and four distance learning sites throughout the state. The four sites were divided among three schools in New Lexington, Stark County, and Richfield, Ohio; and one community-based after-school enrichment program, which used the Cincinnati Zoo as their teleconferencing facility. Five elementary school teachers, one principal , four technology coordinators and seven classes were used for data collection. The student population ranged from second to fifth grade with a combined total of 140 students. This population is representative of Ohio's urban, suburban and rural students.

Qualitative data was gathered through surveys, interviews, observations, field notes, and researcher reflections. Surveys were collected immediately after the CZDLIFE, and interviews were conducted with the teachers and technology coordinators prior to and after the CZDLFE teleconference. The qualitative data was interpreted through the development of common themes generated from the interviews and is being synthesized into assertions about the nature of the experience.

Preliminary Results

The CZDLIFE teleconferences use a view of learning that encourages knowledge creation rather than a knowledge delivery. For most learners having tactual contextual opportunities is critical to accommodate for their learning styles (Thomson, B., et al. 1999). The CZDLIFE program has been effective in providing an opportunity to:

1. Bring to the zoo a wider student audience.
2. Help meet the needs of students who are unable to attend on-site programs.
3. Provide real time face-to-face interaction between classrooms and zoo educators.
4. Involve outside speakers who would otherwise be unavailable to regular zoo visitors.
5. Provide an opportunity to "export" unique exhibits such as the coral reef or some of the endangered animals that can not be used on regular zoo outreach programs.
6. Allow "real time" 2 way audio and video contact between students and the facilitators at the zoo.
7. Incorporate the use of experiential learning activities, live action and pre-recorded video to present interactions carried out at the zoo which are not available to the general public.

Implications

The results and conclusions of this program help provide a better understanding of design process for interactive distance learning field experiences in informal science settings. The study also serves as one of the few studies that examine the outcomes of using two-way interactive distance learning between elementary classrooms and an contextual learning setting.

Abstract: This presentation reports on our current and on-going R&D efforts towards the design and development of multimedia, web-based courses suitable for use through the Internet. We discuss the process that has been adopted in designing the interface and the tools used. An important issue for the implementation of the courses is the use of streaming technology for the reliable transmission of multimedia content material over the Internet. This technology allows us to transmit multimedia data in a more efficient way and to introduce interactive elements using SMIL (Synchronized Multimedia Integration Language).

Introduction

Until now, the traditional educational system has assumed that all students learn identical materials via the same delivery mode. However, it is known that each student's intelligence profile and learning style is unique and therefore, the traditional lecture-based method of classroom instruction cannot accommodate the large number of diverse learning preferences. In this context, the Internet has emerged as a new means for meeting the needs of individual learning diversity and has introduced significant opportunities for the improvement of the educational process.

However, although significant investments have been made for the technological support of this new educational environment, similar steps have not been taken towards the creation of noteworthy educational software. Thus, although a vast amount of electronic educational material currently exists on the Internet, it is usually in the form of simple text occasionally combined with some graphics. Undoubtedly, there is a lack of genuinely qualitative educational content. This is due mainly to the fact that the current Internet infrastructure is incapable of transmitting high-quality multimedia content (a problem which can partially be addressed by the use of streaming technology). In addition, the significant expense and time required for the development of such material are serious prohibiting factors.

This paper discusses our efforts towards the design and development of interactive multimedia, web-based courses suitable for use through the Internet. The primary characteristics of the material developed are the following:

1. It is dynamic and interactive.
2. It supports the concept of collaborative learning i.e. it offers opportunities to simulate real situations of collaboration among various groups of users.
3. It can be transmitted efficiently to users.

Designing the interface

The appropriate design of the interface depends on the specific context that it is intended for. To this purpose, an effort was made to create an interface, which would be used by adult graduate and post-graduate students and would use unambiguous "metaphors" for the effective and consistent delivery of specific concepts to learners. The screen was divided into three vertical frames, the left of which always displays the contents of the course. The middle frame presents each individual course in the form of text while in the third frame, accompanying graphics, video or animation, can be viewed by the user, depending on the requirements of the specific material being worked on. It is important to emphasize that that each lesson is available in several different forms of delivery i.e. text, narration, etc.

Implementation of the educational material

On a technical level, the implementation of the courses was based on the use of:

a) Streaming technology
b) HTML, JavaScript, VBScript, XML (SMIL), ASP

Streaming technology for the efficient transmission of multimedia elements

One of the basic problems encountered during the implementation of a multimedia, web-based course is undoubtedly the limited bandwidth of the Internet. This is perhaps one of the main factors that justify the lack of extremely high-quality multimedia material. The greatest amount of educational software existing presently on the Internet is in the form of simple text, frequently enriched with some graphics. This form, however, proves to be inadequate.

Streaming technology addresses this problem in the following way:

Although, the conventional way of transmitting data through the Internet requires that the entire file (e.g. a video file) be received before it may be viewed by the user, this is not a necessity when streaming technology is the adopted method. In the latter case, the information is presented to the user (e.g. the video file begins to "play") even though the remaining information is still being received and it becomes possible to view the multimedia elements almost simultaneously with the appearance of the rest of the HTML document.

A primary advantage of this kind of technology is that it is possible to transmit very large multimedia files in an efficient and reliable way thus resulting in the preservation of the learner's concentration.

Streaming technology makes use of the RTSP (Real Time Streaming Protocol) instead of the HTTP protocol.

The product selected to deal with the difficulties associated with the network infrastructure of the Internet was the RealServer created by Real Networks. RealServer makes it possible to incorporate high-quality multimedia elements (RTSP is designed to stream clips that have time lines) within a web-based course. Whether the learner has an ISDN line or accesses the Internet through a low-bandwidth connection, s(he) may still view a course that comprises a variety of multimedia elements. There is also a possibility for the dynamic detection of different connection speeds between the client and the server so as to achieve improved transmission.

Emphasis should be given to the fact that it is possible to include additional interactive elements within the educational material (sound, video, animation) through the use of the SMIL language.

Interactivity

An additional item of concern was that the educational material should be enriched with a variety of interactive elements. To this extent, SMIL (Synchronized Multimedia Integration Language) presents notable interactive characteristics.

Based on XML, this language reacts upon the multimedia elements of the course, which are transmitted through the use of streaming technology.

The main reasons that make SMIL so important are:

a) It can integrate and co-ordinate many diverse types of multimedia information. We can capture events that are generated from the interaction between the learner and the multimedia element. This is achieved through the use of callback methods.

c) It can be considered as an "open", platform-independent technology, which is based on W3C XML.

Abstract: Based on case-studies of edutainment Multimedia programmes this study is exploring the affordances of the contextual elements of narrative in relation to interactive Multimedia programmes, the possible cognitive costs that lack of canonical narrative elements may have for the user and the particular possibilities they may offer in a learning environment in which meaning, experience and motivation for further exploration are key elements.

Narrative and the user`s construction of meaning

Educational or edutainment Multimedia programs are offering new environments for learning and communication (Gjedde 1999a) but often these programs are not employing the canonical narrative elements that can be found in popularization of complex information in television, magazines or in books. Instead there has been a natural interest in exploring the non-linear possibilities that the interactive media is offering. This has been done while letting go of the canonical narrative elements and schemata's that typically has a beginning including a notion of time, place and a protagonist, a development and an end (Bartlett 1932 1995; Labov 1972). Research on the relationship between narrative structure and cognitive processes like memory and comprehension has indicated that there tends to be better memory and comprehension for texts that employ a narrative structure than texts that do not use a narrative structure.(Thorndyke 1977; Mandler 1984). Narrative theories are furthermore pointing to its importance for experience, identity and communication. (Schank 1990; Schank and Abelson 1995; Schank 1997).

The structuring and communicative elements of narrative are often not used in educational or edutainment Multimedia programs, which are often encyclopaedic in structure and if using other structures as a motivating factor, tend to use games that often do not have the basic narrative elements. They are not embedding the information offered in the context and structure of a narrative, but it is instead presented in an abstract cyberspace, or in an encyclopedic structure that does not provide the same cognitive and experiential level of support for the user.

This lack of narrativity can have consequences for the ability of the user's to construct meaning from the seeming chaos gathered by experiencing information that is presented out of a context or a known and comprehensible universe.

This can be found in the edutainment/educational genre, where the user may be particularly vulnerable to the lack of cognitive support for the organization of the material, that a narrative structure may provide.(Plowman 1996; Plowman 1998)

The user may also lack the involvement, which the narrative can create through an experiential dimension, through the unfoldment of a narrative, with the possibilities for emotive and identificatory involvement and a narrative logic with an explicit causal structure. These factors may be of importance for the learner's motivation and construction of meaning, particularly the possibility for making a connection between the information they may gather through the program and their present experiences and knowledge structures. (Sarbin 1986; Schank 1990; Gjedde 1998b)

Previous research in this area, has looked at various CD-ROM's in the edutainment and educational genre (Laurillard and Taylor 1994; Plowman 1998). There are indications that a non-narrative or encyclopeadic structure tends not to support the user's construction of knowledge or perception of global coherence to the extent that the narrative that may be found in books and television typically does.

An empirical research project with an experimental design, the MENO-project (Multimedia in Education and Narrative Organisation) has experimentally employed different types of structure in an interactive educational program. (Laurillard and al. 1995) (Plowman, 1999). It was however focused on the structural manipulations and not on a narrative embedding of the material through a consistent main character that provided a focus for identification, or the point of view of a narrator.

This type of narrative embedding may be found in several successful popular science productions. An example of this is the best-selling novel by Jostein Gaarder about the History of philosophy: *Sophies World* (Gaarder 1992), which became the world's most sold book in 1995. A CD-ROM production was made on the basis of this book within the genre of edutainment, which was based on some radically different structures. In the CD-ROM version some of the canonical narrative elements have been replaced by a NLP-generator, which is capable of having a primitive dialogue with the user; and with a number of game elements.

Based on a pilot project with a case-study of some users of this CD-ROM I have identified some potential problems that will be further explored in a study that will involve other CD-ROM's of the same genre that are using narrative. The results from the pilot study are indicating that it might have implications for the user's experience when the basic narrative element are replaced by other elements, which do not support the process of narrative construction, by the user. The narrative is seen as fundamental for the user's experience of meaning and global coherence.(Bruner 1990; Schank 1990; Schank and Abelson J.1995) the narrative is furthermore of importance for the dimension of experience.(Gerrig 1993).

Without the narrative which affords an embedding context the user tends to experience the options offered in the interactivity as lacking in coherence and meaning. This must be seen in relation to the genre of edutainment and that the target group's users, are not supposed to have much previous knowledge about the particular field that the CD-ROM is presenting.

The study is being done in a naturalistic mode, with a high degree of ecologic validity, using natural users of the CD-ROM's with a mobile usability lab. This set up allows for a video-recording to be done with a video of the user as well as a documentation of the activity on the screen through a scan-converter. The study uses a qualitative methodology that involves user's narratives about their experiences with the program and their construction of meaning from it. Using both video-observation and qualitative interviews as well as a questionaire allows for a comparison between the different sets of data..

The focus of the project is to explore the user's experience through narrative and how it translates into a potential greater sense of motivation and possibly cognitive capability for construction of meaning, in relation to the non-linearity of the media.

The aims of the project:

- To provide a greater understanding for the qualitative aspects of narrative in relation to interactive Multimedia and the particular possibilities they offer in a learning environment in which meaning, experience and motivation are key elements.
- To explore the relationship between the contextual elements of a narrative . In particular these which are offered by the elements that constitute a beginning in a canonical narrative (Labov 1967.1997; Mandler 1984) - and the cognitive implications for the user in terms of experience, understanding and interest for the subject and motivation for further explorations into the subject.
- To look at possible connections between the narrative elements in the interactive program and the user's process of narrative construction and focus on the relationship between the narrative organization of the material and user's level of processing.(Laurillard et al. 1984, 1997)
- To explore gender specific preferences in the relation to narrativity (Gjedde 1998b) and multimedia.(Adam 1998).
- To inform the producers of educational multimedia about the implications for using narrative structure and other narrative elements in relation to specific groups.

Graham Kerr
School of Human Movement Studies
Queensland University of Technology
Brisbane, Queensland, 4001, Australia
g.kerr@qut.edu.au

Abstract: The aim of the current project is to design, develop and implement a teaching strategies model and a multimedia template which crosses over curricular boundaries and responds to a wide variety of learning styles of students. The Conversational Framework model as proposed by Laurillard formed a starting point in examining the place of a multimedia template in Academic Learning while the design of the template has been guided by the need to establish reusable resource materials. Key characteristics of such a template were deemed to be accessibility, cohesiveness, supportiveness, flexibility and quality.

Background

According to Laurillard, the teaching - learning process is an interaction between teacher and student operating at two intermingling levels:

Level 1 - Discursive Level - the level of theory 4 stages to reach consensus:	**Level 2 - Interactive level - the level of practice** The way the student acts in the world
1. Teacher articulates the subject matter	1. Teacher sets task
2. Student joins dialogue - asks questions, practices etc	2. Student acts
3. Teacher re-expresses their point to clarify and elaborate. * Teacher uses student understanding to adapt interactive activities and elaborate theory to those appropriate to student needs	3. World responds - includes teacher, other students, experts etc. * Teacher uses student understanding to adapt interactive activities and elaborate theory to those appropriate to student needs
4. Student has another attempt at representing the theory	4. Student modifies action to improve their performance (adaptation and reflection).

The teaching model is designed to provide a framework for the teacher and student for all steps in both levels whilst the multimedia matrix plays a role in only part of the total process. A balanced mix of multimedia resources, face to face interaction, online communication and practical activity could form the components of a complete learning experience.

Teaching Plans

It is the intent of the designers that the multimedia template act as a guiding mechanism for the teacher in order to facilitate the mapping and selection process for the teaching sequence. Through thorough analysis of the learning objectives, the resource selection, interaction planning and assessment strategies are developed and a mapping of strategies is undertaken. Once all aspects of the teaching mix are determined, then the multimedia elements are produced and assembled and supporting technologies are weaved into the virtual learning environment.

A typical analysis by a teacher in planning the learning experiences may be as follows:
* Concept Map is produced showing the interconnecting curriculum and content elements
* Identification of feasible interactions that best achieve learning outcomes
* Development of plans for each interaction eg multimedia matrix, face to face discussion, practical excursion etc
* Topic in Context material is assembled and Themes and associated Activity sequence is determined and designed
* Media Resources are gathered for supporting problem solving as required by activities
* Computer tools are assembled for use by students in carrying out activities
* Delivery proceeds with monitoring and feedback loops built in to the interactions - Evaluation data is gathered and used in review of the model and matrix.

In teaching academic staff to utilise the matrix tool, the above sequence forms the basis for a workshop. This enables the intertwining of a pedagogical and a technological focus and is punctuated by a management theme ie all three focuses become a part of the teaching plan.

The Multimedia Matrix

The matrix template consists of a number of "cells" which may be populated with content or resources which are required for the student to carry out their study of a particular topic. These are as follows:
A) Topic in Context - an overview of the topic and its place in the whole curriculum. The relevance of the topic to the profession is also a key aspect.
B) Topic resources - these are not directly linked to any one theme or activity but rather are more global to the topic eg Extended readings or digressions may be placed in the resource area
C) Themes - In order to create a single environment for students that is self contained but has interconnecting parts, the template allows for the creation of several themes. A concept map highlights the links between themes.
D) Activities - these are the problems and instructions that guide students through the resources and learning experiences designed for them.
E) Tools - These include Glossaries, Concept Map generators, Text editors, Analysis tools and a launch pad for applications that are common place such as word processors and spreadsheets.
F) Media - Video, Audio, Graphics and Text elements can be used in the template - these are dropped into any matrix and become a part of the application.

Progress to date

The use of the matrix in teaching the concepts of *movement* through the specific idea of "gait" has been planned. A plan for the main phases of teaching the sequence has been established and each matrix in a sequence multimedia support applications is being developed. These include Biomechanical, Bioenergetics, Diversity and Neurologic perspectives on gait. Rather than examining gait in each of these aspects separately, the planned sequence moves from an exploratory view through each of these perpectives in order to establish core understanding and then evolution of ideas both quantitative and qualitative from a combined view. To illustrate, a typical activity may require a student to make a series of observations that will lead to understanding of both diversity and biomechanical principles and their interrelation. Use of a common visual resource in supporting such an activity ie the same video sequence, also reinforces this cross curricular notion. The template itself is in BETA phase and has been used to assemble the first of these applications.

The staff development program that is essential in establishing the model for achieving maximum effectiveness of implementation of the Conversational Framework model has begun and a network of colleagues from one faculty group who are in close proximity, has been set up. This is a key feature for staff development in an area that requires complete rethinking and restructuring of teaching and its planning. *Collegiality and support* cannot be underestimated in their power to catalyse best practice teaching. We envisage that the notion of a learning matrix both in terms of the multimedia application itself and of the curriculum structure will provide a clearer view for both students and teachers. In this way the path through the study of a discipline may be made more transparent and flexible. In supporting a student-centred approach to teaching, the initial effort has been significant, however the revolution that will follow will show energy levels that pale these efforts into insignificance.

Being Social in an Anti-Social Environment: Is Cooperative Learning Possible Using Computer-Mediated Communication?

Joseph G. Gregg
Jones International University
United States
jgregg@international.edu

Abstract: The purpose of this study is to investigate which experiences of adult learners in an online cooperative learning environment contribute to the expected evolution from an aggregate of strangers to a group capable of high performance. There is a clear need for a thorough qualitative study focusing on the development of online relationships required for successful cooperative learning groups. . The interview, observation, and journaling methods will provide information to address impression formation, social presence, group development and the conditions of ambiguity and detraining. In addition, the results of this study will help provide a palette of best practices for designers of online learning environments utilizing similar instructional strategies.

Introduction

Providing opportunities for students to take distance education courses is becoming commonplace in higher education. It should come as no surprise that this growth fosters change and with change comes resistance and criticism. Yet, perhaps it is time to listen to that criticism. Historian David Noble, professor at York University, wrote a series of articles criticizing what he characterized as the unmindful haste by higher education institutions to adopt the Internet and World Wide Web for course delivery creating nothing more than a technologically-slick updated version of the correspondence course (summarized in Noble, 1998). Nobles' primary fear is that we are creating courses devoid of any true interaction between the student and instructor.

Course developers and instructors recognize the importance of designing interactions into courses offered by distance education means. The importance and validity of these interactions is amplified in numerous studies in which students reported that their individual success was due, in large part, to a high-level of interaction, typically learner-instructor (Eastmond, 1995; Wegerif, 1998). Likewise, many learning theorists do describe the integral role that interaction plays in the level of learning attained by students (see Reeves & Reeves, 1996, for review). Most studies on communication using computer-mediated communication (CMC) or asynchronous learning networks (ALN) have examined interactions resulting from tasks requiring some type of online discussion (Eastmond, 1995; Hiltz, 1994; Wegerif, 1998) Yet, very few studies have looked at the social aspects of group processes in online environments using cooperative learning techniques.

Reports from distance learning students in collaborative or cooperative learning groups using computer-mediated communication (CMC), specifically, asynchronous learning networks (ALN), indicate that there is a crucial moment in their experience in which they cross a threshold from outsider to insider or from newcomer to old-timer (Eastmond 1994; Wegerif, 1998). Crossing this threshold is crucial for increased positive attitude leading to continuation of the course and higher achievement. Failure to cross this threshold often results in the student dropping out of the course. How does a collection of strangers move from being an aggregate of people to a group capable of high performance using computer-mediated communication (CMC), specifically asynchronous learning networks (ALN), as the sole means of communication?

It stands to reason that understanding interpersonal communication across asynchronous learning networks is crucial to designing and implementing effective cooperative learning. Results from laboratory research led to a set of interpersonal CMC categorized as the "Cues-Filtered-Out Approach" (see Walther, 1994, for review). Essentially those theories postulated that the reduction of nonverbal cues leads to communication that is task oriented and impersonal, resulting in more equal communication among group members but the possibility of very negative interactions ('flaming'). Initially, Walther (1992) stated that the communication process observed within CMC follows that found in face-to-face groups only the time required for certain behaviors to emerge is of much longer duration. In addition, an individual's perception of anticipated future interaction with group members leads to more social relational behavior. His most recent work showed that computer-mediated communication can run the gamut from impersonal to interpersonal, and finally to what he calls hyperpersonal (Walther, 1996).

There are major discrepancies for prescriptions on how to establish and manage groups and cooperative groups, whether face-to-face or online. For example, the need for an individual to identify with the group as a prerequisite for intimacy, affection and social orientation (Bales, 1950) appears to be contrary to the identification of heterogeneous groups as the most successful for cooperative learning (Johnson, Johnson, & Holubec, 1994). Furthermore, there are conflicting theoretical approaches and even haziness in single theories about the ongoing development of thriving groups in CMC. Specifically, there are conflicting indications of how one might go about creating, facilitating, and managing online groups using cooperative learning communicating via ALN/CMC. How can these discrepancies be resolved?

Proposed Research

This study examines the key aspects to consider when using cooperative group instructional strategies for distance learning mediated by text-based Internet communication. Based on components derived from research on small group development, cooperative learning, and relational behavior, instructional strategies are recommended and a set of research questions are proposed.

Understanding the cooperative group processes when using CMC that provide for the development of successful interpersonal communication leading to close interpersonal relationships will 1) provide information for instructional designers and instructors of online courses to guide their design and 2) delivery efforts in terms of group composition, group activities, and facilitation strategies, and guide design of better interfaces and software to enhance effective communication interaction.

Keep facilitating pupils and English teachers appropriately

Bo Han
Foreign Languages Department
National Teachers' College
Inner Mongolia P.R. China
hanbo49@hotmail.com

Abstract: This paper describes a research project on primary school English teaching and teacher training in Inner Mongolia P.R.China where the financial situations of the schools and pupils vary, and English teachers' levels differ greatly. The research group has developed a course, which has a set of kernel textbooks, and there are eight different combinations. This article describes why certain media are chosen and how they are used in order to make sure that teachers can be trained properly and the pupils can get the most possible benefit.

Introduction:

There is no doubt the use of technologies in learning is gathering pace around the world. The use of the multimedia as learning/teaching is changing the way the world thinks and acts. Multimedia has the potential to make teaching and learning more effective but can we use them everywhere? This article describes the research project on primary school English teaching and teacher training in Inner Mongolia and why certain media are chosen and how they are used. Future plan is mentioned and suggestions for improvement are longed for.

Analysis and schemes:

The demand for learning English is greater and greater in this fast developing world. This research project is aimed to meet the need of this demand. To plan for flexibility and adaptation right from the start is very important, if we aim to get good learning results for a long period of time (Griffiths, Heppell, Millwood, &Mladenova, 1994). The following aspects are what we considered when we tried to work out a proper plan:

There are not enough English teachers in Inner Mongolia. Some schools may have one; some other schools may have more. The teachers' English levels and teaching experience vary; Inner Mongolia is a region with different nationalities. The main languages are Mongolian and mandarin which have sharp differences. Mongolian pupils learn Mongolian and mandarin in primary school, so they can only learn English for one or two years in primary schools to make sure that they may not be overloaded; Some schools may have tape recorders, others may have overhead projectors. Video player, etc; locations: Inner Mongolia is a vast area. Primary schools scatter all over the area. To train all the teachers face to face is impossible; Some pupils cannot afford expensive textbooks and tapes. Some schools cannot afford expensive teaching aids; Although Inner Mongolia is a backward region, it is also changing rapidly. The numbers of English teachers in each school will change, the facilities in schools will change, the home appliances will change; How can we use different media for the pupils and teachers in the most appropriate way? (Collis & Deboer, 1998; Griffiths et al., 1994)

After all the above aspects besides teaching methodology being considered, certain media are used in the way as the following: Kernel textbooks and supplementary textbooks have been developed to make sure that the pupils who can only study one or two years may have basic knowledge of English before they go to middle schools and other pupils who have the opportunity to learn more in primary school may well informed. Eight teaching plans with scientifically related teaching materials have been designed to make sure that all the pupils can benefit most efficiently. The textbooks are designed black and white and special revision exercises are designed to make pupils paint the textbooks with colorful pencils by themselves. Therefore the textbooks not only attract pupils attention more and the pupils may remember more of the teaching materials but at the same time the price of the textbooks is cut down; Two sets of tapes are designed. One set is that one tape is offered each term to help the pupils to learn at home and to keep a low price for those pupils who cannot afford two tapes. The other set is that two tapes are offered each term. This is to make sure that there are enough feedbacks and interactive exercises to do, and it makes preview and review convenient. At the same time, these tapes can also be convenient for teachers to prepare their lessons. A special tape is designed only for teachers to check pupils assignment. In this way pupils do not have to buy that tape and teachers will not have trouble with the questions and answers. Transparent sheets for overhead projectors: Two sets of transparent sheets are designed. One is black and white; the other is with color to meet the need of different schools. In this way, teachers may have teaching aids even in schools with limited budgets. We made videotapes for pupils and teacher training so that teachers from remote areas can also have the opportunity to watch other teachers' teaching and understand the theories of teaching. Schools with video players can play the videotapes to their pupils and pupils with video players at home can watch the videotapes to learn better.

Learning should be immediate feedback as many educators have already recognized. However, the above media which have been used are quite limited in the aspect of interactive activities. This means that a lot of potentials from the teachers and pupils have not been cultivated. What should we do to accomplish our goal then? In order to work out our future plan, let's first see what will happen in this part of world in the near future?

The future plan:

In the near future more and more schools in Inner Mongolia will also have computers. Since Internet connection in China is still quite expensive, most of the families in Inner Mongolia will not be able to get an access very soon. But the perspective of using Internet in schools is great. A significant number of schools will have the capability to interact online. It means that teaching materials designed to be used with computers may help more and more teachers and pupils to teach and learn more effectively. The key to successful interactivity, is not simply offering educational access to preexisting networked materials. Rather, a more valuable role is to offer a collaborative environment where users can create, and share information of their own with other users. It's an opportunity that many teachers won't let slip by them. It means that we're reaching a point where teachers can't be competitive in other words, prepare today's children for the university and the modern workplace without the Web. Therefore, our future plan is divided into three steps:

1. To put the teachers books on Internet first and build a forum for teachers to share their teaching experience. In this way, teachers will be well informed and share their experience in teaching, and with the latest version of teachers' books, they can always try to teach their pupils better.
2. To put teaching materials with more interactive activities on CDs. In this way schools with computers and pupils with computers at home can use these materials to teach and learn more efficiently.
3. To establish on line courses for pupils to learn. Besides textbooks with interactive activities, a reading series can be developed. In this way, pupils with internet access not only can learn the textbooks well but can also learn by their own pace to develop their abilities in reading, listening , speaking and writing.

The above are our plan for the near future. We are eager to ask you the specialists in the conference to offer us suggestions in order to make this ideal into reality. All your advice would be greatly appreciated.

Course Production Applying Object Oriented Software Engineering Techniques

Ronald Hartwig, Huberta Kritzenberger, Michael Herczeg
Institute for Multimedia and Interactive Systems
University of Luebeck
Seelandstr. 1a, D-23569 Luebeck, Germany
Hartwig <hartwig, kritzenberger, herczeg>@informatik.mu-luebeck.de

Abstract: Developers of educational material like web-based training and online courses face well known aspects of classic software development processes: Reusability of course units; Supporting cooperation and resource sharing between the members of the design process, like content authors, designers, multimedia producers and quality managers and Quality management. Therefor, software engineering techniques like object-oriented analysis (OOA) based on a central database to be used in iterative design processes will also be useful for the development of educational material. This considerations are the background for our work and experiences in the project Virtual University as described in this paper.

INTRODUCTION

The Project "Virtual University of Applied Science"

This paper reports work done in the project "Virtual University of Applied Sciences" (period of duration 1998-2003, see http://vfh.de). It aims at establishing a location independent university with a curriculum for computer science of multimedia systems and for business engineering (Bachelor, Master).The authors of this paper are involved in the production of web-based courses, in the design of user-adequate learning spaces and in the support of the design process. Their focus is on usability recommendations and quality management for the course material during the development process. Other aspects like teaching strategies, learning processes or technical issues concerning the course production are supervised by other dedicated consulting groups within this project.

Adressed Problems

During the first months of course production for the virtual university several problems got obvious:

- *The lack of a appropriate context of use description.*
  Practice showed that the developers of course material had only an incomplete mental model about the needs and abilities of the intended user groups, like previous knowledge, learning style, preferences in teaching mode, motivation and other information that would be important to adapt the teaching strategies and delivery of hypermedia structure and content accordingly (Kritzenberger 2000). The mental models about this user group and the assigned attributes even differed during development phases.
- *No stable base for the quality management*
  Quality management (e.g. of learning processes, functional correctness, usability) suffers from a lack of basic information about design and implementation requirements.
- ***Consistency of content information and re-use of contents***
  Another problem is that the content or the structure of the course units may get inconsistent during workflow. While the content author has her or his version (e.g. a linear MS-Word-Document), the hypermedia producer has to transfer content and structure to web formats (HTML and sometimes JAVA Add-Ons). Changes in the linear version have to be manually transferred to the hypermedia version. This is a source of errors and often prevents maintainance, because of the extra effort it will take. Keeping such a training unit up to date often requires to start all over again (e.g. with updating the Word-Document) and repeat former development steps.

DESCRIPTION

The main idea is to overcome the problems mentioned above by introducing a central information base which is used by all participants during the design process: content author, designer, producer and quality manager (see figure 1). Using a simple relational database combined with a powerful web frontend seems to be adequate. This database should include all the context information as well as the content of the teaching units. In a first step these informations are only presented to the involved persons but no contents are automatically generated.

For database organization object oriented techniques are used. Classes of information like "user attributes", "organisational requirements", "content", etc. are identified and then may be freely combined into "views". These views are role dependent, for example the content author may concentrate on the analysis data and the contents. Whereas the producer, who has to implement the learning unit, may need additional design rationales added by the designer. A quality manager can base his evaluation of the system on the requirements identified and documented during the analysis phase.

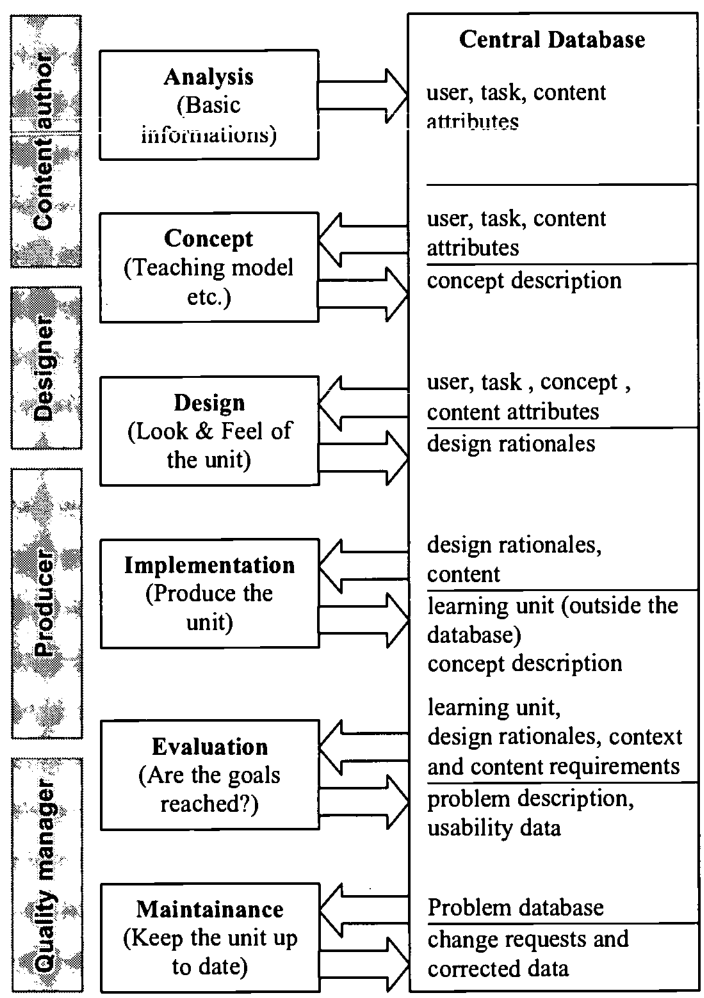

Figure 1: An iterative development process for educational systems (eg. web based training units). Please note that all these steps are to be handled iterativly, that means the whole flow must be done several times.

As the size and the number of the learning units is difficult to handle, techniques of the OOA are used: abstraction, inheritence and generalization. If for instance many different user groups are to be considered, they may be ordered hierarchically: "All users" → "users of the teaching unit" → "A special group within these user group". Attributes of the most general object ("All users") are inherited by all following objects and then, e.g. the designer's view includes all attributes, from the general to the specific ones. OOA techniques, like underspecification and refinement make the handling of large object sets easier and allow all participants to start with rather raw data and to refine them during the lifecycle of the developed system using OOA techniques based on a database has several advantages. The database supports the complete lifecycle of the course unit and makes all information and design rationales available again for maintaining or updating the course. As the contents are HTML-based they can be included into the courses with less manual effort. Furthermore, the connection of each unit to the position and role in the database is kept. nection to the database. Additionally for each production phase there is appropriate additional information available, like design rationales and the related context informations. Updating a content in the database automatically updates the course and avoids inconsistencies.

Current and future work

Currently two major tasks are to be solved: First the different object classes (content and context objects) and views needed for the educational systems must be identified, validated and implemented. Second the database tool has to be implemented and tested.

As the described method is similar to a special OOA technique currently under development in our institute as well (project "TAToo") see (Herczeg 1999), we reuse implementation resources from that project. Actually the database frontend and the needed JAVA/JDBC/JSP-Interface will be the same in both projects.

Abstract: In an Internet environment, users' expectations are diverse due to its on-line characteristics. Internet can be assessed by any user of any age, group, race, nationality, and gender all over the world at any time and at any place. Considering these, web site designers must adhere to certain design standards and properly evaluate their sites to ensure its usability and effectiveness. Despite abundance of studies on web usability, very few of them focus on the political web sites. Using political web sites in Malaysia as an empirical base, this research intends to identify factors affecting the use of political web sites; and then based on the analysis, develop a framework for evaluating the usability of political web sites. The main purpose is to contribute towards the improvement of cyberdemocracy in the information age.

Introduction

The central focus of the debate on the success of a democratic political system is people participation in election, political discussion, and the process of governance. In order to participate, people should possess sound knowledge about political and social issues affecting them. Traditionally, people are mostly dependent on mass media mainly newspapers, magazines, television and radio as sources of political information. Indeed, mass media has been very influential in shaping public opinion about political and social issues in any democratic country. Today, the advent of the Internet has revitalized the whole concept of communication media. Ideally, it does not only provide an alternative source of political information, but it can also be used as an effective political communication medium between and among citizens, public leaders and political parties. This development certainly provides opportunities for the enhancement of democracy whose main emphasis is on citizens' freedom to actively participate in politics by debating and exchanging views on key social and political issues.

Cyberdemocracy and Current Practice

There is little agreement on the exact definition of cyberdemocracy because of its uncommon usage. Clift (1997) states that cyberdemocracy is about the use of online communication tools for many-to-many civic discussions among citizens and public leaders. It is based on the belief that opens communication and participation is the foundation of democracy. According to Alexander and Grabbs (1998), cyberdemocracy refers to the optimized use of internet-based communication technologies by government agencies, interest groups and non-profit organizations to promote public participation in the process of governance. In general, cyberdemocracy is defined as the use of the Internet technology such as World Wide Web (WWW), File Transfer Protocols (FTP), electronic mail (email), conference facilities and net chatting for dissemination of information and exchange of ideas between and among government, political parties and public leaders with the general public. There are a number of examples of efforts carried out by government, political parties and voluntary bodies to establish cyberdemocracy. Minnesota e-democracy project (http://www.e-democracy.org), established in 1994 by a group of volunteers, held the first online debate via email among candidates for governor and United States Senate and launched the MN-POLITICS email discussion forum. Another example is United Kingdom Citizen Online Democracy (http://www.democracy.org.uk), a non-partisan effort, that began work before the 1997 national election. It hosted a number of topical events on such topics as European monetary union efforts and online delivery of government services, and it held an all-party debate during the election.

Web Usability and Research Focus

Usability is basically a very broad concept in system design and difficult to define. In this research, usability refers to how easy, effective and useful it is for a person who uses a political web site to achieve their goals. According to Nielsen and Mack (1994), and Shneiderman (1998), there are 5 main aspects of usability: ease of use, efficiency, satisfaction, rate of users' error and retention over time. The primary focus of this research will be on the usability issues of web sites used as political communication medium. These issues are grouped into seven main factors: Screen design, Content, Accessibility, Navigation, Media Use, Interactivity, Consistency -- abbreviated by the researcher as SCANMIC. These are the generic factors of web usability based on an analysis of current web design guidelines and literature.

Research Question

In an Internet environment, users' expectations are diverse due to its on-line characteristics. Internet can be assessed by any user of any age, group, race, nationality, and gender all over the world at any time and at any place. Considering these, web site designers must adhere to certain design standards and properly evaluate their sites to ensure its usability and effectiveness. Despite abundance of studies on web usability, very few of them focuses on the political web sites. Yet, usability has become one of the most important aspects that determine the success of web sites regardless of their category. With this in mind, this research will address three major questions;

a) What are factors that affect the usability of political web sites?
b) How to evaluate the usability of political parties' web sites?
c) What is the level of the usability of web sites in current cyberdemocracy efforts in Malaysia?

Conclusion

The above research questions will be used to achieve the following objectives:

a) To identify factors that affect the usability of political parties' web sites.
b) To design a framework for evaluating the usability of political web sites. The framework is designed for both technical and non-technical people who are involved in political web site development.
c) To test the applicability of proposed framework.
d) To propose a guideline for developing a usable political web site.

Biggs' Constructive Alignment: Evaluation of a Pedagogical Model Applied to a Web Course

John Hoddinott
University of Alberta
Biological Sciences
Edmonton, Alberta, Canada, T6G 2E9
john.hoddinott@ualberta.ca

Abstract: Biggs' (1996) proposed a pedagogical model where "performances of understanding" specified in course objectives are used to systematically align teaching methods and assessment practices. The model was applied in a plant physiological ecology course delivered at a distance over the web. Students and instructor thought the course format helped learning and that the assessment model, the SOLO Taxonomy, was good. Everyone also concluded that the course workload was too great in spite of ample feedback to discourage such excess. The course may be viewed at: http://www.biology.ualberta.ca/courses.hp/bot431.hp/bot431hp.html

Evidence based good teaching practice seeks to enhance "deep learning" by emphasizing active learning strategies, high expectations, time on task, prompt feedback, respect for diverse ways of learning and student-student and instructor-student interaction. Deep learning is supported by a constructivist pedagogy that argues that it is the learner's activities that aid their construction of meaning to bring about learning.

Biggs (1996) has articulated a "Constructive Alignment" model that is the marriage of two ideas: constructivism as a framework with the learner's activities as central in creating meaning and the instructional designers emphasis on the relationship between the learning objectives and the targets for assessing student performance. In his model, the "performances of understanding" nominated in the objectives are used by the instructional designer to systematically align the teaching methods and the assessment activities.

Biggs and Collis (1982) previously developed a 'Structure of Observed Learning Outcomes (SOLO) Taxonomy' that analyzes the cognitive level of students' written work. It identifies five categories:

1) prestructural - no understanding of the topic,
2) unistructural - nominal understanding of one, or a few, points,
3) multistructural - several aspects understood but used separately,
4) relational - components integrated into coherent wholes,
5) extended abstract - the integrated whole is reconceptualized at a higher level of abstraction.

The taxonomy provides a scheme that served as a basis for giving feedback to students on their written work.

The Constructive Alignment model was applied in a distance delivered web based course for senior undergraduate and graduate students. For each week of the course, the course web site gave details of the learning objectives, required reading, optional supplemental reading and web hyperlinks to resource sites. The web site also provided an extensive background on the pedagogical principles behind the course, the nature of the SOLO Taxonomy, sample responses to a problem and their assessment according to the Taxonomy, and advice on preparing portfolios of evidence that the learning objectives had been achieved.

Students were invited to assemble their own portfolios of evidence that they had achieved the learning objectives. Portfolios were submitted by e-mail and assessment feedback was provided in the terminology of the SOLO Taxonomy. Students had access to a password protected conferencing system that allowed them to interact with each other, the teaching assistant and the instructor in a virtual, asynchronous group environment. An on-line chat room was also available through the conference system. Private communication between participants was available through e-mail.

The course opened with a telephone conference to allow the students to meet each other and interact with the teaching assistant and instructor. The students and the teaching assistant then moved to a computer lab where all students had the opportunity to demonstrate that they were familiar with the computer and software skills required to complete the course work.

Student assessment in the course was based on the submission of three portfolios of evidence of meeting the learning objectives through the term. Take home mid-term and final exams were also given. These exams were integrative of the material in the portfolios and gave the students considerable discretion in selecting the context in which the questions were answered. Exam feedback was again based on the SOLO Taxonomy. As the eight students in the course had no previous experience of distance education or portfolio assessment, they were invited to maintain a reflective journal that was read three times during the course by the instructor. Marks for keeping the journal were given on a credit/no-credit basis.

At the end of the course students were asked to evaluate the course and their learning experience. Evaluations were submitted to the TA who cut and pasted the anonymous student comments into an e-mail message to the instructor.

The evaluations showed that the students thought the course format helped learning, they developed independent learning, time management and communication technology skills, that the web materials on the SOLO Taxonomy were good, that the web material on the course philosophy was good but only in retrospect and that the learning journal material was very helpful.

In the future the students thought that workload in the course should be reduced, feedback increased, course notes provided, more texts should be placed on reserve, a lab should be included and a TA with a background in physiology would be preferable.

Students thought that future offerings of the course should retain the chat room, group camaraderie, learning objectives, the SOLO Taxonomy, and the instructor's understanding.

The instructor's evaluation concluded there should be a reduced workload, more frequent feedback, greater use of an on-line seminar facility and continued use of the SOLO Taxonomy and learning journals.

Workload was an issue for everyone. Despite the feedback given on their portfolios, the volume of evidence provided on each of the three submission dates increased steadily. Students were spending more time assembling evidence and the instructor was spending more time assessing it. Conversations in the chat room emphasized the concern that everyone shared and a phone conference was organized to discuss the problem in real time. Despite encouragement by the instructor to pay attention to the quality of the portfolio contents rather than the quantity, the problem persisted.

Providing more regular feedback would have spaced out the assessment workload for the instructor but it is not clear that it would have helped reduce the pressure the students placed on themselves to submit a large mass of evidence of their learning. The conferencing tool (WebTeach) had a seminar facility where students could have posted questions for their peers relating to the learning objectives. Responses to questions posted by their peers were not readable until participants had submitted their own answer. This facility remained unused although it might have been a vehicle to model the depth of material that was reasonable in a portfolio. It is also possible that students would see use of the seminar facility as even more work.

Everyone involved in the course was satisfied with the SOLO Taxonomy as a framework for assessment. It allowed the students to align their portfolios to the learning objectives and the assessment criteria. Students found preparing a learning journal to be useful. Evidence of concern over workload was recorded in the journals along with recognition of the feedback they were getting on what was anticipated. However, recognition of the issue and a discussion of solutions did not solve the problem.

The learning objectives were well received by the students. However, some continued to think that course notes would have helped. It seems that even these senior students were uncomfortable in assuming a large degree of control over their own learning. It is worth noting that some students commented that the material on the pedagogy behind the course was only useful "in retrospect". If these various opinions were expressed by the same set of individuals, it might suggest that more quickly coming to terms with the pedagogical background might have compensated for the lack of the course notes.

In conclusion, Biggs' pedagogical model of Constructive Alignment is suitable for application in a web environment.

Winnie So
Department of Science
Hong Kong Institute of Education, Hong Kong
wiso@ied.edu.hk

Abstract: This paper introduces an attempt to make use of Information Technology to facilitate teaching and learning in a teacher education institute. A multimedia video bank was being developed to provide with teacher educators and student teachers necessary video clips that could be made use to produce computer- assisted instruction programs that fit the local context. All the videos are intentionally to do without any narration or background music to allow flexibility for the subject teachers to present their materials and to better communicate with the students.

Background

In the First Policy Address of the Chief Executive of the Hong Kong Special Administrative Region (HKSAR) Government, a firm devotion of the Government to develop information technology (IT) in education was first revealed. However the education community in HK is still striving to seek the direction of IT in education that matches the local context, a unique culture of the East and the West. Most of them, especially the primary school teachers are puzzled simply because they do not know how to start with teaching with IT.

Objective

With the aim to facilitate teaching and learning with IT that fits the local context, this project attempts to build up a multimedia resources bank (MMRB) for teacher educators and student teachers in the Hong Kong Institute of Education (a publicly-funded teacher education institute) to develop their own computer-assisted instruction (CAI) programs or to use as part of the teaching materials. It works towards a direction to encourage and promote innovative teaching approaches with an effective use of IT in classrooms.

Multimedia Resources Bank in General Studies

Despite of the resources put in acquiring computer hardware and software, there is hardly any quality interactive CAI program in "General Studies" being developed because there are difficulties facing by the primary school teachers:

[1] The heavy workload does not allow them to have location shooting and video editing that are both needed in developing the CAI programs in "General Studies".

[2] It is not worthwhile for the primary school teachers to heavily involve in video production, as it is not their profession in this aspect.

However, there are enthusiastic primary school teachers who are willing to produce their own multimedia teaching materials provided that there is enough support (Pow, So and Hung, 2000). With this in mind, we therefore tried to build a MMRB in "General Studies" for the primary schools teachers and let them to make use of the resources to tailor make their own CAI programs to facilitate teaching and learning. With the cooperation between a lecturer from Department of Science and education technology professionals from the Centre for Learning, Teaching and Supervision in Hong Kong Institute of Education, the team has produced about a hundred video clips according to the syllabus of the "General Studies" to be put on the MMRB. We chose "General Studies" as the starting point for MMRB as it is a new subject that integrates science, social study and health education in primary school curriculum, and hence at hand resources are still lacking.

The content of the video clips covers a broad area of topics from Hong Kong community services, transportation, housing, etc. to scientific experiments such as the property of magnet, heating, etc. The videos are classified, edited into a reasonable length and stored onto a video server for easy retrieval and viewing. All the videos are intentionally to do without any narration or background music since we would like to allow flexibility for the subject teachers to present their materials and to better communicate with the students. Although it is the Institute that owns the copyrights, staff and students can use it freely in their own works or teaching. Staff and students can instantly view the video clips of their choice at any computer that is linked up with the Institute's Intranet or download these media clips for their own use later on. This MMRB is expected to be able to save up valuable time and resources for those who want to try out teaching with IT but do not have enough time and resources to produce the media on their own. It is hoped that this could contribute partly to promote innovative use of IT in teaching and learning, not just within our Institute but also to the education community at large.

Abstract: The purpose of this study is to examine the effects of learner's PBL authenticity perception on achievement and motivation. There are two major research questions. First, is there a difference on learner's achievement between high and low perception level of authenticity? Second, is there a difference on learner's motivation between high and low perception level of authenticity? The results show the following: (1) There is a significant difference in the learner's achievement between low and high level of authenticity perception ($t=-3.42$, $p<.05$) (2) There is a significant difference in learner's motivation ($t=-3.34$, $p<.05$).

Introduction

In recent years, with the advent of the Information Society, the focus of educational paradigm has been shifting from "teaching" to "learning". This signifies a move to a learner-centered education where the student becomes an active participant in the learning process. Korea's educational reform committee has established a goal to build a learner-centered educational environment to prepare Korea's students to be competitive in 21st century.

"Web's Cool" program has been planned since 1998 to support the learner-centered education system in Korea. Subject areas such as language arts, math, science and ESL(English as a Second Language) for middle school students have been developed on the Web. Since the Web was considered to be an effective medium for learner-centered approach by applying the constructivistic principles, PBL(Problem Based Learning) strategy were applied to provide students opportunities to participate in the learning process actively.

While the Web's Cool has been developed, we wanted to investigate the fact that whether the problem we were using as an authentic task has any effect on learner's motivation and achievement. In order to measure the authenticity of the task, the expert's as well as student's perception level of the authenticity toward the task has been scored by using a 5 point scale. Two tasks were selected as high and low authenticity level of perception by both 10 experts and 10 students to investigate the effects.

The purpose of this study is to examine the effects of the authenticity perception on learner's motivation and achievement. There are two major research problems. First, is there a difference on learner's motivation between high and low perception level of authenticity? Second, is there a difference on learner's achievement between high and low perception level of authenticity?

Research Method

Subjects

Subjects for this study are 51 students of the middle school students. Two learning tasks perceived low and high authenticity are selected.

Results

The results are as follows:

(1) There is a significant difference in the learner's achievement in general between low and high level of authenticity perception ($t=-3.42$, $p< .05$). A significant difference was found in the learner's authentic achievement between low and high level of authenticity perception ($t=-4.54$, $p< .05$). However, no significant difference was found in the learner's logical achievement between low and high level of authenticity perception ($t=-1.75$, $p< .05$).

Achievement	Authenticity perception level	Mean	SD	t	p
Authentic Achievement	High	1.58	.77	-4.54*	.00
	Low	1.05	.88		
Logical Achievement	High	1.69	1.01	-1.75	.09
	Low	1.34	1.03		
Total Achievement	High	3.27	1.56	-3.42*	.00
	Low	2.42	1.99		

(* : p < .05)

(2) There is a significant difference in learner's motivation of a total ($t=-3.34$, $p<.05$), attention($t=-3.16$, $p<.05$), relevance($t=-2.55$, $p<.05$), confidence($t=-2.85$, $p<.05$) and satisfaction($t=-2.34$, $p<.05$) between low and high level of authenticity perception.

Motivation	Authenticity perception level	Mean	SD	t	p
Attention	High	3.68	.57	-3.16*	.003
	Low	3.44	.52		
Relevance	High	3.64	.50	-2.55*	.014
	Low	3.47	.53		
Confidence	High	3.47	.42	-2.85*	.006
	Low	3.29	.41		
Satisfaction	High	3.40	.46	-2.34*	.023
	Low	3.25	.45		
Total	High	3.45	.42	-3.34*	.001
	Low	3.27	.40		

(* : p < .05)

Conclusions

Based on the results of the study, following suggestions were made: (1) Measuring scale of authenticity of the learning task has to be further validated through many different situations and various subjects (2) Authentic assessment of the authentic learning environment has to be studied further.

Abstract: Wireless Application Protocol (WAP) provides a universal open standard for bringing Internet and Intranet content and advanced Value Added Services to mobile phones, PDA's and other wireless devices [1]. The production of WAP applications and content requires new software professionals on the area. In this paper we describe our experiences from the multimedia course where students developed WAP applications as their project work[5].

Background

WAP is an industry standard whose purpose is to achieve universal mobile access to Internet based information services. The application is independent of the underlying digital wireless network technology [1]. WAP applications are developed with Wireless Markup Language (WML) and WML Script. [2]. WML applications can be developed with special toolkits, for example Nokia WAP Development Toolkit , Ericsson WAP development kit or UP.PHONE development environment . These toolkits include smart editors and debuggers, phone simulators and help system. However, its is possible to develop your WML applications using only a simple ASCII editor. The students developed simple WAP applications in the laboratory work and implemented a larger project work in the end of the course.

Wireless Markup Language Specification and WML Script

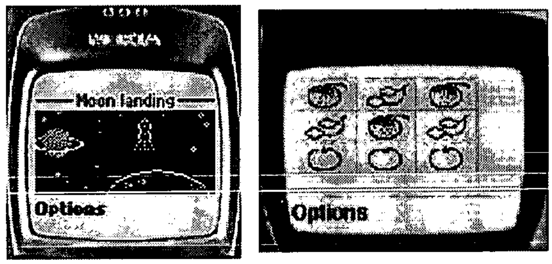
The Wireless Markup Language specification describes the markup language, WML, including the document semantics, Document Type Definition (DTD), and encoding extensions. WML is a markup language based on Extended Markup Language (XML) and is intended for use in specifying content and user interfaces for narrowband devices, including cellular phones and pagers. All information in WML is organized into a collection of cards and decks [3]. WML Script is a scripting language that makes it possible to implement dynamical elements in the WML application.

Student's WAP projects

The students were required to design and implement a real WAP software and document the code in the end of the course. The topic of the project was free and many of the students chose to implement a game in WAP phone. In this chapter we will present three WAP games, namely Moonlanding game, Lucky Wheel, and Jackpot. The idea of the Moonlanding game is to land to the surface of the moon by controlling the fuel consumption of the rocket (Fig. 3). In the Lucky Wheel game your mission is to find out a secret word or words by guessing the missing characters. Jackpot is the WAP implementation of the old casino game (Fig. 3). Some of these applications are being developed furthermore and will be published in the commercial WAP service by the national mobile phone operator.

The first step in the project was the learning of the WAP development environment. The Nokia Wap software toolkit was used in the projects. In general, programming in WML and WMLS is similar than programming in almost any other environment. It is possible to use the toolkit as a stand-alone environment or with Nokia WAP gateway in order to simulate real wireless connections [6]. In our case, it was not required for the students to test their software in real phones. During the development of their software the students find out several problems. One of the most significant problem was the differences between the real phone and the simulated phone. Of course the toolkit itself was beta-level software and was not very reliable. In addition the real WAP phone does not fullfill the WAP specification [4]. For example, the Nokia 7110 WAP phone does not support table feature in the WML content and the WAP applications can use only a little memory - the memory size in the phone is appx. 2 KB.

Figure 3. The moonlanding game and the Jackpot.



Positive aspects in the project were that the project was very motivating, the simulator makes it possible to develop software without the real phone, it was easy to learn to program with WML and WMLS because they are similar than HTML and JavaScript and students used actively WAP discussion groups in internet.

Conclusions

Increasing global competition, digitalization of content the general use of HTML and WML languages and the adoption of mobile broadband data transfer will require software specialists with new skills. In the future content producers, telecommunication companies, IT companies and media companies need workers with good knowledge technological convergence and good ability to use the new content producing technologies like WAP. This is a demand for the educational institutes and universities. We should provide up-to-date technological education and be prepared to modify our curriculum to follow the latest technological innovations. In this paper we have discussed about WAP as a new technology to implement wireless content services. The students at Tampere University of Technology studied the WAP technology and implemented simple WAP applications as their project work. The applications were developed using freely downloadable Nokia WAP development toolkit. The most significant problem was the differencies between the real WAP phone and the simulated WAP phone. From our point of view the projects succeeded well: some of these applications are being developed furthermore and will be published in the commercial WAP service by the national mobile phone operator.

Enhancing Total Patient Management Skills in Dentistry with Interactive Multimedia Simulation

Mike Keppell
Biomedical Multimedia Unit, Faculty of Medicine, Dentistry & Health Sciences

This paper examines a project which aims to improve dental clinical management through case management of medically compromised dental patients. During the past few years, it has become increasingly difficult to access suitable patients, especially child patients, for dental students and consequently for them to become sufficiently experienced in treating patients with medical conditions. Multimedia simulation provides a means to fill this gap and allows interactive learning in a non-threatening environment. This paper examines the design, development, project management and evaluation of the first module – congenital heart disease.

Teaching dental students to treat patients safely and efficiently presents many challenges. The declining availability of suitable patients attending the teaching clinics of the Royal Dental Hospital of Melbourne prevents students from developing a range of experiences in total patient management. A disadvantage of traditional preclinical laboratory teaching is that students are not able to integrate theoretical and practical skills. Consequently there are concerns that dental students are not competent in combining preventive and restorative management philosophies while integrating diagnosis and treatment planning (Suvinen, Messer, Franco, 1998). Multimedia case simulations were considered to be a viable alternative as they replicate the dental clinic without requiring 'live' patients. These modules provide an opportunity to develop and consolidate the concept of integrated patient care.

During 1999 the first module, congenital heart disease (CHD) was designed and completed. During 2000 further funding will allow three other modules to be developed: diabetes, Down syndrome and cleft lip and palate. These medical conditions were chosen as they are the most likely medical conditions to be encountered and are least understood by a dentist in general practice treating children. Each condition will follow the existing template developed for the CHD module except for the diabetes module which will use a 3-D Dental surgery to enhance interactivity. The CHD module contains a description and review of the medical condition, considerations of medical management and dental management. The student is then presented with a case scenario of a child with CHD. The student constructs a treatment plan and management approach after considering a range of treatment options. The module series will replace some tutorial and lecture content for both 4th and 5th final year dental students. The modules will not replace valuable clinical practice; but prior learning from the modules will enhance students' ability to perform clinical work. The modules will also be used for post-graduate students and in Continuing Dental Education programs for dentists.

Design and Development

In designing and developing the CHD module, the project team followed the model utilised by the Biomedical Multimedia Unit (Keppell, 1998). The design phase of the project focussed on developing the macro-structure for the module in the form of a concept map (Novak & Gowin, 1984) and completing the micro-structure in the form of a 'planning grid'. The content experts for the project were experienced specialists and educators in the field of paediatric dentistry. They worked with the instructional designer to develop the concept map and planning grids for the project. **Figure 1** http://www.medfac.unimelb.edu.au/Ed-Media2000/ outlines the resultant concept map which provided a scaffold for the development of the planning grids. The process used to develop the concept map and planning grids followed the Content Production Process (Keppell, 1999). A specific form of storyboard or 'planning grid' has been developed to provide a 'communication tool' for interfacing between the instructional designer, content expert and graphic designer/programmer (Keppell & Buschgens, 1995). The planning grid is useful in streamlining communication and providing a common ground for discussing the multimedia project. The planning grid is analogous to an 'architectural blueprint', which can be applied or 'engineered' by the graphic designer/programmer (see **Figure 2** http://www.medfac.unimelb.edu.au/Ed-Media2000/). The graphic designers developed the interface for the congenital heart disease module and the subsequent modules (see **Figure 3**. http://www.medfac.unimelb.edu.au/Ed-Media2000/)

Project Management & Evaluation

The project management focussed on carefully scoping the project, providing a detailed planning grid to the graphic designer/programmer and establishing the "look and feel" of the interface. England and Finney (1999) suggest that each project will define its "own quality priorities" (p.17). In this project the priorities of target audience, subject, budget and the time available impacted on the project management of the project. England and Finney (1999) also suggest that "design quality for media projects = content and treatment agreement" (p.17). These treatment parameters were carefully considered in the initial stages of the project conceptualisation. The first module was targeted to be completed within an hour by undergraduate users. The macrostructure for integrating the subsequent modules was also considered as an essential characteristic of the project. In order to analyse project costs and as a means to plan for the future modules, the total work hours were tracked for this module. A total of 390 hours was required to produce the CHD module (see **Table 1** http://www.medfac.unimelb.edu.au/Ed-Media2000/). The CHD module was completed in November, 1999 and was evaluated with a group of 15 recent graduates (interns and postgraduate students) at the School of Dental Science in December 1999, using a Likert-style questionnaire. **Table 2** http://www.medfac.unimelb.edu.au/Ed-Media2000/ shows the distribution of responses to questions concerning content. The majority of all responses were either "strongly agree" or "agree", with most modal responses being "strongly agree" (**Table 3**). http://www.medfac.unimelb.edu.au/Ed-Media2000/ Most respondents correctly identified the deliberately placed distractor, "confusing". In general appraisal, the majority of respondents rated the module as "good" or "excellent", and "very easy" to operate and navigate (**Table 4**). http://www.medfac.unimelb.edu.au/Ed-Media2000/ Of interest, one respondent rated the module "very poor" and "difficult" on these points. The module is currently undergoing beta testing at three national and three international locations, in departments of pediatric dentistry.

Discussion

Computer-assisted education in dentistry is in its early stages (Yip and Barnes, 1999). Developments are occurring very rapidly, and educators must evaluate modules developed internally or purchased externally (Mercer and Ralph, 1998). Sound instructional design indicates the goals of instruction must be made clear, so that users know what is expected of them in operating and navigating a module. This may not have been so in the instance of one respondent. Nonetheless, it is concluded that computer assisted instruction was enthusiastically received by most of the recent graduates. Experience in focus groups has shown that participants valued the tutor discussions that were held at the end of the module, which allowed extension of learning and further professional role-modelling.

Abstract: At the George Washington University teacher candidates in the master's program learn to apply technology in teaching and learning within the context of methods and curriculum courses and school-based practicum and internships. Teacher candidates acquire skills and understanding as they prepare presentations, develop curriculum materials, teach lessons, assess student learning, and reflect on practice. This short paper describes the ways in which teacher candidates' development of multimedia electronic portfolios to assess their ability to implement a variety of instructional models assists in learning to use a variety of hardware and software for instructional purposes. It is expected that teacher candidates will, on some level, transfer their proficiency in using technology to the secondary students with whom they work during their teaching internships.

Why Electronic Portfolios?

Performance assessment in teacher education programs commonly includes development of a teaching portfolio during the teacher internship. The purposes of the portfolio are to document professional growth (Campbell, et. al. 2000) and to cultivate outstanding teaching and learning (Wolf, 1996). Fulfilling these purposes requires that the portfolio is a dynamic, flexible documentation of student growth. Emerging technologies facilitate creating electronic portfolios that support flexibility rather than traditional portfolios constructed in 3-ring binders that tend to be collections of artifacts. The electronic format offers several advantages: the ease of storage usually on a computer hard drive or some sort of removable media (floppy disk, Zip disk, CD); easy access to information; portability is enhanced; multiple copies can be created at low cost; the opportunity to add sound, pictures, graphics, and even video make an electronic portfolio more attractive and interactive than traditional style binders; in the process of developing portfolios, students gain valuable technology skills as they create and edit this multimedia document. These skills can be transferred to 6-12 students during the internship and as the successful teacher candidate moves into classroom teaching.

Development of the Electronic Portfolio

A group of teacher candidates in the secondary education graduate program at The George Washington University are expanding their technology proficiencies through developing an electronic portfolio. The primary purpose is to provide teacher candidates with technology related skills that they can transfer to middle and high school students and use to support their teaching. A secondary purpose is to enable teacher candidates to demonstrate their teaching competencies using an alternative method to the binder-style portfolio currently in use in many teacher preparation programs.

The conceptual framework used to develop the portfolios is based on the Interstate New Teacher Assessment and Support Consortium Standards (Darling-Hammond, 1992) and the National Board for Professional Teaching Standards (1991). The domains addressed include: 1) commitment to students and their learning, 2) knowledge of the subjects taught and how to teach those subjects to students, 3) establishment and management of student learning in a positive environment, 4) assessment of student progress and adapting instruction to improve student learning, 5) commitment to reflective practices, and 6) professionalism. Several indicators are provided to students within each domain specifying ways in which each is exemplified in teaching or in course work.

Those participating are currently enrolled (spring 2000) in a class that teaches application of instructional and classroom management models. The instructional models reviewed include Direct Instruction, Inductive, Inquiry, Integrative, and Cooperative Learning. Each of the models represents a cognitive perspective of learning which views learners as active investigators of their environment. In these models, teachers are directly involved in guiding learning through questioning and discussion. Candidates construct a number of products to show their understanding of concepts and theory and their ability to apply them in a teaching-learning situation.

Specifically, teacher candidates learn how to use various technologies as they learn pedagogy. In the course, they will practice using technology to: present information; research content; organize and store data; track and record their development as teachers; and reflect on their teaching behaviors as a process for solving problems and growing professionally. For example, they will learn to use PowerPoint in the context of learning how Howard Gardner's Theory of Multiple Intelligences applies to the teaching of science, math, English, social studies or ESL. Each candidate will design a presentation that outlines how each of the 8 intelligences is used to frame curriculum development of a specific unit topic. Candidates select topics according to their content specialization. Each will focus on the utility of the theory in: 1) designing curriculum, 2) engaging and motivating students, and as 3) assessing students' learning.

In demonstrating their understanding of and ability to apply instructional models, candidates will teach lessons they develop to other members of the class. They will be videotaped using a digital video camera. After receiving feedback from peers and the course instructor, the teacher candidates will view the video and reflect on the effectiveness of their teaching. As a part of the reflective process, they will edit their video to capture those portions that exemplify what they have learned about their teaching and will include this shortened version in the electronic portfolio. In the process of creating the portfolio, teacher candidates will learn how to create a personal website. The goal is to expand their portfolios as they move through the graduate program. Unlike what typically occurs in the binder approach to portfolios in which students organize a collection of artifacts during the teaching internship which illustrate their best work, the approach taken here will concentrate on documenting growth as teacher candidates develop their knowledge and skills in both pedagogy and content. This means that candidates will begin assembling their work during their initial experiences in the program and, the work included in the portfolio will not necessarily showcase their best products. Rather, the final product will reveal the ways and extent to which each candidate has grown as a beginning teacher.

Conclusion

One major area of emphasis in the teacher preparation program at the George Washington University is to prepare teachers who will serve as leaders in the schools where they teach. An important aspect of that leadership role is technology. As our students develop their proficiency in this area, they will be encouraged to explore the connections to teaching in middle or high school. The ways in which technology use can enhance teaching and learning is of particular importance. Specifically, through the development of electronic portfolios, these teacher candidates will consider how the use of technology can assist secondary level students in: learning content; presenting information; conducting research; and, reflecting on their development as learners.

Abstract: This paper is based on experiences with the production of web-based training (WBT) courses for a course of studies in medical computer science. Course production is regarded as software development process, which starts with conceptual models shaping the design and defining the way the software product is presented to the user. This paper reports experiences with conceptual design models and shows the danger of being insufficient or incorrect.

INTRODUCTION

Our project "Distance Education in Medical Computer Science" (started in January 1999) aims at providing a complete course of studies for the specialization of students in medical computer science, offered at a virtual university. Our responsibility is to transfer the linear text documents (mostly MS-Word format) into hypermedia networks and multimedia courses, which means practicing reverse engineering for WBT course development.

PROBLEMS WITH CONCEPTUALIZING WBT COURSES

The transfer of a text document to hypermedia means transformation of format, gain of flexibility, interaction capabilities and so on. Hypermedia and multimedia courses can be used in ways beyond the intentions of the content author. On the other side, people occupying other roles in the development process, like multimedia designers, or quality managers do not know about the content domain or didactic aspects. The static version, which the content author had in mind, has only one dimension of presentation. Accordingly, the semantic (content) structure and the didactic structure of the course are intertwined. Most authors are not able to separate both structures in a way applicable for hypermedia production and vice versa the multimedia experts are normally no experts in the semantic domain or in didactics, therefore, they can hardly explain their needs to the content authors. This lack of knowledge in each others domain results in unintended course structures, unnecessary restrictions or other mismatches. A similar problem arises if the author for example has to start with specifying a semantic model and then would have to design for different learner groups.

Furthermore, we found in our projects, that media designers, producers, and content authors often have insufficient, incomplete, and partly incorrect models about the learners, the task and the situation of use. The models vary at different times during the period of course production.

COURSE PRODUCTION AS SOFTWARE DEVELOPMENT PROCESS

Our approach to course production as practised in our projects is to regard the production of hypermedia and multimedia WBT courses as a software development process. As for many other software systems, it is also true for the development of WBT courses: To realize a user and task adequate human-computer-system, developers have to take into consideration all system components: user, task and situation in order to form a conceptual model that is as adequate as possible [1]. The conceptual model of the developers shape the software product, in our case the WBT course, and therefore, will decide how usable and user-friendly the WBT course will be and how adequately it will support learning processes.

Figure 1 shows the different models we have to deal with in the context of WBT course production. First of all there is the developer's mental model the design process starts with. In the case of WBT course development we have to deal with diverse developers. In our project there is the conceptual models of the content author, of the designer, of the HT/MM producer and of the quality manager. Furthermore, there is the learner's mental model about the application domain, how the WBT course is implemented and how it supports learning processes. And last but not least, there is the system's model, which contains the way the application domain is implemented and sometimes information on the user's interaction with the system. Each model represents the complex domain of interaction with WBT courses from a certain perspective and in a specific way.

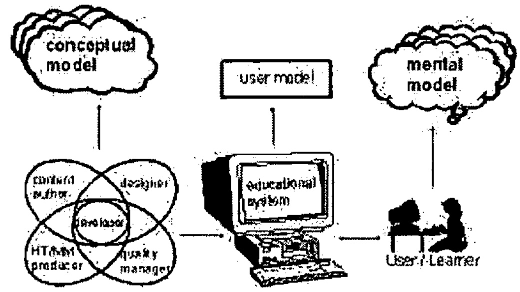

Figure 1 : Models in the context of WBT course production

Mismatches between these models lead to usability problems of the software product. Above all, the importance of the developer's conceptual model for shaping the software product has been noticed for other kinds of software applications for a long time [2], [3]. According to our view, this holds true for WBT courses as well.

CONCEPTUAL MODELS OF DEVELOPERS

A fundamental problem for the development process is, that the developers need substantial and relevant information about the user, the task and the situation of use. They need this information from the very beginning of the design process in order to specify the requirements and shape the WBT course adequately. However, in practice content authors start course production in the traditional way and produce a linear document that includes their conceptual model about domain knowledge and about teaching strategies. This production methods corresponds to the production of traditional lectures for classroom teaching. These courses will not match the situation of use in the virtual university of the future. Lectures on demand have to serve the needs of different user groups and different situations of use. The attributes for users, the task and the situation of use will differ [4] and should have an adequate representation in the conceptual model of all authors. A severe drawback with this situation is, that it is impossible for a content author (and also for the other developers) to take into consideration all these attributes at one time.

In some way, of course, the author is aware of the situations of use and the complexity involved. This might be the reason, why the conceptual model about the user group and the assigned attributes differ from phase to phase of the development process. This is a problem as well. If the conceptual model of the developers includes a prospective mental model of the user and if the design is based on this model, then it will be clear that varying the conceptual model during the development process will result in an inconsistent WBT course, which will be hard to understand and will not support learning processes.

FUTURE WORK

The conceptual models of the diverse developers shape the WBT course and determines the way the educational system is presented to the user and determines if it supports learning processes. Therefore, it is important for the developers to have sufficient and appropriate knowledge about the user, the task and the situation and it is also important that the conceptual models of the diverse authors can be communicated and complement each other during the design process.

With this background we are working on methods to adequately represent conceptual knowledge for the design process [5]. We also want to offer ways to communicate relevant knowledge components between all developers through the whole development process.

Students' Acceptance of Videoconferencing in the Lecture Context

Patrick Kunz
Network for Educational Technology NET
Swiss Federal Institute of Technology (ETH)
Zürich, Switzerland
kunz@diz.ethz.ch

Abstract: The goal of this work was to develop a set of recommendations for the use of videoconferencing in large classrooms. The students' acceptance of synchronous videoconferencing, the role of the instructors as wcll as the influence of videoconferencing on motivation and interactivity were in the focus of this study.
Based on the statements of 178 evaluated students there are three main recommendations that can be made: (1) The didactic approach of the course must concentrate on an more active involvement of the participants. (2) The instructor must be willing to adapt his teaching style to the integration of new media. (3) Technic has to be so perfect, that it guarantees the first two aspects: an undisturbed transmission with possibilities to interact for all participants and support of the instructor to make teaching easy.

Introduction

A lot of studies report about the benefits of videoconferencing in the context of small classes with active student participation. Videoconferencing in small classes has been shown to increase student motivation as well as interaction among students and lecturers often leading to a redefinition of teaching (among others Abotte, Dallat, Livingston, & Robinson, 1994; Bramble & Martin, 1995). Experiences with videoconferencing in the large classroom context however differ at least in part in some of these results. Increased inhibition to speak in front of others and lowered spontaneity seemed to be real problems (Knox, 1997). Further, an improved motivation or satisfaction was not found (Fillion, Limayen, & Bouchard, 1999). The purpose of this study was to find out, which aspects are the most crucial for the use of videoconferencing in large classrooms.

Method

Equipement

The videoconferencing facility used in this evaluation is a synchronous system based on ATM. Its theoretical bandwidth of up to 155 Mbits/s allows the simultaneous transmission of three audio- and video-streams with high quality and perfect audio-video synchronisation between two and more connected sites. The system provides full interaction possibilities to all participants at all connected sites.
The setting in the examined lecture is a two-point configuration consisting of the following components:
Remote classroom: Three screens, projected by beamers, with 1.) the instructor, 2.) the PowerPoint slides and 3.) the other class.
Local classroom: Two screens, projected by beamers, with 1.) the PowerPoint slides and 2.) the remote class. For further technical details see (Walter & Hänni, 1998).

Participants

The examined sample consisted of totally 178 participants of a two year course in pharmaceutical chemistry (86 students in the locat classroom; 92 students in the remote classroom). Gender representation was not equal (139 female and 39 male).
Control data (normal course without videoconference) were collected from students of both locations during summer 1999. The experimental data resulted from the first half (13 weeks) of the academic year 1999/2000.
The constructs and its components consisted of items which were measured using a five-point Likert-type scale (1=strongly disagree to 5=strongly agree).

Results and discussion

The following presented results were based on a minimum level of significance of $p<0.001$.

Acceptance and Motivation

As expected, students in the local classroom accepted with M=3.3 the videoconference better than remote students (M=2.7). Furthermore there was a significant difference in the acceptance which is correlated with the infrastructure: While in location 1 the auditorium used for the transmission consisted of a permanent equipped room, location 2 had to build up all equipment for the lecture every week.

In contrast to studies who reported about increased motivation, the measured motivation construct (consisting of subject interest and self-efficacy) remained the same with versus without videoconference. Nevertheless, with r=0.57, motivation was one of the strongest predictor of the acceptance.

Influence of the quality of the transmission

The participants rated the quality of audio (M=3.9), the level of synchronisation (M=3.7) as well as the quality of the transmitted videos (picture of the lecturer (M=3.8) and projection of the slides (M=4.1)) more than satisfying. Only the video of the remote auditorium was assessed average (M=2.9). The quality of transmission seems to be so good, that there were no correlations greater than r=.34 with the acceptance or the motivation.

Role of interactivity

The largest impact on the acceptance of a videoconference-classroom exerted the possibilities of interaction. Students assessed this kind of lecture in comparison with a normal classroom less stimulating for discussions between them and the lecturer (M=2.5). This variable had with r=.61 thew strongest correlation with acceptance.

The hypothesis, that students were more inhibited to ask questions during the class, can be accepted. However, the level of inhibition was lower than expected (M=3.5). With r=-.27 ($p<0.002$) the correlation between inhibition and acceptance never reached the expected level.

The possibilities of spontaneous intervention were even rated slightly higher than in the traditional classroom setting (M=3.2) and did not coincide with the students' actual hesitance. This high rating is most likely due to the lecturers' efforts to integrate prepared questions in their slides. Its correlation of r=.43 with the acceptance underlined the importance of the possibility to interrupt the speaker at any time.

Role of the instructors

The correlation of r=.38 between the acceptance of videoconferencing and the performance rating of the lecturers (with M=3.6 both were assessed above average) emphasized the important role of the instructors.

It is encouraging to note, that the implementation of videoconferencing had positive side effects on teaching: The cooperation of the two involved professors lead to an overall improvement of the curriculum with better structure, more goal orientation and the integration of prepared questions.

Recommendations

Based on these results, the following guidelines are proposed for the use of videoconference systems in the lecture context with groups consisting of more than 20 participants on each side:

1.) Lecturers have to consciously plan possibilities to interfere and to create an atmosphere that motivates students to undertake a more active part.

2.) The instructor must be above average and be willing to accomplish an extra effort.

3.) The technical infrastructure must guarantee a clear transmission of video and audio as well as the possibility of interaction at anytime for all participants.

Understanding collaborative learning in CMC: A research in an elementary classroom

Qing Li, University of Toronto, Canada

Abstract: This study is intended to understand collaborative learning in a context that enables communication by computer text messaging. Particularly, the study seeks to determine the level of collaboration in a classroom that uses computer-mediated communication (CMC), as well as to examine the relationship between the language functions associated with CMC generated messages and the collaborative learning process. In this study, "language functions refer to ways we can use language to achieve a communicative purpose" (Olsen, 1992). It is what people "can do with language" (McDonell, 1992), or "what people want to do with the language" (Finocchiaro & Brumfit, 1983, p.13), such as: requesting information, requesting confirmation, making suggestion, apologizing, etc.

The study is prompted by following questions

1. What are the levels of collaboration (in terms of interactivity) in the classroom that uses CMC?
2. Are there any patterns in people using of language functions in relation to the degree of collaboration (in terms of interactivity) in the context of CMC? If yes, what are the patterns?
   a). Are there any patterns in people using "requesting information" in relation to the degree of their collaboration (in terms of interactivity)?
   b). Are there any patterns in people using "requesting confirmation" in relation to the degree of their collaboration (in terms of interactivity)?

Computer-mediated communication (CMC), is an effective electronic means of connecting geographically dispersed learners using computers, in order that they may collectively participate in a learning experience where the interaction is mediated. Despite it relatively short history as a distance medium, a great deal of interest has been shown in this technology.

Courses offered by CMC are gaining favor in schools and institutions of higher education. Students can interact at a time and in a place that is personally convenient, discuss issues as fully as desired without constraints (Henri, 1995). CMC promotes interactive activities such as active dialogue and sharing of information and knowledge, which help develop a sense of community among participants (Burge, 1993). The CMC can be used as a powerful tool for group communication and collaborative learning (Crook, 1995). The collaborative learning environment promotes active mental engagement in the experience (Grabowski, 1990).

Despite the large body of literature on peer learning and teaching, there are few acknowledgments of how well CMC may support collaborative learning. Although cognitive and social psychology have already provided much information about how students communicate and its relationship with collaborative learning, the context has usually been the traditional face-to-face setting with its paralinguistic cues to facilitate communication. What we do not yet know in published detail are how people learn collaboratively and how this collaborative learning relates to the communication in the CMC context. In addition, O'Malley (1995) calls for studies of collaborative learning that "focus more on the processes involved in successful peer interaction, rather than just on learning outcomes".

Therefore, this study seeks to understand how people learn collaboratively and how their collaborative learning relates to the communication in the context of CMC. By asking these research questions, I assume that if we, as educators, know more about the process of collaborative learning in a computer-mediated-communication environment, we have a better chance of developing practical guidelines for facilitating learning. In addition, the information obtained from the study may contribute to the present understanding of students learning in CMC environment and may suggest future studies in the area.

For instance, numerous studies (Johnson & Johnson, 1989) dealing with collaborative learning have suggested that students need appropriate social skills in order to be successful in their collaborative learning. Johnson and Johnson (1989) emphasize that collaboration is the most important and basic form of human interaction, and the skills of collaborating successfully are the most important skills anyone needs to master. Coelho (1992) explains that good social skills can promote collaborative learning and some negative behaviors can shut off future collaboration. In addition, the literature on collaborative learning emphasizes the need to teach social skills. Students need assistance in acquiring those social skills and many of these social skills can be regarded as communication skills. For example, Olsen and Kagan (1992) state that "social skills include ways students interact with each other to achieve activity or task objectives (e.g., asking and explaining) and ways students interact as teammates (e.g., praising and recognizing)".

However, all these conclusions are based on the works that have been done in traditional face-to-face settings. Are the conclusions still true in the CMC environment? This remains to be answered and it raises important questions in the field of collaborative learning. This study will try to understand how students go about communicating and learning in the CMC environment. Once we have this understanding, we might then compare the CMC learning strategies with those reported for face-to-face classroom contexts in order to search for new practices to facilitate collaborative learning and better suited to the CMC context. And only when we have a better understanding of computer mediated learning, we can make a better use of CMC.

The subject of this study will be a grade 5-6 classroom in an inner elementary school in Toronto.

Combining Instructional Models and Enabling Technologies to Embed Best Practices in Course Instructional Design

Paul M. Malone, Germanic and Slavic Languages, pmalone@artsmail.uwaterloo.ca
Catherine F. Schryer, English Department, cschryer@watarts.uwaterloo.ca
Vivian Rossner-Merrill, Lt3 Centre, vrmerrill@lt3.uwaterloo.ca
University of Waterloo, Ontario, Canada

Introduction and Overview

Two distinct fields of educational activity should inform instructional design of courses using teaching technologies. These are cognitive theory and instructional theory. Cognitive psychologists tend to analyze cognitive structures and processes at a conceptual level without due regard to how these may be implemented in the instructional setting. Conversely, content designers and instructors do not often recognize the value of undertaking the analysis of content and teaching practices from a cognitive analytic perspective (Reusser, 1993). We propose that one means to combine the best practices of both fields in teaching and learning is to ensure that the instructional design process integrates both perspectives. Three principles inform the proposed framework of design.

- Selected models of instruction that best support the teacher's purpose for mastery of content, and the selection of enabling technologies that mirror the selected model of instruction are combined in the design process.
- Models of instruction and enabling technologies are selected according to the nature of the content to be learned, the teaching styles and preferences of instructors, and the learners concerned.
- Promoting and supporting development of the active nature of the learner underscores the entire design process.

The development of this framework took place through a recursive process of experimentation and teaching in two different university courses. The campus course uses concept-mapping software as a teaching aid and as a study aid for students needing to master the more difficult and abstract content areas in the study of German Thought and Culture. The software used was chosen for its ability to mirror the 'meaningful learning' model of instruction developed by (Ausubel, Novak & Hanesian, 1978) and (Novak, 1998). The online course, Introduction to Academic Writing, uses a Web site as the primary teaching tool and its design mirrors the 'expert instructional scaffolding' model of learning developed by (Hildyard, 1996). This model supports the need to ladder content into instructor supported incremental steps that allows modeling of best writing practices through interactive feedback processes.

UsingVisual Organizers and Meaningful Learning to Teach Cultural History

Students unfamiliar with cultural history are frequently presented with a huge number of facts and dates that have little significance to them, encouraging – if not forcing – them to acquire as much as they can through rote learning. The nature of the assignments and examinations often further reinforces rote learning and tends to discourage the synthesis and creative application of the material. The use of visual organizers coupled with instructional design based on a model of meaningful learning permits the student to see how the information communicated in the course is interrelated internally, and also how it is connected with students' prior knowledge. Relationships and interrelationships can be seen and apprehended quickly and easily when represented visually.

Concept mapping conveys information by reducing it to concepts (perceived regularities in objects or events) and propositions (significant combinations of concepts), which are then structured hierarchically and linked by means of lines representing the relationships between concepts and labeled accordingly. Each concept is thus already presented in a contextual relationship with other concepts. This device can be used either as a visual aid in teaching or more actively as an aid to learning. Novak's strategy of concept mapping is based on Ausubel's principles of meaningful learning designed to promote retention and subsequent related learning. These principles include the following:

- The learner must have prior knowledge related to the new information to be learned
- The new material must be relevant to other information and must contain significant concepts
- The learner must choose to learn meaningfully, rather than by rote.

We focus on concept mapping as the most viable strategy to link prior knowledge with relevant new conceptual material, using the CMapTools software package to support this strategy. The software has the features needed for the strategic learning practices outlined above; it is downloadable as freeware and it is easy to learn and use.

Using 'Expert Scaffolding' and the Web to Teach Academic Writing Skills

The purpose of this course is to provide the foundation for scholarly writing that students can build on through further, related coursework and through application of their writing skills in other university courses. Because writing skills are best acquired sequentially, the material in this course is scaffolded into linked, incremental units that build on each other. Throughout the course, the instructor provides expert modeling through feedback as evaluative discourse. Using WebBoard as a vehicle for threaded discussion, students interact with an experienced writer who supports them until skills are mastered at each level. Drawing from (Langer and Appleby, 1986), four design principles for scaffolding were used to inform teaching practice and design of the Web site

- Students were encouraged to assume ownership of their writing tasks
- The assignments were designed to address students' incremental levels of knowledge
- The assignments were designed to support the sequence of skills acquisition in the course
- The instructor and tutors supported students in a facilitative manner

Successful teaching in a course of this nature requires providing ongoing feedback using multi-faceted dialogue with students through commentary on writing and involvement in peer editing sessions. Feedback comes from the instructor and tutors and from other members of the student group. The course begins with a shared basis of readings – reading groups which present their interpretation of texts – and continues with discussion groups which assist writers to refine and elaborate their thoughts, and concludes with peer revision and editing groups. Thus evaluation is embedded in the design of the course and specifically with the design of the assignments. The assignments and final project include interactive exercises, instructor and peer commentary and editing, and online areas for discussing course content.

Conclusion

To date, we have successfully demonstrated in two courses that instructional theory and enabling technologies can be combined in a useful framework to inform instructional design of a given course. The next step is to design research studies that address the impact of using this framework on teaching and student learning.

To teach remotely by controlling the didactic interaction of a student with a multiapplication environment

Nathalie Masseux
Auvergne University Institute of Teachers Training
20 av. R. Bergougnan
63039 Clermont-Ferrand Cedex 2, France
nmasseux@auvergne.iufm.fr

Conceptual approach

The TeleCabri practices can be articulated with the whole of the experimental studies led these ten last years on remote teaching (Dessus et al. 97) in term of situated learning. The teachers seldom intervening in the realization of the computer-based environments that they use to teach remotely, the purpose of this research is to specify the cognitive influence (Balacheff 91) of the mediation of these environments on the student/teacher interaction. The computer-based didactic systems, with the constructivist meaning of the didactic theory of the situations (Brousseau 86), are its object of study. It is built according to the interactionist approach in HCI (Pochon & Grossen 97) considering these systems as a semiotic mediator by way of the didactic concept of computer-based milieu (Chevallard 92). A computer-based milieu is regarded as knowledge carrier aimed by the learning. We are particulary interested in the milieu which include microworlds or simulators characterized by a significant epistemological validity and a capacity to support a learning guided by the discovery (Masseux & Michau 96). It can thus include a computer-based tool identified like software or/and hardware support of a learning. Here, we center our study on the environments including several educational applications. This study aims at specifying the strategies of didactic regulation engaged by the teacher modelled before in the theory of the didactic situations. These strategies are analyzed using cognitiv models (Anderson et al. 90) of action/feedback between a user and an application who are declined for the student and the teacher. The finality of this research is to develop tools which help the teacher to diagnose in real time the learning activity of the student. It lies within the scope of study of computational didactics applied to mathematics (Balacheff & Kaput 97).

Functional integration of a platform to teach remotely

The functional integration of the platform is based on the capacity of a system to bring answers to the specific constraints of the students and teachers. The functionalities of the platform bring a technological response to the complexity of management of distributed human resources and of which the availability is unforeseeable.

The student/teacher interaction through PCs articulates three types of functionalities:
- functionalities allowing an autonomous work of the student (educational applications)
- functionalities of synchronous collaboration (video, audio, shared applications)
- asynchronous functionalities of interaction (email, sending of files)

Cognitive influence of a multiapplication environment on the remote student/teacher interaction

With TeleCabri, the student and the teacher interact remotely by way of three applications, each one considered here as didactic milieu and each one characterized by an epistemological validity specific to the stake of learning:
- an *oral* milieu, supported by the videocommunication,
- a milieu *Web on the geometry,* including a base of exercises, definitions and properties,

- a milieu *(CabriGéométre)* microworld of direct interaction with geometrical objects provides as a solving board of problem.

To control the student/environment interaction

The regulation which the teacher carries out is conditioned by the sequential organization of the various stages of use of the platform by the student.
This sequential organization can be schematized as follows:
- an autonomous stage of work for the student which precedes the stage by videocommunication with the teacher,
- a stage of videocommunication during which the student requests the assistance of the teacher to solve his difficulties by sharing its applications

The regulation processes of the teachers on the student/environment interaction

The observation underlines the didactic contribution of the property *multiapplication* of the environment. This contribution is observed through the diversity and the accuracy of the regulation processes carried out by the teachers. Those try to exploit the epistemological complementarity of the three *milieu* within the limit of their own functional and cognitive control of the environment.

In short, to control the student/environment interaction, the teachers proceed according to two types of interaction:
- co-operative interactions on the geometrical objects with the interface of CabriGéométre when the teacher focuses himself on the diagnosis while the student concentrates on the autonomous experimental solving of the problem,
- collaborative interactions to create, to modify and to remove objects with the interface of the microworld when the teacher wants to destabilize a balance of action/feedback of the student with the environment.

The process of destabilizing used by the teacher consists in questioning the student on the inaccuracies or the cognitive disjointednesses which arise from the interaction of the student with the three milieu. The regulation in *the oral milieu* in term of formulation, reformulation in the linguistic reference frame of the Euclidean theory, takes into account the collaborative interactions.

The Total Student Experience

Paul McKey
CTO NextEd Ltd
paul.mckey@nexted.com

Abstract

With the advent of online education the Universities of the world are for the first time exposing their wares in a public space, the Internet, in direct competition and comparison to similar commercial offerings.

While the argument for the University offering as being one of 'accredited academic quality' is easy to win against its unaccredited training and professional development competitors it is not necessarily as easy to suggest the university offering is always a better 'product'.

Universities typically have little experience selling their wares in a commercial environment where price, service and immediacy matter. It then comes as no surprise that when a mature adult learner is shopping around universities are often being overlooked for education alternatives more in tune with the requirements of a modern lifestyle.

The Total Student Experience offers a conceptual framework for the discussion, delivery and measure of an online educational system from the student's perspective. It suggests a model with four distinct layers, which individually and collectively, effect the learner's overall satisfaction with the system. The four layers are presentation, function, education and administration with a number of key variables occurring within each layer?

This paper will discuss the use of this framework and the importance of the underlying assumption that the university 'product' in the online environment will be measured not only by its traditional hallmarks but also by the key elements of the medium in which it is offered. When that medium is the Internet these elements are convenience and relevance, service and value, and the antithesis of the mass production era of education, personalisation.

Telematic Post-basic Nursing Education at the

University of Pretoria in South Africa:

Salomé M Meyer
Lecturer: Nursing Education
Manager: Telematic Education
Department of Nursing Science
University of Pretoria, South Africa
e-mail: smeyer@medic.up.ac.za

Abstract: This paper is on the Telematic Education (TE), which is not the mere use of the television set as a teaching tool/aid. . It should be viewed and managed as a strategic resource. TE refers to a comprehensive system of flexible learning. It emphasises the use of technology that will enhance the teaching and learning environment. Nurses/lecturers have been confronted with the fast development of technology for many years, but mostly in clinical practice. The Department of Nursing Science of the University of South Africa is providing in the learning needs of professional nurses in certain rural areas of the country by means of TE.

1. Introduction:

Broadcast television has been a solution to educational requirements such as the widely distributed campuses of some countries such as Australia and Canada, or even the widely distributed student populations of universities (Laurillard. 1993: 113). To be of any value to a student television education must be interactive in nature. This implies that student and lecturer must be able to communicate during a lecture that is being broadcast by means of television. This brings to mind the concept of Telematic Education (TE), which is not the mere use of the television set as a teaching tool/aid.

2. University of Pretoria (UP) :

No university is immune to the impact of technological change. Organisations can benefit tremendously by exploiting technological change. It should be viewed and managed as a strategic resource. The deployment of the Technology Plan of the UP has already borne fruit. The establishment of the unit for Telematic Teaching and the subsequent virtual campus initiative are direct benefits of the Plan.

3. Telematic Education:

Before one should attempt to understand what (TE) is, it is important to know what is meant by 'flexible learning'. According to Dr. Tom Brown of the Telematic Education Department of the University of Pretoria, TE refers to a comprehensive system of flexible learning. It emphasises the use of technology that will enhance the teaching and learning environment. TE is mostly delivered over a distance. The dependent learner will be more directed by the lecturer whereas the autonomous student who are capable of self-study will be able to employ the higher technological learning facilities. In the educational setting, all the dynamics of the traditional classroom are preserved, regardless of the distance separating the locations". This is the ideal situation to which finances and available sources not always lend it.

4. Interaction:

The structure of a typical teaching session must have two parts. During the first part of the lecture the lecturer delivers the lecture, i.e. passing on knowledge to the students. The second part of the lecture can be in the form of a discussion/question session with high interaction between the lecturer and the students (Jameson, Hanlon, Buckton, & Hobsley,1995:114). The need for students to have back up videos/copies of broadcast stems from the fact that some students might not be able to attend broadcast sessions due to employer demands, technical failure or such like reasons (Jameson et al. 1995:45).

5. The Nursing Education Situation:

Nurses/lecturers have been confronted with the fast development of technology for many years, but mostly in clinical practice. Telematic education (TE) is employed in nursing education (NE) for post-basic programs. Post-basic programs imply that people who have already registered as professional nurses at the South African Nursing Council (SANC) are continuing and furthering their skills and knowledge regarding certain specialities in the profession. Continued education for post-basic nursing requires a distance education method that will serve as an academic solution to professional nurses in rural areas of South Africa. The Department of Nursing Science of the University of South Africa is providing in the learning needs of professional nurses in certain rural areas of the country. Jack Yensen (1996:213), who calls this method of teaching 'telenursing', is of the opinion that the two key dimensions are distance and electronic mediation.

6. The Lecturer:

Lecturers who teach by means of telematic education must be skilled, self-confident, understand the uniqueness of the rural students and should be flexible. They should keep the concepts of adult learning in mind and respect the authority of experience that many students bring to the classroom. Lecturers who have not taught by means of this method need sufficient training. They do not need technical courses, but training on how to adjust their method of teaching as well as teaching aids to that of the telematic medium (Yeaworth. 1996:150). The use technology influences educational innovation.

7. Closing Remarks:

The twenty-first century will see many changes, the first of which will be the end of extensive emphasis on classroom teaching. Teachers, students, and preceptors will come together in dialogues to question, to demonstrate, and to participate actively in the learning process. Nursing will hopefully develop a 'world view'. "Remember, the information revolution will continue to roll on – with or without you. So, get on board and begin changing" (Simpson. 1997:27).

Abstract: The greater prevalence of computer technology in the daily lives of middle school students is impacting their learning envrionment. Students of both genders and different levels of socio-economic status are well on their way to becoming part of the digital culture. This paper suggests that the gaps that once existed with regard to computer access, use, and perceived expertise are narrowing significantly. These findings are based upon survey data from 512 middle school students in three areas: (a) self-perception of computer skills and their acquisition; (b) exposure to technology at home and at school; and (c) media style and content preferences.

Introduction

Media and digital technology are pervasive in our lives. The advent of technology into the lives and culture of adolescents is not one of choice but of certainty. If we understand the influences at work among our youth, then perhaps we can address their educational needs in ways that maximize what we already know about how to structure effective content. Are there any signs of technology acculturation at work? Have computer presence and increased proficiency translated into any appreciable closing of the previously documented digital divide with regard to gender and socio-economic variables among middle school students?

The Study

Based on a series of small focus groups with middle school students, the authors compiled a 68-item questionnaire, both closed and open answer, to cover students' preferences and practice using different types of media. Students answered the paper and pencil questionnaire during either a science or computer technology class period. Typically, the questionnaire took 30 minutes to complete.

Between October 1998 and April 1999, 568 middle school students were surveyed from eight different metropolitan-area public and private middle schools covering four different school districts. The students ranged in age from 11 to 15 years ($\underline{M}$ = 12.59, $\underline{SD}$ = 0.66). Students who did not report essential demographic information were dropped from the analysis for a final sample of 512 students. Of the final sample, 43.4% were male ($\underline{n}$ = 222) and 56.6% were female ($\underline{n}$ = 290). Schools were recruited to obtain a diverse student population representative of urban and suburban schools, as well as all ranges of socio-economic status (SES). The final sample contained 31% high disadvantage students ($\underline{n}$=158), 33% middle disadvantage students ($\underline{n}$=170), and 36% low disadvantage students ($\underline{n}$=184). Within each SES category, male and females were represented nearly equally.

Findings

The digital divide separating the confidence levels of male and female adolescents with regard to computer use is narrowing. While some significant differences emerged, the patterns of computer use and the purposes of use were remarkably similar for males and females in our sample. As recently as 1994, one study by Sakomoto indicated that among fourth through sixth grade students considered "heavy users" of computers, the ratio of boys to girls was 4 to 1. Our results indicate that this gap is closing as we found no gender difference among those who could be identified as heavy users of computers. Additionally, when looking at the use of computers for identified school subjects, we found similar levels of self-reported computer use between males and females.

In contrast to previous research, both males and females indicate that games dominate the home use. Even in the school environment, games were one of the prime uses. Games remain an important part of adolescents' computer repertoire. These findings, in particular, argue for ways in which to infuse the gaming format with sufficient intellectual content to make the "game" a valuable learning tool. Some educators have already seized upon this notion and are producing more substantive Internet games that incorporate accepted learning theory. The theoretical framework of curriculum built around problem-based or case-based learning could lend itself to a gaming environment. Crucial issues of how intrinsic the problem is to the game scenario and how well do learning objectives translate into an appealing hypermedia format are all ones that would need to be explored.

Conclusions

While the content of educational web sites targeted for middle school students is still an issue for debate, the data from this survey point clearly toward web sites as an effective delivery mechanism. Access, use, and perceived self-confidence in navigating the Internet are less constrained by gender-related concerns than they were less than a decade ago. In addition to the rapid rise in adolescent female participation in technology, the data also echo the research of others in highlighting the prominence of all types of media in the life of adolescents.

The recent Kaiser survey (Kaiser Family Foundation, 1999) found that the average amount of time each day spent using all types of media for children from 8 to 18 years olds was 6.43 hours. The influence of all media in youth's life was reinforced by our survey participants' choices of "your favorite famous person." Of the 512 responses, 74% were performers or musicians. The remaining types of persons named could be categorized as 18% athletes, 3% historical figures, 2% religious figures, and 4% other.

Media of all types are playing a larger role in children's lives; however, it is mostly a solitary experience. Our data indicate that children are largely using the Internet and computers at home free of supervision. It also may not be the case that the computer is replacing other forms of media in adolescents' lives, but rather it is being "added" to the existing repertoire among those who are already "heavy users" of media.

One of the challenges before us is the creation of sufficient quantity and quality of digital materials to attract and retain adolescents' interest in an unsupervised environment. The materials must be free of gender-bias and bridge the gulf that currently exists between how kids learn and communicate on their own and how they are taught in school. Can the production of high-quality, educationally-grounded, and content significant materials attract adolescents to the world of learning via the Web?

The Development of a Standardized Evaluation Instrument in Educational Technology in a Post Secondary Setting.

Jack E. Morin
George Washington University
Washington, DC
U.S.A
morin@ucalgary.ca

Janice Bakal
The University of Calgary
Calgary, Alberta
bakal@ucalgary.ca

Abstract
This evaluation project examines the required elements for a standardized instrument for the evaluation of educational technology. The project will survey current users of educational technology and seek common threads and patterns in a successful evaluation. This study will attempt to answer this question: What should we be collecting, measuring and examining when evaluating technology in an educational setting? This project is the first step in a multi-stage, two-institution evaluation study that will develop a standardized evaluation instrument for use in the evaluation of education technology. The project will enlist the assistance of two post secondary faculties, clients, developers and students. Each group will be surveyed using an online form. A representative sample from each group will be interviewed in a focus group setting. Expected outcomes of this first stage include the collection of responses from users, developers and clients of educational technology. The survey responses (n=81) have provided a unique opportunity to share and compare educational strategies and concepts between post secondary institution faculty, users and developers. Common patterns were evident within and between groups relative to concepts of educational technology evaluation and important aspects of instructional design.

Introduction
This evaluation project will examine the required elements for a standardized evaluation instrument for educational technology tools and applications. The project will survey current users of educational technology and seek common threads and patterns amongst user groups for the design of a successful evaluation instrument. The goal of this project is to determine what users and developers deem important, valuable and relevant with respect to instructional design and the evaluation of technology in the post secondary arena. The survey data collected will be used to create a standardized evaluation tool. This evaluation tool will assist developers, instructors, teachers, and learners in the design, construction and use of an instructional design model and template suitable for use in the post secondary field of education.

Project Rational and Purpose

First, the research in this area has focused on the application of technology. Evaluation studies on educational technologies have traditionally focused on the particular technology tool and it's impact on the learning environment. While useful in producing data for that tool or application, generalizability to other technologies or application is not possible due to the design of the instrument. Typically these instruments survey specific program issues and fail to consider the larger pedagogical issues of technology (this link provides examples of about 50 instruments of evaluation used in educational technology) [1]. Such programs as the Annerberg's Flashlight Project[2] and McMaster University's EVNet[3] have been leaders in educational technology project, but have failed to develop a standardized instrument, useful in evaluating all types of projects, across multiple users in various circumstances.

Secondly, this project is the first step in a multi stage; two-institution evaluation study dedicated to the development, testing and dissemination of a standardized instrument for educational technology evaluation. The first stage is a necessary step in determining what should be evaluated when examining technology in the education field of study.

Several studies have identified survey instruments and other collection tools for use in educational technology[4 5]. While useful in assessing individual programs for a specific outcome, these types of instrument are difficult to generalize to educational technology, regardless of platforms, users or programs. Determining what should be evaluated in a format that can transferred across technologies and application is a critical next step in valuing educational technology's' contribution to learning.

Conclusions

The first step of this multi-stage evaluation project produced an extensive database of information on what users, developers, clients, and educators think about educational technology and its application to learning. The collection of data ranges from attitudes towards technology to perceptions of technology and its affect on learning. It also provided a resource in the development of a standardized tool for evaluation educational technology.

From this study sample, it is clear that respondents agree on a number of issues in terms of importance and relevance to instructional technology. It is also important to note that there are some differences between respondent groups relative to the evaluation process for educational technology. This information supports previous research in educational technology that has identified key concepts and factors of educational technology.

This first stage of the project provided an opportunity to validate the survey instrument, by seeking some responses to confirm that the evaluation of educational technology is an important aspect of the instructional design process. These findings can be used to development a survey instrument designed to evaluate the important constructs of instructional design with the use of technology.

This first stage of this project provided a unique opportunity to share and compare educational strategies and concepts between two post secondary institutions. It is hoped that the two institutions will share a common ground with respect to the development, application and delivery of educational technology.

Using Mobile Computer Technology and Internet Tools to Promote Constructivist Teaching

Chrystalla Mouza
Teachers College, Columbia University
United States of America
cpm12@columbia.edu

Introduction

This paper investigates how continuous access to laptop technology and telecommunication tools can promote a student-centered, inquiry-based, problem-solving teaching practice. The purpose of the study is to deepen our understanding on how technology and Internet tools can best be utilized in K-12 classrooms. We present an Internet-based project that utilizes laptop computers in a sixth grade classroom.

Research Questions

We explore how laptop computers and Internet tools are used by a sixth grade teacher who has extensive experience with technology and multiple opportunities for professional development. The overall questions that guide this research are as follows: a) What are the teacher's beliefs about teaching and learning? b) What is the nature of students' assignments? c) What is the role of the teacher and the student in the classroom? d) How are laptops being utilized in the curriculum? e) How is the Internet being used in the classroom?

Methodology

This study began in September1998 and takes place in urban elementary and intermediate schools in New York City. The primary data collection techniques that are utilized include classroom observations, teacher interviews, and document analysis. These activities have been carried out during school visits since the academic year of 1998-99. Participants for this initial research effort include a sixth grade teacher and her students. All students in the class are minority students; the teacher is a white female.

The classroom is part of the Laptop Project, which was initiated by the school district in 1997. All students in the project have been issued a laptop computer. The classroom is also part of the Eiffel Project, a major effort of the Institute for Learning Technologies (ILT) at Teachers College, Columbia University to assist schools and teachers integrate computers and telecommunication tools effectively in their classrooms. ILT provides teachers with technological and pedagogical support, as well as with opportunities for communication and collaboration with other teachers and researchers involved in the Eiffel Project.

Project Design and Preliminary Results

Mary, the sixth grade teacher participating in our experiment, started teaching for first time using laptop technology during the academic year of 1997-98. That first experience provided her with valuable training on the use of computers in teaching. Mary was ready to try new ideas, experiment with different projects, and go beyond traditional instruction. Therefore, she volunteered to participate in the Reach the World (RTW) project.

RTW (www.reachtheworld.org) is a virtual expeditionary venture that uses the world circumnavigation of Makulu II, a sailboat, as an interactive tool for classroom teaching in the United States. RTW utilizes the Internet and other telecommunication tools to bridge the student classroom with different cultures of the world. The crew of the Makulu II communicates with students regularly via satellite email. Since September 1998, Mary accommodated her social studies curriculum to the RTW project. Soon after she started participating in the project, she became the most active teacher. Some of the lesson plans she developed are posted on the RTW web-site as examples for other teachers.

Nature of Student Assignments

Planning an Itinerary. In this project students were asked to form groups and conduct research in order to identify possible sites that the Makulu II should visit on their trip to Singapore. Each group researched different attractions and recommended sites of interest. Students used travel brochures to locate tourist attractions, maps to figure out distances and ways of transportation in Singapore, and historical information from the Internet to identify museums of interest. When the final itinerary was put together it was sent out via email to the Makulu II crew. The Makulu II crew completed the tour and sent back relevant information and pictures to the students via email and air-mail.

Comparing religions of the world. Students studied different religions using information and videotapes that were sent by the Makulu II crew. In sequence, students formed groups and selected one religion to study in-depth. Final reports were presented to other sixth grade students in the school using PowerPoint slides.

The Role of the Teacher and the Students

Teaching was organized around two types of pedagogies: Collaborative knowledge construction and direct verbal instruction. Direct instruction did not represent the dominant mean of communicating knowledge to students. Students were rarely asked to memorize facts. They were instead asked to locate facts using CD-ROMs, books, the Internet, and other resources. The information was then analyzed in order to complete projects and solve problems.

The teacher was mostly a facilitator of learning and a "guide on the site". Students were given opportunities for self-directed inquiry. In many cases they were asked to generate their own questions and search for the answers. Laptops were very helpful because they put a lot of the resources into the hands of the students.

Utilization of Laptop Computers and Telecommunication Tools in the Classroom

Laptops were a vehicle to support the curriculum and expand the classroom's walls. Students typically used application programs such as a word processor for typing and editing documents, databases for organizing information, and graphics packages for developing multimedia presentations. Email was also used extensively in the classroom for communication purposes. Moreover, all students used First Class, an Intranet service that allowed them to communicate with their classmates and teacher after school hours.

Laptops were effective in promoting collaborative work and problem solving. Very often students were required to work in groups and create projects. In collaborative projects, students were required to perform research, collect information, analyze it, synthesize it, and produce a final product.

Conclusions

This paper presented an effort to integrate technology in the classroom. Laptop computers and telecommunication tools were used to provide students with authentic, meaningful, and motivating experiences. Learning became a challenge and students exhibited increased levels of control and creativity. Successful use of technology in the classroom depends, however, to a great extend, on the teacher. Therefore, in any implementation effort, adequate time must be devoted in helping teachers become comfortable with the equipment and absorb the new teaching principles associated with the use of the new technologies.

We currently work with a number of teachers in the New York City area assisting them with their technology implementation efforts. Many teachers use laptop computers and Internet tools for instructional purposes. Therefore, we continue our research by observing what is happening in these classrooms and analyzing changes in the instructional beliefs and practices of the teachers.

Scenario Building to Design a Distance Learning Program

Lisa Neal
EDS
3 Valley Road
Lexington, MA 02421 USA
lisa.neal@eds.com

Abstract: Scenario building is a process that can be effectively used to design a distance-learning program. It begins with the identification of the key stakeholders, who are typically students or participants, course developers, teachers or facilitators, support staff, and administration. Then, for each perspective, the relevant characteristics are identified, followed by a determination of what is required to meet the needs of a person in that category. The process also has the benefit of being a group activity that can facilitate team-building and commitment. We have used this process with multiple organizations and report on these case studies.

Introduction

Distance learning programs are designed in many ways: some evolve from individual efforts, some are designed using available technological capabilities, and others, more recently, are purchased from or co-branded with e-learning providers. Scenario building provides a systematic process for the group of people involved in planning and implementing a program to work as a facilitated team to design a program. The process can be used for any type of organization, including a university or business. It involves a number of steps: determining who will be involved in developing, delivering, supporting, administrating, or taking courses, and prioritizing these to order the next phase. Starting with the most important perspective, usually that of the student or participant, the relevant characteristics of members of that category are determined by the group. This may include computer and Internet literacy, work environment, and time commitments. The group then determines what happens when a representative of that category carries out their role, i.e., taking, teaching, or supporting a class. This results in a list, which is then prioritized, of the needs and requirements from that perspective for the distance learning program. Subsequent perspectives are usually easier to consider after the first, and the entire process leads to requirements analysis and planning for the program. This process has been used for a number of organizations that are planning distance learning projects, including the University of Puerto Rico.

The University of Puerto Rico

The Puerto Rican government funded an ambitious distance-learning program at The University of Puerto Rico. To help get the program underway, the university called on a team of EDS consultants to structure and support the program's essential planning and implementation processes. The team began with strategic planning to determine the tasks and responsibilities needed to ensure the program's on-schedule readiness. During this process, it became clear that the distance-learning concept conjured widely different images for members of the steering committee depending on their knowledge of its theory and practice. Many assumptions were based on the association of distance learning with the room-based videoconferencing that dominated distance education prior to the introduction of Web-based technologies in the mid-1990s. Some of these images did not account for the level of interactivity and engagement that students and teachers experience using state-of-the-art distance-learning technologies or failed to accommodate the important differences between learning and teaching in traditional and technology-mediated settings.

The team proceeded with scenario building, an activity designed to help the program's steering committee understand, envision, and specify technology's role in the new distance-learning offering. Scenario planning began by determining the roles that people will play in the university's distance-learning program; those roles are student, professor, teaching assistant, and a number of support and administrative positions. The scenario-planning work led to each role being assigned characteristics that are relevant to the how a person in that role operates in a distance learning program or that give the role dimension and interest. Characteristics of a student, for instance, included age, family/home situation, educational background, technology literacy, Spanish and English literacy, and typing skills.

The goal was to agree upon the role of technology, the specific types of technology, and the support requirements for technology in the distance-learning program. To achieve this goal, we developed a prototypical member of each role in order to envision, as a group, what a day in that person's life would be like. We carried this to the level of detail of which relevant activities they were engaged in, where they carried out the activities, and what technological and human support was required. There were implications from some of the characteristics of a role; to discuss the activities of a person in a day, we needed, for instance, to know if there was access to a computer and, if so, under what conditions or with what possible distractions it would be used. If there was no access, then a staffed computer room must be available during reasonable hours. Additionally, we considered the implications of atypical but plausible cases for each characteristic, such as the ramifications if a student was older and returning after a period out of school.

Conclusions

The scenario-building process uncovered many issues, concerns, assumptions, and previously unarticulated misconceptions, which led to constructive discussion that culminated in a consensus about technology's role in the project and about the people who would manage and support it. Equipped with the scenarios' insights, we completed a thorough analysis of the program's specific technology needs, identifying and prioritizing the components of the supporting technology. In subsequent discussions, we continued to refer to the prototypical characters, and found that they continued to help clarify issues since the group could look at that person's specific (imagined) needs. Ultimately, the process of identifying each role's relevant characteristics and the hypothetical activities and interactions of a person in that role pointed directly to the criteria against which the entire program will be evaluated, ensuring that the overall effort's success will be measurable and more easily repeatable.

Initiating and Sustaining Collaboration in Technology: Critical Elements

Paula Nichols and Stephenie Yearwood
Department of Educational Leadership, Lamar University
pnichols@tenet.edu; yearwoodso@hal.lamar.edu

Abstract: Collaborative technology projects require new types of relationships and distinctive management strategies. This paper outlines three critical elements in creating and continuing such partnerships: common vision, a reward system, and consensus.

Technology ventures often demand collaborative efforts which bring together personnel, financial resources, needs and solutions from diverse entities. Older models of cooperation worked within top-down power structures; new structures of collaboration are complex and require long-term thinking and conflict management. Furthermore, sustaining collaboration is critical because the payoffs of such efforts are often long-term. We identify here three elements critical to building and sustaining collaboration: common vision, a reward system, and consensus operations.

Common Vision

Diverse groups who collaborate in technology ventures always face semantic difficulties, terms are defined differently and goals are stated in language only the originators understand. As a result, common definitions of terms and in-depth discussion about problems, solutions, and common issues are essential (Winer 1994). In this initial establishment of common understanding, group members must adopt a posture of tentative knowing, a non-judgmental stance which reserves value judgments and allows for continuing conversation. Although individuals may be experts in their domains, they need to drop their "know it all" perspective when they work collaboratively. Rarely does any entity get all it wants, but group members must be honest about what they are willing to put into a collaborative effort as well as what they wish to get out of the collaboration.

A Reward System

Different entities have different currencies and rewards. Rewards must come to group members in the currency valuable to them in their system, be it promotion, tenure, credit hours, test scores, or bonuses. Furthermore, different stakeholders define accountability differently, as staying within budget or positive publicity (Report 1997). As specific rewards are discussed, entities must spell out to whom and how they are accountable and how that will affect their participation.

Consensus

In diverse collaborative groups, absolute agreement is rare. Thus it is essential to establish that the group will operate by consensus and to establish a process for achieving consensus and resolving conflicts. Even when members do not agree on an outcome, if they have subscribed to a specified process which has been followed consistently, they will be able to accept the result (Winer 1994). Once established, conflict resolution needs to be called into play quickly when problems arise. Difficulties which drag on are much harder to deal with.

Clearly collaborative ventures in technology are neither simple nor easy. However, the power of successful collaboration is synergistic. Collaborative groups which are able to sustain their efforts can achieve a whole which is indeed greater than the sum of the parts.

Integrating Learning agents in a virtual laboratory

Roger Nkambou and Yan Laporte
Département de Mathématiques et informatique
Université de Sherbrooke, Sherbrooke, J1K 2R1
Canada
roger.nkambou@dmi.usherb.ca

Abstract: This paper presents a system called Cyberscience[1] dedicated to distance education. The learning interface of Cyberscience includes a component consisting in activating an interactive multimedia simulation in which the student can carry out direct manipulation tasks making the simulation a virtual laboratory (vitual lab in short). A virtual lab for genetic study is currently realized. As an intelligent distance learning system, Cyberscience includes a number of intelligent learning agents that operates in the space of the virtual lab in order to help students to achieve their goals. This paper presents an overview of those agents.

Introduction

There is already a lot that has been said about software agents, especially intelligent agents' technology. While this is a really a current trend in software engineering. The concept of intelligent agents is at the same time simple in principle and complex in classification (Jennings and Wooldridge, 1998; Nwana, 1999) While intelligent agents systems are widely being developed, most of the frameworks available simplify the architectural and technical aspects and provide relatively no support to implement agent behavior. The goal of this research is to provide people with a strong basic architecture and shell to handle the complex task of implementing intelligent behavior in software agents. The tools provided must have a fairly generic aspect so they can be applied to a wide variety of problems and systems while still being able to adapt sufficiently to a problem to provide relevant intelligent features. It should be possible to achieve such capability by building a set of general-purpose agents that would be easily customizable and reusable.

A set of multiple agents

The first part of building such a set of agents is to determine a set of feature that are desirable and that are sufficiently high level to be reusable. The current proposal includes a planning agent, a decision making agent, a data mining agent, a rule-based reasoning agent, a data extracting agent and a case based reasoning agent. These agents cooperate in the context of CyberScience in order to: create an action plan for the current instructional objective associated with the selected course or theme, according to the student model, select the relevant resource the student will use to achieve the goal, update the student state of knowledge, help the student during the learning process and so on. In the following, we describe each of the agents.

Data Mining Agent. The Data miner has a high probability of being highly useful to many different applications. Basically, this agent's purpose is to retrieve useful information from databases and electronic documents both on a local machine, a network or even the Internet. Of course it can mean only search for certain keywords but it is also possible to implement more complex and advanced intelligent search algorithms. It remains to be decided how it is most convenient to interface with such an agent. It is also to be considered if such an agent should be mobile or not or even if it should decide whether it should move itself to a different host system to be able to accomplish it's job more efficiently.

Rule-Based Reasoning Agent. The rule-based reasoning agent acts mostly as an expert system. Expert systems have proven over time to be efficient to a large number of tasks. The goal of this agent is to derive conclusions from a knowledge base consisting of facts and knowledge. It needs an engine and a set of

[1] This project is funding by the University of Sherbrooke.

deductive rules. It needs an interface to specify the content of the knowledge base. An interface also needs to be defined to query the truth of undefined facts. The engine would be most likely based on the Rete algorithm that is already well known and extensively used and tested.

Case-Based Reasoning Agent. The case-based reasoning agent on the other hand compares the different cases and makes generalizations out of them. When the case-based reasoning agent is invoked on a particular situation it tries to find already known cases that are similar to the current one.

Planning Agent. The planning agent is software capable of making plans. The goal is to come up with a combination of actions to be executed in the future in order to achieve a desired behavior. The interface to the planner agent is a bit more complicated than previously discussed agents, but this is expected considering the complexity of planning problems. First it needs a way to specify an initial state and a goal specifying the desired task to be achieved. It also needs a set of specifications of the actions feasible by the system. Finally it needs a planning strategy, a starting plan and a set of bound parameters both in time and space. The agent's engine would be most likely to base on SIMPLAN because of its capacity to operate in highly variable environments (Nkambou and Kabanza, 1999). This agent will generate a plan of actions repairing the plan given in input that best satisfies the goal from the initial state, given the restrictions implied by the bound parameters.

Decision-Making Agent. Finally the decision-making agent and the knowledge extraction agents are making extensive use of previously discussed agents in this paper. They would probably encapsulate specific instances of these. The decision-making agent, as its name implies, takes decisions about the different tasks to be done and how they must be accomplished effectively. It would work by using the rule-based agent to generate a goal as of what to do. A planning agent starts to search how to best achieve the goal by calculating a new plan while case based reasoning agent tries to find a relevant plan that was previously used in a similar situation.

Knowledge Extraction Agent. The knowledge extraction agent finds relevant information from different digital data sources, Like the decision-making agent, the knowledge extractor uses a combination of three internal agents. It obviously uses a Data Mining agent to retrieve pieces of documents or database information related to a subject requested by an internal rule-based reasoning agent. But a case-based reasoning agent also tries to find similar cases as where relevant was found to help the data mining agent. Once it is retrieve the information can then be used by the system.

Conclusions

The development of the set of intelligent agents involved in CyberScience will lead to a shell to easily implement intelligent learning agents systems. Most of the required features for each agent have already well known solutions. There are also numerous frameworks that already offer facilities to create agents and to give them mobility abilities. It is expected that a higher level of intelligence in behavior of the system would be achieved by close collaboration of these agents. It has to be defined how it should be organized to provide a generic functionality that would be reusable. Also, it must be established how would the specification for a custom system based on these agents would take place. With this shell the use of intelligent learning agents system is likely to widespread. But the first application it is used on, as a test case, is the Cyberscience virtual laboratory. While it could merely be used as a replacement for current expert system to add them a higher level of intelligence, adaptability and interaction level, it is also expected they could be applied to new breeds of problems directed at a less specialized category of users. It can be easily assumed how this system could be used to create assistants or coaches in a context of an Web-based intelligent tutoring system.

SGML BASED COURSE DEVELOPMENT: BALANCING INSTRUCTIONAL DESIGN AND TECHNOLOGICAL REQUIREMENTS

Solvig Norman, MA
Coordinator of Instructional Development
Open Learning Agency, Canada
snorman@openschool.bc.ca

Abstract

The Open Learning Agency in British Columbia, Canada, is involved in a multi-year project aimed at producing a number of courses that are derived from structured SGML documents. Presently, fourteen courses are being delivered on-line in 33 School Districts throughout British Columbia. This paper describes the use of structured documents for course development with a focus on the benefits and challenges of balancing technological and instructional design issues.

Background

The Open School, a division of the Open Learning Agency, is involved in a multi-year project aimed at producing a number of courses that are derived from structured SGML documents. The goal is to offer innovative and current educational resources for students and teachers that are directly linked to the government's curriculum and provide flexibility through delivery of alternative formats within a distributed learning environment (e.g., for use in a classroom environment and also within an independent self-paced learning environment). Fourteen Grade 11 and 12 courses were developed within a structured document environment using SGML (Standard Generalized Mark-Up Language) technology to meet Open School's goal. These courses are presently being delivered to about 1200 students registered either in one of the nine Distance Education Schools or within one of the regular classroom-based schools in British Columbia.

Open School has traditionally developed large print -based courses with some complimentary wrap around media such as text, video, or audio. Development time from the planning stage to delivery took, on average, two years to complete. Once a course was delivered, it was cumbersome and time consuming to update and maintain. Courses were seen as being out of date, too large, too much work, and provided primarily a singular pathway for students to learn. Open School had some previous experience with developing courses for on-line use, but realized the need to change their course development processes in order to develop more timely and flexible content. The implementation of SGML as an underlying course development tool for planning, development, production and delivery was identified as a means to an end. This technology can facilitate the following:

- creation of courses from instructional design to deliver,
- creation of assessment types and mechanisms,
- identification, association, and categorization of resources within,
- identifies the course architecture,
- creation of custom views of materials for different types of learners,
- storage and management of parts and pieces of course materials,
- output to both print and web, as well as to other media.

SGML has roots in the high tech and publishing industries and is the international standard for representing electronic text in a mark-up language. The mark-up provides a means for interpreting the text. SGML is not dependent on any specific hardware or operating system SGML provides a consistent approach to identifying the components of a document and how they relate to each other. The process permits explicit tagging to identify the components of a "course": lessons, learning outcomes, glossary terms, activities, online resources, etc. There are an infinite number of document structures that can be defined depending on the specific requirements. SGML is a descriptive mark-up language rather than a procedural mark-up language. A descriptive mark-up language uses codes, called elements, to name and categorize parts of a document. Procedural mark-up language, like that of HTML, is often used to represent text in a certain style like bold. SGML also includes a DTD: Document Type Definitions. The DTD defines the "allowed" elements and specifies the order in which the elements may or may not appear. The authoring process must produce documents that conform to the specifications of the DTD.

The Marriage of Instructional Design and SGML: The Benefits

Open School, as part of the Open Learning Agency, has a long history and experience with implementing sound instructional design practices for developing learning materials. Fundamental stages of instructional design including needs assessment, learner analysis, planning (review), development (prototype, formative evaluation), production (evaluation), delivery, and summative evaluation – all have been at the heart of course development practices for over twenty years. Various instructional technologies have been used over the years and have often been perceived as tools whether they were word processing software programs, computer conferencing systems, videos audiotapes, and more recently the World Wide Web/Internet.

However, with the implementation of SGML, instructional design methods became more explicit as part of the structured process dictated by the technology. Open School's SGML based courses have been developed with very explicit Document-Type-Definitions that lay out the architecture of courses from the instructional design planning stage to the delivery stage. This process has permitted course developers to explicitly examine the contents of their courses in a more detail manner that was never before possible. A course basically "grows" from an instructional design plan (e.g., consisting of learning profiles, learning outcomes, resources, proposed activities and assessment) into a fully authored final product (e.g., completed modules with lessons including narrative, instructions, content, activities, and assessment). Because of the structured information approach to course development, "bits and pieces" (e.g., granules, learning objects) of a course can be re-used and re-purposed for other learning situations or outputted to different formats (e.g., print or the Web). Developing 14 courses for on-line and in the print at the same time would not have been possible without the use of SGML as an underlying tool.

The Marriage of Instructional Design and SGML: The Challenges

Although there are many benefits in the implementation of SGML as a course development framework, Open School has also faced a number of challenges. Here is a list of the main challenges:

- Adopting a new technology that entailed a whole new infrastructure (e.g., with new hardware, software, additional staff, extensive training for internal staff, new procedures to follow).
- Reviewing and analyzing existing processes and products in order to come up with consistent structures and language for different course architectures (e.g., deciding on what constitutes a course, a module, a lesson, an activity, etc).
- Designing content to be used in different learning situations. With a database as a backbone, SGML files can be used by other course developers to re-use existing content. There are issues around designing content to be stand-alone (e.g., learning objects). How granular can content be (e.g., a paragraph or a lesson)?
- Ensuring that content which is designed in "bits and pieces" (e.g., learning objects) is pulled together into a cohesive manner which provides an effective learning environment for students.

World Wide Web Course Delivery in Developing Countries: A South African Perspective

Shaun Pather Geoff J.Erwin
School of Mathematics, Information Technology & Computer Science
University of Durban Westville, Private Bag X54001
Durban, South Africa
spather@is.udw.ac.za erwin@is.udw.ac.za

Abstract: There is increasing international usage of the World Wide Web for course delivery. The current South African education system is still structured as a legacy of the apartheid system. The South African government currently promotes the uses of technology to enhance access to education and to foster resource-based learning. The authors report findings of a survey of Web-based course delivery at South African tertiary institutions, including problems being experienced by academics in adopting Web-based techniques.

Introduction

The Internet and the World Wide Web (WWW) are part of a shift away from traditional classroom based course delivery methods (*See* for example Pilgrim & Creek, 1998, p. 189; Kinzie et.al., 1996 p.59). The South African situation does not reflect this trend. South Africa is characterized by a transforming education system that aims to address imbalances brought about by the apartheid era. Disenfranchised sectors of the South African population have historically had limited access to higher education (Christie, 1986).

Background

The South African Department of Education promotes the use of technology (including the World Wide Web) to enhance and widen access to higher education and to foster resource-based learning. The Department of Education is actively engaged in promoting *technology-enhanced learning*. It has initiated a five-year strategic plan, through the National Centre for Educational Technology, to build an infrastructure to support technology-enhanced learning (Department of Education, South Africa). The current social and education systems are still heavily influenced by inheritances from the apartheid political system before 1994. For example, the majority of South Africa's population (mainly black) do not have access to the Internet (*Webcheck* National Survey, 1999). Potential university students have no experience in the use of information and communication technologies (ICTs). Currently, only 0.02% of South African schools have an Internet connection (IDRC, 2000). Their ability to use Web-based education is limited. The lack of telecommunications infrastructure, combined with low levels of technological literacy of the population is a major obstacle to deployment of Web-based material..

The Survey

A survey of academics from fourteen South African tertiary institutions was conducted between June and September 1999. A non-experimental survey method, using a structured questionnaire, was used to investigate the following: *The extent of usage* of specific WWW features for course delivery. In particular the authors assessed to what extent current adopters have used the WWW to move away from traditional teaching methods. Specific features listed in the survey were: Use of Email, posting of syllabi (dynamic & static), detailed course information updated regularly, distribution of lecture notes, links to external sites, feedback mechanisms to students, online chat-room, streaming video, multimedia online lectures, animation, submission of online homework, testing and examinations. *Problems* that exist at tertiary institutions that are impeding the implementation of WWW technology. Specifically the survey examined areas of availability of human and physical resources, organizational conditions, and the attitude of academics to the use of WWW as compared with traditional classroom based methods.

Findings

1. **Current and intended usage of the WWW by South African academics:**

Figure 1 (*see http://is.udw.ac.za/staff/research/web/figure1.htm*) indicates that current levels of adoption of the thirteen WWW based activities listed in the survey fall into two broad categories. The first category reflects a relatively high level of use. The seven activities in this category (e.g. Email, syllabus postings, distribution of lecture notes) are activities that are widely used and are those that support traditional styles of teaching. They do not necessarily change the actual method of classroom-based delivery. A possible reason for this could be that such activities could be implemented at a low cost and with no need to spend a large amount of time doing in-depth planning and design. The second category reflects very low or non-existent levels of use (six activities). This category involves activities (e.g. Chatrooms, multimedia online lectures, online testing) that would significantly move away from traditional teaching methods. These are activities that require intensive planning and design, and are also dependent on a high availability of a technological infrastructure supported by adequately trained staff. There is an increased level of usage. Respondents also indicated an intention to increase level of use of activities that fall into the second category listed above. This is a positive indication, since the activities that fall into this category are those that will realise a paradigm shift away from traditional course delivery methods to a student-centred, constructivist approach.

2. **Comparison of level of South African tertiary institutions with international usage**

The WWW features listed in the survey echoed those from an international survey that was conducted by an American university at the end of 1998 (Peffers & Bloom, 1998). Figure Two (*see http://is.udw.ac.za/staff/research/web/figure2.htm*) provides a comparison between the South African tertiary educators surveyed and those of the international survey. The similarities in the trends are noted in the paper. However, it must be noted that this not imply that the broad state of WWW adoption for course delivery in South Africa is at the same levels of usage as our international counterparts.

3. **Existing difficulties in the implementation of Web-based course delivery.**

Staffing problems: The results of the survey suggest that academic staff do no have the necessary skills to implement Web-based courses. The situation is further compounded by the absence of support staff needed to run Web-based courses. *Organizational conditions*: The Survey suggested that the organizational conditions such as time and flexibility in respect of work commitments do not allow academics (especially if they are novices at implementation of Web technologies) to experiment with WWW technologies. *Financial Restraints*: The problem of shrinking financial resources is affecting service delivery at all levels of education in South Africa. The survey indicates that current budgets do not allow them to invest in Internet technologies.

Conclusion

The desire for on-line teaching at South African tertiary institutions is increasing. The survey indicates that academics acknowledge the positive role of the WWW in course delivery. Key recommendations are: Adopters of Web technology in the classroom need to be encouraged to utilise the Web for more than merely support of traditional lectures; Management at the faculty and institutional level should be encouraged to create the possibility for and invest in adequate training of both academic and support staff. Heads of academic units support the adoption of Web technologies by providing incentives to staff. Tertiary institutions should investigate possible collaboration with external partners in the private sector as a means of alleviating high costs. Some of the issues that require further research and investigation are: international experiences and collaboration with counterparts; Development of guidelines for designing Web-based courses; the long term effectiveness of Web-based teaching on students; the role of academics in developing Web-based courses; and user- friendly authoring tools.

State University, AR 72467

Abstract: This paper looked at the variation of structure and participations for online conferences. Four different structural models were used in designing the conferences, which were (1) Open-ended discussions by expert, (2) Scaffolded discussion with facilitated follow-up, (3) Scaffolded discussion without facilitated follow-up, and (4) Open-ended discussion without facilitated follow-up. Data were collected on frequency of messages, word count of messages, and key word analysis for themes. The findings will provide comparative and descriptive data related to conference structures, participant variables, and levels of participation for future research in online conferencing.

Use of Online Conferencing as a Vehicle for Training Special Educators

There is evidence that materials designed to assist teachers in working with students with behavioral problems are currently in high demand. The design and development of the Internet as a delivery medium for such continuous training in both preservice and inservice teacher education has been documented in special education (Smith, Martin, & Lloyd, 1998). A team of researchers, funded by a U.S. Department of Education grant, has been hosting a series of online conferences for preservice and inservice educators under the auspices of the Virtual Resource Center in Behavioral Disorders (Fitzgerald & Semrau, 1998-2000). These virtual conferences involve the participation of national experts in the behavioral disorders field for the purpose of providing in-depth discussion of topics and social discourse regarding the application of the information.

Design and Structure of the Virtual Conferences

Four different structural models were used in designing the online conferences. Each conference ran for two weeks, but the degree of openness and structure, involvement of the online expert, and the use of discussion facilitators differed across the conferences.

Conference #1: Open-ended Discussion by Expert. 95 participants; 477 messages.
One expert online for two-week duration with all participants in one large discussion group; no required pre-conference preparation or readings; messages not organized by themes or available via archives.

Conference #2: Scaffolded Discussion with Facilitated Follow-up. 105 participants; 283 messages.
One expert online for first week with all participants in large group; participants grouped into four smaller discussion groups directed by project facilitators for second week; required writing of a case scenario; suggested readings offered via web site; messages organized by themes and available on web archives.

Conference #3: Scaffolded Discussion without Facilitated Follow-up. 37 participants; 155 messages.
One expert online for first week with all participants in large group; participants continued discussion for second week without expert or facilitators; pre-conference self-evaluation encouraged; suggested readings offered via web site; messages organized by themes and available on web archives.

Conference #4: Open-ended Discussion without Facilitated Follow-up.
Three national facilitators for first week with all participants in one large discussion group; participants continue for second week without national or project facilitators; no required pre-conference contributions required; free CD-ROM provided prior to conference containing suggested software and resources for viewing; messages organized by themes and available on web archives; greater mix of field teachers participating with preservice teachers.

Preliminary Findings & Importance of the Work

The findings reveal equivalent levels of participation regardless of prior computer experience, teaching experience, access to equipment, typing skills, learning styles, writing anxiety, or frequency of e-mail and Internet use. Writing anxiety may play a role in length of message but not frequency of responding. Graduate students demonstrate significantly higher levels of participation compared to undergraduate students. Less structured conferences allow participants to initiate more of their own topics of concern. Instructors have an important role in providing technical assistance. Instructors and course requirements impact participation and authenticity of involvement of preservice participants. Readings provide common ground for discussion. Written scenarios can be requested from participants, but they emerge naturally. Structure and facilitation provide an even level of participation and ongoing discussion. Messages must be archived by threads for asynchronous access.

This research provides a comparison of online participation <u>during</u> conferences that differ in open-ended vs. scaffolded features and the use of facilitation. Online conferencing appears to be a valid and valued method of providing preservice and inservice training, but the variables of designing and running virtual conferences are more of an art than a science at this stage of research. These studies will provide comparative, descriptive data related to conference structure, participant variables, and levels of participation to guide future research in this mode of instruction.

Burkhard_Toenshoff@med.uni-heidelberg.de

Introduction

In medical education, Problem-Based Learning (PBL) is becoming appreciated more and more. The design and implementation of a problem-oriented medical curriculum, however, is very time-consuming for the educational staff. Case-based, Web-based training systems can help the educators to develop, implement, organise and reuse well-structured multimedia cases. For students, such a system can be used to improve and test their problem-solving competence. With respect to heterogeneous learning environments, the system should be flexible and adaptable. CAMPUS tries to meet these requirements by covering the needs of different user groups (e.g., students, educators, physicians) in different application scenarios (e.g. self-study, presentation, learning groups) to get maximum benefit of integrated medical cases. With the CAMPUS player component (learner's front-end), users can work out medical cases in a simulative - and therefore realistic and interactive - way or let the system present a case in different manners. Users can get help via expert comments or context-sensitive systematic knowledge which is available in addition to the case data. With the CAMPUS authoring component, medical experts can feed the system with cases from any medical field. CAMPUS, part of a comprehensive virtual university project, is going to be integrated in a reformed medical curriculum approach at the University of Heidelberg.

Methods

The idea of CAMPUS is to develop a case-based, Web-based training system in Medicine including a broad variety of usage modes with the aim of minimizing acceptance problems and maximizing the effectiveness and efficiency of case-data input, which is time-consuming and still one of the central problems of case-based systems.
To achieve such a functionality, CAMPUS provides the following features:

a) Integration of medical cases from any medical field
b) Storage of case data in a very detailed manner in a relational database
c) Presentation/treatment of cases in different adaptable ways
   The degree of interactivity/realism of a case presentation/treatment is optional. The most interactive form is 'decision', where the student has to treat a case in a realistic, simulative way leading to a maximum of active knowledge processing. The user has to ask questions of anamnesis, order physical, lab or technical exams, make diagnostic decisions and propose a therapy. In the form 'compact' the student only has to make diagnostic decisions and propose the therapy. The results of the different tests are shown en bloc. If a user is only interested in medical case data he can choose the form 'total', where the whole case is presented at once with no interactivity at all.
   With these different forms of application the user can look at a case the way he likes and is able to. For example, if a user does not want to do the anamnesis on his own for any reason, he may choose the form

'compact'. If, on the other hand, he wants to concentrate his learning activities on the physical exam, he may choose the form 'decision'.

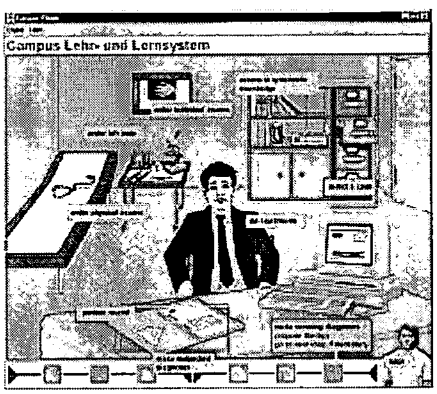
d) Expert comments on demand
It is very important to explain certain things about a case, e.g., why a diagnosis has been made or why a particular exam has been done. Hence, for every particular point within a case the CAMPUS author can define an expert comment.

e) Questions if wanted
Questions are - besides other things - an important aspect of interactivity and active knowledge processing. Thus the case author can define questions of different types on every definable point within a case, e.g., after or before the user gets the answer to a certain question of the anamnesis or after or before the whole physical exam. The user can choose if he wants to see only case-dependent questions, case-dependent and case-independent questions or no questions at all.

f) Distinction between case data and systematic knowledge
Every user has a different state of knowledge. Therefore, every user needs help at different points when working on a case. Hence, CAMPUS shows context-sensitive systematic knowledge only on demand. The knowledge can be internal (integrated by CAMPUS authors) or external (using external knowledge sources from digital libraries over the internet).

g) Detailed case search
Cases are searchable by defining symptoms or diagnoses. For example, one could look for cases with fever, shivering and chest X-ray abnormal. Such a specific search is possible because of the detailed database.

h) Execution over the internet/intranet or locally
To acquire platform-independence, permanent actuality and world-wide access along with all capabilities of a programming language, CAMPUS is implemented in Java as a Browser applet. For users at home, it may be better to have a local application to save time and costs. Therefore, CAMPUS is also executable locally using a local database.



In order to avoid the structure and vocabulary of cases varying from author to author, a case has a well-defined structure and has to use a defined vocabulary for anamnesis questions, exams, diagnosis (ICD-10) and therapies. Every case has the following structure: anamnesis, physical exam, suspected diagnosis followed by one to many passes of a therapy loop with examinations (physical, technical, lab), working diagnosis and therapy. That means that, unlike many other case-based training systems, CAMPUS doesn't stop at the first diagnosis given by the user but considers a case in a more detailed and realistic way.
To give the user an easy to understand user interface, we implemented a so-called situated learning environment, where the 'situation' is a physician's room.

Conclusion

CAMPUS implements a new dimension of flexibility of a case-based, medical Web-based training system. It can be used by different user groups in different learning environments. Therefore, the effectiveness and efficiency of the time-consuming case data input has been improved. CAMPUS offers the chance to develop a case-database with well-structured multimedia cases to be used by students as well as educational staff (especially in problem-oriented curricula) who can use and - more important for the educators - reuse cases in several scenarios.
A first prototype is available and is going to be integrated in the reformed medical curriculum at Heidelberg at least. A comprehensive evaluation is taking place in June/July 2000. An international version of CAMPUS is planned.

Evaluating the Effects of Web-based Collaboration in a Distance Education Program

Paul Rodes, Haejin Chung, Dennis Knapczyk, Carrie Chapman
School of Education, Indiana University, Bloomington, USA.

Abstract: To study the effects of asynchronous web-based collaboration in an existing video-based distance education program, the authors structured coursework to enable evaluation of differences in cognitive and emotional aspects of learning between those using web-based collaboration and those completing assignments through traditional independent methods.

Educators have increasingly recognized the important role collaboration can play in learning. Asynchronous web conferencing has been identified as a unique tool in promoting such collaboration, particularly when applied in distance education coursework [Knapczyk, Chung & Baik 2000, Moller 1998, Duffy et al. 1998, Bonk & Cunningham 1998, Ernest 1995, McMahon, O'Neill & Cunningham 1992]. In the past three years we have integrated web conferencing into our existing video-based distance education program at Indiana University to promote collaboration and ownership among learners [Rodes et al. 2000, Rodes, Knapczyk & Chapman 1999, Chung, Rodes & Knapczyk 1998].

While we have been pleased with the results of web conferencing in our program, we recognize the need to evaluate its effects in verifiable terms. In fact, although much has been written about the benefits of asynchronous web conferencing, few studies have been conducted to verify these findings. The education literature typically offers descriptions of programs and effects, with little controlled study or verification. Furthermore, little has been written on the possibilities of web conferencing when integrated with other distance education technologies. To address this lack, we have been conducting a study in Spring 2000 to investigate the effects of asynchronous web-based conferencing on both cognitive and emotional aspects of learning.

The Collaborative Teacher Education Project at Indiana University offers graduate-level special education coursework to cohort groups of teachers in rural Indiana communities. Classes are delivered via two-way video and are supplemented by e-mail, fax machines, and web-based conferencing using the SiteScape Forums web conferencing system [Knapczyk et al. 2000, Knapczyk, Rodes & Chung 1998]. In the Spring 2000 semester we offered a single course on behavior management to in-service teachers at six sites.

For the current study we divided our course content into four units. The independent variable of our study was the use of asynchronous web-based conferencing. For each unit, we developed two parallel sets of assignments and activities: one set was to be completed individually with collaboration taking place at the learners' discretion; the other set was to be completed collaboratively in web-based learner teams. During each unit, learners at three sites completed their work using web-based collaboration, while learners at the other three sites completed their work using the "traditional" assignments.

To facilitate direct comparison, during every unit each web-based site was paired with a non-web-based site to meet for a video-based course once a week. In this way we ensured that the sites to be compared received the same instruction. After each unit the roles assigned to the groups were reversed. For example, learners in Tell City were linked each week with learners in Spencer in a video session originating from the IU-Bloomington campus where the instructors were located. For the first unit of the course, the Tell City group completed assignments in web-based teams, while the Spencer group completed assignments individually or using informal collaboration. For the second unit of the course, these roles were switched, and so on. By pairing sites in this way, by switching the assigned roles at the end of each unit, and by repeating this full cycle two times during the semester we aimed to minimize the effects of any differences among learner characteristics and environments across the different sites.

The dependent variables we have been investigating reflect both cognitive and emotional aspects of learning. We are evaluating the following three elements of content learning [Bloom 1956]:

- acquisition--through product evaluation and content-based tests
- application--through product evaluation and field reports from learners
- retention--through follow-up tests and surveys on content issues

In the emotional domain, we are using both immediate and follow-up surveys to evaluate learner satisfaction, which is a particularly important factor to consider in working with adult learners [Galbraith 1998].

A specific grading rubric was used to ensure uniformity of evaluation and to be sure products were assessed for issues of applicability as well as acquisition. To facilitate clear comparison, all surveys, testing, and product evaluation have been linked to the four individual units of the course. In this way we can compare the results at each study site not only to the linked cohort site using the opposite approach, but also to the results at that same site during other units, to track any differences as learners moved from web-based to non-web-based activities.

By completing this study we hope to have gathered reliable data on the effects and the effectiveness of web-based collaboration when combined with other distance education technologies. We anticipate that our findings will contribute to an understanding of the importance of collaborative learning and web-based conferencing in distance education programs, and for education in general.

Abstract: *Edubox*® is a system, built at the Open University of The Netherlands, that supports educational innovation processes in higher education. The system allows maximal *flexibility* in that it enables educational designers to model an instructional system completely after their ideas. In this paper the phases of the design, development and implementation of an instructional system are described with particular attention to *Edubox*®.

Introduction

Edubox® is a system, built at the Open University of The Netherlands, that supports educational innovation processes in higher education. The system allows maximal *flexibility* in that it enables educational designers to model an instructional system completely after their ideas, unhindered by implicit didactic beliefs similar systems often harbor.

An *instructional system* is here defined as the assembly of 'objects' that collectively assist a student in acquiring a set of learning objectives. At a more concrete level, an educational system features such items as *people* (e.g. teacher, fellow students, experts), *tools* (e.g. word processor, browser), *knowledge sources* (e.g. books, videos, cd-rom's), and *activities* (e.g. writing a paper, peer-assessing a fellow student).

Design Stage

Edubox® is able to provide the eductional designer with such freedom and flexibility because it makes use of a didactic metamodel embedded in an Educational Markup Language (EML) - a generic XML-based language - as described by Koper (1999).

In principle, everything the learner or teacher will experience in *Edubox*® has to be modelled by the designer. In contrast with traditional electronic learning platforms it does not make any (implicit) assumptions (Onstenk & Meijer,1998; Dabbagh, Bannan-Ritland & Silc, 1999) on preferred didactic scenarios, thus providing the designer with a didactic "clean slate".

When working with *Edubox*® the educational designer, needs to focus his design activities on two main questions right from the start:

- What is the structure of the instructional system needed to support the acquisition of certain learning objectives by students?
- What will be the delivery medium of the designed instructional system?

Decisions on the Instructional System

The instructional system to be developed may be modelled at several levels: the micro-level (e.g.module), meso-level (e.g. course), and macro-level (e.g. curriculum). The designer has to make up his mind about the main level for his design activities. Subsequently, the designer has to opt for a pedagogic approach, taking into account several ingredients of his instructional system:

- educational objectives and prerequisites, (aimed at the acquisition of knowledge, skills, attitudes, competences, complex cognitive skils) and target group
- relations between the stated educational objectives, prerequisites and the structure of the instructional system
- the context in which the education takes place (roles, sources, instruments, on-the-job)
- situational experiences and domain specific information in education
- individual differences
- co-operation and collaboration
- communication
- the use of different educational matcrials
- assessment
- the kind of activities which have to be performed to assure learning processes
- the learning process and transfer processes passes off
- stimulating motivation
- sequencing actvities

Descisions on the Delivery Medium

The educational designer has to make a decision on how the educational system will be delivered to the learners. For example: will the product be a book or will it be delivered on the Internet? Depending on this decision and the level of implementation of the instructional system, the designer will have to design a style sheet for the lay-out of a book or an entire graphical user interface (G.U.I.).

Development

Developing the Instructional System

In the development phase the whole instructional system has to be structured using the Educational Markup Language (EML). For specific pedagogical orientations (e.g. problem-based learning, case-based learning), ready made EML-templates may be available. EML knows the following main elements (Tab.1):

element	description
metadata	all general data concerning an educational object
roles	the different roles persons can have within an instructional activity
objectives	(learning) objectives which are related to an instructional system
prerequisites	prerequisites (e.g. in terms of knowledge, personal charactaristics, instruments available to learner) related to an instructional system
content	all componounds (defined within the elements 'activity' and 'environment') which are conditional for the acquisition of (learning) objectives
activity	a stimulation of the learner to perform certain behavior
environment	componounds (e.g. tests, knowledge sources, instruments) which are conditional for the acquisition of (learning) objectives
method	structure, didactics and processes within an instructional system

Developing the delivery medium

In the development phase the necessary features for publication to the medium chosen during the design phase should be developed.

Implementation

Because of the richness of EML and the flexibility of *Edubox®*, different designers may implement similar ideas in very different ways.

Technological Tests of Educational Theories: A Research Role for the Generative Virtual Classroom

Dr. Lynette Schaverien
Faculty of Education, University of Technology, Sydney
PO Box 222,
Lindfield NSW 2070 Australia
Lynette.Schaverien@uts.edu.au

Abstract: Throughout history, technological advances have led to scientific breakthroughs. Computer-mediated learning environments have the potential to function similarly: as technological tests of educational theories. Here, this unexplored research role, for one such learning environment, is illuminated. The Generative Virtual Classroom, a web-delivered virtual classroom for teacher education, is demonstrated and preliminary research findings with respect to theory advancement reported. Some emerging implications for computer-mediated learning and for the generation of educational knowledge are discussed.

Cultural development is littered with striking examples of technological advances that have led to scientific breakthroughs. The successful building of European cathedrals provoked the development of a detailed engineering science (Bronowski 1973/1992). In our own time, pioneering brain-imaging technologies have brought important new neuroscientific insights (see, for example, Carter 1998 and McCrone 1999). Similarly, technological tools for learning, especially those designed on particular educational principles, ought to expose the worth of those principles. In action, such technologies may well constitute a potent and, as yet, unexplored research tool by means of which educational theorising can be advanced. In this work-in-progress paper, I explore this research role for one such technological tool for learning: the Generative Virtual Classroom.

The Generative Virtual Classroom

This paper begins by demonstrating the Generative Virtual Classroom itself, so as to elucidate its educational principles. Emerging from a series of classroom studies of learning and learning to teach (in particular, Cosgrove & Schaverien 1996 and Schaverien & Cosgrove 1997), this web-delivered learning environment attempts sophisticated computer-mediated teacher education in elementary technology-and-science. Its design embodies a generative view of learning in which learning is conceived as a generating and testing cycle (after Minsky 1986, Wittrock 1974, 1994 and Plotkin 1994,1997). According to this view, learners generate ideas that they then test on their value, keeping those that survive their tests (Schaverien & Cosgrove 1999, 2000). In a nested pair of virtual classrooms (a virtual elementary one and a virtual tertiary one), Education students can develop their views of learning by observing exemplary learning by young children from an archive of pre-recorded digitised video excerpts. They can formulate their thoughts about these excerpts and communicate with others about them, considering others' views of them, including, in particular, a generative view of learning. As an environment in which learners can develop a generative view of learning, in ways consistent with such a theory, the Generative Virtual Classroom is poised to be a powerful technological test of this generative theory itself.

Do Learners Learn Generatively in the Generative Virtual Classroom?

Already, pilot research conducted in the Generative Virtual Classroom affirms the fruitfulness of viewing learning generatively. For example, in a nine-month autobiographical study of the development of her views of learning in the Generative Virtual Classroom (Allard 1998), an Honours Education student was able to establish her conceptual progression, for herself, and to identify what she still needed to understand. On analysis, this student's learning was well explained in generative terms; and, as well, on the basis of her experience, minor alterations were able to be made to the learning environment itself. Such studies suggest the value of proceeding to larger scale tests of the worth of this theory. Consequently, a large-scale collaborative research trial of the Classroom is now in its beginning stages. In this trial, a full cohort of First Year Education students (n=~100) has begun to work in the Generative Virtual Classroom, yielding early data on the nature of the learning of a diverse range of individual students over a semester. Students' text contributions to the Classroom's community database and e-mail discussion group will be collated, described and analysed for evidence of generativity, in an attempt to assess the worth of such a theory in making sense of what they did.

Implications for Computer-mediated Learning and the Generation of Educational Knowledge

Clearly, the recent proliferation of technologically mediated environments in which learners can teach themselves has brought new opportunities to explore the nature of learning. Even more recently, such writers, inter alia, as Alexander & McKenzie 1998 and Hannafin, Hannafin & Oliver 1997 have begun to insist that these new learning environments be explicitly grounded in educational principles. From these positions, it is a short but significant step to conceiving of computer-mediated learning environments as instruments for the testing of educational theories, an idea whose time has come. Once crystallised in these terms, such a research program has the potential to redress long-standing dissatisfaction with the apparent lack of theoretical progression in Education in particular (Thagard 1992) and in the social sciences in general (Ziman 1978/1991). The paper closes speculatively by discussing the implications of such a re-conceptualisation for computer-mediated learning and for the generation of educational knowledge.

Abstract: This paper draws on data gathered during a year-long ethnographic study of graduate education classes in a 2-way audio 2-way video distance education classroom. Cultural analysis of transcript excerpts indicating student reactions to their experiences in the technologically mediated classroom highlight the anxiety and confusion they experience in making the shift from the familiarity of traditional classroom culture to the uncertainty of a new, often strange environment. This transition phase in classroom cultures, what Turner (1969) calls the liminal phase, is a time of high anxiety but also of high learning. Our data suggests that instructors who take on the role of technology guide and provide students the opportunity to vent anxiety and learn about the technology, create environments that significantly increase the comfort levels of students and receive much higher ratings from them.

Introduction

Distance learning, via web based and two-way interactive video classes has changed the market areas of educational institutions from how far faculty are willing to drive to how far the Internet or phone lines will reach. Given this new global market, institutions of higher education are rushing to fill the niche. Students are recruited, new learning environments are created and faculty are suddenly asked to teach classes in front of computer screens and cameras. Although the literature encourages the use of instructional design principles when teaching this way (Moore & Kearsley 1996), in the rush to stake out new territory, such classes are often thrown together with little planning and less understanding.

According to Willis (1993), "research suggests that distance education and traditionally delivered instruction can be equally effective if the distance educator puts adequate preparation into understanding the needs of the student and adapting the instruction accordingly" (p. 22). But how does one do that? How can students and teachers anticipate their needs in a substantially new learning environment? Are these new learning environments traditional classrooms with a few technological add-ons where the assumption can be made that student's needs are little changed? Or are they complex new environments that require descriptive and analytic illumination by researchers such that student needs can be assessed and then addressed? Our research suggests the latter.

It is our contention, that the situation people face in distant classes is, from a cultural perspective, radically different from the traditional classroom. The enculturation process that occurs during years of schooling solidifies in the learner norms for the role of the teacher, for methods of classroom communication, and for student interaction that lasts a lifetime (Henry, 1955). The entire dynamic of teaching and learning, which is deeply grounded in traditional classroom culture, is changed in complex and nuanced ways when the class becomes technologically mediated. The study on which this paper is based used the approach of ethnography and the perspectives of cultural anthropology (Geertz 1973) and social interactionism (Mead 1934) to uncover these changes in classroom culture and illuminate changes in the teaching/learning dynamic.

In this brief paper we can do little more than present fragments of interviews to show how descriptions by students of their distance education experiences and an awareness of traditionally based student expectations can inform a deeper understanding of the needs of students. This understanding then becomes the basis for strategies that instructors can use to help learners through the cultural transformation process and to have more successful learning experiences.

The Study

The study is based on data gathered for an ethnographic case study of graduate education classes during the inaugural year of a 2-way audio 2-way video interactive distance learning classroom. Courses included in the study varied significantly in teaching style, course objectives, course content and student responses. Traditional ethnographic and qualitative research methods facilitated data gathering and analysis (Agar 1996; Maxwell 1996). Data gathering involved more than 400 hours of participant observations in classrooms, formal interviews and informal conversations with students and faculty, weekly e-mail correspondence, open ended surveys, focus group interviews, and video of all classes. Thematic coding, frequency counts, and frequent debriefings between ethnographers L. and R. Schmertzing contributed to interpretation and ongoing analysis of the data (Spradley & Mann 1975).

The Data

Excerpts of student comments from e-mails and interview transcripts introduce the complex culturally based issues that students face in the interactive televised classroom. All of the following passages were written by students in response to questions from the researchers regarding the students first night in the distance classroom. We will present the excerpts in the data section and comment on them in our discussion.

> When I saw the room set up I was in shock, actually. It was my first interactive distance learning class and I walked into the room thinking "why did I sign up for this?" At the sight of all these different video screens and cameras all around the room, I didn't think that the grades would be the same. I thought they would favor the class that had the most physical interaction with the professor. I became sort of jealous of the other campus and resented the fact that she (the instructor) was there. I felt like I was at the main campus where the professor should have been. If the other class was at a branch campus, they should have primarily been in the distance learning aspect of it. My GPA is very important to me. I feel that the grade I earn will be affected by how much time I will have to spend watching her on a monitor. There were so many distractions, it was hard for me to stay focused. Also, there was so much zooming in and out with the video cameras, I honestly got motion sickness and walked out of class feeling sick to my stomach with a headache. I did not like it. The cameras were set up in awkward angles and you couldn't see the professor's head when she was talking. We got great views of the back of her head.

Many students made similar comments, although the attitudes of others were more like the following who noticed the difference but struggled to adjust.

> I was really surprised at my reaction. I've taken a web-based class before and I have seen the equipment for this classroom before. I didn't think I would feel any different, but I did! I was surprised at how I looked on camera and feel that I will have to work on this so that it doesn't impact my participation. Also, I forgot several times, where to "look" so I would be facing the remote group when I "spoke". I also found that as the night wore on, I kind of avoided responding to questions 'cause I felt like I was monopolizing the session. I did like being able to "face" the other group and do not feel that the experience effected my learning. I found myself "concerned" about the remote site when we had a few technical problems and am concerned about the learning experience when the instructor goes to the other class and I am in the remote site, having to rely on the technology.

For some students the two-way audio/video class they participated in was an entirely positive experience. "After the first night of class I am totally satisfied with everything. I especially enjoy being able to take the class at this campus and am excited to have the opportunity to be a part of this class."

Other students cited particular elements of the technologically mediated classroom that fed their anxieties and complicated their ability to focus in the classroom. "I'm just much more aware of asking questions and making contributions, because I have to do this mechanical thing." The necessity to physically encounter technology in order to participate in class confused students and contributed to a magnified concern for the value of their own comments. "You don't have the ability to just sit there and say, 'Wait a minute;' you're on camera now, you're on air-time, and so if you have what you think may be a *little* question, you're wasting class time [if you ask it]."

Discussion

The variation in student responses points toward the diversity and complexity in their perspectives. Students from each class all have different ideas about their experiences in their new classroom environment. They all, however, enter the classroom with an understanding of the way a traditional class works and quickly confront the differences. Students expect the classroom to look a certain way; they expect to focus on a teacher standing at the front of their classroom; they expect to have easy means to speak and be heard. When these culturally based expectations are not met, students are often left with a sense of anxiety and feelings of uncertainty. We found that complex technologically mediated interactions between learners, instructors, and content forced the re-construction of the way participants had previously "done class." Learners, caught between the old way and the new way, moved through a liminal state (Turner 1969) to find a balance that provided enough comfort with the environment so that distractions were minimized and learning maximized. The student need indicated in this paper is the need to be guided through this liminal state, the need to be helped through the adjustment phase. In such a context, the new role for the instructor is as a guide.

Instructors that we observed to be successful guides used various strategies to speed up and enhance students' adaptation to the new classroom. Students found balance more quickly when instructors recognized, articulated, and showed sympathy for the "awkward," "uncomfortable," "surprising," "overwhelming" state of the learner. When instructors talked to their students in an "up front," "understanding," "sensitive," (from student transcripts) manner about the strangeness of having class in the new environment, students were more responsive to instructions on how to use the technology to accomplish class goals. When learners were allowed opportunities to express their feelings about the environment without fear of repercussions, they appeared to overcome the added burden of "hiding [their] anxieties" about to taking a distance class and became more "willing" to work with the new technologically-mediated environment. The instructor who provided students the opportunity to "vent" through both class discussions and online threaded discussions achieved the highest rating for classroom interaction of all the instructors considered in this study and did so in the least amount of time.

The style, manner, and attitude an instructor established the first night of class was also a key factor in how long it took students to learn the technological system and for the ease and speed with which they learned to function effectively. First class meetings rated highly by students were those that were characterized as "fun," "calm," and "slow enough to understand." Instructors who, in early classes, laid ground rules for communication, clearly and completely explained the technology of the classroom, gave students an opportunity to use the system in a non-threatening manner, and provided a thorough picture of what would be expected throughout the semester built bridges between participants and the technology. Once the bridge was built and the connection made, the environment felt "safer" and interaction took place more easily.

These are a few of the insights and strategies that have emerged from our analysis so far. We expect that our continued analysis will produce many more.

Introduction of a New Media Concept for a Teaching Profession Degree in „Computer Science“: A Formative Evaluation

Axel Hunger, Stefan Werner, André Bresges and Frank Schwarz
Gerhard Mercator University Duisburg, Department of Dataprocessing
Bismarckstr. 81, 47057 Duisburg, Germany
e-mail: {hunger | swerner | bresges | schwarz}@uni-duisburg.de

Abstract
Within the scope of the development of a new multimedia education concept for the teaching profession "Computer Science", the strengths and weaknesses need to be constituted already during the development-phase and weaknesses need to be eliminated if necessary. Therefore, the concept is examined within the formative evaluation on its tangibility and effectiveness.
The newly developed education concept, which was developed at the Gerhard Mercator University Duisburg under usage of new media, aims at creating new possibilities for differentiation and decentralized learning by a multimedia teaching and learning concept. The didactical new conception of the course is supposed to take the students different learning prerequisites into account. Thus, procurement methods are striven for that enable individual preparation, consultation and practice dependent on the students educational background.

Introduction

The teaching profession with the vocational field "Computer Science" at the Gerhard Mercator University Duisburg can be attended by students with different main subjects. Students can combine the specialized professional field "Computer Science" with different main subjects, e.g. mechanical engineering, chemistry technique or textile and clothing technique. So a teaching concept had to be developed due to the different bases in the information technical education of the different courses. It has to consider the heterogeneous foreknowledge of the students and offer according intensive procurement methods.
The developed concept is used in the basic course "Fundamentals of Computer Science" as first trial phase. The course covers topics such as the Boolean algebra or switching algebra, the technical implementation of logical operations, which are based on the Boolean algebra and finally the fundamental digital circuits and systems as well as simple digital computers, which are based on these operations.
The procurement of contents and the conversion of the quoted objective requires the completion of the course forms so far by means of a suitable concept on computer base and the transfer by means of multimedia technique. The interactive, multimedia teaching and learning software is set up in such a way that the different learning methods of the students are taken into account. Therefore, different points of entry are available for the software.
One entry point runs over the content structure, here the student can choose his learning path in accordance with the content of the lecture. The course so far included exercises for practicing and applying the taught methods. This exercise part is also integrated in a suitable form into the interactive learning concept. The second entry point clarifies the interaction between the acquired knowledge and the latter practice on the basis of a descriptive task. Thus, a learning goal oriented or res. a problem based learning is enabled. The student receives an course of action. A detailed description of the concept is given in (Schwarz, Hunger, Werner, 1999).

Initial Considerations for Evaluation

Sources of information that are available for a study group are on the one hand conservative sources such as books, scripts and patterns, the instructor and laboratory/experiment device. Additionally, fellow students also count as information source, since notes, sources of information and interpretations can be exchanged with them.

New media can take the place of an information source (book) and the place of an experiment device (simulations). It can also partly take over the role of a teacher, by answering standard questions and checking exercise results, as far as the exercises are machine controllable. Furthermore, new media creates more extensive communication possibilities (Dweck, 1988).

The entire focus during the introduction of new media in complex, problem based learning situations is determined and already distributed on different learning tasks. The attention can not be increased by the introduction of new media! In the case of new channels being available, the individual must redistribute its bandwidth and thus its attention on the available channels. A rearrangement takes place on expense of other channels. Refocusing might lead to a favoring of channels due to improved accessibility of information through new media, which enables individuals to receive information more easily and thus the attention on other channels is encouraged. We can speak of a positive modification of the social behavior induced by introducing new media, if both possibilities deal with the channels which the individual use to interact with other members of the group.

Formative Evaluation

The concept is evaluated in several steps. In the first step, the teaching and learning processes are evaluated by observing and interviewing the participants. The experiences of students from different subgroups are of importance and thus raised in particular. The members of the group are interviewed by using a questionnaire. This questionnaire ranks important data through accordingly formulated questions on socio-metric matters for the 4 partitions of the theory model (economy of attention, social behavior, motivation control, accessibility of information). The behavior and movements of the user is recorded at the same time. Thus, it is to be determined, whether the mapped mental model is applicable on the learning group and whether weaknesses in the navigation and comprehensibility can be discovered. The results flow directly into the development. Furthermore, an expert workshop is set up in order to determine suitable scenarios of different emphasis. The expert workshop primarily consists of professors of the respective field.

The evaluation leads to the following results:

70 participants were interviewed, among them where 25% that use MODULO regularly. The participants hardly use MODULO for stringent reading, but rather for the direct search of information. This functions well to outstanding; students indicated that finding information under usage of MODULO is substantially better. The links between exercise and lecture were considered as helpful. The complex scenarios, which are supposed to clarify the application of knowledge in vocational practice, are considered less helpful for understanding the material. Most students rather find the scenarios helpful at ranking the material into vocational practice.

In a further step, a summative evaluation will take place after final completion in order to elevate the acquired knowledge of numerous years and using it for advancements of the concept.

Summary and Prospect

In this article a new concept for supporting the theory of the teaching profession course "Computer Science" and an appending formative evaluation was presented. The concept aims at media-technical editing of the disposition, the development of a training concept and the development and implementation of a WEB-database with dynamic access. This concept holds the advantage of being able to go into different needs, previous knowledge and learning methods of students, due its modular structure. It enables a self-controlled learning, promotes media competence and offers demanding possibilities of acting.

The first evaluation which accompanied the development of the system had positive results and constructive criticism. The entire system is to be completed by September 2000, so that the summative evaluation can be started in the winter semester 2000/01.

bboyer@calstatela.edu

Abstract: CSULA was charged with assisting the NSA in the research, development, documentation and the necessary expertise to convert a traditional face-to-face platform course to a multimedia web-based course. We converted a platform-based course taught by the NSA called "EEO 100: Equal Employment Opportunity Law and Diversity Training for Selection Boards." To accomplish the task, an interdisciplinary team of graduate and undergraduate students from Instructional Technology, Art Education, Computer Science, and Design collaborated on producing the website.

Constructivism

Recent studies in education have promoted the constructivist approach to learning "...where students develop their knowledge through team collaboration, discuss different interpretations of a problem, and negotiate and synthesize ideas drawing from various disciplines" (Boyer & Semrau, 1995, 14). Technology can play a significant role in this process by having students become more proactive in their own learning and more independent in their search for knowledge. Students using technology have access to ongoing real world problems, on-line dialog with scientists, and access to the latest technological advances. Ultimately, students will be engaged in their learning, see relevance in it, and take on an ownership in it. To meet the needs and interests of students, education must emphasize problem solving and application of information, instead of memorization of facts. Roberts et al state, "...students need to be able to find and use relevant information, share and discuss data and ideas, and collaborate on problem solving" (1990, 116).

Year One of Project

July of 1998, California State University, Los Angeles (CSULA) began a 3-year project sponsored by the National Security Agency (NSA) entitled "NSA Partnership with Cal State L.A.: Courseware Conversion and Evaluation Project."

CSULA was charged with assisting the NSA in the research, development, documentation and the necessary expertise to convert a traditional face-to-face course to a multimedia web-based course. CSULA students were selected to work on the project with a focus on collaborative group work and a constructivist approach to learning. An interdisciplinary team of graduate and undergraduate students from Instructional Technology, Art Education, Computer Science, and Design were brought together under the direction of two faculty members.

In this project we are converting to the web a platform-based course taught by the NSA called "EEO 100: Equal Employment Opportunity Law and Diversity Training for Selection Boards." EEO100 is directed to employees who serve or who may serve on boards, panels, or committees charged with the responsibility of rating workers for selection purposes. The course is designed to provide participants with an understanding of the extent to which their rating activities are subject to applicable civil rights laws, and to appreciate the value and contributions of every candidate. Students after taking this course will be able to:

1. Understand the requirement for EEO 100
2. Understand legal rights and responsibilities for fair and equal treatment in the decision-making process
3. Gain a common understanding of "diversity"
4. Recognize "blind spots" and conditioning from society, and how these factors impact decisions
5. Provide a hands-on opportunity to improve the decision-making process
6. Appreciate the value and contributions of every individual

Training was provided to the CSULA student team on the basics of html, Adobe Photoshop, Premiere, and Pagemill in order for them to be able to undertake the task of courseware conversion to the web. They were also trained on the use of WebCT for developing the website, uploading of web pages to website, and designing of web pages. . WebCT is an online Internet authoring tool for web-based courses. The students were guided regarding the overall layout and screen designs. For a foundation in working collaboratively in building a website the students first designed a demonstration site on streaming media—RealAudio and RealVideo. The demonstration site was developed for sharing our research and for communication among the students and project faculty. Focus was placed on developing an educational website demonstrating various applications of streaming video and audio in education as well as being a source of research data and instruction for creating streaming video and audio for web-based training.

The students investigated the hardware and software requirements for streaming media, selected examples of streaming video, and html coded web pages documenting their gathered data about streaming media and its role in web-based training. The WebCT course site also offered additional built-in communication features including e-mail, chat rooms, a bulletin board, and white board. Students used the bulletin board to provide help to each other and to assess each other's web pages.

For the foundational first part of our collaborative work, the students researched and structured their content on streaming media into the following sub-areas:

1. Introduction to Streaming Media
2. How Does It Work--Streaming Video?
3. How Does It Work--Streaming Audio?
4. Aesthetics of Streaming Video
5. Aesthetics of Streaming Audio
6. Educational Applications of Streaming Media
7. Our Examples of Streaming Video
8. Project Report 1998-99
9. About Us

Each student was charged with the design, structure, research, and development of one content sub-area.

Year Two of Project

During the fall, 1999 we moved onto converting the EEO 100 course content into a web-based course. We followed the pattern established in the prior year where each student was assigned full responsibility for the research, design, development, and coding of a topic. The EEO 100 content was subdivided into the following main topic areas: Current requirements, additional requirements, definitions of discrimination, disparate impact, harassment, affirmative action review, and tools. Each student studied and learned the EEO 100 course content and was then individually tested on it. In the process of understanding the content, they realized that it would be necessary to rewrite and revise the content, as well as integrate multimedia to accommodate a web-based learning environment. Next they html coded the EEO 100 course content and thus begun the creation of the web-based course. One of the students developed the screen design incorporating American Disabilities Association (ADA) guidelines.

They developed new test items for the content. They researched websites and selected appropriate ones related to the content and created external links to these websites. We designed draft layout for structuring the menu and content. And, we investigated, selected, and adapted a quiz format for use in this website to set up pop quizzes that were integrated within content areas.

In the winter of 2000, the students analyzed a video that was a tape of an original face-to-face traditional approach to teaching the class, which was provided by the NSA. They made a list of the video clips matching the content they were responsible for. Before we started digitizing the content, we inspected the length and filesize of each video clip to determine how to reduce the size of very large clips. We came up with several solutions which included digitizing only the audio for certain clips and accompanying the audio with still diagrams of key points and cutting up the longer clips in to shorter segments. Next the students captured the video using Adobe Premiere and the Osprey 100 video card in a Dell Precision 401 computer. They edited down the clips using Adobe Premiere. The audio was captured and edited with SoundForge. Next, the clips were streamed with RealProducer and html coded into their relevant web pages of content.

To polish off the interface design, we brought on an art student who was charged with developing an easy to use menu of topics and navigational system.

In the spring of 2000, it is our intent to synthesize various course components (content, video, test items) into a final course website and to design visual learning aids (diagrams, charts, and pictures) and tools (glossary, law books, and court cases) to enhance learning of the course content. We are preparing to design and incorporate simulations into the website. NSA has been encouraging and supportive of this idea as an extended project.

Conclusion

The new web-based version of this course will make the content accessible to more NSA employees located in various places throughout the world. Plus, the online version will include interactive pop quizzes with immediate scoring and feedback as well as streaming media lectures to complement the course content, which is presented as text on the web pages.

Through this project the students became constructively involved in their own learning and have acquired in-depth experiences in collaborative learning. The students became empowered to be creators of their own curricular materials and web pages instead of being passive viewers of others'. In this project all of Bloom's higher level taxonomies are implemented. Students are analyzing websites, synthesizing criteria that they have researched, applying their book readings, comparing and contrasting their criteria, designing and producing their own web pages, and more.

The Internet Chemistry Set: Web-based Remote Laboratories for Distance Education in Chemistry

Frederick A. Senese
Dept. of Chemistry, Frostburg State University, USA (senese@antoine.frostburg.edu)

Christopher Bender
Dept. of Chemistry, Frostburg State University, USA (bender@antoine.frostburg.edu)

Abstract: The convergence of modern data acquisition technologies with the Web's interactivity, connectivity and multimedia capabilities presents an exceptional opportunity for distance education in the physical sciences. Web-mediated access and control of laboratory equipment can improve utilization of expensive and specialized instruments, facilitate collaborative data sharing and analysis, and provide essential practical experience in physical science courses delivered at a distance.

This paper describes a remotely controlled experiment for determining the rates of fast chemical reactions. The experiment is not a simulation; it involves actual equipment controlled in real time from remote locations on the Web. The experiment is the first in a series designed to provide a pedagogically on-line laboratory experience for Web-delivered general chemistry courses. Students use the experiment's Web interface to collect data, to obtain interactive technical support and background information, and to display and analyze results. Each experiment is designed to encourage sharing of data and collaboration with users at other institutions, providing students with a valuable first look at work in a distributed laboratory environment.

Introduction

Chemistry is an experimental subject. Chemists construct knowledge by systematically examining quantitative data for patterns. Patterns suggest hypotheses, which in turn form the basis for theories. Theories are then critically evaluated in the light of new experimental data. This is the only sanctioned approach for progress in science. Pedagogy that is not founded on the interplay between theory and experiment poorly serves students by not involving them in the essential process of science.

The experimental nature of chemistry presents severe challenges for teaching the subject at a distance. Many current online chemistry courses either have no laboratory experience at all or use simple kits or 'kitchen chemistry' experiments that can be performed with household materials. Obtaining accurate, quantitative data from which relevant and interesting conclusions can be drawn is difficult with such simple equipment.

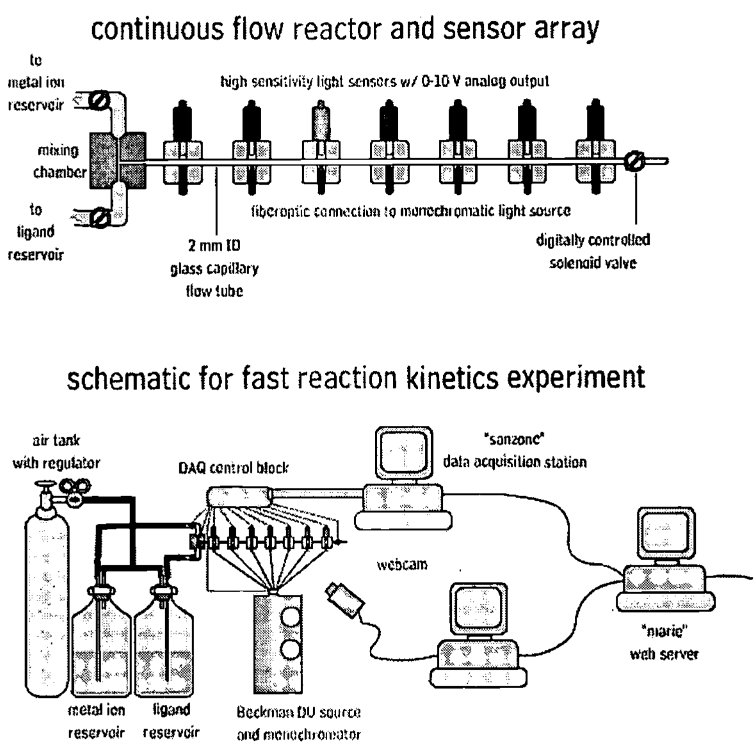
Online chemistry courses often make heavy use of simulations. While simulations can be quite effective, they are theoretical constructs that cannot substitute for practical experience. For example, students regarded the output of simulations in a statistical analysis experiment at Oxford University as "pretend" data (Cartwright, 1998). They sometimes failed to carry over the lessons learned from analyzing simulated data to data collected in actual experiments. Concerns about the pedagogical quality of the simulations were addressed by the development of a simple, economical "optical rig" (Cartwright, 1999), which allows students to collect and analyze actual data over the Internet.

This project addresses the problem of practical experience in Web-delivered courses by providing students with remote access and control of real equipment. A remote-control reaction kinetics experiment suitable for chemistry students at the undergraduate or advanced secondary level is described. The apparatus monitors the course of a fast chemical reaction spectrophotometrically using a simple continuous-flow method. Students can use the data they collect to determine the rate laws for the reaction under a variety of conditions. By collaboratively analyzing the results of a large group of experiments performed by peers, students can propose mechanisms for the reaction. While the experiment is conceptually quite simple, it involves specialized apparatus that is unavailable in most undergraduate laboratories. Rapid data acquisition can allow many users to perform experiments in real time, and nearly spontaneously.

Method

The experiment is an adaptation of a classic continuous flow method for studying the rates of fast reactions (Dalziel, 1953; Roughton & Chance, 1963). The apparatus can be used to determine the rate of any sufficiently fast reaction that produces a colored product, although practical considerations limit the choice of reaction(Shoemaker, 1974). Pilot investigations studied the formation of $FeSCN^{2+}$ (an orange complex that absorbs at blue light at 455 nm) and "Prussian blue", an intensely colored complex used in blueprinting, paints and inks (Sharpe, 1976).

A schematic diagram of the apparatus is shown in (Fig. 1).



Reactant solutions are forced from large reservoirs into a T-shaped chamber, where they mix completely in less than 1 millisecond. The reacting mixture then travels down a long capillary tube. The product of the reaction is intensely colored and strongly absorbs a characteristic wavelength of light. Product concentration rises as the mixture moves along the tube. Seven light sensors placed at fixed positions along the tube monitor the increase in concentration. Monochromatic light is passed through the capillary at each position using a fiber-optic cable. High sensitivity photocells placed on the opposite side of the tube record the intensity of transmitted light at each point; the intensity drop caused by absorption of the light by the complex is simply related to the concentration. A flow rate sensor allows the position of each of the spectrophotometers to be associated with a reaction time.

Data from the sensors is acquired by "sanzone", a 500-MHz PC equipped with a National Instruments data acquisition card. A LabView program collects, labels, and writes the absorbance, temperature, and flow rate data to an "outgoing" queue. The program then checks for requests in an "incoming" queue. If one exists, a new run is started. Otherwise, the system is flushed and the valves are closed to avoid unnecessary waste of reagent solutions.

A Webcam collects pictures of the apparatus during the run. The camera view includes the reservoir manometer and a digital thermometer, so it is used for data collection as well as for helping students monitor the progress of the reaction. The Webcam is attached to a second PC to avoid contention.

A Unix Web server (Marie) mounts Sanzone's hard drive across the local network. Perl scripts running on Marie fetch data from the outgoing queue, interpret it, and prepare the results for display.

Students perform the experiments via a "smart" instrument panel served from Marie, displayed in a standard browser. The instrument panel recreates the actual look and feel of the remote experiment. Operators immediately see the results of their actions via the Webcam, as well as on a rich data display. The panel's panic button launches a conferencing connection with the system's caretaker via Netmeeting during working hours and by email at other times. The panel monitors and interprets student activity to diagnose and correct conceptual problems and to prevent actions that could damage or tie up the apparatus for long periods of time.

The instrument panel front end is implemented in JavaScript and Macromedia Flash. When students submit a run from the instrument panel, backend Perl scripts label and process the request and write it to an "incoming" queue on Sanzone and the expected time of completion for the job is displayed on the panel. Jobs complete within a few seconds when the incoming queue is empty. Queues are intelligently managed by consecutively scheduling jobs with similar operating parameters and by assigning lower priority to non-local IP addresses (to prevent 'walk-in' users from monopolizing the experiment).

Future versions of the experiment will allow students to manipulate additional parameters, such as reagent concentrations, pH, temperature, ionic strength, and flow rate. Data from different groups can then be pooled and analyzed. Students will then use these results to evaluate proposed mechanisms for the reaction. Further developments will be outlined on the project home page at http://antoine.frostburg.edu/chem/senese/inetchemset.

A Distance-Learning Model Based on Web Mining

Ruimin Shen
Qijun Wang
Dept. Of Computer Science and Technology
Shanghai Jiaotong University, Shanghai, 200030, P.R.C
Email: rmshen@mail.sjtu.edu.cn

Abstract: Distance-Learning based on WWW has become a trend for the development of education. But the distance-learning site based on WWW is static, the designers of the courses don't know whether the design of courses is rational or consistent with the teaching law. While there is a lot of students' information accumulated in the web site, and the information is useful for our course designers. In this study, we present a distance-learning model based on Web Mining, which can take advantage of those students' information accumulated in the web site.

1.introduction

Distance-learning based on WWW has become a trend for the development of education. The available distance-learning model based on WWW is discussed in (Xuejun Li 1999). But recently the distance-learning site based on WWW is static, and the designers of the courses don't know whether the design of courses is rational and consistent with the teaching law. While there is a lot of students' information accumulated in the web sites, such as students' access patterns and registration and communication data information, and these information is useful for our course designers and teachers.

In this study, we present a distance-learning model based on Web Mining, which can take full advantage of those students' information accumulated in the web sites.

2.A Distance-Learning Based on Web Mining

The model integrates the Web Mining technology into the available model base on WWW. It's architecture is shown (Fig.1). In this model, we add the Web Mining module into the available model. The Web Mining model is located in the server-side and performs in the server-side.

According to our special system for distance learning, the Web Mining process as shown in (Fig.4). The Web Mining module has three phases(Robert cooley et al. 1998): Preprocessing(Yilin yang et al.1999), mining process and pattern analysis.

3.Conclusion

our model has following points: The course designers can reconstruct a Web sites in order to better serve the needs of students of a site according to these information such as the students' access patterns and page access frequency statistics; it can provide individualised page or different course content for individual student; and it can provide teachers the students' feedback, and teachers can redesign their teaching plans,too.

Scenario-Based Prototyping: a User-Centered Method for the Design of CALL Systems

Jae-Eun Shin
Department of Computer Science
University of Manchester
United Kingdom
jshin@cs.man.ac.uk

David G. Wastell
Department of Computer Science
University of Manchester
United Kingdom
dwastell@cs.man.ac.uk

Introduction

The aim of this paper is to illustrate and demonstrate the value of a user-centered method for CALL systems development. We accept the argument of Hubbard (1996), Levy (1997) and other the deficiencies of current CALL system can be attributed to the lack of a systematic methodological theory guiding their design. Accordingly, a CALL design method has been developed which draws on recent developments in the field of human-computer interaction regarding scenario-based design and prototyping in relate to the user-centered design of computer-based learning material.

Scenario-Based Prototyping

The main features of the method include the use of scenarios to identify user requirements (Carroll, 1995), the development of prototypes embodying key design issues, and a series of formative workshops to evaluate the prototypes. The overall results confirm the general validity of the user-centered, scenario-based methodological approach.

There were three cycles of prototyping process in this research. Each cycle was based on a set of User Satisfaction Scenarios. The scenarios were used to build prototypes in two different ways: user dissatisfaction scenarios were used to define existing problems that have been found from the current CALL products; and user satisfaction scenarios were used to clarify possible problems that could be found in the CALL product to be built. A template for scenarios is proposed for the educational environment. The template include the user environment (i.e., age, school, class, user's conception toward CALL system, motivation of using CALL software, software type), learning environment (i.e., classroom, self-studying, group-studying), and narrative user interaction scenario to define features user satisfied/dissatisfied. Overall, this paper is to suggest the method of use of scenarios explicitly for designing CALL systems, not to show the results of prototypes which have been constructed and evaluated

Developing prototypes is an integral part of iterative user-centered design process because it enables designers to try out their ideas with real users and to gather feedback. There were three major cycles of prototyping process with different prototypes embodied different design issues, which is based on user-satisfaction scenarios. The main design issue of the first prototype systems was to find how user-control could affect to achieve high quality CALL systems in terms of both educational and technical value. Two comparative systems were built for this initial stage: one was a high user-control (learner-based) system, and the other was a low user-control (teacher-oriented) system. According to the feedback from a series of formative user workshops, it has been found that the effectiveness of user-control were dependent on learners' experience in CALL systems and their learning environments. Based on the feedback from the first workshops, the user satisfaction scenarios were revised to find the design issues for the second prototype.

The second prototype system was a hyperlink system between three different systems: Tutorial system for listening skills with low user-control, Main Lesson system for practicing listening skills with high user-control for experienced users, and a sub-system called Speaking Dictionary to provide learners linguistic help. The user response about the hyperlink system was that it would be better to have a different user-control by learning stages concerning user experiences. Users also showed positive opinions about the user satisfaction scenarios because they agreed that scenarios make it easy to visualize the real-world environment and to comprehend users' perspective toward CALL systems. On the other hand, users responded that learners need more support to control their learning process more effectively.

Therefore, the third prototype constructed was focused to investigate the effectiveness of Teaching Agent to support learners' learning process with respects of HCI aspects and educational achievement. At this stage, we argue that TA should have domain knowledge (i.e. English), Training knowledge (i.e. listening skills), and Specific pupil knowledge. Here, the specific pupil knowledge is the most significant to advise learners what to do next. While the knowledge of domain and training are static and independent on student or teacher, the knowledge of specific pupil depends on followings: how well is the learner doing?; what listening skills have been used?; what personality does the learner have?; and what is the learning goals? The TA system called Magic Mirror has been developed to apply those aspects based on the revised user satisfaction scenarios, in which learner personality and learning goal of specific pupil knowledge were not considered. The result from the third workshop with teachers was positive towards the concept of TA in general, but some teachers questioned how TA could act as a substitute for a teacher. On the other hand, learners showed more positive attitude towards the TA because they compared the TA with Help functions in other CALL system, not with their teachers. The conclusion is that TA could make CALL systems more effective if all the aspects of the specific pupil knowledge are regarded on the development.

Conclusion

The essential elements of this user-centered method for designing CALL systems are scenarios, prototypes, and formative workshops. Prototyping helps designers to make user-oriented decisions by eliciting information from the formative evaluations of users, and scenarios are useful to articulating new design concepts like TA. In HCI practice, *scenarios of use* are increasingly being used to help set overall design objectives for guiding various aspects of the design process. Carroll (1995) argues that if we believe the scenario approach to be a valuable enhancement of current development practice, we must ask how the use of scenarios in system development can be evoked, supported, and brought to bear on various activities within the system development cycle. Overall, this user-centered method is very effective regarding the following aspects. Firstly, Scenarios are used as a bridge between designers and users to define learners' or teachers' needs and learning environment in order to achieve learning goals. Secondly, prototypes are used to apply design issues and to demonstrate the expected learning environment concerning pedagogical value. Finally, user workshops are held to investigate user satisfaction to evaluate design issues and principles in terms of both technical and educational value.

Flexibility and Facilities In Children's Electronic Textbooks

Norshuhada Shiratuddin
Department of Information Science, University of Strathclyde, Glasgow, UK
shuhada@dis.strath.ac.uk, shuhada@uum.edu.my

Monica Landoni, PhD
Department of Information Science, University of Strathclyde, Glasgow, UK
monica@dis.strath.ac.uk

Abstract: Design of electronic books should take into account the diversity of learning styles, intelligences and preferences of each user. This project main aim is to provide high level of electronic book interaction and flexibility by matching different categories of electronic pages (graphic page, talking page, hypermedia page and web page) to the different learning styles. Each page exhibits programs and activities that attempt to cater for each learning style. The same content in each page will be presented in four different presentation modes. In addition to the technical system development, a conceptual model of children's electronic textbook will also be proposed. This model is based on Howard Gardner's theory of Multiple Intelligences and Philip Barker's generalization of electronic books model.

Introduction and definition of electronic book

Educational environment stresses the importance of reading materials: textbooks, reference books, encyclopaedias, magazines and newspapers as media of knowledge carriers. Hence converting printed publications especially textbook into interactive electronic form should prove to be extremely useful and helpful. There are various definitions of electronic book (e-book). Bonime et al. (1998) described any kind of information ranging from a CD-ROM title to an online interactive database including collection of web pages as electronic book. Barker (1998) defined e-book as essentially a computer-based information storage that embeds a book metaphor. More precisely (Barker, 1999), e-book is usually considered to be composed of a collection of reactive pages of electronic information that are organised in a thematic way and that exhibit many of the characteristic features and properties of a conventional book. Barker categorises e-book into ten types depending on the types of information embedded: textbooks, picture books, talking books, moving picture books, multimedia books, polymedia books, hypermedia books, intelligent books, telemedia books and cyberbooks. While Barker categorises ten types of e-book, Landoni et al. (1993) classified e-book according to three different criteria: books which are portable (e.g. personal digital assistant), books which preserve the logical structure (i.e. chapters, sections and subsections) and lastly, books that support both the physical and logical aspects of a paper book. In context of this project, definition of an e-book will be defined when the study is completed.

Research Question

Children learn in different ways. There are many theories on how people learn and one example is the Multiple Intelligences (MI) theory proposed by Howard Gardner (1993). This theory states that there exist seven intelligences (thus seven learning styles): verbal/linguistic, logical-mathematical, visual/spatial, bodily-kinesthetic, musical, interpersonal and intrapersonal (to date, two more intelligences have been added). Based on this theory, Armstrong (1994) wrote a book on how to apply this theory into the classroom environment. He identifies that each child could learn in any one of these ways or through a combination of several ways. With these different learning styles, design of e-books should take into account these diversity and attitudes of each user particularly young children. Thus, one question can be extracted: how to give young children better flexibility so as to cater their differences?

Proposed Solution: Giving E-Book Flexibility

There are many methods to give flexibility in e-books. One example is by providing tools or facilities, which can be used by users while consulting the e-book. Landoni et. al (1993) in her project provided users with facilities such as personalisation (highlighting, bookmarking, note taking), searching through TOC table of content and index, and printing. Other examples include providing system adaptivity, supporting for group-based learning, considering the likelihood that teachers will use the program in class and including different levels of contents in the books.

It is the intention of this on going project to suggest that another method to achieve flexibility is through flexible presentation modes that include programs and activities which match each learning style. The following gives few examples on how to match MI theory to the existing e-book model:
(a) Verbal/linguistic – Is matched with e-book concept of *hypermedia page* through programs such as letting users create essays, read aloud and include storytelling.
(b) Visual/spatial – Is matched with e-book concept of *graphic page* through programs such as letting users draw and paint and allowing users to read and see information as graphics, maps, charts and diagrams.
(c) Musical – Is matched with e-book concept of *talking page* through programs such as combining stories with songs and letting users sing along.
(d) Interpersonal – Is matched with e-book concept of *web page* by including programs, which need two or more users at the same time and group project or discussion.

Proposed electronic book model

Page = Contents + [Object A + Object B + Object C + Object D]
Object A = Graphic page + {Program G1 | Program G2 | …| Program Gn}
Object B = Talking page + {Program T1 | Program T2 | …| Program Tn}
Object C = Hypermedia page + {Program H1 | Program H2 | …| Program Hn}
Object D = Web page + {Program W1 | Program W2 | …| Program Wn}

Conclusion

In conclusion, our e-book shall exhibit four different concepts and include a number of presentation modes and styles, in order to provide readers with a high level of flexibility. Users can choose between the four different presentation modes when he/she opens any page. Upon completion, this project will be used to prove these assumptions:

H1:It is possible to address diverse learning styles by providing users with flexible presentation modes of each page.
H2:These flexible presentation modes are probably more appropriate to use and as such give e-book high level of flexibility.
H3:It is then possible to suggest that due to this high level of e-book flexibility, users are more likely to prefer this type of e-book.
H4:If H1,H2 and H3 are proven, then we could postulate that an additional desirable feature for e-book would be to present contents by mixing many presentation modes.

What Is So Revolutionary About The Internet In Education?

Peter B. Sloep, Ellen Rusman
Educational Technology Expertise Center, Open University of The Netherlands
The Netherlands
peter.sloep@ou.nl; ellen.rusman@ou.nl

Abstract: The Internet is making inroads into almost all quarters of our society. Education is no exception to that, nor should it. Exciting new ways of building content, of delivering it, of interacting with our students, indeed of managing our educational 'industry' can be seen to evolve. Even if one may not wholeheartedly support all these innovations, particularly for all those with an inquisitive mind it is inspiring to see education being rethought in so many and fundamental ways. Or is it?

The Internet revolution clearly is a technological revolution. It pushes developments in various fields, education being no exception to that. However, are the new technologies used to innovate education, that is, to bring about a genuine transformation; or do they just substitute older technologies for new ones?

An educational model that is widely implemented these days - although it doesn't alway go by this name - is that of the *extended classroom*. As the name suggests, an extended classroom takes the ordinary classroom as its starting point and extends it, mainly spatially. So the dominant didactic model here still is a teacher who addresses a group of students; students and teacher are simultaneously present; the teacher takes the lead; students may ask questions but those only serve to clarify the exposition of the teacher; students seldom interfere with the choice of content, which is the teacher's exclusive realm; students hardly ever have a say in the didactics used, this also is the teacher's prerogative. In the extended classroom, teacher and students may be in different locations, the distance being bridged by television, videoconferencing, audiographics and similar technologies. Put extremely, with the extended classroom one aims to mimick a regular classroom to the largest possible extent. Hence the call for ever larger bandwith, for systems that allow for 'natural' interactions between the teacher and the remote classroom, etc.

However cleverly designed our communication systems, however large our bandwidth, extended classrooms will always be second best, a substitution for the real thing, only useful as a means to reach out to the remote student, perhaps to serve larger groups of students and achieve some economy of scale. Lecture notes that are being put on the web as a service to the students, or e-mail and newsgroups that deliver additional support only serve to underline the main conclusion: in the extended classroom technology is used to substitute or augment existing teaching modalities.

Obviously, there is nothing inherently wrong with this. Technology is a means to an end and should be used accordingly, that is, how *we* see fit. However, if it is our lack of imagination or if it is the rigidity of our institutions that prevent us from using technology in more creative ways, then we should not rest content. We should reexamine our educational practices and ask ourselves to what extent they were limited by existing technologies and to what extent the new technologies empower us to innovate. And indeed, it is our claim that we only stand at the beginnings of truly innovative educational practices and genuinely new didactic principles.

Distributed learning is a term that is often used in this context. In distributed learning systems, there are no classrooms anymore, no teachers offering students prepackaged chunks of education carefully aranged to conform to the needs and capacities of the average student. Students now occupy center stage, assembling and arranging content that fits their specific needs; they take it in when and where it suits them best, perhaps in a didactic style that optimally matches their learning style. The role of the teacher now is not communicating knowledge, but to make it available, to empower students via intakes and assessments and help them assimilate knowledge, to offer custom support. In distributed learning, technological innovation is not the push behind educational innovation, as is the case in the extended classroom. Rather, the converse holds true, educational innovation pushing technology. And indeed, distributed learning requires specific technologies that extend beyond the mere facilitation of communication. Technologies are needed for creating learner centered content, for the delivery of such content, for flexible intake and assessment procedures, for portfolio management, etc. In our presentation we will discuss these technologies at some length.

Online Mentoring: A Case Study Involving Cognitive Apprenticeship and a Technology-Enabled Learning Environment

This paper describes a study aimed at investigating the impact of a technology-enabled training program for Project Executives (PE's) in the IBM Corporation. The program is focused on a mentoring approach to learning whereby PE's considered to be experts in specific skills coach less experienced colleagues in the development of critical skills. Since job demands prevent ongoing face-to-face mentoring relationships, technology which enables collaboration at a distance is implemented to support the mentoring relationship. Of interest in this study is the effectiveness of instructional design approach, the impact of the technology-enabled learning environment on sustaining mentoring relationships, and the nature of online discussions between experts and students.

IBM PE's are responsible for managing large information technology contracts. These professionals deliver on commitments to customers, ensure customer satisfaction, secure business opportunities, and mentor other project executives. Their role of mentor is critical to the professional development of less experienced colleagues. While traditional face-to-face mentoring is desired and encouraged, job demands often prevent mentors and students from sustaining the type of relationships needed for the transfer of critical skills.

In the current study, a combination of face-to-face instruction and a technology enabled learning environment is used to develop and sustain mentoring relationships among expert PE's and less experienced colleagues. The face-to-face instruction includes a two day workshop consisting of five sessions led by the expert PE's. The purpose of the workshop sessions is to 1) initiate a mentoring relationship among expert PE's and a group of colleagues and 2) to begin the mentoring process which includes the transfer of a specific set of problem-solving skills.

At the conclusion of the workshop participants are introduced to *e-mentor*, a Lotus Notes discussion database which can be accessed using a Lotus Notes Client or a Web browser. The discussion database is used to provide an online learning environment in which the mentor-protégé relationship is preserved. Mentors post mini-lessons on topics relevant to the development of complex problem-solving skills needed in customer situations. Participants respond to the lessons in discussion format, post questions and collaborate with one another in solving customer problems. Mentors are available to assist participants with appropriate strategies for addressing customer problems.

The instructional design approach used in the workshop and online is based on cognitive apprenticeship, an instructional approach developed by Collins, Brown and Newman (1989). Cognitive apprenticeship focuses on the development of higher level thinking skills such as problem-solving. Because of its focus on the teaching of cognitive and metacognitive knowledge, cognitive apprenticeship may be a more appropriate instructional design model for online mentoring than more traditional instructional designs such as a lecture approach. Whereas text and lecture-based instructional design models focus on teaching concepts, facts, and procedures in non-situated environments, cognitive apprenticeship focuses on teaching the processes and strategies used in expertise and how this knowledge is used to solve real-world problems. Snyder (2000) demonstrated the effectiveness of cognitive apprenticeship as an instructional design approach for teaching technical skills in an online environment.

Collins, Brown, and Newman (1989) and Collins (1991) identify four aspects of cognitive apprenticeship learning: content, instructional methods, sequencing of instruction, and sociology. Content refers to the different types of knowledge required for expertise and includes domain knowledge and strategic knowledge. Domain knowledge consists of concepts, facts, and procedures; strategic knowledge refers to knowledge which underlies an expert's ability to make use of concepts, facts, and procedures to solve problems.

Instructional methods are the learning activities used during instruction to help students construct, use, manage, and acquire new knowledge (Collins, Brown, & Newman, 1989). Seven instructional methods are recommended. These methods include teachers "modeling" skills, "coaching" learners as they attempt to mimic expert skills, providing "scaffolding" in the form of support for learners, and gradually "fading" support, as learners become more proficient. Learners are also encouraged to "articulate" their knowledge, "reflect" on their problem-solving processes, and "explore" new approaches to problem solve on their own.

Sequencing involves the staging of learning whereby tasks are presented in increasing complexity and diversity so that students develop a broad understanding of the domain of expertise. Sociology deals with the authenticity of the learning environment. Technological, social, time, and motivational characteristics of real-world situations are designed into the learning environment so that students will learn when, where, and how the knowledge applies to other situations (Collins, Brown, & Newman, 1989).

The PE workshop in this study and the e-mentor database are designed to incorporate the four aspects of cognitive apprenticeship learning. In the workshop, learning takes place in the context of solving a variety of real-world complex customer problems. Mentors begin sessions with an introduction a complex customer problem. Facts and concepts about the customer environment are presented (domain knowledge) and followed by modeling of the strategies and processes used to solve the problem. During this activity, mentors use think-aloud protocols to model the strategic thinking required to solve the problem. Next, tips and techniques (scaffolds) for remembering the processes and strategies are provided to students. Students are then assigned to small teams of six and work together to develop a solution to an existing customer problem. The problems used in this exercise are real-world and are brought to the workshop by students. Students are required to articulate the processes and strategies used to address the customer problem and then briefly explore alternative approaches to problem-solving. At the conclusion of this exercise, mentors model their thinking with respect to solving the team problems. When the two-day workshop ends, the mentor- protégé relationship is maintained using the Lotus Notes discussion database. Workshop participants use the database to request help from colleagues and mentors regarding problems experienced in the workplace. Mentors use of the cognitive apprenticeship method when responding in the online environment.

The results of this study to date have been successful in that this combination of face-to-face and online mentoring has enabled a community of IT executives who are geographically dispersed to form working relationships and share knowledge on a regular basis. This model has also provided participants with an environment for continuous learning on a just-in-time basis, convenient to their demanding work schedules. The instructional design approach has been notably successful in providing an effective way for PE's to learn new skills. Participants in the workshop quickly adopted the habit of thinking about problem-solving from a strategic perspective (that is, identifying the processes and strategies needed to solve customer problems and using reflection and exploration techniques before identifying a solution). This learning approach has also provided a common ground for PE's to work together to solve customer problems. Results of a survey administered to participants of the workshop indicated high ratings with respect to the methods fostering working relationships among PE's, the value of the content of the workshop, its structure (instructional design approach) and the value of the e-mentor database in providing a continuous learning environment which facilitates collaboration.

Abstract: This work-in-progress paper describes a pedagogical approach to designing an online collaborative learning environment that scaffolds learners in becoming better collaborative learners. This environment is based on Collaborative Problem Solving (CPS) instructional theory. The paper will overview the need for the environment, and the design principles used to design and develop it.

Need

As online education becomes more prevalent as a system for distance education, a need arises for an online structure that supports instructors and learners engaging in small group collaborative problem solving or project work at a distance from one another. Particularly, there is an increasing need for online learning environments that support effective, efficient collaborative processes, such as those used by expert group problem solvers.

When online environments impose restrictive structures or do not account fully for these processes, they may hinder the flow of learning, and curtail effective, efficient problem solving. Most online environments that attempt to use collaboration as a learning strategy incorporate a smorgasbord of communications technologies that are not structured according to research into the most effective ways to scaffold effective collaborative interactions. Furthermore, the applications included in these systems (such as email, threaded discussions, and file storage) are generally lower-level communication tools as opposed to tools that could support robust collaboration. Because they do not use a guiding theory that is pedagogically based, the resulting interaction often do not adequately address the social, intellectual, and logistical complexity of effective collaborative learning. This is partially due to the fact that until recently, no comprehesive theory capable of support effective online collaboration existed.

Specifically, the weakness of these approaches is their primary reliance on a document-based paradigm (such as Lotus QuickPlace or Hyperwave), conferencing-based paradigm (such as Microsoft NetMeeting or Lotus Sametime), or room-based paradigm (such as BioMOO or Diversity University) (Miao, Fleschutz, & Zentel 1999). For the design to fully support a cohesive collaborative learning approach, the strengths of each of these approaches must be synthesized into a context-based system that allows for a more flexible combination of people, places, tools, documents, and interactions than these other types of systems afford, thus providing robust support for the communication, collaboration, and coordination necessary to learn effectively as a small group.

Proposed Solution

We propose to design, develop, implement, and evaluate an online collaborative learning environment that both supports pedagogically sound instruction and provides appropriate scaffolding for moving learners from novice to expert collaborative learners. It will be based on Collaborative Problem Solving (CPS), an instructional theory designed for effective, efficient small-group problem solving (Nelson 1999). This theory outlines a detailed collaborative learning process derived from a series of carefully documented case studies of expert learning groups integrated with findings from current research in areas such as small group dynamics, cooperative learning, and problem-based learning. The goal of this theory is to provide step-by-step scaffolding to both instructors and learners that will help learners make the difficult transition from novice to expert collaborative learners.

Unlike existing tools that merely provide a collaboration platform, this online system will be designed to serve as a robust teaching and learning environment that will provide guidance for both instructors (in designing their instruction and in appropriately monitoring, supporting, and assessing the learners' progress) and learners (in developing effective collaborative skills while learning at a distance). This learning environment will be capable of scaling to any number of small groups and will support instruction in a variety of disciplines desiring to engage learners in project- or problem-based learning around complex, real-world problems. Its structure will afford support for every phase of effective small group collaboration, from building readiness to providing closure, by providing all the collaborative learning spaces, tools, and resources necessary to do so, such as "just-in-time instruction" for learners as they progress through the given project or problem scenario.

Project Goals

The goal is to create an online learning environment that has the following features and characteristics:

- Teaches and supports the nine phases, not just isolated activities, of Nelson's effective collaborative problem solving process, which includes: building readiness, forming and norming the groups, determining a preliminary problem definition, defining and assigning roles, engaging in an iterative collaborative problem-solving process, finalizing the solution or project, synthesizing and reflecting, assessing products and processes, and providing closure to the learning experience,
- Employs proven pedagogical theory and arrays tools around this theoretical structure,
- Responds to the needs of the users by being flexible, customizable, and reconfigurable,
- Runs entirely on open standards-based Internet protocols,
- Enables distributed groups to learn and work together at least as effectively as co-located groups,
- Provides guidance for both instructors and learners in effective collaborative learning, and
- Archives the work of small groups for both the group's reference and for research analysis.

Project Design

Our design approach is to translate each element of CPS theory into a corresponding aspect or structure of the environment, such that it both implicitly and explicitly supports effective, efficient collaborative problem solving philosophy and methods. From this blueprint, we will work with a software designer to create a data model. From the data model, the software designers will create a database-driven, internet-based collaborative environment that will scale to any number of small teams. Simultaneously, we will begin a paper prototyping phase to determine the initial visual design, working with a target user pool of instructors and students at the two distance education entities. We will then employ a rapid prototyping method to improve our visual design and address the usability issues of instructors and learners testing alpha versions of the system. Once we have a beta quality environment, we will conduct pilot studies with instructors and learners in diverse content areas and geographical locations. Finally, we will evaluate case studies of the system fully implemented in a variety of learning, work, and research settings and use the data to refine a final version that we will release for use on the local servers of any interested partners.

Abstract: This paper describes the implementation of a pilot project involving the formation of networked technology learning communities designed to nurture the growth and sharing of expertise in meaningful uses and integration of technologies into teaching and learning among college faculty members, student teacher candidates and classroom teachers. The paper focuses on issues related to the establishment of technology learning communities and includes brief studies of selected members of the learning communities.

Introduction

Recent studies (Trotter, 1997; U.S. Department of Education, 1998) indicate that a large majority of classroom teachers in the U. S. continue to feel inadequately prepared to integrate technology into classroom instruction. This work-in-progress paper describes the implementation of a pilot project that focuses on ways to address this problem. The project involves the formation of networked technology learning communities designed to nurture the growth and sharing of technological expertise among college faculty members, teacher candidates and classroom teachers in the integration of technologies into teaching. The project studies potential for such communities to enlarge the number of technologically proficient current and future teachers by increasing the number of college faculty members who model the use of technologies in their teaching, the number of teacher candidates exposed to technology-proficient college and classroom teachers, and the pool of technologically proficient classroom mentor teachers. Ultimately, the goal for this project is to support a cycle of increased meaningful integration of technology into teaching.

Technology Learning Communities

Technology learning communities provide "a culture of adult learning and mutual support" (McKenzie, 1999, p. 71) that enable individuals with different skill levels to assist each other in the learning of ways to integrate technologies meaningfully into teaching. Technology learning by members occurs in both informal and formal settings, with support and expertise provided when requested by members of the communities. These communities sustain the different learning styles of the members. The strength of a learning community lies in the emphasis on members teaching each other what needs to be learned and at a pace that meets individual needs and preferences (McKenzie, 1999). Emphasis in the pilot learning communities is on supporting projects that have a direct impact on teaching and learning.

Inherent in the formation of learning communities with membership from diverse groups, i.e. college faculty, college students, and classroom teachers, are many challenges. If a learning community is to be successful, membership must be "flat and non-hierarchical" (McKenzie, 1999) in the sense that all members are equal partners. Ideally, the learning communities should have an impact on education that radiates beyond the communities. The focus of each member of a community must be on ways to use technology to improve teaching, not simply on the development of individual technological expertise. Members of a learning community must accept the responsibility to take the acquired skills and knowledge back to their circle of professionals. Each member must be willing to build on acquired skills and knowledge, even after the pilot project ends.

Each ten member learning community in this project is composed of college faculty members, teacher candidates, and preK-5 teachers, with varying degrees of technological expertise. Criteria for membership were established prior to the formation of the learning communities. Student members were selected based on meeting those criteria and documented faculty support for their membership. Faculty members and K-5 teachers meeting the criteria and having a range of technological expertise were identified and invited by project leaders to participate in the project. The members of the current learning communities appear to have successfully established a non-hierarchical relationship partly due to the selection process. Each member of the learning communities is equipped with a laptop computer and Internet access to facilitate collaboration.

In the initial meeting of the learning communities, members were surveyed on their levels of technology expertise and discussed their learning expectations. This information assisted the coordinator of the learning communities in planning group learning sessions. In addition to these face-to-face meetings, members of the communities interact using email and a discussion list. The discussion list, TechTalk, provides a mechanism for members to share and request resources, and to obtain fast response to technology-related inquiries. With support from learning community members, the college faculty members are increasing technology use in the courses they teach. The teacher candidates have the opportunity to assist in the implementation of technology-based lessons, to design lessons and materials to be used during student teaching with preK-12 students, and to work with the college faculty members as they integrate technology into courses. The classroom teachers are sharing and expanding their expertise in integrating technology into the preK-5 curriculum.

Members of the learning communities have formed partnerships as reflected in interviews done with one student and one faculty member in the communities. Faculty Member A is a beginning technology user, though she is knowledgeable about the Internet. As a college history professor, she wants to explore the use of the Internet not as an electronic library reflected in the web sites that she includes in her syllabus bibliography, but as a vehicle to encourage her education students to think critically about events in history. She finds the learning communities helpful in learning about social studies issues important to elementary teachers but receives the most help from one-on-one tutoring from individual members. She is especially appreciative of the help from Student B, an above average technology user, who acquired many of her skills at the college. In addition to tutoring Faculty Member A, Student B is helping two classroom teachers in her learning community to teach their students HyperStudio. She finds that the learning communities aid her goal of being a teacher because through this collaboration she is spending time in a classroom setting working with children.

Evaluation of the progress being made by members of the learning communities in meeting the initial goals of this pilot project is encouraging. This project is providing the groundwork for modification and expansion of future technology learning communities.

Four Challenges for TeleTeachers in Rural Schools

Ken Stevens, Memorial University of Newfoundland, Canada

The introduction of telelearning in schools in Canada, as in other developed countries, has been particularly noticeable in rural areas and has been influenced by declining school enrolments. There are four challenges common to the technological enhancement of rural schools: the building of appropriate infrastructures, the location of appropriate technologies, the development of pedagogy for teleteaching and the need for on-going professional development.

Challenge One: Building Appropriate Structures (Digital Intranets)

By constructing web-sites both teachers and students in a rural school can enable people located almost anywhere to connect with them and learn about their programs and activities. In Canada regional and national educational networks link classes in schools on dispersed sites. Stem-Net in Newfoundland and Labrador in eastern Canada is the provincial arm of the federal SchoolNet System. These federated electronic structures enable teachers to extend the curriculum available to learners in dispersed and, often, very isolated sites. Schools in rural Canada are developing open and flexible academic and administrative structures as they electronically link with one another. These new structures exist within the traditional and, by comparison, closed school systems in each school district. In the open educational structure of teleteaching within digital intranets, constructed to link schools for the delivery of specific courses for some students, participating institutions academically and administratively interface for that part of the school day during which classes are being taught. This is a very different educational structure from the traditional and, by comparison, closed educational environment of the autonomous school with its own teachers and its own students. In Canadian networks such as Stem-net, each site becomes an inter-dependent part of a virtual school, without which it could not provide all the courses that local people are increasingly accessing.

Challenge Two: Finding Appropriate Technology

As schools become teaching and learning sites within digital Intranets, there is increasing demand for adequate technological support and co-ordination. Few teachers have the skills to provide adequate technological support for the increasing numbers of computers and computer users in their schools. The result is that the emerging teaching and learning infrastructure in many places is often very fragile. An essential aspect of the development of open electronic classes is the coordination of both hardware and software between schools. Without coordinated technology, schools cannot fully participate in electronic networks. However, the purchase of appropriate hardware and software is a matter of confusion for many principals, teachers and School Boards who seek support and advice. Many rural schools with open electronic classes realize that the successful administration of a network requires local technical support. Unless adequate technical support systems can be established, electronic networked classes could be curtailed by teachers who could argue, with justification, that there is insufficient back-up to justify their investment in telelearning. The need to have people in schools, or available to schools, to maintain information technology hardware and software is, for many teachers, a matter of growing importance. In geographically isolated communities the assurance of adequate technical backup is, however, often particularly difficult to provide for teachers and principals. In schools in Newfoundland and Labrador, the majority of which are designated rural, telelearning often depends on the goodwill of one or two teachers with enough knowledge to keep computers going when they mal-function.

Challenge Three: Pedagogy for TeleTeaching

In the changing technological environment, teachers often have a choice of teaching face to face and, for part of a school day, providing or receiving instruction for their students at a distance. This can be done in synchronous or asynchronous mode, with a range of technologies, and with a range of learners. The use of information technologies in schools has been vigorously promoted by the federal agency, Industry Canada (Information Highway Advisory Council, 1995;1997). Students often have more independence in managing their learning in open electronic classes but most have to be assisted by teachers in the setting of goals, the meeting of deadlines and in evaluating their progress (Stevens, 1996). Teachers are effective in open electronic classes if they can be flexible in ways that they allow students to participate in on-line lessons. Strategies and protocols for on-line teaching have to be developed between participating schools if all students are to be able to fully participate. The introduction of a rural school to an open electronic network considerably improves its resource base for both teachers and learners, but does not solve all of its problems. It is often difficult to coordinate the timetables of networked schools and a considerable measure of inter-institutional and intra-institutional cooperation is required to develop detailed and effective plans for collaboration. The need for rural networked schools to have a close relationship with the suppliers of technology has become increasingly apparent to schools, school boards and to technology retailers. Rural schools with telelearning infrastructures require expert advice and support from technology suppliers at the network rather than at the individual school level. There are several immediate pedagogical challenges to be considered for effective teaching in a digital Intranet:

1. Teachers have to learn to teach from one site to another. This is fundamental to the success of teleteaching. Teaching face to face and on-line are different skills.
2. Teachers have to learn to teach collaboratively with colleagues from multiple sites.
3. Teachers have to judge when it is appropriate to teach on-line and when it is appropriate to teach students in traditional face-to-face ways. These judgements have to be defended on the basis of sound pedagogy.

Challenge Four: Professional Development for TeleTeaching

A difficulty many teachers face in Canadian schools is simply finding the time in their busy days to learn about information and communication technologies. It is impossible for some teachers to do this, let alone reflect on how new technologies can be integrated into their classrooms and their professional lives. There is not only a widespread need for professional development for teleteaching; there is a need for it to be provided on a continuous basis. A second challenge facing many teachers is finding effective ways of integrating information and communication technologies, including the Internet, into teaching and learning. It is not difficult to add information and communication technologies to any classroom but it requires considerable planning to integrate technological developments so that both teaching and learning are enhanced. A third challenge for the professional development of teachers is to be able to justify, on the basis of professional judgements, why the Internet and other technologies should be used in teaching and learning at all.

Conclusion

The introduction of inter-school electronic networks has added a new dimension to rural education in Canada and in other developed countries. In Canada and in many other places, teachers and researchers are seeking appropriate ways of using existing as well as emerging technologies to enhance teaching and learning. The teachers and researchers who are collaborating in the development of new electronic structures for delivering education to dispersed, rural sites in Atlantic Canada are very conscious of being pioneers. Both realize there is a lot to learn to about both teaching and learning in this new environment.

Group interaction as a predictor of learning effectiveness in a computer supported collaborative problem solving

Neli Stoyanova
Faculty of Educational Science and Technology, University of Twente

AE 7500 Enschede, The Netherlands.
stoyanovn@edte.utwente.nl

Abstract: The paper presents an experimental validation of learning effectiveness of three different types of group interaction for computer mediated collaborative learning and problem solving. The assumption underlying this research is that the form in which knowledge is shared in collaborative learning is a substantial for cognitive construction and reconstruction. The experiment revealed that the learning effectiveness is influenced significantly by the mode of group interaction that depends on the extend to which students share their learning not only as results but also as a process of knowledge acquisition and creation by a direct interaction.

Theoretical background and research question

Rapidly changing technologies generate new requirements for creating computer environments that support learning in the broad context of global networking communities. Different theoretical perspectives emphasise collaboration as a successful and powerful activity for learning and problem solving.

Collaboration creates an extension of the internal cognition of the personality in outside world (Perkins, 1993). According Salomon (1993) the individuals' and the shared group cognitions interact with one another in a spiral-like fashion whereby individual inputs, through students' collaborative activities, affect the nature of the joint, shared system, which in turn affects their cognitions. It is emphasised that reconstruction of individual cognition requires a profound and mutual understanding of collaborators' perspectives and shared interpretations of the problem. Only the knowledge that is meaningful for individuals could be internalised.

The assumption underlying this research is that the form in which knowledge is shared in collaborative learning is a substantial for cognitive construction and reconstruction. The main research question is: *Is the mode of group interaction a predictor of learning effectiveness in a computer based collaborative problem solving design?*

Collaborative scenarios

Three scenarios of problem solving group interaction have been designed, based on the assumption that knowledge exists in three forms: as individual mental constructs and precepts, as knowledge in action, and as knowledge embodied in artefacts (Hedlund & Nonaka, 1994)

1. *Distributed interaction.* Group members work autonomously and produce intermediate artefacts embodying their knowledge and visions, which are passed to the other members. This circuit is repeated until all group members reach a common vision of the problem. The process of knowledge acquisition, creation and internalisation is individual.
2. *Moderated interaction.* Interaction process is facilitated by a group moderator (the role is taken by one of the group members) adjusting individually produced artefacts until a common group vision is reached. The representations of individual cognitive structures are not directly accessible but group members are involved in the process of negotiation of meanings and ideas that take place between them and the group moderator.
3. *Shared interaction.* Group members interact directly by synchronous activity and common efforts to solve the problem as a group. They share their knowledge in action. Knowledge is communicated in the process of its acquisition and creation and is not mediated by intermediate artefacts. Collaborative actions of students are the individual inputs toward shared cognition.

Experimental validation

The learning effectiveness of the three modes of group interaction was tested experimentally. The experimental design was a random assignment pre-test post test control group. The independent variable was the mode of group interaction with three levels – "Distributed" "Moderated" and "Shared".

The dependent variable was learning effectiveness operationalised as individual learning achievements in terms of: *fluency* (number of concepts representing individual understanding of the problem), *flexibility* (variety of concepts and ideas), *knowledge acquisition* (number of new concepts acquired), *individual-to-group transfer* (individuals' inputs in the group solution), *group-to-individual transfer* (concepts derived from the group solution), *reconfiguration* (changes in the concepts' structure), *retention* (contra indicated by the reduced concepts), and *creativity* (new concepts and ideas generated individually after the collaboration).

Twenty-six students (6 groups) of University of Twente, Faculty of Educational Science and Technology, enrolled in "Linear and Hypermedia" course, were selected as experimental subjects and were randomly assigned to the three collaborative scenarios. The group task was formulated as an open-ended problem. Concept mapping technique was chosen for representation and communication of knowledge because of its effectiveness as a tool for externalisation and representation of cognition. (Stoyanov & Kommers, 1999). Data was analysed applying one-way ANOVA procedure by SPSS 9.0 statistical package.

Results and Discussion

The results are significantly predictive for the learning effectiveness of the three group interaction scenarios. The mode of group interaction influences significantly the knowledge fluency (Sig. = .047), concepts acquisition (Sig. = .045), and group-to-individual transfer (Sig. = .004). On these criteria students in Shared groups scored significantly higher than students in Moderated and Distributed groups.

All three scenarios enabled students to present and incorporate their knowledge in the group process. No significant difference was found on individual-to-group transfer.

Shared mode was highly beneficial for acquiring knowledge both from each other and from taking new perspectives in exploring the problem space. A significant part of the knowledge that was elaborated in group session were incorporated as a meaningful part of students' cognitive structures and transferred to individual cognitions.

Students working in Moderated mode incorporated less new concepts in their personal cognitive structure than students in Shared mode. Only those aspects of the group solution that were developed by the personal participation of a particular student were internalised in his/her cognition.

Regardless that students in Distributed mode had a broad access to all other students' knowledge representation they were not able to gain enough from the externalised experience of the others.

Both the Shared and Moderated mode proved their potential for reconstruction of the individual cognition represented mainly by reshaping of map spatial configuration. Significant interdependence between common group problem solution and the individual outputs was found. Students working within Distributed mode resist on their prior conceptual structure.

No significant difference was found on criteria of knowledge flexibility. The three types of groups were able to explore the problem space from different perspectives and within different conceptual paradigms.

Surprisingly, the individual creativity was not influenced by the mode of group interaction.

Nevertheless no significant difference was found (Sig. = .345), it should be stated that students working in Shared mode showed a lower level of retention of their initial concepts than the students in the other two modes.

In summary, the experiment revealed that the learning effectiveness is influenced significantly by the mode of group interaction. In general, Shared interaction scenario proved to be the most effective in collaborative learning and problem solving. These leads to the conclusion that the learning effectiveness depends on the extend to which students share their learning not only as results but also as a process of knowledge acquisition and creation by a direct interaction.

Re-usability problems in large-scale content management of database driven Web based environments

Abstract: Thc use of databases involves assigning resources to users with changing access rights. How will the information be presented to the right users? How can resources be reused for different audiences and how should access rights be provided. Who has the right to change, who can read it and who is owner of the objects in a resource base?

Introduction

The faculty of Educational Science and Technology started a faculty wide implementation of Telelearning with the TeleTop project in 1997. The aim of the project was to support teachers and students with a web based database driven environment. Two years later the entire university, including ten faculties, is ready to the implement the Teletop system. How reuse of material should be provided is a point of research because content management can make the use of objects more efficient.

The problem of assigning resources to people

Scaling up a course management system means that more information will be stored. Reusing includes retrieving stored information. Finding relevant material and assigning this material to the right users is a problem because of the large amount of objects and the large scale of users. A second point of attention is the use of access rights. Access rights are used to give users rights to read or change objects. Using databases includes controlled access to different objects for different users.

Objects:

Every object has users that can read or use the object, users who are able to change or create the object and users that can actual delete an object. These rights are set in the access control list and every database uses some sort of access control list to control access objects in a database. These objects can consist of (elements of) learning material, course descriptions, assignments, multimedia fragments, HTML pages or any other type of digital content. Controlling access to information is needed so that copyrights or confidential material can be stored in a protected environment; i.e. an environment that is not accessible for unauthorized users.

Users:

Users are mostly unaware of these access control lists, because software developers make these environments as easy as possible by not showing objects that users are not authorized to see. The problem in most cases is that objects may be accessible for one user, but not for another. Resources available for teachers may not be accessible for students. Assigning students to these resources may result in irrelevant links for the students. This makes reuse for different users and audiences a difficult issue. This problem has not earlier been identified because most web-based environments are still pilots or prototypes. A faculty wide implementation includes a large number of users who can create objects and even more users that should be able to use these objects. Dealing with a large scale of objects and really reusing these in database driven courses is a new development.

Solution for large numbers of objects

Maintaining access control for every single object in a very large resource base is not manageable. Managing many (more than 10.000) users over many (more than 10.000) objects is a realistic example in our situation at the University of Twente. Combining a number of related objects in a course is a solution to make control access rights manageable. In this way it is possible to assign a set of objects to several predefined user groups comprised of teachers or students. One group can be assigned the role of author and other groups as readers. Copying objects to new courses can involve reuse of objects. This method has been sufficient until now, because in most cases instructors wanted to reuse only the material created by themselves. Reuse as described gives the possibility to make changes to objects for the new audience.

Making objects more flexible

Considering the results of reuse we recently developed a new model for access rights. This model is based on roles that are assigned to user groups. A user group is a list of people who can access the same functionality in a database. So the access control of every object in a course depends on the role a user has. Three roles where identified: Teacher, student and administrator. Using roles makes reuse possible by employing an abstract access level that can be used over courses and provides a consistent control of rights. Objects can be used in every course without changing access control lists of involved courses. The development of a resource browser is in progress. In the first place reuse of objects within a course is being researched, in the second place exchange of objects between courses will be researched.

Challenge, future plans

In the next years reuse of objects at the university level should be supported. Objects should be reused within courses, between courses and faculties. Even different universities should be able to reuse objects in courses. Therefore, interfaces should be developed that support users selecting the right resources. Also, access right models have to be developed. Another objective of our research should be directed at the ownership of objects; i.e. copyrights. Ownership can be seen as part of the access rights involved with objects. Is a user who creates an object the owner and is this user the only one who may reuse or add or edit this object? Who owns such copyrights? All these points need further research. In this respect it is important to note that a number of organizations involving standards for learning technology and related issues are aware of these problems and are trying to find solutions, but until now there is not a standard way to handle large scale resource bases. Examples of these organizations are the Instructional Management Systems project (IMS)[1], the Alliance of Remote Instructional Authoring and Distribution Networks for Europe (ARIADNE)[2], the IEEE 1484P Learning Technology Systems Architecture (LTSA)[3], Advanced Distributed Learning (ADL)[4] and the Aviation Industry CBT Committee (AICC)[5].

Abstract: As the Internet brings new means of presenting information to learners, the need for meaningful assessment increases. We describe the design and development of a computer tool to facilitate a particular form of assessment that can be meaningful in online learning contexts. The tool combines a web browser with an annotation facility, a database, and special means for visualizing assessment data captured with the tool.

Introduction:

As educators explore the many possibilities for delivering instruction online via the Internet, they tend to focus primarily upon delivering presentations of information. The forms of presentation include web pages and web sites, text, images, audio clips, video clips, queries to databases, and Java applets that run simulations. In addition to the information itself, the Internet also enables the online gathering and experience of groups of people who might (or might not) be physically distant from one another. The online communities of learners can be formed such that the members are all at a very similar level of expertise in the subject they are studying. What is largely missing from these innovations, however, is a form of educational assessment that is well adapted to the new patterns of learning.

Assessment is sometimes regarded as the unpleasant part of education, in part because traditional testing is sometimes distasteful to students and because assessment is typically considered less important to the presentation of information. However, studies of assessment in support of learning (rather than in support of administration or of college admission, for example) have lead to recommendations for alternative assessment methods such as performance assessment, authentic assessment, portfolio-based assessment, and continuous assessment (see Tanimoto, 1998). These methods offer the possibility to make assessment a more "natural" part of the learning process, and to permit learning to occur with less stress and in ways more in line with workplace goals. Yet these methods are often difficult to implement because they may require more teacher training, more teachers' time spent on assessment, and because their results may seem to be more subjective than the results of standardized tests. We have developed a software tool for assessment to help us explore one approach to assessing online learning. The tool, called INFACT, permits the assessment to be performed unobtrusively in a manner reminiscent of psychologists' observations from behind the glass wall.

Pedagogical Approach

Our approach to assessment takes place within a particular pedagogical methodology. We have applied the methodology in two subject areas: high-school physics and undergraduate statistics. Students in the class are divided into groups of 4-6 students each. An instructional unit lasts one week. On Monday, a problem that requires conceptual thinking is posed by the teacher. Each student in the class is told to make her/his own interpretation of the problem and suggestion for solving it and to write and post a newsgroup entry using a specially modified version of the HyperNews software from the University of Illinois. The posting is due by 12 noon on Tuesday. This initial post is invisible to other students until a virtual curtain is lifted shortly after noon on Tuesday, at which time it becomes visible to the other members of the student's group. The students are then required to respond to each other's postings in an online discussion, and they are told to come up with a group solution by Friday. Over the course of the week, their postings accumulate, creating an archive which feeds our assessment tool, INFACT.

INFACT stands for "Integrated Networked Facet-Based Assessment Capture Tool." It is used by teachers to view and annotate student newsgroup postings in such a way as to build up a database of assessment information that can be used to track student and group progress in understanding the concepts of the instructional unit. INFACT makes use of catalogs of standard misconceptions that students commonly have about a subject. Each misconception is called a facet, and facets are grouped into clusters such that all facets in a cluster represent misconceptions about the same concept. A facet catalog must be compiled in advance of using INFACT for assessment. However, it is possible to refine a facet catalog in the course of assessment. INFACT makes the assumption that facets can be linearly ordered by their "level of expertise" (see Minstrell 1992 and Hunt and Minstrell 1994 for details).

The Design of INFACT

INFACT comprises the following components: an integrated web browser, a database (currently an MSQL database), dialogs for creating and editing assessment items, and a visualization component. The browser component permits the teacher to load and view HyperNews postings in essentially the same form that the students see when they read and post. This component also supports creating selections of text within the document being viewed. The INFACT software determines (insofar as possible given the limitations of available browser software) the start and end positions within the document where the selection occurs. Selections of this form can then be annotated.

Annotations of two types are permitted: facet annotations and free annotations. A facet annotation represents an atomic assessment item, and it consists of the text selection, a reference to the document in which the text occurs, identification of the student who authored the text, identification of the assessor, reference a particular facet for which this text provides evidence, a certainty value given by the assessor, the date of authoring and the date of assessment. A free annotation is simply a comment associated with the selection. The assessor can check a box associated with each annotation to make it visible to the student. The database is used to keep track of the annotations and to make assessment items retrievable by student, by facet cluster, by date, etc. The database also holds the facet catalog. The visualization portion on INFACT permits the user (usually the teacher) to call up assessment data by student, by group, by date, or by facet cluster. The user can also view graphs that help to reveal trends in the data. Two types of graphs supported by INFACT are (a) histograms of facet frequencies, and (b) facet transition diagrams. The latter show how one or more students' misconceptions about a concept change over time.

As a teacher reads student postings with INFACT and makes annotations, s/he can use INFACT to send feedback to the students. INFACT supports two means of feedback: direct email and student-visible annotations. Direct email permits the teacher to send a message to a student in the context of an assessment item. This can be used to get clarification from the student about something not clear from the posting. It can also be used to commend the student or to make a suggestion. However, its main value over email from ordinary mail programs is the automatic association created between the message and the assessment context in which it originates. INFACT makes it possible for the teacher to include a multiple-choice question in the message that when answered online, provides additional evidence in favor of one facet or another within the facet cluster associated with the assessment item. For a screen shot of INFACT, see http://www.cs.washington.edu/research/metip/crlt/infact-1.gif

E-mail: mvirvou @unipi.gr, vtsir@unipi.gr, eagle@ath.fothnet.gr

Introduction

The primary aim of educational software is to help students learn. Therefore, evaluation of this kind of software is crucial. Its aim is to test the functionality and usability of the design and to identify and rectify any problems (Dix et al. 1993). In particular, formative evaluation is one of the most critical steps in the development of learning materials because it helps the designer improve the cost-effectiveness of the software and this increases the likelihood that the final product will achieve its stated goals (Chou 1999). In this paper, we present and discuss the evaluation of an intelligent tutoring system for the passive voice of the English language using the CIAO! framework (Jones et al. 1999).

The Passive Voice Tutor

The tutoring system that we developed and evaluated is called Passive Voice Tutor (Virvou & Maras 1999a; 1999b). The Passive Voice Tutor complies with the architecture of most ITSs, which consists of the domain knowledge, the student modeller, the advice generator and the user interface (Wenger 1987).

In particular, the domain knowledge of the Passive Voice Tutor comprises knowledge about how to convert a sentence from active to passive voice and vice versa. It also provides the knowledge needed for the dynamic construction of new exercise sentences. Finally, it comprises knowledge about the semantic relation between the words used for the construction of new sentences.

The student modeller checks the student's answer and in case of error, it performs error diagnosis. It contains a bug library of the most common student errors and generic mal-rules that students often apply when they have misconceptions. Another responsibility of the student modeller is to keep a history record concerning each student's progress in learning. This record is used in cases were ambiguity arises, so that the system attributes a particular error to a category of errors that the student seems to be prone to.

The advice generator is responsible for responding in the most appropriate way to a student's error, by informing the user about the cause of the error and by showing to him/her the relevant part of the theory. Finally, the user interface of the Passive Voice Tutor, is a multimedia user interface, which involves animations, sounds and a limited form of natural language so that it can attract the student's interest.

The Evaluation

The CIAO! framework outlines three dimensions to evaluate: (i) context; (ii) interactions; and (iii) attitudes and outcomes. One important aspect of context is the reason why CAL is adopted in the first place, i.e. the underlying rationale for its development and use; different rationales require different evaluation approaches. According to the framework, the reason for looking at students' interactions with the software is in order to understand more about their learning processes; such interactions can provide protocol data for later analysis. Finally, at the "outcomes" stage, information from a variety of sources needs to be used including, pre and post-achievement tests, interviews and questionnaires with students and tutors. The overall emphasis of this framework is on educational issues.

There are many other evaluation techniques, such as the JIGSAW model (Squire & Preece 1996) or the 'set of learning with software heuristics' (Squires & Preece 1999), which also address the problem of integrating both usability and learning issues in the evaluation of educational software. In the JIGSAW model, the evaluation is performed in three levels. In Level 1, the subtasks of the learning and operational tasks are considered independently of each other. As we move from Level 1 to Level 2, integration within the learning and the operational tasks is considered. At Level 3 integration between the learning and operational tasks is considered. On the other hand, the set of 'learning with software' heuristics, are an adaptation of the "usability heuristics" presented in Nielsen (1994), so as to relate them to socio-constructivist criteria for learning. These heuristics include the need to consider appropriate levels of learner control, the need for the prevention of peripheral cognitive errors and the need for strategies for the cognitive error recognition, diagnosis and recovery cycle. The CIAO! framework, seemed to be a more suitable method, in the sense that it also evaluated the students' use of the resource package.

For the evaluation along the dimensions of the CIAO! framework, presented above, we have done the following:

i) **Context**: The underlying rationale for the development and use of the Passive Voice Tutor is to help students during the process of learning. Hence, one of the primary aims of the system is to address individual learners' misconceptions and help them correct their errors. Evaluation in terms of the context has been addressed by questionnaires to human tutors before their students had ever used the system. This was done so that the domain knowledge and student modeller could be evaluated. In particular, tutors were given a set of erroneous answers to questions relating to the domain, which were generated using the system's domain knowledge and bug library. For each question, each tutor had to provide an explanation as to what s/he thought the underlying misconception of the error was. Each human tutor's explanation was compared to the Passive Voice Tutor's explanation. A satisfactory degree of compatibility was found (45%). However, the comparisons also showed that the explanations could be improved at a later version of the Passive Voice Tutor.

ii) **Interactions**: On a second phase, tutors were asked to evaluate the system, after their students had interacted with the Passive Voice Tutor. Protocol data was collected through the individual long term user model of each student. This kind of protocol data was first automatically analysed by the student modeller and resulted in information that concerned the student's individual way of learning. Then, human tutors were also given the same set of students' protocols and were asked to analyse them. Finally the tutors' analysis was compared to the system's analysis. To a large extent, human tutors had similar beliefs to the system's beliefs about the students who took part in this evaluation stage.

iii) **Attitudes and Outcomes**: In the case of the Passive Voice Tutor, at the outcomes stage, questionnaires were given to students and tutors. Students' questions included the following: "Did you consider the system responses to your errors helpful for understanding your mistakes?" Tutors were also asked to evaluate the outcome of the use of the system, after their students had interacted with the Passive Voice Tutor. Therefore, the teachers were asked to provide information about whether the software helped them to understand better the difficulties that their students had in learning the passive voice of the English language. Tutors also seemed quite satisfied by the system's student modelling component. Finally, the progress statistics of each student that had been recorded in his/her long term student model was also used at this stage of the evaluation. The analysis of this kind of data showed that the majority of students (57%) made a progress in their learning, whereas only 43% did not seem to have any progress in their learning of the passive voice. This is an encouraging result in terms of the educational effectiveness of the system.

Conclusions

The CIAO! framework for evaluating educational software has provided insight for several aspects of the software that needed evaluation at several stages; e.g. before any student had interacted with the software and after. In this way, both learning effects and usability issues could be evaluated. The results of the evaluation showed that the Passive Voice Tutor was quite satisfactory but there is scope for improvement in terms of the explanations provided by the system.

Introduction

Web-based education has the obvious benefit of allowing platform independent access to easily updated teaching material. Recently, a large number of educational applications have been delivered through the World Wide Web. Unfortunately, most of these systems are static, they do not maintain a student model and thus they are unable to provide individualised tutoring. Nonetheless, the future of web-based education seems promising since researchers in the field of Intelligent Tutoring Systems have made quite successful attempts to either move existing ITSs to the WWW or build from scratch web-based ITSs (Eliot et al., 1997; Stern et al., 1997). However, the development of an ITS requires the involvement of a large number of people, including experts of the specific domain, instructors and programmers. A way to overcome these problems may be the development of authoring tools, which will help construct cost-effective and reusable ITSs in various domains. One such authoring tool for ITSs is WEAR (WEb-based authoring tool for Algebra Related domains). WEAR incorporates knowledge about the construction of exercises and a mechanism for student error diagnosis that is applicable to many domains that can be "described" by algebraic equations (Virvou & Moundridou, 1999).

WEAR uses a talking head in its interface with the students. Animated characters have often been used in the interfaces of systems (Rist et al., 1997; Stone & Lester, 1996). Such an interface makes a system more appealing and attractive to the user and if talking about an educational application it may also promote the learning objectives. Walker et al. (1994) investigated subjects' responses to a synthesised talking head displayed on a computer screen in the context of a questionnaire study. Their findings showed that compared to subjects who answered questions presented via text display on a screen, subjects who answered the same questions spoken by a talking head spent more time, made fewer mistakes, and wrote more comments. In this paper we describe how the talking head is used in the whole educational application.

Description of the System and its Interface

WEAR aims to be useful to teachers and students of domains that make use of algebraic equations. Such domains could be chemistry, economics, physics etc. In particular the tool accepts input from a human instructor about a specific equation-related domain (e.g. physics). This input consists of knowledge about variables, units of measure, formulae and their relation. When the human instructor wishes to create exercises s/he is guided by the system through a step by step procedure. At each step of this procedure the instructor specifies values for some parameters needed to construct an exercise. Such parameters could be for example what is given and what is asked in the exercise to be constructed. After the completion of this procedure the tool constructs the full problem text and provides consistency checks that help the instructor verify its completeness and correctness.

WEAR assigns to each student a level of knowledge according to his/her past performance in solving problems with the tool. The tool suggests each student to try the problems corresponding to his/her level of knowledge. When a student attempts to solve an exercise the system provides an environment where the student gives the solution step by step. The system compares the student's solution to its own. The system's solution is generated by the domain knowledge about algebraic equations and about the specific domain in which the exercise belongs (e.g. economics). While the student is in the process of solving the exercise the system monitors his/her actions. If the student makes a mistake, the diagnostic component of the system will attempt to diagnose the cause of it.

When interacting with the students WEAR responds through a talking head, representing in some cases the instructor and in some others a co-student. The talking head component of the system uses speech synthesis to automatically produce speech output from text using MBROLA, a freely available speech synthesiser (http://tcts.fpms.ac.be/synthesis/mbrola.html). The talking head renders the interface quite attractive to students through the sound of speech. Moreover, since WEAR is an authoring tool for ITSs there are a lot messages that are dynamically formed during the execution of the application. Therefore, the authoring tool could not use pre-stored material for the speech feature but rather a speech synthesiser.

In the case when the talking head represents the instructor it guides the student to the environment, recommends what problem to solve next and reads the problem text from the database of the authoring tool. Since WEAR is an authoring tool, new exercises are continuously added to its database. When the student begins to solve the problem, s/he may choose to solve it either with a simulated "co-student" or with the "instructor". These two different choices are only on the level of the user interface. This means that they use the same underlying reasoning abilities from the diagnostic component of WEAR.

If the student selects the mode of the "co-student" then the talking head provides very friendly messages as a peer to the student. This simulated student is responsible for providing positive feedback when the student's actions are correct and for pointing out the student's underlying misconception in case of an erroneous action. The information concerning which actions are considered correct or not and also the messages that the simulated student should say are provided by the diagnostic component of WEAR. The talking head as a simulated student is aimed at increasing the student's attention and possibly collaboration attitude (although in a limited form). Indeed as VanLehn et al. (1994) have pointed out peer learning even in a setting where the other peer is a simulated student may increase students' collaboration skills.

If the student selects the mode of the "instructor" then the talking head provides messages similar to the "co-student" but they are more formal and the diagnosis of misconceptions goes one step further to resolve ambiguities using the long term student model. Indeed, there may be cases where a student's erroneous action may be attributed to more than one misconception. In such cases, the diagnostic component first consults the long term student model and then through the talking face asks the student a question to determine his/her underlying misconception and resolve the ambiguity. The benefit of directly asking the student is twofold: firstly, the system may find out the real reason for the erroneous action and provide appropriate feedback and secondly, the student through explaining why s/he acted in that way gains more knowledge and understanding. It is a common finding in many researches that explaining things either to oneself or to another student helps one's understanding (Webb, 1989; Pressley et al., 1992).

Conclusions

In this paper we described the work in progress of the development of a web-based authoring tool for Intelligent Tutoring Systems. The tool, called WEAR, aims to be used by teachers and students working in domains that make use of algebraic equations. In this paper we focussed on the interface of the ITSs that are generated by WEAR: animated talking heads are used to simulate both the instructor and a co-learner of the student solving a problem. In that way, instruction and feedback are more "human-like" resulting in friendlier and more appealing ITSs. Furthermore, the students interacting with WEAR, may gain better understanding of the domain being taught and also improve their ability to collaborate with others; benefits that arise from the peer learning situation in which the students are involved.

A Domain-Independent Reasoning Mechanism for an ITS Authoring Tool

Maria Virvou
Department of Informatics, University of Piraeus,
80, Karaoli and Dimitriou St., Piraeus 185 34, Greece
mvirvou@unipi.gr

Introduction

Intelligent Tutoring Systems have traditionally been very good at providing dynamic aspects to the educational system's reasoning. This is usually due to the student modelling component that attempts to follow the student's way of learning taking into account possible misconceptions that the student may have. Other important dynamic features of ITSs are due to the advice generator that models the tutoring strategy by which the student is going to be taught the domain.

However, ITSs have often been criticised that they represent immensely complex approaches to building learning environments (Boyle, 1997). A solution to this problem may be authoring tools that provide the facility of building multiple ITSs. In particular, as Murray (1999) points out ITS authoring tools may give the instructional designer a combination of facilities to produce visually appealing, interactive screens and a deep representation of content and pedagogy.

This paper describes an authoring tool for ITSs that incorporates a domain-independent reasoning mechanism. The reasoning mechanism is used for the student modelling and the tutoring strategy of the resulting ITS.

Related Work

The domain-independent reasoning mechanism of the authoring tool described in this paper, is based on an adaptation of a cognitive theory called Human Plausible Reasoning (Collins & Michalski, 1989). Human Plausible Reasoning theory (henceforth referred to as HPR) is a domain-independent theory originally based on a corpus of people's answers to everyday questions. HPR formalises the plausible inferences based on similarities, dissimilarities, generalisations and specialisations that people often use to make plausible guesses about matters that they only know partially. These inferences may lead to either correct or incorrect guesses; in any case these guesses are plausible.

This theory can be used as a domain-independent generator of plausible human errors or as a way of reasoning for open questions. Indeed in previous research we adapted and used HPR in the user modelling component of an intelligent help system for UNIX users (Virvou, 1998; Virvou & DuBoulay, 1999) and in an intelligent learning environment for novice users of a GUI (Virvou & Stavrianou, 1999; Virvou & Kabassi, 2000). In the present research we adapted and used HPR for the student modelling of multiple domains, such as geography, biology etc. and as a tutoring strategy for teaching students how to deal plausibly with open questions. In addition we have provided the facility to human instructors to construct the knowledge - base of the domain to be taught to students.

Operation of the Authoring Tool

The initial input to the authoring tool is a description of factual knowledge of a specific domain given by a human teacher. Then the tool constructs a knowledge base concerning the specific domain in the form of hierarchies, which is compatible with HPR. The human teacher may also construct tests that consist of questions concerning the factual knowledge of the domain.

The resulting ITS may be used by students who can be shown facts from the knowledge base. In addition students may test their knowledge by answering the questions that the human teacher has given. The student modelling component examines the correctness of each student's knowledge and the soundness of the reasoning s/he has used. Information about each student is kept in a long term student model. This kind of information may be used to measure the student's progress and record persistent misconceptions and weaknesses of the particular student.

The tutoring component of the resulting ITS poses questions to the student who is asked to give an answer and an explanation for this answer. For example, in the domain of geography the tutor may pose the question: "Does Italy produce lemons?" Then the student may answer either "Yes" or "No" and give an explanation for his/her answer. An explanation could be "Yes, because I know it does". If the student does not possess the factual knowledge needed for this answer s/he may say: "My guess is yes. I know Spain produces lemons; Spain is similar to Italy in terms of agricultural products. Therefore, Italy probably produces lemons". In this case, both the answer and the reasoning are examined by the ITS. There may be cases where the student's answer may be incorrect but the reasoning reveals that the student has a good knowledge of geography and uses it in a plausible way.

In particular, there may be several cases of combinations in terms of the correctness of the guessed answer and the correctness of the reasoning. One case is both the guessed answer and the reasoning used to be correct. Another case is the guessed answer to be wrong but the reasoning used to be correct. In this case the tutor informs the student about the mistake but admits that the reasoning that the student used was plausible. A third case is the guessed answer to be correct but the reasoning used to be incorrect. In this case the tutor informs the student that the answer was correct by chance. There are also cases where the reasoning used may be correct but the factual knowledge of relevant topics may be incorrect. For example, if the student was asked whether Italy produced coffee and answered "My guess is yes because Spain produces coffee and Spain is similar to Italy in agricultural products". In this example Spain is similar to Italy but it does not produce coffee.

The learning environments that result from this authoring tool are more open than tutoring systems which do not have any reasoning abilities about correct and incorrect knowledge. For example, Ohlsson (1993) suggests the analysis of epistemic activities (arguing, describing, explaining, predicting, etc.) to be more relevant for higher order learning of declarative knowledge than the study of goal-oriented action. In addition, Andriessen & Sandberg (1999) point out that the process of becoming an expert in a certain domain should no longer be solely viewed as the acquisition of a representation of correct knowledge; the knowledge to be acquired should flexibly manage open problems. In this sense the authoring tool provides support in the student's learning of factual knowledge and the reasoning that may manage this knowledge.

Conclusion

In this paper we described the work in progress of an ITS authoring tool that incorporates a domain-independent reasoning mechanism. The reasoning mechanism is based on HPR, which is a cognitive theory about how people make plausible guesses. In this way, the resulting ITSs may provide quite open learning environments for the students to practice their factual knowledge on a certain topic, factual knowledge on possibly relevant topics and the reasoning they use to deal with open problems by combining factual knowledge from relevant topics.

The authoring tool is in the process of being evaluated in the domain of geography and biology.

Abstract: This paper reports on the results of the project "Open and Distance Learning Network in Information Technology and Microelectronics - EDIT" run by University "Politehnica" of Bucharest, Technical University of Cluj, Technical University "Gh. Asachi" of Iasi, University of Craiova, Romania and IBM Global Services, Education&Training, La Hulpe, Belgium. The paper focuses on the description of the main objectives, technical infrastructure, course materials, impact/target groups, type of learning environment and further developments. A distributed web-based learning environment has been developed within the EDIT project.

Objectives

The main objective of EDIT Project was to develop the first Romanian academic open and distance education network aimed at training the students and academics from the four partners universities. In the long run the network will extend to link the main technical universities in Romania, including researchers and experts from other institutions. The project is financial supported by the Romanian National Higher Education Funding Council for a period of three years.

The project's specific objectives are: 1) to setup and to develop the technical infrastructure; 2) to design and to implement some good examples of education/training course materials in the field of IT and Microelectronics; 3) to deliver the designed courses to our students/customers; 4) to find the best suited learning environments for a given topic/target group; 5) to support itself through contracts with different customers at the end of the three years period.

The Technical Infrastructure

Because of the unique distance learning environment of the Web and the availability in all Romanian universities the EDIT Project focuses on web-based learning environments.

The Design and Implementation of Course Materials

In 1998, EDIT Distance Learning Network starts to deliver his first course on Modeling and Simulation of Semiconductor Processes and Devices (MSSPD) for the MSc students from Department of Electronics and Telecommunications (Drondoe et al. 1998) using an in-house designed web-based learning environment: EDIT Learning Environment - ELE. Presently, we offer four courses for Department of

Electronics and Telecommunications: Electron, Devices and Circuits, MSSPD, Optimization Methodologies and Particle Simulation in Nanostructures (Drondoe et al. 1999).

Impact/Target Groups

The courses are open for undergraduate and graduate students, academics and researchers that can choose between different level of complexity depending on their previous knowledge and personal goals.

The Type of Learning Environment

Depending on the topic and/or target group the chosen learning environment used for implementation of the course material was either ELE and/or two well-known distance learning commercial products (i.e. LOTUS Learning Space and IBM Distance Learning Space/DLS).

The main features of ELE are (see Zolti et al. 1999): www dedicated arhitecture, distributed way of working both in design and exploitation, high degree of reusability, integrated communication system (e-mail and virtual classrooms), web-based publishing system, web-based voting system and secure web access to the database.

Sustainability

The sustainability of the project is envisaged through contracts with online continuing education courses on demand dedicated to enhancement of adults' knowledge/skills and/or to professional reorientation of the unemployed people. A special attention is also given to distance training of the work-force in the corporate sector.

Conclusions and Further Development

A distributed web-based learning network has been presented. At the basis of this implementation lies WWW dedicated architectures. This has allowed us to reach a high level of reusability and also cost-effectiveness. Currently, there is much work in progress to implement more courses within EDIT Distance Learning Network and to further develop the ELE by establishing some efficient authentication methods that would make awarding certificates more legitimate.

Design Processes Involved in the Creation of Computer Based Learning Environments: Preliminary Results

Steve Wakeham. M.Ed.*
e-mail: swakeh@po-box.mcgill.ca

Robert J. Bracewell, Ph.D.*
email: ed13@musica.mcgill.ca

* Educational & Counselling Psychology, McGill University

This short paper describes dissertation work in progress investigating the cognitive processes and social practices involved in the creation of computer based learning environments (CBLEs). Unfortunately, knowledge regarding the actual design process is very limited. Formal instructional design prescriptions (Dick & Carey 1985; Gagne Briggs & Wager 1988) and design principles based on cognitive psychology (Duffy & Cunningham 1996; Wasson, 1996) do exist but it is not clear how these prescriptions and design principles are used in 'real life'. Research into the cognitive processes involved in instructional design tasks is limited. Studies have examined such things as the extent and nature of alternative designs and stopping rules (Kerr, 1983), expert-novice differences in problem understanding and problem solution (Rowland, 1992) and, expert-novice differences in declarative and procedural knowledge and representations of design (Perez & Emery, 1995). There are very few studies of the design process involved in the creation of CBLEs. The lack of empirical work regarding the design processes and practices involved in the creation of CBLEs is surprising given the important contributions this type of knowledge could bring to future design activities. Studies of the process could indicate where typical difficulties exist and suggest strategies to overcome them. Additionally, it would be interesting to observe the effect of the application of one of design principles on the actual design process.

Theoretical Perspective

The theoretical perspective adopted in this study combines traditional human problem-solving (Newell & Simon, 1972) perspective with an activity theory (Engstrom, 1989) one. Problem-solving research focuses on the internal mental process involved in problem-solving and has been used to investigate instructional design problem-solving process but it has not been used rigorously to study designers of computer material. On the other hand, activity theory investigates how social systems influence human practice. Activity theory has not been used to study the design processes involved in the creation of computer based material but has been used to study other computer design activities. Research that combines human-problem solving and activity perspectives provides a theoretical perspective that recognizes the cognitive and social dimensions of design activities (Bracewell & Witte 1997; Cobb, 1994; Portes 1996).

Questions and Method

(1) What problem-solving processes are involved in developing computer-based learning environments (human-problem solving perspective)

(2) What social practices are involved in the creation of developing computer-based learning environments (activity theory perspective)

A case study of a design team at a local multimedia development firm was conducted over several weeks. Participants included one subject matter expert, an editors and a graphic artists. Data consists of participant observation field notes collected over several weeks, interviews and think-aloud protocols.

Results

Preliminary results indicate that the problem-solving activity of team members is goal directed and involves establishing numerous local plans and frequent evaluations. It is clear that a concurrent analysis that combines problem-solving and activity theory is a very promising approach. It provides data that allows researchers to analyse and interpret the relationship between internal mental processes and social context.

FM Radio Stations – Broadcasting with the Sun

David Walker
The Commonwealth of Learning
600-1285 West Broadway
Vancouver, British Columbia, Canada
dwalker@col.org

Abstract: This paper describes a case study on the use of community-based low powered FM radio that has been undertaken in Uganda as part of the work of the Commonwealth of Learning. It describes a media solution that employs low-powered FM radio as an effective method of delivering education and information to a rural community. It also describes the inhibitors to proliferation of community radio stations and reflects on the future directions for the use of radio as a delivery system for education.

Introduction

"All available instruments and channels of information, communications, and social action could be used to help convey essential knowledge and inform and educate people on social issues. In addition to the traditional means, libraries, television, radio and other media can be mobilized to realise their potential towards meeting basic education need of all". Final Report World Conference for All: Meeting Basic Learning Needs, Jomtien, Thailand, 1990.

Why Community Radio?

Community radio is an immensely powerful technology for the delivery of education with enormous potential reach globally. Creating opportunities for communities to utilise this delivery system will enable disadvantaged groups to engage in a development agenda, sensitive to their needs and aspirations. In order to serve the underprivileged and rural poor, mass media such as radio must create conditions and mechanisms that provide people with genuine access to useful information. Such mechanisms will offer ways in which people can express their sentiments, opinions, views, dreams and aspirations, their fears and insecurities, their strengths and capabilities, and, of course, their ideas for development.

High illiteracy rates and low levels of schooling among disadvantaged groups, especially women, in many developing countries continues to limit their ability to lift themselves out of poverty. The existing educational system has shown itself to be unable to respond to the massive demand for increased education. This is especially true in many poverty-stricken countries with respect to meeting the massive education needs of the rural poor. Consequently, disadvantaged groups continue to be denied access to information, knowledge, skills and technology transfer.

The answer is to deploy Distance Education techniques and delivery systems such as radio and television based at the community level to address directly local issues and needs.

In order to empower disadvantaged groups as equal partners in development, the limitations of formal and non-formal education are now being challenged. Urgent and new ways to achieve mass education, that can be both efficient and effective, are being sought. In this context, radio, an effective telecommunications medium, was proposed at the Jomtien, Thailand UNESCO Education of All conference in 1990 as one massive solution. Radio can cut across geographic and cultural boundaries. Given its availability, accessibility, cost-effectiveness and power, radio represents a practical and creative medium for facilitating mass education in a rural setting. However ten years on since Jomtien, radio still continues to be an underutilized technology in education. This is especially surprising because from a learner's point of view, radio is user friendly, accessible and a well-established medium. From an educational provider's point of view it is easy to set up, produce and broadcast programmes. After almost hundred years of broadcasting history most nations of the world have more than a respectable level of engineering skills and broadcasting talent to apply the technology in education. In the last ten years, radio has been greatly enhanced by the emergence of new technologies, which have opened up new opportunities for a variety of forms of delivery and access for both broadcaster and listener. For example, portable, low cost FM transmitting stations have been developed and digital radio systems that transmit via satellite and/or cellular are being implemented in many parts of the globe. Internet streaming audio software technology has emerged recently to allow a global audience to listen the news from a distant country. And windup and solar radios have been developed thus freeing radios from expensive power sources. COL is addressing the issue of education for all with creative media solutions that fall under the banner of an initiative called The Commonwealth of Learning Media Empowerment (COLME).

COLME – A Template for a Media Projects

COLME is building creative media models for delivery of information and training in the area of non-formal and formal education.

COLME strives to:

- Provide new skills in the use of technology for the disadvantaged
- Provide media models that will stress local participation and transfer of knowledge and skills
- Provide opportunities for disadvantaged groups to participate and benefit from new technology and media based initiatives
- Create a capacity for dialogue among government sectors, institutions and different interest groups
- Create a research base and body of knowledge that can be utilised by Commonwealth governments, organisation and communities as models for media and technology based initiatives.

Media projects in radio stations and projection, video and audio production, and computing solutions have all been part of the work of COLME in the past several years. The focus here is a portable FM radio station that has been used in several developing countries of the Commonwealth such as Uganda, Namibia and South Africa.

Overview of the Station

Radio is a very powerful technology that can allow large sectors of the population to be reached with information, quickly and economically. Due to national broadcast regulations in many countries, community radio stations have not developed. Also the cost of transmitters, infrastructures, and equipment, has placed most potential community broadcasters at a disadvantage, especially those in the remote rural areas. There is a distinct information gap to the rural corners of some countries resulting from the lack of service by national broadcasters who in some cases have weak or non-existent signal coverage. Under COLME, portable FM radio systems have been tested and implemented as part of media project work over the past three years. The station configuration that was first developed has, with input and data gathered from COLME initiatives in the field, have aided the manufacturer in altering the station to address the each community's need. The station configurations range in price from three for five thousand dollars US including all elements, antenna, transmitter, console, mixer, microphones and CD and tape decks (**Figure 1**). The stations can run from 12 V DC or 120/240 AC.

Figure 1 – Pictured is a station in its watertight carrying case (on the consul starting on the left top the gooseneck microphone, below is the mixer, top right are two tape decks, below are two CD decks). The transmitter and power supply, not pictured, are housed under the consul. The consul is removed from the carrying case when in operation (see Figure 4 for operational mode).

Keys Elements to Success

There are number technological factors that are important in the initial needs analysis before a station can be considered. First the physical landscape must be conducive to an FM signal to reach the intended target audience especially if rebroadcast of the origin station signal is not possible due to cost or licensing regulations. If the landscape is mountainous then there will be difficulty in the signal reaching a large radius of users. Secondly, the station target audience must have radios or access to radios. Thirdly, there must a situation where there is a steady flow of content and a regular broadcast schedule.

Fourthly, the station must be targeted to the local users so that they can directly relate to the content, language, and situations discussed.

In the feasibility stage before station implementation certain conditions must exist to improve the element of sustainability. In-country stakeholders are identified for each of the stations. Their role is to insure infrastructure is in place for FM radio and that all licensing and issues pertaining to community broadcasting are dealt with.

Another important factor is that the broadcasts are in languages that are used daily in the local community level. The national or regional stations do not have the capacity to aim linguistically or at the level of information detail for rural community issues. Community-based stations can be effective if well managed in providing information and training directly to the community. In the case of the COLME installed community station in Uganda, it was imperative that the station be able, by law, to rebroadcast Radio Uganda in the event of important political announcements. Therefore, among the technological upgrades in the design of the station, in addition to the interface for telephone calls, extra microphone inputs for group discussions, and a more powerful transmitter, a facility for radio rebroadcast of the national government station, (in Uganda, Radio Uganda) and international broadcasters (such as the BBC) was implemented.

The overriding factor to the success of these stations has been the proper community access and ownership, which was paramount in the initial project design. If the station is or becomes an integral part of the voice of the community and local interest groups have an equal say in the information that is disseminated via the station, then there is a lesser risk of failure in the long-term sustainability of the station. This can be achieved with good station management that works with community leaders and committees consisting of both political and community leaders.

The local stakeholders, with the aid of COLME, will provide on going evaluation of the stations via listener surveys and media expert evaluation. Workshops will be given in production and survey techniques that will aid broadcasters with improving programming to suit the needs of the community. Local broadcasters will be tapped to train in advanced broadcasting techniques and programme development that will improve community radio personnel.

A Solar Station on the Move – A COLME Case Study

Apac, Uganda is located in the northern region of Uganda. This COLME project was a cooperative effort with the Minister of State and Tourism, The Right Hon. Akaki, to work with community leaders to implement an FM radio station in the Apac region. The COLME feasibility study revealed several limitations with the electrical infrastructure, which was not reliable. This was a result of load sharing throughout the country (Apac would not receive power for several days). The power was also not usable for electronic equipment due to the dramatic power fluctuations. Therefore, it was decided that in order to maintain a reliable broadcasting schedule and develop the station as a center point to community activities by different groups, Radio Apac would be operated entirely by solar power. This would free the project from the constraints of electrical situation and the tariffs associated with it. A configuration was determined, in consultation with a solar distributor in Kampala, to allow the station to stay operational during the eighteen-hour broadcast day. Eight solar panels and seven deep cycle batteries were installed at the station, which now provide lighting and all the station power requirements for daily broadcasting (**see Figures 2 to 4**). The lifespan of solar installations is over a decade with low maintenance costs.

A committee was organized and a station manager appointed. This person works directly with the community to develop programming and allow the development of community involvement. The station has a rebroadcast facility incorporated for programmes from the national broadcaster as well as the BBC and WorldSpace. A further radius of listeners will be taken in Spring 2000 with a retransmission unit that will allow the signal to take in other populated areas. It is anticipated that the total potential listening audience will be over one million. A VHF/UHF radio system will also be implemented to act as a community telephone that will interface into the FM radio system. This will allow the broadcasters to out to the community and speak directly to groups live on air thus eliminating the issue of travel to the station by people such as farmers and medical officers. Links have been made to educational programmers in South Africa to supply educational programmes to the station. The station has been used by the government for health related issues and announcements. There is also an element of income generating by the station with the interest of local businesses in advertising their services.

Figure 2 - Receiving the solar panels at the station site

Figure 3 – Installing the panels

Figure 4 – Radio Apac, 92.9 FM on air, powered by the sun

Conclusion

Radio is an effective system for delivery of education to large numbers of people. It facilitates information exchange at the community level, acting as a "community telephone" and can be effective in literacy and formal/non formal education. Analogue systems for radio will be supplanted by digital broadcasting in the coming decade, however digital radio will pose issues including cost of radio receivers and renewal of broadcasting infrastructure. Analogue radio systems, such as the portable solution that COL and others have utilised in community FM radio initiatives, can be effective in delivering education to the masses without the high infrastructure costs associated with radio broadcasting. With community broadcasting not only can broadcasters focus on addressing local needs through their own produced programming, but also have the choice among a tremendous variety of quality educational content that is available via rebroadcast from national and international sources whether it is delivered via satellite or via the Internet. Rebroadcasting also should be balanced with the needs of the local community and the provision of appropriate and relevant programming content.

There is a marriage between the digital and the FM analogue systems that is taking place. The convergence also includes Internet streamed audio based broadcasters that can effectively be employed by the community FM station in a rebroadcast mode. Will we be able to say in ten years that radio's potential for educational delivery to millions of disadvantaged groups has finally been realised? With the many varied formulas for convergence of digital and analogue technology and the vast selection of content and tools to create original culturally sensitive material for education at the community level, we state clearly - yes. But will the bodies that regulate frequencies for community radio initiatives reform regulations to reflect the current technological developments and pressing need for mass media to meet the goal for education for all in the next ten years? We can only hope. The past ten years and the failure of Jomtien is a heavy burden to bear. The next ten should see the harnessing of radio, analogue, and more so digital, as the powerhouse for delivery of education. Governments should be prepared to adjust broadcasting regulations to adhere to technological developments and realities, and also consider community based mass media delivery as an effective solution for improving a nation's human resource development towards the goal of education for all.

ABSTRACT The authors will describe the programs used in the preparation of faculty who are participating in an Web-based Integrated Curriculum in Engineering (ICE). The programs are a blend of efforts between faculty and the Educational Technology Team.

The ICE program is a comprehensive effort between engineering faculty, humanities faculty, physics and mathematics faculty. The ICE program includes specifically designed sections of the foundation courses required of all engineering students: the calculus sequence, the physics sequence, the humanities sequence, social science, and introductory engineering courses. What differentiates the ICE program from traditional engineering curricula is that all courses incorporate active and collaborative learning and a reliance on computer and web technology. In addition, the ICE program promotes team learning, team design projects, and a well-documented series of assessment practices.

Background of ICE:

The motivation behind this program includes:

- high attrition rates in calculus, physics, and chemistry;
- perceptions of the faculty that these students do not read and write well;
- a lack of comprehension of the building nature of the foundation courses and their relationship to the engineering curriculum;
- the lack of continuous use of common computer technology;
- failure of students to adjust to the university environment,
- and the isolation that many students feel in such programs of study.

The Integrated Curriculum for Engineers was introduced in 1997 to a volunteer group of 65 entering freshmen selected from a pool of 130 initial volunteers. In succeeding years, similar sized classes have volunteered to enter this program.

This paper describes the programs specifically designed by the Educational Technology Team and the programs put together to teach faculty how to use active and cooperative learning in the various courses which are included in ICE.

Description of ICE methodology

Computer and web technology are crucial to the implementation of the ICE program. Students in this program must have laptops for use in each course. Classrooms have been wired so students have access to the campus network and access to the Internet. Common software in use includes Maple, Microsoft Office, Bentley Microstation, and Internet access. All courses are web-based so that students have access to each course in the program, to reference materials, tutorials, reviews for exams, and to each faculty member and to their peers. Forums, emails, chat rooms and links to other sites are all available to every student. Students can plug their laptops into any campus port as well as their dorm room. The authors will discuss examples of daily classroom usage of a web-course and we will comment on the active and collaborative nature of the courses by showing how these are incorporated.

Another crucial component of the ICE program is the use of cooperative and collaborative learning in each course. Thus, in addition to restructuring the content, all courses have been redesigned for an active and collaborative learning environment. Each course assigns team exercises, daily or weekly, which are to be done both in and outside of the classroom. In any of these courses, it is common to ask a team to present their work to their peers at the end of a daily class. In addition, the mathematics faculty designs external team problems that are reported in class about a week later. For each such team problem it is required that the problem be written using a word processor and the report is graded for composition and exposition as well as the mathematics. Class presentations are oral and each team receives a grade based upon accuracy, style and clarity of exposition.

Students in the program are assigned to a team of four. A team is selected based on the class rank condition. A team stays together through all the courses during that semester. The engineering faculty devote the first week of the introductory engineering course to team building skills and continue to monitor the effectiveness of the teams throughout the semester. This engineering course also serves as a student success course based on the University 101 model and include topics such as time management, study skills as well as adjustment and orientation to the university.

Programs of the Educational Technology Team

Most of the faculty who teach at Embry-Riddle use word processing, spreadsheets, and email. A few of the ICE faculty had some acquaintance with use of the web, but none had ever put a course up on the web and many were apprehensive about trying A template was designed specifically for the web-based portion of the ICE program, and faculty members were provided with training on how to develop and post materials in the template.

Because the ICE faculty were technically proficient in specialized areas and working with a web template specific to their program, a customized training program was developed for them by the university Educational Technology Team. A description of the ICE web template and training program and ongoing support for the ICE faculty will be presented in this talk

Programs used to acquaint faculty with Active and Cooperative Learning.

When faculty think of teaching, they think of lecturing - the me- centered model of education. Active learning is participatory - an idea or theme is selected, the students think about it, promote their own understanding, and share it with the class. Collaborative learning is group based - in our case, team-based. It requires the team to work together in and out of class on assignments.

Assessment

Assessment of these training programs include informal and formal components. In this presentation, the authors will comment on each, including what worked and what did not. In addition, we will comment upon some of the measures used by faculty in the ICE program itself. These include attitudinal surveys about use of teams, use of active learning, use of computer technology, use of computer software, use of web-based courses, adjustments to the university, and a variety of other topics. Assessment of use of web-based materials is done by formal assessment at the end of the term. All aspects of assessment will be shared with the audience.

FutureBoard: Supporting Collaborative Learning with Design Activities

Abstract: The FutureBoard system has been developed to support the collaborative learning process, especially design activities in Project Based Learning.
Two kinds of board system have been created: one is a Personal Board for supporting the personal reflective thinking process based on a wireless note PC, and the other is a Collaboration Board for supporting collaborative learning and the creative process based on a 50 inch monitor with pen input support.

Project Based Learning and Design Activities

In Japan, the national curriculum standards will be changed in 2002, and Project-based learning known as "The period of integrated study" will be introduced to elementary and secondary schools. During the process of project-based learning, design activities such as making books and posters are critical because they give students the chance to reflect on their ideas. Computers have been used for the design activities in project-based learning, however they are limited to student's individual expression when using graphic software and DTP software.
We believe computers can render the process more dynamic when designing activities such as in collaborative design for the social construction of ideas, by many professional designers do.

Design Process of Professional Designers

We have analyzed the design process of professional interface designers (a university professor and two professional designers in a private corporation) in order to clarify points to support the collaborative design process.

1. Using Tracing Paper
All used tracing paper in the collaborative design process. One designer drew an idea on paper, while the other put tracing paper on it, revised and added new ideas to previous ideas.
2. Fast and Interactive Process
This process was fast-paced and interactive. They sketched ideas in a few seconds and talked like a "This is better," pointing the revised idea.
3. Using Personal Spaces
Sometimes, Personal spaces were used such as on a small memo or a corner of the tracing paper to dot down their ideas.

Outline of the FutureBoard System

Following this analysis, we made design policies for the new system that supports the collaborative design process. We named it "FutureBoard".

1. Tracing Paper Function
FutureBoard contains 8 layers of tracing paper wherein the level of transparency can be modified. The lowest layer is called the "Master Layer", a special layer for guiding design activities such as Maps, Axes, Tables, etc.

2. Pen Input and Drawing Tool
A user can employ the pen input (or his/her finger) similar to ordinary paper resulting in the interaction being much quicker. Moreover, the software becomes not just a paint tool but a drawing tool, so that each object drawn can be moved or deleted.

3. Personal Board and Collaboration Board
Two kinds of board system have been developed: one is a Personal Board for supporting the personal reflective thinking process based on a wireless note PC, and the other is a Collaboration Board for supporting collaborative learning and the creative process based on a 50 inch monitor with pen input support.

Personal Board and Collaboration Board

The hardware of the Collaboration Board system (CB) consists of a PC and a 50 inch projection monitor with pen input support and a wireless LAN station.

The software of CB is a simple drawing programme with 7 half transparent layers. The user can control the visible/invisible aspects of the specific layers as well as control the 5 levels of transparency. All operations are assigned to the icons, thereby eliminating the menu bar.

The hardware of the Personal Board (PB) system consists of a pen-based PC and a wireless LAN card.

The software of PB is a subset of the Collaboration Board that has two layers and is optimized for SVGA screen. (The CB is of XGA size)

Initially, students will use the PB, and then send the work to the CB's layer. With the CB, they can lay ideas on the other half of the transparent layers. And CB's data can be downloaded to a PB using the wireless LAN system.

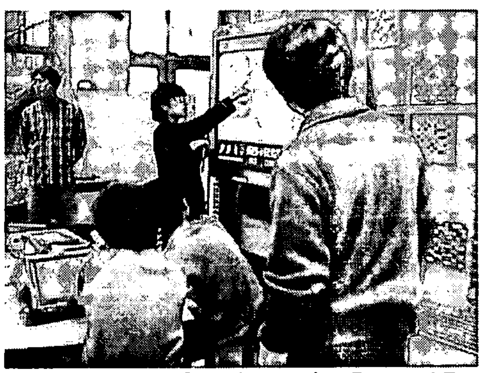

FIGURE 1: Jr.HS students using Personal Board and Collaboration Board

Evaluation

The FutureBoard system was evaluated from November to December of 1999 at Utase Junior High School in Chiba Prefecture, JAPAN. The system was used in project-based learning about "Makuhari Bay Town" where the students live. To meet the goals of the curriculum, Small groups were formed. The students explored and researched many aspects of their town, such as the traffic system and road safety, the soundscape of the town. They reported the result of their research on the Personal Board and transferred the data to the Collaboration Board. Using Collaboration board, They discovered new ideas from the overlapped information and made final presentations to an audience composed of classmates, teachers, municipal officials and parents.

We are now evaluating how these tools supported the collaborative process by protocol analysis and interviewing. The main points of the evaluation center around how 8 half-transparent layers and drawing tools work as a cognitive resource in collaborative process.

Acknowledgements

This research is generously supported by an IPA (IT Promotion Agency, JAPAN) Grant. We deeply appreciate the cooperation of the students and teachers at Utase Junior High School in furthering our research.

Merging Physical Manipulatives and Digital Interface in Educational Software

Anna Zacchi, Nancy Amato
Dept. of Computer Science
Texas A&M University
USA
{zacchia, amato}@cs.tamu.edu

Abstract: In this paper we describe how elementary school students used physical manipulatives in conjunction with the digital interface of educational software for geometry. The blending of physical manipulatives and digital interface may help them to overcome the limits of the representation and interaction modalities of the digital interface.

Introduction

Our study used SuperTangrams (Sedighian & Westrom 1997), a program developed by the EGEMS group at the University of British Columbia. We introduced manipulatives that students could use while playing with the software. The idea was to use manipulatives in conjunction with the software in order to overcome the representational problems of the interface. Manipulatives allow the students to experience what they are doing on the screen in the real world.

SuperTangrams. SuperTangrams is a computer-based learning environment for two-dimensional transformational geometry. Learning of this mathematical domain is situated in the context of the traditional tangram puzzles game activity. The player is challenged to put together several geometric shapes to fill a given outline. To move the shapes on the screen the student selects and applies to them one of three transformations: translation, rotation, and reflection.

Subjects and Settings. The study involved approximately 180 fifth grade students at a College Station, Texas, elementary school. The task of each student was to play with SuperTangrams to solve the tangram puzzles. The student was free to use the tools that we placed on the side of his computer. Data collection techniques included class observations, video-recordings, scratch paper used, pre-tests and post-tests, questionnaires and log files of computer sessions.

Use of Physical Manipulatives

First set of manipulatives

During a first study session (two weeks), we provided the students with the following manipulatives:
1) a set of tangram plastic shapes, 2) a reflection mirror, 3) a colored grid board with a rotating stick.
The board had two different drawings on it: a line for reflection and a circle divided in 16 sectors of equal size. This is consistent with the software that allows the minimal angle to be $1/16^{th}$ of a circle. A stick is connected to a hub at the center of the circle and can rotate 360°. The idea was that the students would place a shape on the circle and then rotate it by pushing against it with the stick. We intended for them to use the reflection mirror with the line drawn on the grid board to find the reflection line.

Rotation. One common use of the shapes was to put them on the screen and animate them. A video recording shows a girl using them for rotation. She started superimposing one plastic shape on the digital shape on the screen, and then she moved the shape along the arc of rotation trying to move and rotate it at the same time. In this operation she paid attention to the position of the shape on the screen, but not to the orientation, or angle of rotation. The students who used the grid positioned the plastic shape on the circular drawing, trying to position the shape in the same orientation as the one on the screen. Then they would push the shape with the stick until the shape could reach the orientation of the target. They would count the number of sectors the stick moved and move the digital handle accordingly. Some students felt comfortable with the board, while some others preferred to bring the shapes directly to the screen.

Reflection. Students did not use the mirror on the grid board with the plastic shapes as we had expected. Instead, they placed the mirror directly on the screen and looked for the reflected image of the digital shape. The first operation involved was to position the mirror until they could see the reflected image superimposed on the target. Once the position was found, they had to play with the digital handles to position the reflection line along the position found for the mirror.

New Manipulatives

The use the students made of the manipulatives surprised us, since they preferred to use them on the screen, merging the physical operations with the digital ones. Thus, for the second session, with a second group of students, we modified the manipulatives to make it easier for the students to use them on the screen. We eliminated the grid board and built a rotation tool consisting of two popsicle sticks joined together at one end in such a way that they could rotate, and placed some sticky paste on the other ends. The popsicle stick had more success than the grid. The students would stick the chosen shape at the end of one stick, and position the two overlying sticks directly on the digital radius of rotation, with the plastic shape matching the digital shape. Then they would rotate the stick holding the shape and keep the empty stick in the initial position. When the plastic shape reached the target, the opening of the two popsicle sticks represented the sought after angle. In this case they could hold the right "angle" in their hand. Finally, they would recreate the digital angle playing with handles, holding the physical one as a model.

Student reactions

The second set of tools had more success than the first. It was more natural for the children to bring the tools to the screen, and they could physically experiment with the transformations. In the questionnaires we asked children if it was good to have manipulatives, and if they helped them learn. Here are some of the answers:

> *"They helped because they were 3D;" "they helped you to learn the movement;" "all tools because they helped you think ahead;" "you need some reference to look at;" "because it is important to have stuff you can work with in your hand;" "it helps understand."*

Conclusions And Future Work

Software running on a computer is something abstract: when the student drags a handle with the mouse something happens on the screen. In educational software for geometry it is important that the student learns to relate what happens on the screen to the real word. Our preliminary findings indicate that physical manipulatives can be a valuable addition to educational software. We noticed how the use of manipulatives helped students overcome limits of the representation and of the types of interaction allowed by the interface. For example, additional information on the screen whose purpose was to help the students, such as additional lines, actually confused them, causing them to miss important concepts. Using a physical representation of those concepts, such as an angle between two popsicle sticks joined together, helped them to focus on the main aspects of the transformation without being lost in representation details. During our study we collected log files and data relative to pre-test and post-test. The statistical analysis of this data will determine the effect on learning of the different tools.

Montréal (Québec), H2L 2M2
carole_poirier@radio-canada.ca

Contemporary education needs to be connected to the very world it purports to study. In this context, media archives and documents are value-added material that can support both traditional pedagogical practices and media literacy related activities. Public broadcasting archives and related documents can play an edifying role in offering various sources through which to grasp a host of current and historical issues. Recognizing the educational value of its media assets, Radio-Canada is working with schools, colleges, and universities in exploring a variety of pedagogical scenarios in which media content can complement traditional study material. This presentation will illustrate how Canada's public broadcaster can, by means of forging partnerships with various organizations (multimedia, cultural, or educational), and repurposing of media archives, play an active role in the development of educational Web content as part of a constructionist approach to learning.

Learning Code

Suzanne Rhodes, Human Code, USA

Who We Are

The Learning CodeTM development team extends beyond the walls of our studios to include the clients we work with and the learners we work for as well as a passionate and compassionate team of education specialists which includes the following professionals:

- Educators
- Interaction Specialists
- Producers
- Artists
- Technologists

What We Do

At Human Code, our mission is to humanize technology to fundamentally transform the way people learn, work and play. Human Code's Learning Technology Group meets this challenge by designing spectacular learning environments.

Our approach affords the Learning Technology Group with the discipline to manage the complexity of tasks that characterize each design stage, as well as the flexibility to provide appropriate consideration to the six interrelated components that define each of our spectacular learning environments. These components include:

- Setting
- Community
- Content
- Pedagogy
- Tools and Technologies
- Assessment

How We Do It

Derived from years of best practices and research in the field of learning technologies, our Learning CodeTM approach to educational environment design is an iterative process that motivates our team of specialists through the following comprehensive design stages:

- Envision
- Design
- Produce
- Implement
- Integrated, On-going Reflection

Who Benefits?

Targeted learners

Learning Code TM engages the learner in an experience that is personal, relevant and meaningful. Our environments engender a love of learning, content mastery, higher-order thinking, and inspire life-long learning.

Clients and Educational Partners

Learning Code's collaborative nature transforms clients into development associates. Skillfully managed projects, delivered on-time and on-budget meet the needs, goals, and expectations of our client partners.

Human Code

Each project affords our company teams with heightened knowledge, skills, and abilities that inform future designs and techniques. The result is continually evolving processes, products, and services.

About Human Code

Human Code is a leading developer of interactive experiences for e-commerce, games, learning systems and marketing communications. The company's approach combines creativity, consulting and technology to create user-centered solutions that change the way people learn, work and play. Human Code's creativity and client-service focus are maintained through the company's Studio Network, which includes Austin Studios, Presage Studios in San Rafael, CA, Human Code Japan in Tokyo, and Human Code Shanghai. The company was founded by industrial designers in Austin, Texas in 1993, and received venture investments from Austin Ventures and Applied Technology in 1995 and 1999. Additional information on Human Code can be found at www.humancode.com.

Human Code's Learning Technologies Group is emerging as a market leader in creating spectacular learning environments. From a statewide initiative in Idaho to programs that provide entry-level technology workers with training in hard and soft skills, Human Code is becoming known as a true total solutions provider for educational technologies.

Teaching and learning in a virtual campus: The model of the Universitat Oberta de Catalunya

Albert Sangrà
e-Education Laboratory
Universitat Oberta de Catalunya
asangra@campus.uoc.es

Lourdes Guardia
Head of Instructional Design Unit
Universitat Oberta de Catalunya
lguardia@campus.uoc.es

By combining the latest technologies with both a solid pedagogical foundation and continuous evaluation, the Universitat Oberta de Catalunya has built a Virtual Campus: an electronic communications environment that provides the means to effectively support the tutoring of students, and the provision of university resources and social activities.

It has presently a total of 13.000 registered students. Eight main degree programs are offered, as well as Master programs, postgraduate courses and a wide offer of continuous education programs.

The organization is also working on the *Metacampus*, which mission is to demonstrate the global, virtual co-operation of universities; a concept known as the flexible university which is achieved by interconnecting the partners virtual services and infrastructures.

It will be able to capture, register, invoice, teach, assess and accredit courses and provide all the administrative services in a global scale, using the Internet as the only medium to support all these educational processes.

Deploying Web-Based Assessments

Eric Shepherd

Learn the principles of creating and administering Web-based tests and assessments using Question Mark™ Perception™ software. Find out how to use Perception's authoring wizard to create questions in a variety of formats: multiple choice, multiple response, hot spot, text, numeric, selection, and matrix questions as well as explanation screens that can include text, graphics, and multimedia. Participants will also learn how to create multiple question banks from which to assemble tests, surveys, and questionnaires. Other topics include how to set up interactive feedback, create adaptive tests, analyze test results, and create reports. . Example questions will be presented from various applications including competency testing, employee recruitment, customer satisfaction questionnaires, study aids, diagnostic tests, skills assessments, product knowledge exams, course evaluations, and certifications. The presentation will cover such issues as test security, linking with learning management systems, and the use of Perception Secure Browser for high-stakes tests.

CORPORATE SHOWCASE PAPERS

The LearningStation.com

The LearningStation.com is dedicated to providing a realistic and cost-effective way to manage technology and make it available to the teachers, students, and administrators who will transform the educational process to meet the expectations of the information economy.

The LearningStation.com is the leading and largest Application Service Provider (ASP) and portal in the educational market, providing online access to educational content, tools, and applications, on a subscription basis. With The LearningStation.com, a managed and maintained library of applications is made available to PCs, Macintosh systems, and thin-client devices across the school's network and over the Internet. The LearningStation.com Chief of Innovation and Co-Founder Jim Pennington states, *"Schools are extremely excited to hear that they can get out of the software management business, and focus on using software rather than delivering it," says Pennington, "and the fact that they can make good use of their installed base of cross-platform computers has a significant impact on their ability to make technology accessible to more students and teachers."*

The Education Market Opportunity

Technology is now accepted as an integral part of education in Canada. As awareness of the importance of preparing students for the information age grows, school boards are turning an increasing amount of attention to this process. Educational spending now accounts for 8% of Canada's budget, and technology is fast becoming a priority, including significant investment in hardware, software, and cabling. In the 1997 - 1998 school year, $230 million was invested in bringing computer technology into Canadian classrooms.

Despite a high level of spending, most schools are equipped with a collection of computers ranging from Apple II to x386 to Pentium-based computers. This presents an implementation nightmare. It is currently impossible for schools to incorporate new software applications into their curriculum without consistently upgrading their hardware, a situation which is neither desirable nor cost-efficient. Regular overhauls of computer equipment is financially impossible for schools with limited budgets. This issue is probably the single largest barrier to institutional technology integration.

The Learningstation.com presents a solution to this problem. It has the potential to completely reorganize instructional computing as we know it. It would allow schools to run brand new applications, as well as provide web access and e-mail, while removing the financial burden of having to constantly upgrade hardware. It would also allow schools to use equipment donated through programs such as the Computers for Schools Program, which provides schools with recycled business and government computers.

What is thin-client computing?

Citrix Systems, the world leader in server-based computing, reports over 2,000,000 ports in place supporting over 10,000,000 users today. The idea behind the thin client is simple: concentrate computing power, storage, applications, and data on "servers" (powerful computers) and provide users with a simple "client" computer that is easy to install and maintenance-free. Users connect to The LearningStation.com servers over the Internet to process applications, access files, print, and perform all other services available to ordinary computers. Since the applications and data are kept on a server, only keystrokes, mouse clicks and screen updates travel the network, so just a fraction of the normal bandwidth is required to run applications. Thin-client delivery has the flexibility to support any device—from full-featured computers like PCs, Macintosh systems, and UNIX workstations, to Windows-based terminals and hand-held information appliances.

How do schools benefit from using an Application Service Provider (ASP)?

- **Reliability and Ease of Use**

ASPs allows teachers and students to spend more time working on technology projects such as accessing information on the Internet and using educational software—rather than spending class time fixing and upgrading PCs or adjusting software programs to suit each individual workstation. Users simply log on and access their applications and data.

- **Simplified, Centralized Management**

The LearningStation.com's servers are managed by skilled network administrators, removing this responsibility from educators. Updates and additions are made only once at the server and are immediately available to all users.

- **Lower Cost of Technology**

Zona Research, a technology research firm, estimates that organizations will save 54-57% of their systems administration costs over a period of 5 years with a thin-client computing approach. Using the services of an ASP further reduces costs by eliminating software upgrades and inefficient purchasing volumes.

- **Security**

Vital data and applications may be kept on The LearningStation.com servers creating a higher level of security. Sensitive applications and data are made available to authorized users only via password protection. Data is effectively secured and backed-up in one central location either on a local customer server or at The LearningStation.com.

- **Universal Access**

Since applications and data are stored on the server, access is available to students and faculty from any machine at any location and at any time via an Internet connection and the desktop appearance is always consistent.

Strategic Alliances

The LearningStation.com has created a network of strategic partners supporting thin-client delivery of applications to the education market. The LearningStation.com is continually looking for new strategic partners to enhance it's offering to education customers.

Software Publishers and Online Content—The LearningStation.com has strategic agreements to offer products from:

- Microsoft
- The Learning Company
- Sunburst Communications
- Saratoga Group
- Infonautics
- Schepp-Turner Productions
- CBT Training
- Lotus
- Learning Outfitters
- Steck Vaughn
- MediaSeek
- Webivore
- Fog Cutter
- SkillsBank
- And many others

Technology Partners—The LearningStation.com has strategic agreements with:

- Citrix
- Sun Microsystems
- Empower Corporation
- MCNC
- Wyse Technology
- Computer Network Power
- Boundless Technologies
- Boca Research
- OZ New Media

Server Access Accounts

The LearningStation.com customers use Server Access Accounts (SAA) that allow access to the LearningStation.com server farm via the Internet. Users have access to a basic package of applications and services that include:

- Reference.Center, a customized version of Infonautic's Electronic Library
- Adventure Online, real world-based core learning materials
- Star Office Suite, an online suite of productivity tools
- Facilitator, conferencing tools for collaborative learning
- Internet filtering and virus protection utilities

Additional products and services can be added as desired including:

- Microsoft Office or Works
- SkillsBank or Cornerstone basic skills software
- Classroom Planner, a comprehensive teacher productivity tool
- Webivore, a directory of educationally reviewed web content
- Explorasource, a curriculum correlation tool for teachers.
- Many, many more

Schools require a Local Area Network (LAN) to provide users access to The LearningStation.com. A T-1 line, or a fast broadband connection like high speed cable modems, is recommended for school site access, while an individual account can gain access over a modem. SAA's are for concurrent usage, so schools only need to purchase as many accounts as they will use at one time. Access is 24 hours a day, seven days a week, allowing teachers, students and parents to gain access from home and after hours as well.

Total Cost of Ownership

Typically, educational technology purchase decisions are made on the basis of acquisition cost and compatibility. As technology usage becomes more pervasive, educators will need to pay more attention to the Total Cost of Ownership (TCO) which includes support and maintenance costs, reliability, and lifecycle replacement costs. And in these areas, thin clients continue to out perform new PCs in cost effectiveness by a wide margin.

Zona Research, a technology research firm, estimates that organizations will save 54-57% of their systems administration costs over a period of 5 years with a thin-client computing approach. And this cost savings is in addition to the lower cost thin-client devices and ability to leverage your current computing infrastructure—hardware, applications, networks and training—to extend the reach of your thin-client network.

A study by the Gartner Group released in June 1999 estimated that thin-client applications require 80 percent less management than traditional PC deployment (Computer Reseller News Online, 6/1/99).

Here are some details of the Gartner Group Study for annual PC cost of ownership:

- Actual cost of the PC Three-year depreciation $677
- Non-Labor Expenses Software, network connectivity, etc. $1677
- Technical Support Service, Maintenance, Help desk $1089
- Network Capital Cabling, Servers, etc. $585
- Network Support Management, virus control, etc. $544
- End User Admin Backups, upgrades, productivity loss $981 from downtime, etc.

Total Cost of Ownership $6507

Thin-Client Computing Cost Savings

While schools typically cannot provide the type of support that is described above, the information serves to illustrate the cost savings that thin client computing provides. In fact, the lack of resources available to support PCs makes an even stronger case for thin-client devices in education. The cost savings of thin-client computing in education are just starting to be quantified:

- Thin client devices can have an effective life of 5 - 10 years
- Your current PC's can be easily utilized as Thin client devices
- Software is a fixed annual expense without hidden version upgrade expenses
- Network support can be provided centrally on servers instead of desktops
- End users have a common, easy-to-learn desktop environment
- Downtime loss from viruses, hardware failures and vandalism are all but eliminated
- Universal access enhances productivity and leverages the technology to more users

SPECIAL INTEREST GROUPS

Campus Notebook Computer Programmes

Craig Blurton, University of Hong Kong, China

Notebook computer programmes are proliferating as many universities move from "corporate" ownership of computing resources to individual ownership. Benefits of such programmes have been widely touted by universities and commercial notebook computer vendors including enhancement of universities marketing position, decreased IT expenses because of cost-sharing between institutions and students, extended learning opportunities, and enhanced IT skills.

But how each individual programme is implcmented is highly contextualized on local goals, needs, and circumstances. This special interest group meeting will give representatives from tertiary institutions an opportunity to interact, share success stories, identify common concerns, and perhaps develop collaborative efforts around the issues of "assured access" and "mobile computing."

Issues that may be discussed include:

* Planning and implementing such programmes.
* Multiple or single vendor solutions
* Cost-effectiveness
* Bridging the gap between academia and business
* Managing vendor relationships
* Equity of implementation
* Staff support and development
* Barriers to success
* Programme evaluation

Providing Quality Distance Education in an Outcomes-Oriented Program

Dr. Ginny Engman
Fort Lewis College
52 Hesperus Hall
Durango, Colorado 81301..
engman_v@FORTLEWIS.EDU

Abstract: Providing on-line programs for pre-service teachers has presented many issues. Assessing the effectiveness of one's teaching in the classroom is difficult under the best of circumstances; doing so through distance education is even more challenging. The program at Fort Lewis College has addressed these issues and, while resolving many of them, has developed some concerns that require further study.

Quality Distance Education in an Outcomes-Oriented Program

The development of an on-line program in elementary and early childhood licensure has raised many issues. It has also caused some dissension among the faculty. The program consists of all courses in the traditional program being offered through Top Class and Web CT. Currently two faculty (of the 10 full-time faculty) have been responsible for the majority of the program delivery. There has been an increase in the number of students who have opted for this avenue since its inception three years ago. Students are admitted to the program in the same way that students are admitted to the on-campus program: minimum gpa of 2.5, proof of having worked with children, pass a state basic skills test, pass and oral exam, and adequate ACT/SAT score.

Causes For Concern

There are three major causes for concern. First, after an initial orientation meeting on campus, the faculty have little or no face-to-face contact with the students. They must rely on the written evaluations and comments of the public school teachers with whom the students are placed. Historically, these assessments have been somewhat skewed toward the positive. In fact, the teachers are willing to be more objective if they do not have to put their observation in writing. However, for legal purposes we need to keep a "paper trail". The problem arises when we face a disconnect between what the teachers are writing and the actual effectiveness of the student (teacher candidate). It comes to a head at the student teaching experience—after the student has finished all course work and pre-student teaching practica. The dilemma we face is that the students are out of our service are (hence, the term distance education) so that it is not possible for our faculty to observe and evaluate them on-site. when predicted teacher How do we balance this with our commitment to preparing qualified, caring and competent teachers?

Second, besides the teacher education courses, there is a need for courses outside the department to be delivered on-line. There are auxiliary courses in Exercise Science, Art and Music that our students need as part of their licensure program. Additionally, if the are seeking a degree in Arts and Sciences, they will need to take classes in they major. There has been much resistance on the part of faculty to develop an electronic delivery of their courses. How can we break through the barrier that keeps faculty from taking a risk in the area of distance education?

Third, and lastly, until recently, the upper level administration has been reluctant (not necessarily resistant) to invest significantly in distance education. There is a skepticism about the ability to have high quality and require high standards in an electronically delivered program. How can we educate decision-makers so that we can get their buy-in for distance education?

How to Prepare Teachers for Integrating Multimedia and Technology into K-12 Classrooms

Barbara G. Foster, Ed.D. – Spalding University: Louisville, KY USA bfoster@spalding.edu

Abstract: To meet the needs of diverse learners, teachers must be able to integrate multimedia and technology into K-12 classrooms. Participants will walk away from this session with practical assignments and constructivist activities to enhance professional productivity and support instruction, successful assessment strategies that promote positive attitudes for facilitating the lifelong learning of various technologies by teachers and students, and samples of student work. Topics will include: knowledge of basic multimedia terminology, applications, and technologies; development of basic skills in operating multimedia hardware to support instruction and learning; development of basic skills in using and integrating the Internet and multimedia applications into the curriculum to meet the needs of learners at different age levels and in different subject areas; experience in making presentations using multimedia technologies; experience in designing and planning instruction that integrates multimedia technologies into the curriculum; and awareness of the copyright laws as they relate to educational technology.

Educational Technology and Context: an exploration of values, roles, and concerns from Lecturers, tutors and instructors.

Introduction

Educational and instructional technologies are increasingly becoming part of learning and teaching in higher education institutions. There is no doubt therefore that the adoption of such technologies in this context impacts upon many areas of university life. It could be argued however, that in addition to significant benefits to the institution and its students, the increasing use of educational technologies raise a number problematic issues and areas of uncertainty.

This special interest discussion therefore seeks to get to grips with a number of key issues around the role of educational technology in the learning and teaching equation from the perspective of the lecturer/tutor/instructor. It is considered therefore that by generating discussion around a number of important areas of interest to educational practitioners, some improved awareness of obstacles as well as examples of best practice can be made. From this starting point, greater understanding and progression may be encouraged or developed.

Applications and categorization of software-based scaffolding

Koos Winnips, University of Twente, Netherlands; Catherine McLoughlin, University of New England, Australia

The increasing popularity of computer-based learning environments, combined with a need for time-flexible and self-reliant learning, has caused an increase in the demand for scaffolding embedded in instructional software environments (see for example Acovelli & Gamble, 1997; Guzdial & Kehoe, 1998; Tabak & Reiser, 1997; Rada & Yazdani, 1998). The aim of software-based scaffolding is to provide some of the same kinds of support a teacher could provide in a classroom setting, but now in a computer-based learning environment. In this setting it is assumed that face-to-face contact between student and teacher is reduced or impossible. Software scaffolding can be defined by the following three characteristics (Guzdial, 1995, Zhao, 1997, Winnips, 1998):
- Modeling: the desired behavior is modeled by providing a kind of structure, communicating what is desired, or presentation of an expert model.
- Support is given to the learner so that the learner can perform a task independently.
- Fading takes place so that students become self-reliant.

While many applications and examples of software scaffolding are now known, a categorization of these examples has not emerged yet. Applications of scaffolding can be categorized according to who regulates the scaffolding (teacher, peer-student, computer, self), technology used, pedagogy used, or according to its intended learning outcome. An example of a categorization, based on types of support given is found below:
- Providing examples: ideally these examples should not only focus on products, but also on a process. Providing examples links to the concept of modeling as Bandura (1965) described it, where a teacher would serve as a role model.
- Helping students, by giving away (physical) parts of the solution. This can serve to help students with a solution, or the help may just serve to support students on very time-consuming tasks that are not absolutely necessary for learning (Acovelli & Gamble, 1997).
- Providing a model for design, or a structure to design in. For example providing design guidelines (Collis & Winnips, 1998).
- Cueing/hinting: helping students with a solution by providing a hint or cue to a possible path of the solution (Acovelli & Gamble, 1997).
- Coaching comments (Jonassen, 1998). These comments are intended for motivation, providing feedback and advice on performance, and provoking reflection.
- Asking questions, pointing out weaknesses, asking for a motivation, in order to enhance reflection.
- Metacognitive support: stating why the above types of support are given, in order to model the type of metacognition that experts would use.
- Providing a timeline, with fixed dates and goals built in. This structure could be present, to help students appearring to be very goal directed to build in multiple evaluation moments into the actual experience of studying.

Aim of this SIG discussion is to reach consensus about a number of categories for scaffolding and to construct guidelines about the relationship of learning outcomes to particular forms of scaffolding. This in order to provide structure for future research and to be able to better link previous experiences in software scaffolding to future experiments.

TUTORIAL PAPERS

EDMEDIA2000 TUTORIAL

PLANNING ONLINE COURSES and LEARNING RESOURCES

Andrew Litchfield
Lecturer in Learning and Teaching
Centre for Professional Development
Macquarie University
SYDNEY NSW 2109

Tel: +61 2 9850 9780
Email: andrew.litchfield@mq.edu.au

Session Number: 5553
Maximum Participants: 20
Duration: 3 hours

WORKSHOP OBJECTIVES

By the completion of the workshop participants should be able to;

1. understand the processes, phases and activities involved in planning online courses and learning resources

2. develop a persuasive proposal for project funding including concept, rationale, team formation, learner profile, timeline and budget

3. locate potential sources of project funding

4. understand the pedagogic principles of designing online courses and learning resources

5. identify project learning and teaching strategies

6. develop the content for online courses and learning resources

7. understand the legal issues involved with the design of online courses and learning resources

INTENDED AUDIENCE/EXPERTISE LEVEL

This tutorial is for faculty and staff developers who want to fund, design, develop, implement and evaluate online courses and multiple media learning resources. The tutorial is set at an introductory and moderate level.

ABSTRACT

In this tutorial we discuss and commence the crucial planning tasks required to successfully fund, design, develop, implement and evaluate online courses and learning resources. The tutorial will be of most benefit to participants who come with a specific project idea they want to develop further.

We discuss a learner-centred project framework that consists of proposal, media production and educational design processes, phases and activities. You will use the framework to start developing a persuasive proposal including the project concept, rationale, objectives, team formation and learner profile. You then use the framework to develop sound project timelines and a justifiable budget. Potential sources of project funding are identified.

Design principles for online courses and learning resources are discussed based on the instructional design process, Bigg's concept of 'alignment', and Laurillard's 'conversational model' of the learning and teaching process. You will commence identifying your project's learning and teaching strategies. We discuss methods of developing the content for your project and the relevant legal issues.

TUTORIAL OUTLINE

1. Introduction - participant's projects
2. Learner-centered project proposal, media production & educational design processes, phases and activities
3. *Activity #1: Develop project concept, rationale, objectives, team and learner profile*
4. Timelines for online educational projects
5. *Activity #2: Develop project timeline*
6. Budgeting for online educational projects
7. *Activity #3: Develop project budget*
8. Funding sources
9. Design principles for online courses and learning resources
10. *Activity #4: Identify project learning and teaching strategies*
11. Developing educational content

12. Relevant legal issues

13. Plenary Discussion

14. Conclusion and tutorial evaluation

PRESENTER'S QUALIFICATIONS & EXPERIENCE:

Andrew Litchfield lectures in Learning and Teaching at the Centre for Professional Development, Macquarie University. He is responsible for supporting Macquarie University staff in course design, the use of educational technology, and the planning, design and management of teaching innovations and learning resources. His academic experience also includes lectureships in Media Communications and in Educational Technology.

Andrew's media company, Positive Image, has produced numerous large-scale educational media projects. He has extensive project management and media design experience and has produced four award-winning projects funded by the Australian Government as 'Projects of National Significance'.

POSTER / DEMO PAPERS

Research & evaluation of online systems for teaching & learning

Anne A'Herran, James Cook University, Australia

Piecemeal adoption of methods of online educational delivery can duplicate effort and waste an institution's resources. Early enthusiasm for online delivery of courses soon fades without strategic initiatives on the institution's part. In August 1999 a Web Educational Development Advisor was appointed at JCU to research and evaluate systems for online teaching and learning, with a view to integrating the selected system university wide. That research and evaluation is the subject of this paper.

The relationship between learners' personality types to their performance in computer-mediated distance education

Justin Ahn, Fairfield University, USA; MiLee Ahn, Hanyang University, South Korea

Many distance education programs tend to be focused on programs rather than on individuals and their characteristics with the goal of improving the learners' performance. More research into the effects of distance education should be oriented toward the individual learners. Little is known about the personal factors that promote or inhibit success in distance education environments. This study examined the relationship between learners' personality types and their performance in computer-mediated distance education. This study found that Perceiving types posted fewer but longer messages, Judging types posted more but shorter messages, Feeling types perceived that they had gained knowledge more than other types, and Sensing types were less satisfied with the CMC experience. There were no significant relationships between personality types to grades, level of small group collaboration, and level of leadership influence. Students indicated that the leadership changed from topic to topic and learning in CMC can be achieved without a leader. They used others' frequency and quality of postings, writing skills, and feedback to postings as a factor in determining the leadership.

Tutoring Skills for Instructors in Distance Delivery

Mohamed Ally, Athabasca University, Canada

The growth in use of the Internet and other telecommunications technologies in education is changing the role of the instructor from that of a provider of information to that of a tutor. This new role of the instructor requires different skills to work with students in a virtual and distributed environment. This session will present the tutoring skills that are required by tutors to function in a distance delivery mode.

Development of an Introductory Financial Accounting Text in Print-based and Electronic Multimedia Environments

David Annand, School of Business, Athabasca University, Canada

Athabasca University is Canada's largest distance-based, open university. Students presently registering in the University's introductory financial accounting course are provided with a paper-based textbook, solutions manual, study guide, and assignment manual. These materials are all developed and printed in-house. The 800-page textbook was recently converted to on-screen presentation format. The amount of material was significantly reduced by moving discussion cases to an on-line instructors' manual. The material was edited for on-screen use by altering backgrounds, screen breaks, and page size. The files were then converted into Authorware Professional®. Information presentation was streamlined and interactive elements were incorporated. Feedback for selected text problems was inserted at appropriate points. Audio/visual segments, two computer simulations, and navigation and index systems were developed. The final product will be packaged on a CD-ROM, included with each print-based course package sent to students, and incorporated into the University's Virtual Teaching and Learning (ViTAL) electronic environment.

The Biotechnology Project: A Case Study on Integrating the Use of The Internet for Research and On-Line Communication in a Brazilian School

Cristiana Assumpção, Columbia University, USA

This project was developed in a model private school in Brazil, Colégio Bandeirantes, having the reputation for its high academic level and vision for the future. Using an advanced topic in Biology, students were challenged to go beyond normal academic activities, acquiring skills to integrate technology and become lifelong learners. They have had the opportunity to interact with researchers in the field of Biotechnology, as well as with peers in New York. Students have learned to use the Internet as a research tool as well as a place for collaboration and content building. This is a study of the role of technology in empowering students to become active learners and researchers, as well as adaptation to these new methods of communication. Interesting patterns have emerged on how students communicate online versus face to face. The study continues on how to create pedagogically sound best practices for technology integration.

Utilization of BBS for ESL class

Hideyuki Baba, Keio Gijuku Girls High School, Japan

We introduced the usage of a BBS system into ESL learning to enhance English reading and writing competence of our high school students. The BBS system can enable our students to learn English in a totally relaxed and comfortable way. They are expected to find an English file by using a Web browzer and write down their reaction on a page designed in the BBS. Students are also expected to name the URL on the top of the reaction writing so that we can easily trace back what kind of file our students have read and what kind of viewpoint they have taken. The BBS system itself is not so complicated. The program was originally created by a Japanese college student and made to adapt our learning goals later. The good points of this system is (1) it is quite easy to grasp the several stages of developing process of our studets' English learning only by giving a look at the writing page, (2) students can read and write English in a non-stressed way, (3) the English the sudents are likely to write is not so intimate or personal, which is one of the disadvantages of "pen-pal, or mail-pal" type of writing, (4) anyone concerned can write comments to the writings so that a kind of dialogue is possible among the people inside the system.

The eMINTS Project: Enhancing Missouri's Instructional Networked Teaching Strategies -- Promising Developments and Projected Outcomes

Adam Bickford, OSEDA/University of Missouri Extension, USA; Bill Elder, OSEDA/University of Missouri Extension, USA; Barbara Hammer, OSEDA/University of Missouri Extension, USA; Patrick McGinty, OSEDA/University of Missouri Extension, USA; Priscilla McKinley, OSEDA/University of Missouri Extension, USA; Susan Mitchell, OSEDA/University of Missouri Extension, USA

The eMINTS Project is an ongoing cooperative initiative between the Missouri Department of Elementary and Secondary Education (MoDESE), the Missouri Research and Education Network (MOREnet) and 98 elementary classrooms in 44 school districts. eMINTS classrooms are provided with an extensive technological infrastructure: high-speed internet connectivity, enough student computers to provide one computer for every two students, a high capacity teacher workstation with video conferencing capabilities, and a computer projector and a Smart Board. In addition to the computing infrastructure, participating teachers receive extensive training in constructivist, inquiry-based teaching methods which are supported by the University of Missouri College of Education, which provides full-time assistance in locating and using on-line instructional resources. Results from the first wave of this project, the MINTs Project, have demonstrated that well trained teachers working in technologically rich classrooms, can focus student interest and improve student scores on measures of academic achievement.

LEZI: a Tool for Easy Development of Interactive Video for Education

Mario A. Bochicchio, University of Lecce, Italy; Roberto Paiano, University of Lecce, Italy; Paolo Paolini, Politecnico di Milano, Italy; Elisabetta Andreassi, University of Lecce, Italy; Tiziana Montanaro, University of Lecce, Italy

The design and implementation of complex multimedia application is an extensive effort, requiring time, technical skills and sizable budgets. In few cases, therefore, in educational environment it's possible to realize complete hypermedia applications. It's true, nevertheless, that within several academic institutions there is the capability of developing high quality educational content, traditionally delivered as paper, while it could be more efficiently delivered in multimedia format. Our Laboratory is devoted to development of Multimedia applications, some of them concerning educational subjects in collaboration with several professors from the Humanities. Many of them asked for developing their own "cultural" application, but may be they don't have the budget, human resources or technical skills to carry on the job. With this requirements in mind we conceived LEZI, a tool that requires a minimal computer expertise in order to develop in a quick manner educational multimedia application based on interactive video and electronic documents.

New Views on Community and Collaboration: Building and Sharing Dynamic Worlds in Cyberspace

Paula Bonta, LCSI, Canada; Richard Borovoy, MIT Media Lab, USA; Susan Einhorn, Consultant, Canada; Brian Silverman, MIT Media Lab, USA

Abstract: The Internet has the potential to provide an unprecedented dynamic, interactive learning environment - one in which students from around the globe can collaborate in the construction of exciting new worlds. Despite the Internet's capabilities, there is a lack of applications geared towards fulfilling this need. This poster session will present a prototype, the Kids Internet Construction Kit (KICK), that allows K-12 students to create and share dynamic worlds on the Internet.

Reeves Ten-Dimensional Model: Application for the Design and Development of Web-Based Learning Scenario on Learning Theories

Caroline Brassard, Universite du Quebec a Chicoutimi, Canada; Jacqueline Bourdeau, Universite du Quebec a Chicoutimi, Canada; Pauline Minier, Universite du Quebec a Chicoutimi, Canada

This poster presentation covers the design and development of a media-based learning scenario and Web environment with a view to implementing a pedagogical design that integrates new technologies. The scenario responds to concerns regarding pedagogical innovation in "Teachers Training". It tries to facilitate the development of the skills required within the larger framework of courses where theoretical content is high and cooperative learning methods must be supported. The focus was therefore placed on the ability to "make links" and on the socio-constructivist approach. The results showed the importance of design, the need for cognitive strategies, the inherent pedagogical value of cooperative learning and developing the ability to "make links". The creation of links can go beyond the context to encompass any training session that contains a wide range of theories and a broad body of knowledge. It appears that the need for a design that produces the most appropriate overall educational formula may lead to proven pedagogical effectiveness.

The Creative Network:the development of a collaborative learning community for mature professionals

Helen Brown, University of Central England, Birmingham Institute of Art and Design, England

The hypothesis underlying the formation of the Creative Network is that a radical approach to Continuing Professional Development in the U.K. is needed to prepare those employed in the Creative Industries for:

1. the portfolio career
2. short term contracts
3. rapidly changing technologies/materials
4. structural changes in the companies, flatter hierarchies, featuring multi-skilling and cross functional teams
5. e-business (e-commerce and e-volution)

The Creative Network web site is the gateway to a learning community. There is no standard course or assessment. Instead the Creative Network tutors work with each individual learner or company to analyse their development needs and structure a training plan. The Creative Network aims to facilitate deep learning based upon a spirit of facilitation which helps learners to contextualise new learning and construct personal relevance and meaning.

Breathing New Life Into The Classroom

Lawrence Bundy, Nebraska Department of Education, USA

Two Nebraska projects, funded by grants from the United States Department of Education, will work together to prepare teachers to use technology in the classroom. The Connections Project, a five-year Education Technology Innovation Challenge grant, works with in-service teachers. Introductory, intensive five-day summer workshops focus on classroom uses of technology, brain-compatible teaching strategies, life skills, multiple learning styles, and integrated curriculum models. On-going staff development follows the workshops at local sites throughout the academic year. The teachers create curriculum units incorporating the strategies they have learned and post them on the project Web site—http://ois.unomaha.edu/connections. They also create CD-ROMs of the workshop presentations, which will be distributed to over 6,000 teachers. The Catalyst Project, a three-year Preparing Tomorrow's Teachers to use Technology (PTTT) grant, involves seventeen higher education institutions that are engaged in active systemic changes to prepare pre-service teachers to use educational technology. The two projects will work together to identify and develop a cadre of K-12 teachers who are leaders in the use of educational technology. This cadre will act as resources in the higher education classroom and as cooperating teachers for teacher education programs.

Improving Collaboration in Face-to-Face Groups using Technology

Robert W. Cavenagh, Jr., Dickinson College, USA

Abstract: Face-to-face collaborative work is an essential tenet of much contemporary teaching, especially within constructivist models. The practical use of technology by small intact groups has received relatively little research attention. Observation of learners in existing settings suggests that commonplace computing facilities may limit effective collaborative work by more than two individuals. The design of facilities and strategies specifically for collaboration has been demonstrated to improve the effectiveness of such work. This PosterDemo reviews applicable research, presents design and cost criteria for and photographic examples of purpose-built facilities, and delineates pedagogic strategies found useful, including both assignment and assessment strategies. It summarizes findings and future topics to explore. It also simulates the look and feel of one such collaborative facility.

Educational Applications of Hypervideo

Teresa Chambel, University of Lisbon, Portuga

Video clips can greatly enhance the authenticity of a computer based learning environment. Something constructivists have been strongly arguing for. Broadcast television does not afford composition or the time to reflect. But, television and video, when properly constructed, can be a powerful tool for reflection. If the user can select what is to be seen and control the pace of the material, and it is easy to go back and forth, to stop, to make annotations, to compare and to relate to other materials. Effective reflection requires some structure and organization, the main issues in hypermedia. Hypervideo refers to the integration of video in truly hypermedia documents, taking into account its spatial and temporal dimensions, and defining the semantic and mechanisms to link and navigate video and other media. In this presentation, different mechanisms for the integration and navigation of video in educational applications are demonstrated. These were developed using HTIMEL, an extension to HTML and existing Web tools, being developed and used in the Unibase project on distance learning.

Collaboration between T&T3 Project Team and ETU/CeLTS at HKIEd in Promoting Teaching Skills and IT for HE

Thomas YH Chan, Lingnan University, Hong Kong, China; Julianne WY Wong, Hong Kong Institute of Education, Hong Kong, China; Elson Szeto, Hong Kong Institute of Education, Hong Kong, China

We are presenting the fruit of our collaboration in the context of the T&T Project --- a publicly-funded inter-institutional collaborative initiative for all academic and professional staff in Hong Kong's HE institutions. Project mission is to pull together human and instructional resources from all institutions in a collaborative effort in promoting, fostering and advancing quality teaching and learning. We are going to share with conference participants the following:

- Designing and conducting sessions on IT in teaching and learning for academic and professional staff from all tertiary institutions in Hong Kong, in particular on:
- formatting and layout of text
- digital graphics
- perfecting presentation skills
- other digital media for enhancing teaching and learning
- Designing and producing for colleagues' use self-instructional multimedia packages for enabling IT self-sufficiency (in CD-ROM format)
- Initiating audio and video streaming for the "T&T Project Website" and related on-line multimedia packages

Teaching Symbol Recognition with Interactive Java GUI

Li Chao, University of Houston-Victoria, USA

Abstract: The ease of learning Java, its reliability, and its portability make this programming language more and more popular among students and faculty. It has gained much attention through its power of multithreading, networking, and computer graphics. As an assistant in teaching computer vision such as symbol recognition, Java has the flexibility needed to develop classroom demonstrations which are accessible through Internet. The objective of this paper is to present an interactive Java based GUI to assist the teaching of symbol recognition.

Kabisa: A computer-based training program for diagnostic reasoning in tropical medicine

Geraldine Clarebout, Univerisity of Leuven, Belgium; Jan Elen, University of Leuven, Belgium; Joost Lowyck, Univerisity of Leuven, Belgium; Jef Van den Ende, Institute of Tropical Medicine, Belgium; Stefano Laganà, Italy

A shift took place in educational goals from knowing everything in a certain domain, to knowing how to deal with complex problems. The reasoning process has become more important than the amount of information to memorize. In medical education the same evolution took place. A computer-based training program that is developed to guide and help to develop diagnostic reasoning skills in tropical medicine is KABISA. In this poster, the program will be presented and all its functionalities, as well as a user-test that was performed. This test was done to identify whether KABISA really contributes to the development of reasoning skills in tropical medicine. The main aim of this test is to determine what has to be changed to the program to provide students with an efficient learning environment to learn diagnostic reasoning and to optimize the program. Use was made of a thinking aloud method and log file analysis.

WEB-LIT: Web-Based Support for Learning Theory and Instructional Design

Ken Clinkenbeard, University of Bergen, Norway; J. Michael Spector, University of Bergen, Norway

The primary objectives of our project include creating an open and flexible web site to host materials on learning theory and instructional design. We will find and evaluate existing web-based materials on these topics which reflect a wide variety of perspectives, applications and lessons learned and organize the site so that materials can be posted and easily accessed. Interactivity also plays a key role. Opportunities are provided for users to comment on existing materials and/or submit new materials. Our goal is not to create an online course in the area of instructional design of learning theory, but to augment the design of these courses by offering support resources. A secondary goal of this site is to create a web-based set of resources that can provide a source of evaluation data on the use of web-based materials in graduate education.

Realism and Credibility in a Simulation-Based Virtual Physics Laboratory (VPLab): An Empirical Study

Marc Couture, Télé-université, Canada; Alexandre Francis, Université de Montréal, Canada

Realism and effectiveness of computer simulation-based learning or training environments have been examined in several studies. It was shown that under certain conditions, simulations can be as efficient as real experiments, and that increased realism may result in gains in 'practical appreciation'. However, few have investigated the relationship between realism and credibility, or between credibility and effectiveness. The VPLab is a simulation-based learning environment featuring many characteristics and constraints normally associated with real experiments. These include uncertainty in measurement, random fluctuation of parameters, and limitations in user control over the simulation. This approach distinguishes the VPLab from most existing simulation-based laboratories. We will present first results of an experimentation with first-year university science students, in which we sought to identify the factors, most notably those associated with our approach of realism, that may enhance the credibility of such an environment and/or its perceived relevance as a tool for learning laboratory skills as well as science concepts.

A Web-based Tutorial on Optical Communications

Ignacio de Miguel, University of Valladolid, Spain; Carlos Jesus Fuertes, University of Valladolid, Spain; Abel Prieto, University of Valladolid, Spain; Patricia Fernandez, University of Valladolid, Spain; Miguel Lopez, University of Valladolid, Spain; Fernando Gonzalez, University of Valladolid, Spain; Juan Carlos Aguado, University of Valladolid, Spain; Ruben M. Lorenzo, University of Valladolid, Spain; Evaristo J. Abril, University of Valladolid, Spain

We are developing a tutorial on optical communications in order to increase the interest of the students in this area and to clear up some concepts. The tutorial is divided into four didactical units: Propagation of Signals; Components and Devices; Optical Communication Systems; and Optical Communication Networks. Within each unit, basic information is provided as well as simulators and animations. The students can also perform self-evaluations to check their progress. The self-evaluations are randomly generated from the contents of a database according to the students' preferences (topics, difficulty and kind of items: questions and/or short problems). The tutorial is being developed at http://pesquera.tel.uva.es/tutorial. The utilization of web technologies allows the students to access the tutorial from their homes, and we hope it will facilitate the collaboration with other groups working in these topics. This work is partially supported by Consejeria de Educacion y Cultura (Junta de Castilla y Leon).

Posting Visual Cues on Threaded-Message Boards in Science Curricula: Enhancing Transfer of Theory Knowledge to Clinical Practice

Gregory A. DeBourgh, University of San Francisco, USA

Results of a pilot study (16 baccalaureate nursing students) suggest posting thematic, integrated photographs, graphic, and text data on asynchronous, threaded-message boards facilitates transfer of theory knowledge to clinical practice and supports the acquisition of skills in clinical reasoning (pattern recognition, critical analysis, problem solving, and identification of therapeutic interventions). Visual cues provide powerful representations of reality that enable students to recognize manifestations and patterns of clinical pathologies. Text-based learning prompts stimulate reflective thinking and collaborative problem solving. Used synergistically, they create clinical context, authentic complexity, and scaffold learning. Provided both words and pictures during instruction, learners encode information in such a manner that recall is facilitated and transfer of knowledge enhanced. Students report on-line interaction results in the positive experience of belonging to a professional community during learning, affords support and opportunities for collaboration, and increases access to the instructor to clarify "accuracy of learning" and provide feedback. Using visually-enriched on-line conferencing is an enjoyable, convenient, and satisfying way to amplify and enhance learning, and "brings the course content alive".

The «BacVert» or «Blue Box» - A Knowledge Recycling Bin for Students

Céline Desjardins, Centre de recherche LICEF, Canada; Éfoé Wallace, Centre de recherche LICEF, Canada; Claude Ricciardi-Rigault, Centre de recherche LICEF, Canada

While it has become common to provide students with a list of documents to peruse on the Internet, information gathering, net-surfing and annotation all have an exploratory, individual and work-in-progress quality. Sharing insights gained through these activities, especially in distance education, is complicated and requires highly structured settings. The INF9002 «BacVert» web-based dispositif at Télé-université supports such sharing. The natural language parsing performed by Nomino provides flexible automatic structuration, both of the core Internet material proposed by the teacher to which the students gradually add their findings, and of the comments about these documents produced by the students. By allowing a group of students to constitute an evolutive information base, to comment on it and to compare notes, the INF9002 «BacVert» constitutes a step towards tackling the complexity and heterogeneity of the information environment, while supporting exchanges among peers about the material at hand.

Building Global Information Communities: the University of Iowa Center for Electronic Resources in African Studies (CERAS)

Barbara Dewey, University of Iowa Libraries, USA

This poster session provides a case study of the issues and lessons learned regarding development of the University of Iowa's Center for Electronic Resources in African Studies (CERAS) (http://sdrc.lib.uiowa.edu/ceras/). The Center is a "virtual" space for creating, disseminating, and accessing scholarly electronic resources in text, multimedia, and interactive format, and a "virtual" place for further development of electronic resources (textual and multimedia-based) pertaining to Africa created by scholars from the United States as well as from Africa and other parts of the world (http://sdrc.lib.uiowa.edu/ceras/). CERAS is part of the University Libraries' Scholarly Digital Resources Center supporting students and faculty engaged in African Studies research and teaching at the University of Iowa, and scholars nationally and internationally. CERAS is also a venue for U.S. and African scholars for creating and disseminating African Studies scholarship and information resources in electronic format. Several CERAS initiatives have focused on image creation, particularly in the field of African art, a strength at the University of Iowa. CERAS will serve as a venue for digitizing projects related to Africana scholarship (i.e. museum collections, selected non-copyrighted collections, archival materials, and documents). Other goals include bringing high quality African Studies scholarly electronic collections and web sites currently in existence into a user-friendly digital library web page; providing a venue for "publishing" original materials, including pre-prints, (articles, books, conference proceedings) as well as creating significant thematic textual and multimedia collections of materials in electronic format; and developing an electronic international community of Africana scholars where dialogue about issues, research, and projects can take place. This latter feature is intended to provide a broader opportunity for Africana scholars to post drafts of research papers and projects for critique and discussion by other Africanists from around the world. The University of Iowa Libraries is seeking collaborative projects and partnerships with institutions and Africana scholars from around the world.

Introducing a Distance Learning version of a Postgraduate Program on Networking in Argentina

Dean Javier Díaz, University of La Plata, Argentine; Maria Alejandra Osorio, University of La Plata, Argentine; Ana Paola Amadeo, University of La Plata, Argentine

The great popularity of the Internet and the widespread use of the World Wide Web are promoting a new methodology for distance learning. The main advantage of the Internet based courses is possibility to promote a bi-directional communication between the students and the professor and to highly, motivate the student due to an adequate feedback. This poster describe the introduction of Internet tools (such as www, e-mail, IRC, FTP, mailing list) in the distance learning postgraduate program of the 'Magister de Redes' (http://www.linti.unlp.edu.ar/master) of the UNLP . The ongoing experience was successful due to certain facts that are stated in the poster which also mentions some drawbacks and the strategy for overcoming them. The distance-learning version of the program started in 1998 as way to reduce the obstacles for he students (professionals from the engineering and the computer science field in the networking area), mainly the traveling expenses and the time it takes due the large geography of our country and the long distances.

The Bones Of The Skull: Creating Anatomical Models With Quicktime Vr

Marilyn Dispensa, The University of Iowa, USA; Jim Duncan, The University of Iowa, USA; Jerry Moon, The University of Iowa, USA

This electronic demonstration will provide an overview of QuickTime Virtual Reality (QTVR) and its utility in the development of virtual anatomical models which can be used alone or integrated into computer-based-learning (CBL) software. The Bones of the Skull: A 3-D Learning Tool is a CD-ROM-based module designed to help college-level anatomy students learn the bones and important landmarks of the skull. The software has two main features: 1. A collection of Quicktime VR movies that allow the user to rotate and view the skull and its bones in three dimensions. 2. An interactive "textbook" that contains high quality 2-D images, descriptive text and many embedded activities to encourage interaction with the content. This presentation will demonstrate the product and provide an overview of QuickTime VR, including technical requirements and hardware/software costs. The Bones of the Skull won the 1999 Sandoz/Slice of Life Student Software Award.

The impact of establishing a virtual university: a case study at NUST

Nomusa Dlodlo, National University of Science and Technology, Zimbabwe

The purpose of establishing any university is to cater for the educational needs of the surrounding community. In developing countries universities fail to cope with large numbers of applicants. The reason is that the number of universities in such countries is limited due partly to historical circumstances and partly due to financial constraints. The exercise of building brick and mortar universities and acquiring skilled staff to run them is expensive.

A Distributed Maritime Simulation Training Environment based on HLA

Mirko Dobermann, Computer Graphics Center ZGDV, Germany; Harro Kucharzewski, MarineSoft GmbH, Germany

A new approach for advanced training systems is the integration of computer simulation into such applications, allowing students to experiment in complex scenarios. The presentation introduces a distributed simulation-based training scenario , generated in a distributed environment, which that offers extended functionality for interaction and demonstration within a maritime training scenarioapplication. The main objectives of the solution are threefold: to set up and establish a distributed simulation-based training environment, to provide real-time interaction functionality during run-time, as well asand to integrate already available simulators that are currently on the market. The infrastructure for this simulation is based on HLA/RTI, while which already offers functionality to couple embedded applications with networked simulation applications. The Computer Graphics Center in Rostock (ZGDV) currently focuses on maritime scenarios related to competency training for crews aboard and ashore. The development of the simulation environment is part of a research project in collaboration with regional enterprises in the Maritime sector.

Human Anatomy Predissection Lecture-On-Demand at The National University of Singapore

Gilles Doiron, National University of Singapore, Singapore

The NUS Integrated Virtual Learning Environment (IVLE) was developed so that staff and students could use this information technology infrastructure to communicate, exchange documents and information, discuss, chat, and access custom learning materials and course related web sites. IVLE also enabled the university to consider new pedagogical approaches, which would utilise its campus-wide broadband access to meet specific teaching and learning needs. A "lecture-on-demand" (LoD) delivery was seen as a viable tool that would allow students to take more responsibility for their learning and enable them to have greater control over their time schedule. With the collaboration of the Faculty of Medicine, the Center for Instructional Technology and the Centre for Development of Teaching & Learning, a prototype anatomy pre-dissection LoD, "The Abdominal Wall & Inguinal Canal", was produced. This paper examines the design and development issues addressed in building the prototype. Field test data on the technical reliability, and ratings, and comments from student feedback are presented.

ExploraGraph and CINEMA

Aude Dufresne, Univ. of Montreal, Canada; Claire Isabelle, Univ. of Moncton, Canada; Roger Nkambou, Univ.of Montreal, Canada; Yan Laporte, Univ. of Montreal, Canada; Frank Ferront, Univ. of Montreal, Canada

The ExploraGraph interface was designed to facilitate interaction in the context of distant learning. It was developed as an alternative to simple web interaction, in order to increase flexibility, visibility, and structure in the learning environment. It may be used as a front end to existing courses on the web and to support learner in them. The ExploraGraph Navigator makes it possible to navigate through conceptual graphs with automatic arrangement of elements, zoom and "fish eye" effects. Each node of the graph may have a description attached to it and may give direct access to an application, a document or an Internet site. Graphic structures may thus be used to represent the organization of tools, activities, concepts or documents. The Navigator offers each user a tool to specify his goals and the system can support him, using multiple modalities: Hypertext, graphical cues, Ms Agents avatars, voice, visual demonstrations and force feedback guiding.

Future Special Education Teachers' Abilities to Integrate New Technology Into Teaching Reading Comprehension

Catherine Dumoulin, Universite du Quebec a Chicoutimi, Canada; Jacqueline Bourdeau, Universite du Quebec a Chicoutimi, Canada

This study questions future teachers' abilities to integrate new technology into their teaching. A pedagogical scenario based on a cognitive approach was proposed to graduating students of the bachelor of Special Education program in order to teach Grade 3 students with reading comprehension difficulties. This pedagogical scenario integrated new technology via the "Village Prologue", a computerized environment. Future teachers were found to organize pedagogical activities, create learning situations suitable for teaching reading comprehension, help motivate children to read, and finally, guide children in their learning processes within the computerized environment. Furthermore, the pedagogical scenario helped in motivating future teachers to include new technology in their future teaching. The computerized environment also permitted the future teachers to adapt their teaching to the specific needs of children with reading comprehension difficulties.

School Festival on the Internet - Project-based and cooperative learning -

Hironori Egi, Keio University, JAPAN; Yoshitomo Tsutsui, Kamogata High school, JAPAN; Yuuki Nishimura, Keio University, JAPAN; Keiichirou Ishibashi, Keio University, JAPAN

We report a case of project-based and cooperative learning activities, School Festival on the Internet, Okayama 1999 (SF99) in Japan. Three public high schools in Okayama, Keio University and Kurashiki University of Science and the Arts participated in SF99. The goal of SF99 was to put the school festivals held at each of the high school on the web so that the students efforts could be widely appreciated. School festivals are considered as an educational event in Japan, and we implemented SF99 as a project-based and cooperative activity. The festival provides students with opportunities to present achievements of their research or their other interests. Video streams and online communication through a Bulletin Board System (BBS) were the main applications used to achieve the end. SF99 is one of the few examples were extra-curricular activities such as school festivals were digitalized. Information-based learning and extra-curricular activity have similar goals. We also analyzed the achievements of SF99 and discussed the educational effect of information-based learning using the Internet.

The ParlEuNet-project: Problems with the validation of socio-constructivist design principles in ecological settings

Jan Elen, University of Leuven, Belgium; Geraldine Clarebout, University of Leuven, Belgium

Instructional design aims at generating indications about optimal relationships between learner-related and instruction-related variables in view of the attainment of instructional and/or learning goals. In this poster, a study is presented in which it was started from socio-constructivist view on learning and instruction to identify a number of design principles. These principles were used to design and develop a concrete and innovative rich technological leaning environment, the ParlEuNet learning environment. The main features of the this environment can be described as follows:

- A variety of technologies
- A problem-based learning environment where use is made of ill-structured tasks
- International collaboration

It was hypothesized that such an environment would have an influence on certain learning environment. In this poster the environment and the results of the research will be presented, which indicate that there is an influence of the learning environment, however in a different direction than was expected.

Examining Medical Students' Attitudes and Learning Experiences in BioWorld

Sonia Faremo, McGill University, Canada; Susanne Lajoie, McGill University, Canada; David Fleiszer, Faculty of Medicine, McGill University, Canada

This poster presents BioWorld (Lajoie et al., 1998), a computer-based learning environment (CBLE) that engages learners in realistic problem solving as they attempt to diagnose medical cases. Its design is consistent with both problem-based learning (PBL) and cognitive principles of instruction. Solving a BioWorld case involves interpreting case history information, ordering diagnostic tests, developing diagnostic hypotheses, and reflecting on one's own performance. As part of a larger study, the data for this poster consisted of measures of the attitudes and learning experiences of medical students using BioWorld. The experimental procedure involved having medical students individually diagnose a set of BioWorld cases and complete a questionnaire concerning their experiences. Students rated several aspects of the system (level of interest, difficulty, utility of learning activities, etc.). The results have implications for the design of CBLEs for complex domains. They also suggest that BioWorld is an effective learning environment.

CyberARTS: A Integrated Arts Curriculum

Tito Faria, Don Mills Collegiate Insititute, Canada; Sholom Eisenstat, Don Mills Collegiate Institute, Canada

The CyberARTS program is offered at a number of school sites in Toronto. CyberARTS uses a constructivist methodology to deliver visual integrated arts, media communication, computer technology and now Gr. 9 Geography credits. Students have constant access to labs of Macs and PCs and a range of peripherals. Teams of teachers work collaboratively creating and delivering the curriculum. Senior students complete the program with a co-op experience. Their placements include: Alias Wavefront, Web Feat, Apple, Microsoft, the Design Exchange and Nelvana. Our partners include: Waterloo University, Apple, Kodak, Rogers Cable and SoftImage. Our senior class was involved in designing and producing the first edition of "RE: DESIGN", a web "zine" about design for teachers and students by students. www.dxnet.net. Currently a number of senior co-op students have placements at the Design Exchange where they are working on the website for Toronto's Olympic bid. Our program has won an Apple School of Distinction Award and some of its teachers have won a 1999 Prime Minister's Award for Achievement. We will focus on:

- problem oriented curriculum projects and units
- subject integration and authentic learning assessment techniques
- real-world connections and business partners

Managing Electronic Resources - Auto-registration for Distance Learning

Richard Fasse, Rochester Institute of Technology, US; Damon Betlow, Rochester Institute of Technology, US; Randy Overbeck, Rochester Institute of Technology, US

Electronic resources used in distance learning are often restricted to registered students through login ids and passwords. As electronic resources proliferate, so do the problems with managing these accounts for both students and administrators. One option is a form of auto-registration with "course keys" that allows users to select their own login id and password, but restricts registration to only those who received the "course key" in a handout or email.

Interactive Training Materials for Early Childhood Educators: Cases, Tools, and Reflection

Gail Fitzgerald, University of Missouri-Columbia, USA; Louis Semrau, Arkansas State University, USA

Materials to assist early childhood educators in working with young children with behavioral problems are currently in high demand. Multimedia programs offer an effective method for providing instruction based on authentic cases for developing necessary knowledge and skills. In the multimedia program, "Trisha," users can seek professional knowledge from an information database, watch Trisha in multiple settings, interview her teachers and other care providers, read case records, listen to expert commentators discuss theoretical approaches and care recommendations, and carry out a series of real-world activities related to Trisha's needs. Following problem-solving activities, users engage in a series of reflective prompts to review their decisions based on best practices. The program contains electronic performance support tools that can be used within the program as well as in actual job situations. "Trisha" is designed for implementation with workers in childcare settings and preservice courses. Additional information is available at http://www.coe.missouri.edu/~vrcbd/.

Integrating computer ethics into the computer science and computer engineering curricula

John Fodor, Educational Media Resources, Inc., USA

This demonstration will show how to integrate computer ethics into the computer science and computer engineering curricula by using the interactive CD-ROM Understanding Computer Ethics. (UCE was made possible by grants from the National Science Foundation and has won AXIEM, Communicator and International CINDY Awards.) We will discuss such topics as computer privacy, computer security, ownership of intellectual property, software piracy, hacking and professional responsibility. We will examine ways of developing skills, sensitivities, and understandings to "human value" issues and problems raised by computing and information technologies, including ways to elicit more reflective performance understandings. We will analyze four ways specific ways of integrating computer ethics into the computer science and computer engineering curricula:

1) as a stand-alone class,
2) incorporating computer ethics into existing cs & ce classes,
3) as part of a capstone senior project, and
4) as an independent study class.

Development and Implementation of Computerized Instructional Materials: The Mismatch Between Formal and Informal Technology Support Structures in a Medical College

Cynthia Frank, The University of Arizona, U.S.A.

This study focused on the development and implementation of instructional computer materials in the everyday teaching environment of a southwestern U.S. medical college. What happened between the time an instructor voluntarily decided to implement computer technologies in a course and the time a student could actually use the technologies? The existence of formal technology support structures led to the assumption that instructors would utilize professional help. This turned out not to be the case. The majority of instructors used informal support structures to develop and implement their materials. Much of the work was done by students who had no training in instructional design, multimedia programming, or graphic design. This preliminary finding indicates a fundamental mismatch between the type of support professors selected and the type of support offered by the institution.

Putting Curriculum in Control: Interactive Courseware Development with the TechDisc Instructional Design Template

Traig Friedrich, Sencore, Inc., United States; Bill Wann, Sencore, Inc., United States; Karen Korth, University of South Dakota, United States; Mike Hoadley, University of South Dakota, United States; Dan Eastmond, University of South Dakota, United States

The Technology for Training and Development division at the University of South Dakota has joined forces with Sencore, Inc., a multimedia application provider, in the development of an innovative multimedia authoring tool. Designed specifically to apply recognized instructional design techniques to "drag-and-drop" multimedia development, this tool puts interactive courseware authoring into the hands of the classroom educator. This approach to multimedia application development benefits everyone involved in K-12 education by enhancing the classroom teacher's control of course curriculum and specific course content. During this demonstration of the TechDisc Instructional Design Template, participants are welcome to engage in open discussions of the tool, trends in multimedia project authoring, and other issues surrounding interactive courseware development.

Using Virtual Reality to Assist Air Travelers With Disabilities

Clark Germann, Metropolitan State College of Denver, USA; Jane Broida, Metropolitan State College of Denver, USA

Getting to the airport, checking our luggage, going through security, boarding the plane--these are all tasks most of us take for granted each time we fly. But to persons with physical disabilities who use a wheel chair, the above tasks can be difficult and intimidating. No two airports are exactly the same, and procedures for air travelers with disabilities differ with each air carrier. To help ease the anxiety, faculty and students at Metropolitan State College of Denver have used computer technology to duplicate one major airport into virtual reality. Now, future air travelers can preview the experience first on the computer prior to going to the airport in person. With 135,000 people in wheelchairs in Colorado alone, provision of resources for air travel is especially pertinent. Survey research and anecdotal evidence has shown that these virtual representations can be helpful in reducing anxiety in persons with disabilities by providing a preview of a location prior to visiting it in person.

Gender and Race: The Accuracy of Internet Clip Art

Carol Gilley, University of Arkansas, USA; Elaine Terrell, University of Arkansas, USA

Abstract: Computers are being used to create various print media as well as multimedia. Some questions are being raised in developing these media materials. Is there a supply of free clip art on the Internet that represents the real world? Do viewers see themselves in clip art used in print and computer-based multimedia? This study explores the issues of equity and stereotyping with regard to the images in free Internet clip art by investigating the following two hypothesis. 1) There is no significant difference between the proportion of men, women, boys, and girls represented in free Internet clip art and the proportion of men, women, boys, and girls in the general population. 2) There is no significant difference between the proportion of White, Blacks, and other minorities represented in free Internet clip art and the proportion of White, Blacks, and other minorities in the general population.

How To Be Innovative Designing Educational And Interactive Environments For Children

Gloria Elena Gomez Escobar, University of Los Andes, Colombia

LUDOMATICA PROJECT looks to effectively attend children's educational needs. It seeks to help them to creatively think and act, validating their rights to high-quality education and to actively participate as social change agents. This validation is accomplished through innovations in formal, non-formal and informal education, using Information and Telecommunication Technologies within a non-conventional pedagogical. We want to develop the intellectual potential and cognitive abilities of children who live in high-risk situations, taking advantage of their adverse learning to stimulate creative potentials, communicative resources and have them discover their own adventurous spirit and creative capabilities. The interactive game THE FANTASTIC CITY is one of the environments created for these purposes. This is a digital multimedia microworld that motivates and develops children's fantasy and creativity by means of enigmas and puzzles, seeking to generate cognitive and affective imbalances. This interactive environment leads children to action. It promotes curiosity and experiential learning; it allows speculating, discovering, learning from mistakes; and it stimulates the desire to learn.

Teaching Dynamics of Dairy Herd Health and Management

Claudia Haferkamp-Wise, Cornell University, USA; Heather G. Allore, Cornell University, USA; Yrjo T. Grohn, Cornell University, USA; Lorin D. Warnick, Cornell University, USA

Cornell University offers "Dynamics of Dairy Herd Health and Management" (http://courseinfo.cit.cornell.edu/courses/vetmed745) - a newly designed web-based distribution course to its on-campus veterinary students and to students at 9 off-campus test sites within the United States and abroad. This course uses a computer-based instructional delivery system (DairySim) to teach basic concepts of epidemiology and economics of dairy cattle disorders, experimental design, and statistics. The courseware provides two simulation models - SIMHEALTH and SIMMAST - with an interactive user-friendly interface and output analysis - thus making research tools accessible to a broader audience. DairySim and its accompanying user guides are available on-line. Lectures can be attended in person on-campus or viewed via the internet. Students can print handouts for use in computer laboratory sessions, take on-line quizzes and download homework assignments. Completed assignments are handed in by uploading the documents. Instructor-student and student-student communication for off-campus students takes place via email and an on-line discussion board.

A Comprehensive Model for Improving Technology in Teacher Education

Robert (Bob) Hannafin, College of William and Mary, US; Robert (Bob) Hanny, College of William and Mary, US.

This paper identifies the professional development model developed at the College of William and Mary to close the gaps between its strategic vision for the teacher education program and its capacity. The College's vision is to produce teachers who seamlessly integrate technology by designing and assessing authentic student-centered learning activities. Three areas were identified as requiring parallel effort: faculty development, institutional development, and clinical faculty/PDS development. Goals were established that addressed capacity shortfall and advance the program to the point where significant innovation could occur. Both our students and faculty needed to master both basic technology skills and the subtler art of practicing creative integration strategies. It also required placing our students with teachers who are competent technology users and encouraging in technologically-adequate classrooms. Institutional changes were necessary on two fronts: upgrading the technology available in School classrooms, and instituting incentives to entice faculty to use and integrate technology.

Web-Based Tools For Courses On Transport Phenomena

Bernardo Hernandez-Morales, Universidad Nacional Autonoma de Mexico, Mexico; Rafael Fernandez-Flores, Universidad Nacional Autonoma de Mexico, Mexico; Jorge Tellez-Martinez, Universidad Nacional Autonoma de Mexico, Mexico

Even though multimedia applications have been extensively used in many courses, the field of transport phenomena has received comparatively less attention. Thus, we are developing interactive tools, to be accessed through Internet, to solve problems observed when traditional teaching techniques are used. The material consists of modules to solve typical problems in transport phenomena. Each module is a Webpage that includes the theoretical background (with hyperlinks to all course material) and an interactive worksheet to solve a particular problem. The worksheets are built with Java applets (JDK 1.1. compatible) and may may be used in any of three modes: example mode (fixed set of values), training mode (variable set of values), and exploration mode (range of values of a key independent variable). Thus, unlike problems found in traditional textbooks, the student may explore a range of values for key independent variables to establish its influence on the dependent variables.

Shaknoma: A collaborative tool for shared knowledge management

Oriel Herrera, Pontificia Universidad Catolica de Chile, Chile; Sergio Ochoa, Pontificia Universidad Catolica de Chile, Chile; Vidal Rodriguez, Pontificia Universidad Catolica de Chile, Chile; David Fuller, Pontificia Universidad Catolica de Chile, Chile

Nowadays, the amount of scientific knowledge produced is overwhelming and it is clear that it will grow even more. Shaknoma (Shared Knowledge Manager) is a tool useful to make available and share the people's individual knowledge. The activities carried out on this tool respond to a model that ensure the input, validation, use and evolution of the knowledge. The process is implemented through four major components: the shared repository, the management model (see Herrera et al. 2000), the representation language of the knowledge, and the collaborative environment. The knowledge management model provides decision-making mechanisms, which mainly includes discussion and voting activities. As a way of structuring and graphic representation, Shaknoma uses a language based on conceptual maps (Novak 1984). The information repository does not store only knowledge, but also the information of its use and evolution.

Teachers and Computer Technology Training

David Hofmeister, Central Missouri State University, USA; Gerry Peterson, Central Missouri State University, USA

The poster session provides an overview of the processes and materials used to advance the integration of computer technology into student learning in K-12 schools.

Results and conclusions from a Learning Software Design Competition

Brad Hokanson, University Of Minnesota, USA; Simon Hooper, University Of Minnesota, USA; Paul Bernhardt, University Of Minneosta, USA

The University of Minnesota's Design Institute is sponsoring a competition to recognize the design of innovative educational software. The competition was open to professional and not-for-profit educational software designers in such areas as higher education, K-12 education and commercial training. Prizes will be given in each category, and entries for the competitions were due February 15, 2000. Winners of the competition were announced April 10, 2000. One of the competition's goals is to establish a bank of exemplary educational software that can be examined by designers and students of educational software design. To facilitate this goal, winning designs (and others selected for inclusion) will be compiled and made available to the public. We will present the results of the competition in a workshop format at ED-MEDIA 2000. The intended audience is educators and practitioners in the field of educational technology.

Constructive Hypertext for Learning

Hsi-chi Huang, The Ohio State University, USA

This study focuses on teachers as designers using constructive hypertext and teachers' perspectives on the use of the World Wide Web in educational contexts and its implications. Constructive hypertext encourages the participants not only to be users of hypertext, but also to be designers of hypertext. The study describes the participants' experiences as designers and their thoughts on designing hypertext for learning. In designing Web-based hypertext learning environments, educators can make use of the Web from three approaches: the Web as a resource for information, the Web as a medium of expression-representation, and the Web as a space for dialogue. The distribution perspective takes advantage of the Web as an information network. The expression-representation perspective uses the Web as a space for publishing, and expressing ideas and creativity. The Web as a space for dialogue has the capacity to encourage and embrace different voices. To participate in the dialogue is to create voices. The dialogue space provides possibilities for students to converse and exchange learning experiences.

Internet Infrastructure with ATM for Small Countries; Case Studies

Necdet ICIL, Eastern Mediterranean University, TURKIYE

Rapid development on communication technologies, become easy to support QoS (Quality of Services) application on Internet. As a case study, North Cyprus which is a small country with 5 small cities, develop a project to connect all cities with ATM BackBone. The purposes of the project is to connect all the local government offices to the cities node and to use all multimedia and information facilities on the BackBone. All governmental documentation will be send electronically between the offices. Virtual meeting will be possible by using video conferencing facilities. Also all schools will connect to the Ministry of Education to use educational facilities which are prepared by the trainers.

NACSIS-ILL Distance Training System in IDLE Distance Learning Project

Tomo'o Inoue, National Institute of Informatics, Japan; Haruki Ueno, National Institute of Informatics, Japan

We have started the distance learning project named IDLE (Integrated Distance Learning Environment) in 1998. The primary motivation of beginning the project is to meet the social needs. There are not many practical and sustainable DL systems in Japan, while on the other hand DL is already recognized as a natural form of getting education in the US. Current core product of IDLE is NACSIS-ILL Distance Training System, a WWW based system for training NACSIS-ILL operators. NACSIS-ILL is a system that our institute offers to nearly 700 university libraries to support exchange of information for the inter-library loan service. Our institute also offers NACSIS-ILL Training Courses to train the staff in the inter-library loan sections of the participating libraries. We have put emphasis on its practicality in the project and applied DL to the training course. The system will be in actual use this year.

Linking Active Learning to Web-based Instruction: Students Teaching Students through Multimedia Productions

James S. Javenkoski, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA; Elizabeth F. Reutter, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA; James E. Painter, Department of Food Science and Human Nutrition, University of Illinois at Urbana-Champaign, USA

Instructors (academic teachers and corporate trainers) recognize the value of video as an educational medium. Video provides learners (students and trainees) with opportunities to observe phenomenological examples that reinforce the concepts that are verbally described during classroom and laboratory sessions and on-the-job-training. Until recently, educational video production was a multi-step, multi-component process requiring at the minimum a camera or VCR, a computer (with a high speed processor, very large hard drive, and video editing and processing software installed), and a high speed serial I/O connection to transfer the video data between hardware devices. The new Apple© iMac™ DV desktop computer and iMovie™ software offer a simple, accessible, and affordable solution to instructors who wish to create continuous media (audio and video) for use in their courses. Our demonstration will showcase the QuickTime streaming videos produced in UIUC's FSHN 199: Business Etiquette and Protocol and FSHN 355: Fine Dining Management courses.

Using Tailored, Interactive Soap Operas for Breast Cancer Education of High-Risk Hispanic Women

Maria Jibaja, Baylor College of Medicine, USA; Paul Kingery, Hamilton Fish Institute, USA; Nancy Neff, Baylor College of Medicine, USA; Quentin Smith, Baylor College of Medicine, USA; Jennifer Bowman, USA; J. David Holcomb, USA

While Hispanic women have lower rates of breast cancer than other groups, among women from all ethnic groups, they are the least likely to undergo screening exams. This study evaluated a culturally sensitive and linguistically appropriate tailored computer-based educational program on breast cancer early detection aimed at high-risk Hispanic women. Spanish-speaking Hispanic women from an inner-city community health clinic were recruited and randomly assigned to either a computer intervention with an interactive soap-opera format (n=118) or a comparison group (n=60). True-false pre- and post-tests were used to identify any change in breast cancer related knowledge/beliefs. Both younger (18-40 y.o.) and older (41-65 y.o.) women in the intervention group increased significantly their knowledge/beliefs as compared to the younger and older women in the comparison group ($p<.05$). Computer-based tailored and interactive soap operas that are linguistically and culturally appropriate are effective in increasing breast cancer screening knowledge/beliefs in high-risk Spanish-speaking Hispanic women.

webStract - a Distributed Tool for Collaborative, Project-driven Learning on the Internet

Werner B. Joerg, NetEssence / U of Alberta, USA

webStract is a combined software tool that supports the construction and delivery of Internet based courseware. It embodies a project-driven paradigm - a problem based learning approach guided by the needs of student projects. It allows content providers to make effective use of the vast knowledge source of the World Wide Web and to present the students with qualified material in a structured manner. It takes advantage also of the interaction capabilities of the Internet, to enable focused synchronous and asynchronous communication among distributed teams and team members. Following a brief introduction of the motivation and the learning paradigm, our presentation centers on the three principal areas of service covered by webStract: knowledge qualification and structuring tools for the content provider, collaboration and management tools for the teams, and knowledge management tools for the individual student. webStract is currently being used in experimental courses. We'll report feedback from those experiments.

Digital Learning System: Web's Cool

Myunghee Kang, Ewha Womans University, Korea

Web's Cool (can also be pronounced Web School) program with SRL(Self-Regulated Learning) principles, PBL(Problem Based Learning) approaches and Keller's ARCS model for motivation has been designed by the author and developed by Samsung Electronics Company in Korea. Now, all the contents and study modules are completed in CD-ROM and the total service including Q&A and real tutorial help is now available on the UNITEL web service.

Learning Amidst A Sea Of Information In The New Millennium

Dan Kauwell, University of Illinois, Urbana-Champaign, USA; Jim Levin, University of Illinois, Urbana-Champaign, USA; Daniel Schiff, University of Illinois, Urbana-Champaign, USA; Young-Jin Lee, University of Illinois, Urbana-Champaign, USA

Visualization can improve our ability to access information and construct knowledge. Information visualization is particularly well suited for the location and analysis of information found on the Internet and, for the construction of knowledge from that information. Our research has led us to develop VisIT, a tool for the visualization of Internet based information and the analysis of that information. Instead of lengthy lists of search results, the user is presented with a graphical, spatial representation of the search space. Now the user can "see" the hits returned by the search engine as well as other pages from the same site. When any of the pages are clicked, the appropriate page is displayed in the browser window. Furthermore, VisIT facilitates the knowledge construction process by allowing its graphical displays to bc cdited, saved and re-opened later.

An@tomedia: A New Approach TO Medical Education Developments In Anatomy

David M. Kennedy, Monash University, Australia; Norm Eizenberg, The University of Melbourne, Australia; Chris Briggs, The University of Melbourne, Australia; Ivica Grkovic, The University of Melbourne, Australia; Priscilla Barker, The University of Melbourne, Australia

Evaluations have indicated that students find An@tomedia very engaging (Kennedy, Eizenberg, & Kennedy, In this volume). An@tomedia supports students actively in their learning tasks, fostering a deeper understanding of human structure, with a stronger basis for clinical diagnosis and procedures. The new medical course has focused less on traditional teaching, instead emphasising on focussed dissection, problem-based and self-directed learning. An@tomedia provides multiple perspectives of the human body. Each module is independent and of equal importance. The modules are:

1. Back,
2. Abdomen,
3. Thorax,
4. Neck,
5. Upper Limb,
6. Lower Limb,
7. Head, and
8. Pelvis.

The first 3 of the 8 modules, the Back, Abdomen, and Thorax have been completed, each organised into 4 major perspectives.

1. 'Dissection' includes practical (including emergency) procedures.
2. 'Imaging' incorporates sectional and endoscopic anatomy.
3. 'Regions' incorporates surface and functional anatomy.
4. 'Systems' incorporates conceptual and clinical anatomy.

Offering Online Degree Programs: A Case Study Issues, Challenges, Successes, and Lessons Learned

Gerard Kickul, University of St. Francis, USA; Laurel Jeris, University of St. Francis, USA; Michael LaRocco, University of St. Francis, USA

Offering degree programs online offers an attractive option in the higher education environment. As schools confront this opportunity, familiar issues of quality, access, participation, retention, and assessment take on new meaning. Online delivery systems parallel traditional classrooms, including discussion and assignment areas, chat rooms, and online assessments. After experiencing high student dropout rates the University focused on several solutions to reduce its student dropout rate. These included online support systems with a centralized approach to addressing faculty and student technical concerns, complaints, and requests for assistance. A new assessment procedure consists of a two-phase process, a pre-course assessment and a more traditional assessment occurring during the final three weeks of the course. Finally, feedback from faculty on the various instructional design challenges including learning curve, time commitment, recommended class size, ethical issues, adaptability of subject matter content, and practical suggestions for reconceptualizing syllabi and assignments for online learning will be included.

Developing a Distance Education Infrastructure

Gerard Kickul, University of St. Francis, USA; Mark Snodgrass, University of St. Francis, USA

Development of distance learning infrastructure is a multifaceted project, from the desktop to the far reaches of the Internet. Attention must be focused on the outgoing data and information, as well as, incoming data and information. There are four basic areas of concern when designing an infrastructure to facilitate Internet distance education solutions: hardware, software, support, and security. Providing the proper hardware to developers and support personnel is crucial in creating a productive and efficient work environment. Reliable and efficient Internet access is essential, with 24-hour availability and minimal down time. Software components for development and support are key ingredients to success. From a student and faculty standpoint, the course software must be user friendly with a high degree of stability. Support must be considered from both a human and a technological standpoint. Essential to any online endeavor is secure access and distance learning demands the highest levels of security.

Content Management for Web Based Learning

Thomas Kleinberger, TECMATH AG, Germany; Paul Müller, University of Kaiserslautern, Germany

With the help of the newest information and communication technology all the needs of modern educational systems can be met for the first time in one tool: the computer. Computer based solutions provide the technological support necessary for the whole teaching and learning process. The greatest advantage of this tool is the possible combination of all its usable instruments, their flexibility and configurability. With new technologies and new media types it will be possible to support all kinds of training, self-study and continuing education. It is clear that these new methods and technologies require new methods and solutions for the tasks content creation, delivery and archiving. Especially the use of new media sets high requirements on these tasks. This article describes how content management systems, a technology already used in other kinds of business, can support these tasks in web based teaching and learning. A definition of content management is made and refined for the area of web based learning. The main building blocks and features of content management systems are described and the improvements for web based learning are highlighted.

Computer-Mediated Communication for Distance Education: Developing and Teaching a Second Language Course in Academic Reading

Esther Klein-Wohl, Open University of Israel, Israel

The Open University of Israel is searching for ways to improve its distance education methods. Taking advantage of the flexibility of computer-mediated communication (CMC), we will describe the application of CMC to academic reading. We chose e-mail support, which allows students to work on texts, and to receive feedback and help when needed. Reading - a mode of language use, and distance education - a mode of language instruction, feature striking parallels: the reader (in "real life") and the learner (when learning to read) each functions in isolation when interacting with a text. Discourse is enacted at a distance, a disassociated first person (the author or the instructor) is actively present, and no reciprocity is manifest, within the interactive context. Therefore, reading instruction and distance education seem very well-suited. Because CMC is particularly learner-centered, it seemed appropriate to adopt this more motivating medium of instruction to our traditional reading program.

The Major Promise of Distance Education Is On Campus

W. R. (Bill) Klemm, Texas A&M University, USA

Distance Education (DE) is reforming on-campus instruction. DE's impact extends beyond the mere use of technology to put more razzle-dazzle into classroom presentations and beyond the advantages of assisted learning via computer simulations, drills, and animations. DE should force teachers to re-examine teaching philosophies, style, and tactics. Distance Education shows that learning need not depend on classroom lecturing. Indeed, we should now re-consider the whole purpose of the classroom environment. DE prompts us to re-examine accrediting criteria of "contact hours" and "credit hours." Teachers, now freed from the lecturing straight-jacket, can explore creative ways to show students how to find, comprehend, manage, integrate, and apply information. DE reveals the value and need in teaching for more interpersonal communication, between teachers and students and among students. I see a revival of interest among teachers in group work. Specific strategies for this new kind of classroom teaching are illustrated in the poster.

Interactive Ophthalmic Pathology Tutor

Gordon K. Klintworth, Duke University Medical Center, USA; Anthony N. Benson, Duke University Medical Center, USA; Ann L. Bushyhead, Duke University Medical Center, USA

A CD-ROM interactive, instructional course on ophthalmic pathology and relevant anatomy with hundreds of high quality images has been developed for users with different knowledge backgrounds.

Cognitive Idea Processor --- Modified Mandal-Art

Kagemasa Kozuki, Konami Co, Japan; Atsushi Tsubokura, Osaka Electro Communiation Univ., Japan; Shogo Harima, Osaka Electro Communiation Univ., Japan; Noboru Ashida, Osaka Electro Communiation Univ., Japan; Katsuhide Tsushima, Osaka Electro Communiation Univ., Japan

The new idea processor called modified Mandal-Art which can assist a user in his associative thinking between given item have been developed in which a user can communicate with the system using eye movement , finger-hand motion and voice. A user of this idea processor is forced to associate by seeing only nine items on the matrix called Mandala on CRT at a time. We have measured this information retrieve behavior from item pool of our testee putting on eye mark recorder and data gloves. Human associative thinking in his problem solving is accelerated by using this cognitive idea processor. This type of idea processor may brings us innovation of educational style on the computer by using the student model which take account the real time associative behavior of a learner.

Dilemma of Inquiry and Reflection Through and With Technology: New Directions for Research in Post-Secondary Teaching

Olga Kritskaya, Michigan State University, USA; Tony Clay. Michigan State University, USA

The study explored the issues of pedagogy for teaching reflective inquiry in the undergraduate program in Educational Psychology. The analysis focused on the role of the learners' imagination and the use of instructional hyper-media texts in construction of meanings associated with the course content. Particular attention was paid to the development of student design ideas that they use for the arrangement of images, which reflect, as a special form of narrative, on their understanding of the disciplinary concepts, personalities and life experiences. The data illuminate the instructional conditions when the student's act of arranging information becomes an act of insight. The computer-based student projects (Teacher's Portfolio, Multi-Media Gallery), along with the instructional hyper-media texts, reveal a critical instructional shift in the pedagogy of teaching reflective thinking-from structure to process, from enforcing students' competence to engaging them into performance-that fosters a deeper understanding of the dialectics of socio-cultural processes.

Assessing and Training Admunct Faculty with Technology: Enhancing their Classroom Learning

Karen Krupar, Metropolitan State College of Denver, USA

Increasing numbers of adjunct faulty at all major institutions of higher education has made it imperative that institutions examine the technology competencies of this large contingent of faculty who now instruct 40% of the courses on the undergraduate level. Very little effort is being made to provide development or training for these faculty in technology applications that would keep their students current in the rapidly altering global world of the 21st century. Metropolitan State College of Denver reviewed their 650 adjunct faulty and found many interesting factors that will be reported during this poster session. It is evident that adjunct faculty need assistance in both learning specific technology programs and in applying the technology into their coursework.

Design an Enhanced Virtual Experiment Environment Using Science Process Skills on WWW

Li-Ping Kuo, Chung Yuan Christian University, Taiwan, R.O.C; Da-Xian Dong, Chung Yuan Christian University, Taiwan, R.O.C; Chang-Kai Hsu, Chung Yuan Christian University, Taiwan, R.O.C; Jia-Sheng Heh, Chung Yuan Christian University, Taiwan, R.O.C

This paper proposes a methodology of applying a proper distance learning system following Seven Steps of Problem Solving and Science Process Skills. To complete this process of distance learning, this paper also suggests some tools for student undergoing all the process needed in the problem solving. Virtual Experiment Environment and Experiment Record are presented for some new notions in this paper. In Virtual Experiment Environment, Visual Lab is a new idea to operate experiment in Internet and show the reality of experiment. Experiment Record solves the difficult of implementing sheet and chart in HTML document. An environment for teacher design Science Process Skills is also presented in this paper.

Analysis of messages on the Only One Earth Club; TV-based collaborative learning site on the Internet

Haruo Kurokami, Kanazawa University, Japan; Tatsuya Horita, Toyama University, Japan; Yuhei Yamauchi, Ibaraki University, Japan

Messages sent to our BBS for collaborative learning can be classified to 10 categories. Each of these categories has some types of interactions among participants and site-staffs. The types of interactions are promotion of in-depth learning, discussion, and question & answers.

Aged and Disability Care training: A CD-ROM based project

Mark Laidler, RMIT UNIVERSITY, Australia

This demonstration has been developed to highlight one solution for delivering high quality work-based training in a multimedia environment.

Civilization in the 21st Century

David F. Lancy, Utah State University, USA; David DeBry, Utah State University, USA; Megan Andrew-Hobbs, Utah State University, USA

We will report on the evolution of an on-line course. The Civilization/Humanities course had its origins in the reform of the university's General Education curriculum in 1994-95. It was one of several classes created to replace existing requirements. The reform effort was designed to create interdisciplinary classes that would put the emphasis on universal aspects of inquiry rather than the narrow focus of typical introductory classes. Other expected features of these new courses were an emphasis on writing and the integration of technology. The initial Civilization/Humanities class met these criteria and was, by several measures, quite successful. In developing his version of the class, Dr. Lancy digitized his very large slide library and students were thus able to more readily access the collection for study and review. Another milestone occurred in 1998 when the library adopted an Electronic Reserve policy. Forced to incorporate this system into his class, Lancy went further and adopted many of the built-in features of ERes" such as the "Bulletin Board." Civilization/ Humanities was moving towards the new millennium as it were. It became clear in the second year of implementing the new Gen Ed program (referred to as University Studies) that not enough faculty were signing on to teach the new courses. A bottleneck emerged which provided further incentives to adapt the few classes that had been developed to meet the new criteria for delivery to a larger audience. The most recent stage in this evolutionary process we will report on is the transformation of the Civilization course from a (primarily) classroom to (primarily) on-line delivery. In concluding we will generalize about this evolutionary process from cases gathered across the curriculum on our campus.

Wired for Learning

Donna Landin, West Virginia Deaprtment of Education, United States; Roberta Taylor, IBM, United States; Lynn Blaney, Wheeling Park High School, United States; Susan Alkire, Romney Junior HIgh School, United States

The Reinventing Education project was established under a $2 million dollar grant from IBM to the West Virginia Department of Education. Its purpose is to define and validate criteria for creating instructional plans that use the power of the Internet to address the West Virginia Instructional Goals and Objectives and improve student achievement and learning. A Criteria for Excellence was created, then employed by a group of pilot teachers to develop lesson plans that would be peer reviewed, validated by field testing, observed during classroom implementation, and repeatedly revised. The resulting lesson plans have resulted in significant learning improvement and have been placed in the Best Practices database and shared with all teachers in West Virginia. Instructional plans have been developed for K-12 classrooms in the areas of math, language arts, social studies and science by teams of teachers, pre-service teachers and college instructors. On line professional development facilitates implementation of the instructional-collaborative environment.

Redesigning An Individualized Paper-Based Course

Stéphane Lavoie, SOFAD, Canada; Jo-Ann Stanton, SOFAD, Canada

Web-based courses that are an adaptation of a paper-based version rarely take full advantage of the Internet and related technologies. Taking this into account, we developed a successful interactive web version of a French grammar course. This poster session will show how "Du français sans fautes" was reengineered to avoid the pitfalls of shovelware using an Oracle database created with Visual Basic applications. We will offer an insight into the most challenging aspect of the process: the development of interactive exercices. We will focus on how we worked around technical constraints in order to maintain our pedagogical goals. More than 1500 students have enrolled in the course since it went online in September 1998. You may access "Du français sans fautes" at http://www.dfsf.com.

Team-paced versus Self-paced: The Effects of Educational Game Design on Collaboration, Learning and Attitude towards Information Technology

Edith Law, University of British Columbia, Canada; Maria Klawe, University of British Columbia, Canada; Cristina Conati, University of British Columbia, Canada; John Meech, National Research Council, Canada

Avalanche is a multi-player game where players must cooperate to achieve a common goal. Using Avalanche, a pilot study was conducted to investigate (a) the effects of cooperative (team-paced) and independent (self-paced) learning on communication patterns, performance, learning and attitude of the players, and (b) whether there exists any gender differences in how boys and girls interact with the computer and their teammates in a cooperative gaming environment. 16 elementary school children, in same-gender groups of four, played Avalanche for two-hour sessions. Results suggest that although team-paced learning foster a positive, cooperative team dynamics, self-paced learning has a more significant effect on learning itself. In addition, boys and girls react to the two versions of the game differently. In particular, the self-paced female group demonstrates more cooperative and help seeking/giving behavior than the team-paced female group, while the reverse was observed among the boys.

Assured Quality Strategies in Web-based Accredited Programs

Judy Lee, University of Central Florida, USA

Distance learning poses a challenge to voluntary accreditation. Quality assurance in emerging technology mediated distance learning is a central issue for accredited programs. The Council for Higher Education Accreditation report (CHEA, 1998) defines "quality assurance" as the means by which the institutions or providers set their accredited programs goals and measure results against those goals in distance learning. Regional and specialized accrediting organizations are currently engaged in assuring quality in distance learning as part of their ongoing review of institutions and programs. "Distance learning is seen by many as transformative vehicle for increasing the pace of change and reform in higher education. For these and other reasons, analysis of quality assurance is an essential topic for national, state and institutional policy development (CHEA, 1998)." Areas of interest regarding Quality Assurance Strategies include course and program concerns and needs, faculty and student concerns and needs, technical needs, and administrative support.

Council for Higher Education Accreditation (1998, April) . Assuring quality in distance learning . Washington, DC: The Institute for Higher Education Policy

Training Students to Be Self-Learners in Educational Hypermedia and Technology Courses

Amy S. C. Leh, California State University San Bernardino, USA;

Modern technology is changing our education paradigm. Due to technology advancement, instructors can no longer play the role of "information-giver", rather have to become a facilitator. Facing tremendous amount of technology information, students in Educational Technology need to feel comfortable of learning technologies by themselves. The presenter employed a variety of instructional strategies in her graduate courses to train her students to be technology self-learners. In the courses, her students searched for Internet tools useful for instruction, selected computer applications that they would like to study, learned the selected tools in a team, and trained other class members the use of the tools they learned. In this poster session, the author will present teaching strategies, instructional activities, and course assignments that are related to the training. She will also report students' feedback on this kind of training.

Effective Use of Client-Server Software and Teaching Strategies in Online Courses

Amy S. C. Leh, California State University San Bernardino, USA; Laura Howzell Young, California State University San Bernardino, USA

In the field of education, many professors are incorporating online teaching into traditional courses. What is the impact? The authors received a university internal grant to convert two education courses—an instructional technology course and a course in adolescent development—to include online components. They report the benefits and challenges of using WebCT (course tools) with a variety of teaching methodologies. The poster session reflects results of a pre- and post- survey used in both courses to determine teacher attitudes toward online coursework. Students in both courses appreciated the flexible schedule of online work and time saved by not having to commute. The majority of teachers in both classes had not previously taken online courses; many liked the threaded group discussions and online testing, but a few who did not believe at the outset that on-line teaching is beneficial continued to reject it. For most of the participants, technology improved learning and achievement.

Stepnet: quality newspapers and web-based learning in the Netherlands

Jan Lepeltak, Meulenhoff Educatief, The Netherlands

Stepnet is a web-based newspaper-project in the Netherlands. Due to some educational reforms students in the upper grades of the Dutch secondary schools are to study partly individually, which implies that teachers are obliged to provide them with proper assignments. The results of these are part of the students' final examination. The use of ICT should also be part of their activities and a relation with daily (world-) news-events is strongly recommended. In order to facilitate the above aproach for teachers and students, PCM, a Dutch publishing company consisting of newspaper and educational publishing houses, developed a web-site. This site contains a D-base filled with assignments related to the contents of two daily national quality newspapers. Every three weeks during the annual schoolterm a special magazine is published. Schools will pay a fee and will receive a licence in return, which entitles all participating students and teachers to receive a copy of this magazine called the "@krant", as well as access to the assignment D-base and the @krant D-base containing the newspaper articles. In addition, teachers will receive a half a day on-the-job training about working with Stepnet.

Custom-Authored Hypermedia Exercises for Use in College Classrooms

Amy Lobben, Central Michigan University, USA

Continuously improving technology now allows educators new opportunities to move beyond traditional lecture style methods to create custom-authored multimedia, hypermedia, and animation presentations for use in classroom demonstrations or as computer-run student exercises. The development of new software programs and faster, more powerful computers, is beginning to change the creation process of dynamic presentations (multimedia, hypermedia, and animation). The once time consuming, programming intensive, and complicated methods of authoring such presentations have become manageable tasks through the use of improving computer programs, many of which are easy to learn and use. A series of computer-administered lessons have been created using Macromedia Director and Freehand. Each interactive lesson is designed to explain a specific topic and includes animation, graphics, photographs, quizzes, while maintaining stringent design guidelines. Applications such as these could have profound effects in large college classrooms, where traditional lecture-style approaches limit the individual, active learning by students.

Groupware Tools: Web File System Allows Students to Access Information Anywhere, Anytime

Tyrone Lobo, SiteScape, Inc., Canada

This poster/demo is based on SiteScape's Web File System and will explore how the Web File System allows users to securely store and manage large volumes of information entirely over the Web, giving students the freedom to access information from any industry-standard web browser.

A Web-based Hypermedia Pedagogical Course

Alla N. Makarova, St-Petersburg State Pedagogical Univeristy, Russia

The success of any hypermedia distance-learning course strongly depends on its psychological and pedagogical aspects. A study was made of the practical realization of some common pedagogical/psychological criteria in a Web-based hypermedia course. As a result of this study a template was developed which includes these criteria. This template may be included as a building block for many different hypermedia courses devoted to a particular subject. Some open problems with the template are discussed and analyzed.

Info Pursuits

Kerrie Manning, Leichhardt High School, Australia; Rosemary Ward, UTS, Australia; Tony Ward, Award Consulting Enterprises, Australia

Info Pursuits is an interactive CD-ROM game designed to teach and practice Library Information Skills. Students will answer Trivial Pursuits style questions and will be offered Information/Research Skills hints and suggestions as part of the feedback. These will include such things as techniques for finding resources, using encyclopaedias, dictionaries, non-print resources, Internet, statistical resources, telephone books, indexes, directories, interviews etc. Positive experience in using these resources may stimulate students to use them again in a different research task. The same skills are practiced many times with different resources and in different contexts, to facilitate transfer. The questions will be arranged in teaching area groups, to be used by teachers in ordinary lessons within the standard curriculum, or as extension work within standard curriculum areas. Many questions will practise general skills, but each curriculum area will provide experience with subject-specific resources.

Content Area Integration: A Step Toward Emiratisation

Reo H. McBride, Dubai Women's College, United Arab Emirates; Michael Ford, Dubai Women's College, United Arab Emirates; David Thomson, Dubai Women's College, United Arab Emirates; Raymond Yarsley, Dubai Women's College, United Arab Emirates; Laila Hawker, Dubai Women's College, United Arab Emirates

The Higher Colleges of Technology (HCT) is dedicated to the delivery of technical and professional programs of the highest quality to the citizens of the United Arab Emirates (U.A.E.). This is the goal of "Emiratisation": an affirmative action policy of employing nationals in larger numbers in the workforce, which is currently dominated by ex-patriot workers. The authors of this article state that the most effective way to better prepare our students in fulfilling their roles in the task of emiratisation, is to integrate the skills taught in English, Math and Basic Computing in the classroom, and NOT teach them as completely separate entities. In essence, integrating the skills taught in English, Math and Basic Computing develops in students greater linguistic abilities, technical skills, intellectual capacities, and leadership potential. This study describes efforts made toward accomplishing such a daunting yet absolutely necessary task for college students in the U.A.E.

High Tech Classrooms-Going The Distance with Distance Education

Patricia McNames, Indiana University Southeast, USA

The rapidly evolving paradigm of interactive distance education is changing the learning environment on and off campuses and schools nationwide. Educators are suddenly surrounded by not only the opportunities of distance education, but also by its demands. Thus, when educators begin using these boundary-spanning technologies to enhance the learning process, it does dramatically require teachers and students to change what they do. The purpose of this paper and poster/demo is to serve as a resource for educators who may be considering incorporating distance education approaches into their courses. In cyberspace, time and place are fourth dimensional. The four dimensions that will be discussed in this presentation are 1) defining the appropriate distance education system, 2) designing the interactive course, 3) developing a virtual learning community, and 4) dealing with technical difficulties.

An on-line introduction to quantitative methods

Moira McPherson, Lakehead University, Canada; William Montelpare, Lakehead University, Canada

This poster/demo describes the development, implementation, and evaluation of an "on-line" introduction to an undergraduate course in quantitative methods. The virtual curriculum modules developed for the course provided a forum in which information, knowledge, expertise, and questions could be explored and updated throughout the course. Working asynchronously, the user completed six assignments. Questions which arose during the user's session were passed to "experts" that provided feedback, electronically. The "question - feedback" loop was a dynamic component of the organizational structure and used different modes of communication, including e-mail, electronic conference rooms, bulletin boards, and on-line help pages. The assignments were submitted electronically to teaching assistants who evaluated the submissions and provided feedback directly to the users. The inclusion of direct feedback communication between experts and users reduced the impersonal characteristics that might arise within an asynchronous learning-environment.

Principles Of Cognitive Evaluation For An Educational CD-ROM For History

Christina Metaxaki-Kossionides, University of Thrace, Greece; Elevtheria Gonida, University of Thrace, Greece; Stavroula Lialiou, University of Athens, Greece; Georgios Kouroupetroglou, University of Athens, Greece

The evaluation of CD-ROMs and multimedia products used in educational environments ,is a major topic. One of the erasing problems is the formation of a set of pedagogical principles or concepts and their technological implementation. We present the formation of a set of cognitive principles. Those are included in the set of evaluation , concerning a CD-ROM developed by us. The topic was a history lesson about the Homer period. We have selected two types of principles which , together with the ones for software development, should form the set for the formative evaluation. The one sub - set included the pedagogical requirements for the lesson of history. The other sub - set included the principles delivered by the cognitive scientists. These last ones were developed for the specific topic. They mainly refer to the nature and processes of learning and instruction. The set of the cognitive requirements were added explicitly as fields for a database for software evaluation.

Authoring Multimedia, Designing Animations for Physics Education

Donald J. Metz, University of Winnipeg, Canada

Computer animations used in high school physics instruction are demonstrated. The programs are written using Asymetrix Multimedia Toolbook and are designed to address the specific needs of the students and their learning environment.

Dynamic Communication Layer Between Virtual Laboratory and Intelligent Agents

Kaufmann Meudja, UniversitT de Sherbrooke, Canada; Roger Nkambou, UniversitT de Sherbrooke, Canada

In the last few Years, virtual laboratory has become an important part in online courses. Some of those virtual labs involve intelligent behaviour. However, this intelligent behaviour is usually hard-coded in the virtual lab and therefore, limit the possibility of using reusable intelligent agents that are completely separate from the virtual lab and which can control most users actions in the virtual laboratory environment. We propose a way to separate intelligent behaviour from the virtual lab by the implementation of a communication layer between the virtual laboratory and intelligent learning agents.

Design, Delivery, and Evaluation of Online Courses: A Primer

Jerold Miller, United States International University, USA

Online learning environments can be highly interactive and student-centered. Incorporating the contributions and experiences of each member of a learning community into the coursework encourages students to contribute more of themselves to the course and allows them to learn more from their teachers and peers. Creation of functional online learning environments is contingent upon the effective design, delivery, and evaluation of online courses. This session will address the design of online courses and adaptation of traditional courses to the online delivery mode. Participants will understand appropriate online delivery methods, explore teacher-centered vs. student-centered learning, understand effective strategies for communication online, know how to adapt content and curriculum for online teaching, discover new assessment strategies for distance learning, and learn how to create an online community of learners.

Discovering xyAlgebra: Intelligent Interactive Internet Instruction

John Miller, The City College of CUNY, USA

Abstract: Passive activities such as watching presentations, listening to explanations of general principles and watching experts solve sample problems are helpful, but peripheral, to the mathematical learning process. For students the indispensable step is solving problems for themselves. Yet most commercial mathematics software still concentrates on presentations and sample problems, while sending students off line to do practice problems on paper without interactive support. Answers are either multiple choice or limited to a single simplified final step. Early Internet courses are even less interactive. In contrast, students using xyAlgebra can enter each step of each problem solution. They enjoy intelligent support at every step as xyAlgebra's suggested solution strategy changes in response to their steps in simplifying expressions, solving equations and even in setting up and solving verbal problems. The next version of xyAlgebra will support instruction over the Internet, yet the entire package can be downloaded without cost at math0.sci.ccny.cuny.edu/xyalgebra.

Problem-based Learning and Flash 4.0: An Experiment in Science Education

Leslie Miller, Rice University, USA; Janice Mayes, Rice University, USA; Donna Smith, Rice University, USA

How does one design learning resources that will reach large audiences, capture the imagination, and compete with the game environments that are popular among of middle school students? The Reconstructors is a new episodic adventure series, designed for the Web, with a substantive educational message. See http://reconstructors.rice.edu where a student enters a futuristic world in which he or she assumes the role of a "reconstructor." In the interactive mystery format, a student learns science and history relevant to the discovery and use of opiates. Over the course of four episodes or missions, students "solve the problem." The concepts of neurotransmission, the neurobiology underlying drug addiction, drug tolerance, and analgesia, as well as the history of opium use are presented.

On-Line Education Using Video Broadcasting Delivered from Perth Campus, Algonquin College

Maike Luiken Miller, Algonquin College, Canada; Dave Osborne, Algonquin College, Canada; Ian McCormick, Algonquin College, Canada

As part of the LCN (Lanark Communications Network) TAP project, Algonquin College at Perth Campus engaged in a video broadcast/conferencing pilot to deliver a course, "The History and Philosophy of Architectural Conservation" (ARC9001), simultaneously in 2 modes: lectures with electronic slides and traditional black board work and, in parallel, video broadcasts (IN@SEC VP Broadcaster) with e-mail feedback. This pilot demonstrated successfully that on-line co-delivery allows to teach students simultaneously at different locations employing video, audio and text via a network using relatively inexpensive broadcasting/conferencing software with minimal set-up requirements at the clients' site. Course delivery improved. Students enjoyed the choice of delivery modes to suit their learning styles. Professor appreciated more time for interacting with the students. Re-broadcasting at a later time possible. The delivery model - independent of the specific broadcasting tool - provides a means to reach remote connected students everywhere - be it rural or elsewhere around the world.

TLC : Teachers' And Learners' Collaborascope – A Platform For Analysing And Evaluating Online Education

Michelle Montgomery Masters, University of Glasgow, UK; Stewart Macneill, University of Glasgow, UK; Prof Malcolm Atkinson, University of Glasgow, UK

Millions is being spent on installing networks, computers and assembling distance learning material and ICT (information and communications technology) software. Yet the network technology is not being used to assemble databases which researchers, managers and politicians can "data mine" to guide their investment. In the TLC project we are pioneering techniques for assembling and querying educational data. Our goal is to initiate research into the best methods of rapidly assessing the effectiveness of resources deployed and then interpreting the data to improve our educational performance. We are not trying to reinvent the wheel and produce yet another online learning environment like WebCT or Virtual-U. Instead we are building tools which will work in collaboration with these existing learning environments and provide teachers and students with valuable information about the usage of their learning environment. The TLC project aims to utilise the emerging standards such as those from the IMS project.

The Third Dimension For World Of Knowledge: An Acceptable Way To Get In

Mikhail Morozov, Mari State Thechnical University, Russia; Aleksander Markov, Mari State Thechnical University, Russia

Educational CD-ROMs should be as interesting and attractive for children as computer games. The approach offered by the authors allows to reduce the existing gap between multimedia for education and for entertainment. It is achieved due to the unusual design of 3D interface and by using a special technique of development. As a general metaphor for organisation of multimedia environment the metaphor of theatre with all appropriate attributes was

chosen: the stage with visual educational content, side- scenes, a curtain, etc. For presentation of educational material in addition to traditional multimedia components, the new integrated forms are used. Because of complexity and richness of information of the CD-ROM model, its realization is based on graph of program transitions and application of script paradigm, which is accepted for the description of structure of the educational and navigating information. These solutions can be recommended for creation of a new generation of "three-dimensional" educational multimedia CD-ROMs.

Using a Web Site to Increase Student Motivation to Write and Enhance the Reading/Writing Relationship

Susan Nelson, Elm Street Elementary School, USA; Harrison Yang, State University of New York at Oswego, USA

This action research project is an example of how Internet technology is being used in an elementary classroom as a means to increase student achievement. The project explores the relationship between writing and reading and its affects on early literacy development. It also explores the concept of motivating students to write by publishing student work for real life audiences. The project uses the current technology of an Internet web site as a source for publishing student writing. It explores the effects that this type of publication has on student attitude, motivation to write, and literacy development.

TELSI, Web-Based Software For Collaborative Learning

Graciela Nielsen, Norwegian State Center for Adult Education, Norway; Boo Hever, Majornas Vuxengymnasium, Sweden; Aase Steinmetz, Undervisningsministerium, Denmark

The TELSI software has been developed with the support of the European Union under the SIMULAB-project. SIMULAB is a concept for Web-based collaborative tasks. TELSI has been created to cater for the needs of this type of activity, and is a flexible and user-friendly environment.

Development of Speech Input System for Web-based Courseware

Ryuichi Nisimura, Nara Institute of Science and Technology , Japan; Shoji Kajita, Nagoya University, Japan; Kazuya Takeda, Nagoya University, Japan; Fumitada Itakura, Nagoya University, Japan

We proposes WebSPEAC(Web SPEech Acquisition for Courseware) System that provides a speech-input function for Web-based online education system. WebSPEAC has the following three features; (1) easy to maintain the system by the use of a simple speech input program in Web browsers, while the other speech processing are performed on the Web server, (2) a natural interactivity between Web server and users by using the server push techonology, (3) a simple installation and no needs of external programs on client machines. To show the effectiveness, an Web-based speech analysis system, a speech recognition system and a student identification system are developed as the examples of WebSPEAC System. By using the speech analysis system, it is clarified that WebSPEAC System can significantly reduce task steps, error steps and elasped time for speech-input task, compared with the conventional method (file upload).

The Instructional Portal Project

Kevin Oliver, Virginia Tech, USA

The Instructional Portal is a clearinghouse of information, resources, tools, and services at Virginia Tech, designed to facilitate practical instructional design among faculty. Faculty can increasingly adopt and easily utilize educational technologies in their courses. While some faculty use technology to modify and improve teaching and learning practices, too many rely on tools to simply make their existing teaching practices more efficient. The portal is designed to help faculty integrate technology more effectively by applying three instructional design components. The analysis component outlines strategies and instruments to account for environmental and learner characteristics, and provides information about structuring course content. The strategy component describes instructional methods and models that utilize technology effectively, and provides teaching modules covering popular web-based instruction and interface design issues. The evaluation component describes evaluation methods and models and provides tools to help faculty revise and improve their technology innovations. Visit the portal at: http://www.edtech.vt.edu/edtech/portal/index.html

Integrating and Adapting Multimedia Resources

Mary Panko, UNITEC Institute of Technology, New Zealand

In UNITEC students enrolled on an Automotive Trades course have access to a series of 32 CDX disks, entitled The Automotive Trainee Series that provides them with a learning resource in addition to their basic theoretical and practical teaching. This study attempted to:

- discover what beneficial learning effects the students perceived as being currently provided by the multimedia component;
- examine the extent to which the tutors integrated and adapted the multimedia material as part of their teaching; and

- compare patterns of current disk utilization with those of the previous year.

Results showed that although both staff and students thought the multimedia material valuable, its overall utilization by students had diminished over time. The reason for this appears to be the lack of integration of the resource by tutors into their teaching. Furthermore, tutors had generally not adapted the material for their own needs although where workbooks had been provided, this seemed to increase the students' satisfaction.

DISCETECH-BIMBOTECH: An Experimental Project For Introducing Innovative Technology Within The Italian School System

Paolo Paolini, Politecnico di Milano, Italy; Pierluigi Della Vigna, Politecnico di Milano, Italy; Francesca Collina, Politecnico di Milano, Italy; Paolo Magatti, Politecnico di Milano, Italy; Silvia Moiola, Politecnico di Milano, Italy

Since 1996 Politecnico di Milano has launched a program for experimenting, within the Italian school system, the use of advanced technology for teaching and learning. Two projects (in Como and Lecce) have involved more than 700 teachers and more than 8.000 pupils, being the largest of this kind in Italy, both in High Schools (Discetech project) and grammar schools (Bimbotech). The project emphasizes the role of the teachers, who are trained on multimedia and Internet technology first. Secondly they are "guided" and assisted in shaping up specific activities with usage of either multimedia CD-ROM's or Internet Sites. A large collection of CD-ROM's has been created and several hundreds educational Websites, on different subjects, have been classified. The project has been very successful with the teachers (many of them have never used advanced technology before) and the pupils, the learning and the interest of which has been evaluated as sharply improved.

Learning Experiences in New Learning Environments

Heli Pekkala, University of Jyvaskyla, Finland

One of the outcomes of a departmental action research project at our language centre is a modernised Learning Centre, where students and staff of the university have access to learning materials in over 30 languages. The philosophy and pedagogical framework underlying the operations of the centre is to support and encourage students in developing their learning skills and self-directiveness for continuous language learning and for making effective use of new learning environments . This poster presents the Learning Centre (interactive studios, writing studio, multimedia studio etc.) and reports student experiences of learning a new language independently. One part of this learner training course Learning to Learn Languages was a self-access project during which students were requested to reflect upon the kinds of qualities and procedures that self-directed language learning requires from a learner. They also evaluated what areas of language were possible to access without external structuring and teaching.

Microsoft Office as a Learning and Teaching Tool

Craig Place, Acadia University, Canada; Michael Shaw, Acadia University, Canada

Many useful features in popular software applications often go unnoticed by many users. Often thought of as a business application, Microsoft Office is one such suite of applications that is often overlooked as a tool for use in the teaching and learning environment at most grades, and at the university and college level. With just Word, Excel and PowerPoint, MS Office can be used as a tool to develop the basic understanding and expertise for a number of other applications including photo-editors, drawing and animation programs, multimedia authoring and web-development tools. Used as a stepping stone to more advanced applications in this way, the interface of each of these 3 applications can be simplified to be useful at a number of different grade levels, or levels of expertise. Using a combination of examples and hands-on exercises the workshop will illustrate to the participants how MS Office can be used to easily and effectively create multimedia hyper-documents, dynamic learning-objects, student review exercises and interactive non-linear presentations. Specific examples will be the use of PowerPoint as a concept-mapping tool and as a multimedia authoring and animation tool. Using Excel to assist in language learning and create dynamic graphs for interactive what-if scenarios, and using Word to develop hypermedia templates and collaborative writing documents. Several examples of the usefulness and creation of macros will also be shown.

Students' expectations and perceptions of efficacy for self-regulated learning in mediated learning environments: Partial results of an evaluation

Laura Helena Porras, Universidad de las Americas, Puebla, Mexico

This paper discusses partial results of an evaluation applied to an educational teleconferencing system in a Mexican higher-education institution. Courses offered through the system are based on a pedagogical model, which emphasizes the active role of the learner as responsible of her own learning. Therefore, perceptions of the self, and self-regulatory processes become key components in this learning environment. Conclusions here presented correspond only to: (i) students' expectancies, (ii) perceptions of efficacy for self-regulated learning, and perceptions of the course, and of the teacher and learner's work. Results indicate students' expectancies focus on "learning more than in face-to face situations", followed by "using technology", and "having freedom and initiative". Perceptions of efficacy for self-regulated learning were high overall. Nevertheless, analyses of individual items identify specific areas of improvement. Qualitative data on perceptions of the course, and teacher's and learner's work suggest that these courses are more demanding than the face-to-face ones they are taking. Students' responses include attitudinal and cognitive adjustments needed for these learning environments. These results have led to improvements, which are presently being applied.

An Online Model For Precalculus

Hari Pulapaka, Valdosta State University, USA; Denise Reid, Valdosta State University, USA

Some of the greatest challenges to designing and delivering a completely online mathematics course are effective and efficient uses of the leading technologies that are available for this purpose. The authors have just completed designing the first version of a precalculus course that is being delivered through a combination of synchronous and asynchronous environments. Precalculus was chosen over other mathematics courses for several reasons. The course has been planned as a model online course for any mathematics course (especially at the early levels). Future versions of this course and related courses will undoubtedly incorporate additional technologies and components in an effort to improve student learning, interactivity, and end-user feasibility. Future plans for the course include development and refeinement of the unfinished sections of the course and tighter integration with graphing calculator and/or mathematical software.

IMAGUS: An Environment To Design Video Applications For Digital Libraries

Andre Luis Alice Raabe, Pontificia Universidade Catolica do Rio Grande do Sul, Brasil; Lucia Maria Martins Giraffa, Pontificia Universidade Catolica do Rio Grande do Sul, Brasil

This poster presents the description of the IMAGUS environment. IMAGUS has tools to built video applications supported by Internet. This environment has being developed in order to contribute for the construction of the PUCRS digital library collection.

Art, Poetry, and Instructional Media

Thomas Reinartz, Rosemount High School, USA; Brad Hokanson, University of Minnesota, USA

In many high school English courses, students are trained to seek out proper form and work toward clarity in their writing assignments. They are taught to write using complete sentences and complete thoughts, fix their punctuation and grammar, and strive for polish in all written work. That is what English is all about. On one level, we can be pleased with their concern. However, this quest for excellence and perfection seems to interfere with the poetry writing process. Many successful poems lack complete sentences, defy traditional uses of punctuation, and contain word combinations that require readers to make inferential connections, often sacrificing the writing clarity that English teachers work so hard teach. We have taught them to be concise, clear, and correct in all writing endeavors, which in most cases, is sound advice. Writing poetry, however, demands skills that require us to play with words and dwell in areas where word juxtapositions and combinations are limited only by one's imagination. The many choices in this "zone" of possibility are frighteningly endless, so it is no wonder students resist entering. They may get lost. To help foster an awareness about word choice and imagery, we developed an interactive program to generate "found" poetry with student input and used it in a twelve week American literature class taught by T. J. Reinartz, one of the authors. The program evolved from discussion between the authors regarding the use of computers to inspire poetry writing. A multi modal qualitative research study was undertaken involving classroom observation, video taping, survey questions and analysis of poetry segments. The findings of that research and analysis will be presented, with broader observations of the use of computers 'in the service' of poetry, and their appropriate use in the high school classroom.

Students as Producers: Changing the Way we Teach and Learn

Gail Ring, University of Florida, USA; Sebastian Foti, University of Florida, USA; Melissa McCallister, University of Florida, USA; Tamara Pearson, University of Florida, USA; Ebraheem Alkazeemi, University of Florida, USA

Educational technology courses at the University of Florida are modeling the concept of students as producers. Through student-based projects such as an online support center, educational software, student portfolios, and documentary-type CD-roms our students are producing educational products. These 'real' activities are improving our courses as students learn by doing, thereby creating a constructivist learning environment. Relevant, contextual projects such as these provide students with an increased sense of empowerment and ownership. In our presentation we will share how the traditional roles of instructor and learner may no longer appropriate.

The GPB project; A successful PHD seminar using Videoconference in real time and a list to communicatebetween the classes

Claire Roberge, University of Quebec in Montreal, Canada

This winter 2000, a seminar was offered at the PHD level in the departement of Communication at the University of Québec in Montréal.Three teachers participated, one from Montréal, one from Paris and one from Grenoble. Seven sessions were offered in videoconference to all students enrolled. A website and a list were added tools offered to the students to communicate between the sessions. The sessions in videoconference were in real time.

Teachers and students made presentations and periods of questions were planned at the end of each of those presentations.The experience which will be renewed next winter was a success. Technology was used wisely, the teachers made sure the environment available enhance the learning process of their students.The differences in cultural habitus and in the uses of technology were taken in consideration.An evaluation was made taking seriously all factors.

Multimedia Training , Virtual Instrumentation and Remote Laboratory a New Approach to the Electronic Courseware

Nicoletta Sala, Academy of arch. University of Italian Switzerland, Switzerland

This work describes a project developed at the Department of Electronic Politecnico of Torino in the field of multimedia technologies in educational process. The goal was to allow the students to carry out a pre-training activity outside the laboratory and possibly at home; each student could thus individually adequate the learning rate to his own capabilities. After this pre-training phase, students who enter the laboratory require reduced assistance and less time to complete the training activity. This approach can reduce the qualified assistance that is not easily found. For this reason several hypermedia mod-ules have been developed (using Multimedia Toolbook) to assist the students to acquire the fundamentals of the basic electronic instrumentation. The subjects developed are:

- fundamentals of the analog and digital oscilloscope, which includes practical exercises;
- fundamentals of the analog and digital voltmeters and their operating theory;
- the IEEE488 standard interface for programmable instrumentation;
- the logic analyzer;
- the spectrum analyzer.

Virtual instruments are implemented in order to allow simple simulations of the real instruments during the self-training phase A client-server system has been designed in order to allow the students to operate on a remote laboratory for experimental training. The idea is to design a laboratory that is simultaneously and remotely accessible to several students, who concurrently share the same instrumentation, but not necessarily the same experiment. The instrumentation and the other hardware resources are accessible in a sort of time sharing process, which is managed by a server and transparent to the user. The virtual laboratory architecture is composed of two kinds of subsystems: the measurement Server and the measurement clients.

Strategies for Teaching and Learning: Lessons Gained from an Ethnography of Graduate Classes in an Interactive Distance Learning Studio

Lorraine C. Schmertzing, University of West Florida, USA; Richard W. Schmertzing, Valdosta State University, USA

This poster session is based on data collected during a one-year ethnographic case study of graduate education classes during the inaugural year of a 2-way audio/2-way video interactive distance learning classroom at a regional university in the southern United States. Cultural anthropology and symbolic interactionism acted as guide to uncover and describe the processes through which adult learners transformed traditional classroom culture as they implicitly redefined that culture during their initial exposure to a specific distance learning environment. This poster session addresses the often un-addressed complexities inherent in re-defining ones learning environment so that effective learning can occur and offers strategies for teaching and learning based on these complexities. Strategies include ideas for the first night of class, cultural awareness activities, feedback forums, and rules of engagement.

Use of Telecommunications Technology in Radiation Accident Simulation

Domenic Screnci, Boston University School of Medicine, USA; Kirsten Levy, Boston University School of Medicine, USA; Erwin Hirsch, Boston University School of Medicine, USA; Richard Aghababian, University of Massachusetts Medical School, USA; Tracey Russo, Boston University School of Medicine, USA

Radiation accidents are rare but increasing in frequency. Partners in a regional project are providing training on radiation accident preparedness in Eastern Europe and the New Independent States. Recently, the partners devised a radiation accident exercise to simulate radiation exposure and test inter-regional cooperation among eight nations. A variety of multimedia, communication and distance learning technologies was used to execute the exercise. This poster describes:

- Objectives
- Design
- Procedures
- Communication Plan
- Educational Technologies

The exercise demonstrates a live response to a simulated radiation accident; the ability to exchange information among peers, request resources and notify appropriate agencies; and the use of communication technologies to debrief the experience. Also demonstrated is the use of distance learning technology to cultivate regional harmonization of response in a field in which preparedness is essential but practical exercises lacking.

Teaching data analysis using thin client technology for remote access

Robert Seidman, San Diego State University, USA; K. Michael Peddecord, San Diego State University, USA

This poster describes implementation and outcomes of using thin client technology to provide remote access in a data analysis course. All software applications run on the course server, so no downloading of data or software is required. Results from statistical analyses are transmitted to students' client machines. Students were able to launch applications and complete assignments from any location that had Internet access. In addition to 7/24 access, students were able to use software they did not own and large data files they did not have on their own computers. While they generally expressed satisfaction with this remote access capability, drawbacks included initial programming time and cost of the server software, lack of familiarity with operating in a networked environment, frustration with server-side disconnects or ISP interruptions, and occasional inability to print at home because the server software does not include all old printer drivers.

Multimedia Guide to Fractal Geometry

Vladimir Shlyk, Belarusian State Pedagogical University, Belarus

Fractal geometry has changed our view of natural processes and geometric forms. The Guide is a software kit supporting a university course on this science. It contains an introductory electronic textbook, annotated list of publications, favorite Internet links and provides facilities to run programs. One program of the project visualizes the mechanism of birth of classical and IFS fractals. A student can grow fractals by himself and explore their features by trying different generators and mappings. Another program demonstrates connection between the Mandelbrot and Julia sets. It throws a bridge from fractal geometry to nonlinear dynamics and chaos theory by showing different variants of behaviour inherent in underlying quadratic process. Having advantages over analogous programs, it is already being used at several universities. To create the most complete educational software on fractal geometry we would be pleased to collaborate with other specialists and enthusiasts.

Project-Based Learning + Multimedia: Adding Value to Students' Education

Michael Simkins, Silicon Valley Network, USA; William R. Penuel, SRI International, USA

"Does technology really make a difference in student learning?" Definitely, according to the Challenge 2000 Multimedia Project, one of the original Technology Innovation Challenge Grants funded by the U.S. Department of Education. The Project has demonstrated significant educational results when technology investment includes teacher training, technical support staffing, and curriculum materials development. In a five-year evaluation of the $6.2 million project in California's Silicon Valley, SRI evaluators found that technology-using students surpassed their non-technology-using peers in developing some of the most critical skills for the new economy of the 21st century. These skill advantages included better communication, teamwork and problem-solving. Researchers also found important positive changes in teachers classroom practices that support a constructivist approach to learning. In addition, these same students equaled their non-technology-using peers in learning the basic skills measured in standardized tests. In short, students in technology-using classes not only "got the basics," they got more.

The Search for the Skunk Ape: An Information Literacy WebQuest

Charlotte Slater, The Walden Institute, USA; Pamela Sawallis, Florida Gulf Coast University, USA

A web-based instructional resource for distance and on-campus learners uses elements of goal based scenarios (Schank, 1994) and WebQuests (Dodge, 1997) to provide a "fun," story-based environment for learning information literacy skills. This project represents a partnership between instructional technology and library services at a state university.

Online Learning in a 3-D Robotics Workshop: The NASA ROVer Ranch

Stephanie Smith, NASA/LinCom, USA

The ROVer Ranch is an online environment based on NASA's mission as it relates to robotics engineering. Students are situated where they learn about robots and then build and run simulated robots in a 3-D virtual world. The robotics workshop has all the components to build a "soft" version of a robot and the tools needed to instruct the robot to complete its mission. Student engineers or teams select a mission, review the mission goals then design a robot with the appropriate attributes (power source, navigation planning, tools, etc.) based on the mission objectives. Once the robot is constructed, students plan a navigation path and then place the robot in the simulation to execute the mission. This simplified design and programming exercise is an interactive method to learn science and math skills both individually and in a team setting as students share their experience in journals and team message boards.

OATS: Operational Amplifier Tutorial Simulation; a dynamic presentation

Sarah Sniderman, Concordia University, Canada; Gary Boyd, Concordia University, Canada; Geza Joos, Concordia University, Canada

Abstract: Operational Amplifiers are among the most important components used in analog electronic devices. They are complex and initially counter-intuitive in behaviour. Electrical engineering and electrotechnology students frequently need special tutorial help to understand them and configure them to work properly in various circuits. The main advantage of simulation programs for higher education in technical fields is that, when carefully designed, they can promote higher level instructional goals of prime meta-cognitive value, especially those involving the autonomous active construction and exploration of knowledge at a pace appropriate for the learners. Note, however, that such free exploration of knowledge at a responsive pace is not a quality inherent in multimedia instruction. High-level interactivity involves more than guided clicking through branched instruction. A truer understanding requires a learning environment which accommodates the testing, falsifying, validating, and elaboration of understandings.

The Munchhausen-Trick: Learning Internet by Internet

Ralph Sontag, TU Chemnitz, Germany; Dietrich Thie, TU Chemnitz, Germany

The Chemnitz University of Technology is the first one in Germany, which is able to offer an internet-based study about information and communication technology. The participants of the courses are able to collect fundamental and applicable knowledge about internet-related technologies using it - a problem comparable to the baron of Munchhausen, which drags himself at his tuft out of a marsh. After two introducing lessons the communication between learners and teachers is stricly internet-based. Stepwise the students are qualified to understand and maintain complex situations in management of ip-networks and servers. The knowledge can be proofed in a remote managed, but actually existing laboratory. Moreover we had to consider the very heterogenous working times of our participants. We prefer asynchronous communication with short turn-around-times in conjunction with online-tools like "virtual seminars", tests or experiments. The consequently platform-independent project uses open protocols and standardized document formats like HTML or XML.

In defence of 'shovelware': A powerful tool in staff development for online teaching and learning

Heather Sparrow, Edith Cowen University, Australia; Jan Herrington, Edith Cowen University, Australia; Tony Herrington, Edith Cowen University, Australia

A significant challenge for universities creating effective online learning environments is educating and empowering teaching staff. Those who are not confident using technology are frequently unconvinced about the benefits and are concerned that it will force unwanted changes on their current practices. This poster outlines a project which introduced a large number of variously experienced academic staff to online teaching, whilst maintaining or enhancing effective learning. The project included the simple conversion of print-based external units to an online mode, as one of several strategies of development. Whilst this process is often referred to derogatively as shovelware, some of the positive and immediate outcomes achieved will be described, and challenges will be made to extremely negative attitudes towards such conversions.

An Evaluation of Video Compression Schemes for Teleteaching Applications

Ognjen Stanovcic, Open Systems AG Zurich, Switzerland; Thomas Walter, Swiss Federal Institute of Technology Zurich, Switzerland; Bernhard Plattner, Swiss Federal Institute of Technology Zurich, Switzerland

Synchronous, interactive teleteaching is demanding with respect to required network bandwidth and short end-to-end delays. An uncompressed digital video, e.g., requires a data rate of 261 MBit/s. Video compression is a method to reduce required network bandwidth. Efficient video compression is almost lossless with respect to perceived video quality at the receiving site, but it is time intensive. In support of interactivity, however, response times must be short to allow participants to audio-visually communicate like being in the same room. This implies that the end-to-end communication delay should be less than 150 ms. This requirement puts a hard constraint on video compression since compression time is only one factor that adds to the overall end-to-end delay. We present a framework for the evaluation of video compression schemes. We define evaluation criteria such as compression delay and compression efficiency. The video compression schemes evaluated are Motion JPEG, MPEG, H.261 and H.263.

Multibook: making web based learning resources personal

Achim Steinacker, TU Darmstadt, Germany; Cornelia Seeberg, GMD IPSi, Germany; Ralf Steinmetz, GMD IPSI, Germany

Considering the amount of knowledge accumulated on the Web, the discussion of an effective use of the web resources becomes urgent. The main question is how to find the relevant information . In our web based teaching system Multibook we use modularized learning content stored in a knowledge base and describe these modules such that the combination of modules can be matched to the users preferences, represented in a user profile. In this demo we will show our knowledge base containing both the actual multimedia learning resource and the metadata in form of a terminological ontology, attributes for the resources and relations between the resources. Then we sketch the user profile and finally we show how these components are matched together

Math and Science Curriculum Revision: A Collaborative Approach to Improving Preservice Teachers' Use of Technology Knowledge and Instructional Skills.

David Stokes, Westminster College, USA; Carolyn Jenkins, Westminster College, USA; Lorel Huhnke, Westminster College, USA; Gothard Grey, Westminster College, USA; Cheryl Manning, Bryant Intermediate School, USA

Reports on a Preparing Tomorrow's Teachers to use Technology Capacity Grant project, a consortium comprising Bryant Intermediate School, and Westminster College, both of Salt Lake City, Utah. The consortium participants engaged in collaborative curriculum development to provide preservice teachers greater exposure to the instructional uses of technology in education. Skills in the application of communication, presentations, and CLE technologies were explored. Teaching units integrating sound curriculum with technologies including: video-microscopes, CBL probes, graphing calculators, Excell, PowerPoint, various software programs, and the Internet were developed. Outcomes suggest improved teaching with technology skills, better real-world collaborative inquiry, greater focus upon multiple learning styles; and gains in extending the power of scientific inquiry into mathematical and scientific reasoning.

Integrating pedagogy, content and technology into your curriculum

David Stokes, Westminster College, USA; Wanda Carrasquillo-Gomez, Westminster College, USA

Perhaps there are fewer more daunting tasks to teacher educators than to find the time, means, and information to begin to more fully integrate technology as an instructional and learning tool into their courses. Over the past year the authors conducted a thorough curricular revision of technology courses offered in the Master of Education program at Westminster College in Salt Lake City. Courses were redesigned focusing curriculum upon technology as a communication rather than a presentation medium. Outcomes suggest this approach is beneficial to generating increased understanding of the role technology can play in teaching and learning, and in strengthening key linkages between constructivist theory and teaching practice.

SMILE Maker - An Intelligent Learning Environment for Problem Solving

Svetoslav Stoyanov, University of Twente, The Netherlands

This poster introduces SMILE Maker - a web-based tool supporting ill-structured problem solving activities of students involved in problem-based learning. SMILE Maker stands for Solution, Mapping, Intelligent Learning Environment. It is both a problem solving and a learning tool. As a problem solving tool it proposes a method for creative problem solving based on the synergy of some mapping approaches like concept mapping, mind mapping, cognitive mapping, flowscapping, and process mapping, and a systematic creative problem solving methodology. The method facilitates elicitation of tacit knowledge, an effective organization of the explicit knowledge, and avoidance of some negative individual problem solving syndromes like analysis-paralysis, functional fixedness, premature judgment, and etc. As a learning method it provides an individualized learning environment for studying and applying this method. It adapts learning to four personal constructs such as learning styles, problem solving styles, learning locus of control and prior knowledge.

An Adaptive Web-based Course in Financial Engineering with Dynamic Assessment

Alberto Suárez, Universidad Autónoma de Madrid, Spain; Estrella Pulido, Universidad Autónoma de Madrid, Spain; Rosa Carro, Universidad Autónoma de Madrid, Spain

The increasing relevance of interdisciplinary skills calls for the design and implementation of novel strategies to address the problem of teaching a corpus of knowledge to a heterogeneous audience. We have chosen a problem in financial engineering, the valuation of European options, whose mastery requires the interplay of mathematical, computational and financial tools. The target audience in financial engineering courses is generally composed students of either financial background or from a scientific, non-financial area (mathematics, computer science, physics). The course is designed within the framework of the TANGOW system (http://www.ii.uam.es/esp/investigacion/tangow/present.html), which provides the necessary mechanisms to construct a web-based course whose contents are dynamically generated according to the student's profile and actions. The system includes the possibility of dynamic assessment, which involves testing not only the student's ability to understand static knowledge, but also his/her ability to actively design procedures (programming analytical formulas, realization of simulations) to achieve the prescribed goal.

Building Learner and Teacher Autonomy for New Learning Environments

Leena Subra, University of Jyvaskyla, Finland; Liisa Kallio, University of Jyvaskyla, Finland; Ulla Lautiainen, University of Jyvaskyla, Finland

The poster reports on the experiences of our departmental action research project aiming to explore the use of ICT-enhanced methods in promoting both learner and teacher autonomy/self-directedness in discipline-based language learning and instruction. The action research approach involves continuous staff development, needs identification and aims-setting, teacher and learner self-assessment, learner training, and development of a variety of learning tasks suitable for self-directed learning in both authentic and virtual learning environments. It also involves an attempt of creating a set of ICT-enhanced course formats which - without significant, time-consuming and technically demanding modifications - could be used in teaching and learning languages. The poster describes pilot courses which use different approaches, materials and programmes, and are aimed at different kinds of learners. They cover a variety of possibilities and combinations but remain within the same pedagogical framework, since learner and teacher autonomy are the basic guidelines in all the pilot courses.

Development of a Computer Aided Cooperative Classroom Environment

Akira Suganuma, Kyushu University, Japan; Ryunosuke Fujimoto, Kyushu University, Japan; Yutaka Tsutsumi, Kumamoto Gakuen University, Japan

In the educational domain, a popularization of computers and the Internet enable us to hold lectures using Web contents as a teaching material. We propose CACCE, Computer Aided Cooperative Classroom Environment, which is an WWW-based supporting system for a classroom teaching. CACCE consists of a server-software and a client-software, that is to say, a teacher's browser and a student's browser. These browsers are connected together by a socket connection, sends and receives some messages such as a URL and the CACCE's command. There are three main features of CACCE. First, CACCE automatically refreshes student's browsers. Secondly, CACCE displays a cooperated mark and text on these browsers. Finally, student's browsers automatically report an URL of page shown by them to teacher's browser. This information is used as one of the guidelines for teaching. It is concluded that CACCE is not only a tool that broadcasts the document on a teacher's browser to students, but also a cooperative environment.

Using Knowledge Models in Intelligent Tutoring Systems

Stephen G. Taylor, Champlain Regional College, Canada

The Virtual Tutee system will be introduced as a prototype of an intelligent tutoring system. The user of this system adopts the role of the tutor and studies photosynthesis by tutoring a virtual tutee residing within the software. The system was produced as a simulation based on a model of the tutoring learning situation called the Knowledge Modelling Approach, which will also be introduced. Fifty college students participated in a test of the system.

An Evaluation of Interactive Studio Physics I

Holly Traver, Rensselaer Polytechnic Institute, USA; Michael Kalsher, Rensselaer Polytechnic Institute, USA; Karen Cummings, Rensselaer Polytechnic Institute, USA; Keith Hmieleski, Rensselaer Polytechnic Institute, USA

Rensselaer Polytechnic Institute has implemented an innovative physics course ("Studio Physics") that promotes collaborative interaction. Students work in groups of 2-4 on computers connected to the local network and Internet. Class time is spent on short lecture and group exercises. This research study evaluated Studio Physics in terms of grades and alumni responses. An examination of course grades from students who took the first courses of Studio Physics yielded no significant difference between traditional lecture and studio courses. However, as the studio course has evolved, learning has improved. Alumni were contacted and asked for their opinions on all types of courses, including studio. Alumni indicated working collaboratively with others helped them to improve communication, interpersonal, and computer skills, as well as the abilities to work with others, learn new material, and perform at their current job. This finding is important for work organizations, since much of work today is group-based.

Grasp of Few body element's correlative operation using Multi points measure data-Compair with 2 kind selection-

Atsushi Tsubokura, Osaka Electro-Communiation Univ., Japan; Kiyoshi Masui, Osaka Electro-Communication Univ., Japan; Noboru Ashida, Osaka Electro-Communication Univ., Japan; Kagemasa Kozuki, Konami Co., Japan; Katsuhide Tsushima, Osaka Electro-Communication Univ., Japan

Expert Operator has any skill for machine operation.But novice has a little skill.The novice do and error operate when try need to new operation skill.Our target is to trace the Operator's skill learning process and the task identificate for the skill learned.The newer operation skill based another already learned operation skill.These Operator's skil was changing during Try Operating.The changed operation can show operation timming and used skill for operation. We used few body's measure data and identificate his operation using symbolic way.Measure device is Eye Mark Recorder,3D position or degress sencer(for Arm Motion),Data Grove.This paper propose the symbolic way for Multi Points Measure data's correlation and single measure data's characteristic, and evaluate the measure data using these way.This paper is introduction of these reserch.

Offline projects for cross-cultural competence improvement

Victoria Tuzlukova, Rostov State Pedagogical University, Russia; Irina Rozina, Rostov State Pedagogical University, Russia; Cyndy Woods, Arizona state University, USA

Russian and U.S faculty members from the Department of Foreign Languages, Rostov State Pedagogical University - RSPU, Russia and Arizona State University, Phoenix, USA, developed off-line writing projects designed to increase language proficiency, cross-cultural awareness, computer and networking skills. Targeting EFL students (English as a Foreign Language), the project has demonstrated that students not only increase English language proficiency, but students learn more about the way of life, basic values, and cultural background of the people, whose language they study.

Analyzing Artists' Interaction with an Artificial Reality

Elpida Tzafestas, National Technical University of Athens, Greece

Our long term goal is to understand how humans build models of biological phenomena. To this end, we are studying the relation between an artificial reality and the model of it that an observer deduces. The study is currently based on the observation of how Digital Art students interact with "PainterAnts", an educational simulation software that is used for laboratory work on intelligent and complex systems. The software is a special-purpose ant population demo that tries to convey and teach regulation principles using graphical means. Artists have shown a high motivation to experiment with the system, partly because they tend to regard it as a simple abstract art tool. They manage to create a functional model of complexity, without really understanding the underlying models. Few experiments with users of different background, have shown that humans, independently of background knowledge, tend to find complex top-down explanations to apparently complex phenomena.

Supporting Virtual Classrooms through Extranet technology: the Eurydices system

Kostas Bovilas, University of Patras, Greece; Aspasia Kanta,University of Patras, Greece; Nikos Piskopos, University of Patras, Greece; Bill Vassiliadis, University of Patras, Greece; Athanassios Tsakalidis, University of Patras, Greece; John Tsaknakis, University of Patras, Greece; Evangelos Sakkopoulos, University of Patras, Greece; Christos Makris, University of Patras, Greece

This work describes how collaborative, extranet-based services can be used to teach virtual classes to geographically-dispersed academic participants. Eurydices is an extranet-based training application, whose aim is the efficient management of the great variety of users and courses provided by the Greek Universities Network (GUNet).

A Web-based educational tool for solving equations

Maria Virvou, University of Piraeus, Greece; Maria Moundridou, University of Piraeus, Greece; Michael Loizos, University of Piraeus, Greece; Athanasios Papachristou, University of Piraeus, Greece; Nikolaos Polyzotis, University of Piraeus, Greece

This paper describes a web-based intelligent authoring tool for constructing problems in the area of equation solving. The main objective of this tool is to be useful to teachers and students of high school level in the area of algebraic equations. The teacher using this tool is able to provide the information needed to construct an exercise through a user-friendly interface on the web. Every exercise that has been constructed is immediately available to students. The tool also monitors students closely while they are solving the exercises through its student modelling component. The aspects we consider important in this tool are:

- The authoring capabilities it embodies. Teachers can continuously add new exercises and be assisted at their construction. Therefore the tool can be very useful for the construction of student assignments and/or exam tests.
- It is a Web-based tool. Therefore it can be used as a support tool for distance learning. It can also be used in classrooms and/or home as homework, exam tests, student practice or tutorial.
- The tool has ITS features such as the diagnostic capability. In this sense the tool can help the teacher to assess his/her students' progress and level of knowledge. It can also be very helpful at marking the assignments and/or exam tests. In addition it can be very useful to students in two ways. First for the self-assessment of their skills and second for the practice they can have with the provision of individualised feedback.

Constructing a Learning Environment for Knowledge Advancement

Feng-Kwei Wang, University of Missouri - Columbia, USA

The purpose of this research is to introduce the use of technology to construct a learning environment for knowledge advancement through three levels of knowledge -- know-what, know-how, and know-why. Know-what is concept-based domain content which is prepackaged and generalized. Know-how translates know-what into action-oriented skills. Know-why permits one to renew know-what and know-how and thus to solve larger and more complex problems. Different levels of knowledge require different learning methods and entail different learning activities. The most efficient approach to acquiring know-what is through comprehension and feedback. The process-based know-how can be best achieved through practices in simulation and case studies. Know-why can only be built over time through personal encounters with many different problems and solutions in real-world projects. This poster session will depict the theoretical grounds of this knowledge advancement framework and show how technology is employed to construct a learning environment based on this framework.

The Use of Cooperative and Collaborative learning in a Web-based Integrated Curriculum for the First Two Years of an Engineering Program of Study

John Watret, Embry-Riddle Aeronautical University, USA; Charles Martin, Embry-Riddle Aeronautical University, USA

The authors will describe and present the results of an innovative Integrated Curriculum in Engineering (ICE) designed for the first two years of an engineering program. Entering freshmen engineering student volunteers are placed into specifically designed sections of the foundation courses required of all engineering students: the calculus sequence, the physics sequence, the humanities sequence, social science, and introductory engineering courses. What differentiates the ICE program from traditional engineering curricula is that all courses incorporate cooperative and collaborative learning and a reliance in computer and web technology. In addition, the ICE program promotes team learning, team design projects, and a well-documented series of assessment practices. Although our program was written for an engineering curriculum, the underlying philosophy is applicable to a wide spectrum of programs of study as well as the general education component of many degrees.

Distance Learning For Government Agencies / Online Academies

Joseph Wilczak, American West Enterprise, USA

Government agencies are turning to online presentation formats for computer based instruction related to distance learning. CBT lends itself well to innovative visual curriculum and realtime information sharing. The educational / training implications that combine computer technology, the internet, email, and telecommunications are enormously untapped. CD Rom, online student / instructor interaction through chat rooms, or both are utilized. Material is presented in text supported with voice overs, and graphics. While writing screen text, voice over scripts should be written simultaneously, and graphics last. Lectures can be conducted online supported by video telecommunications. A final online exam is provided at the completion of each course with follow up sessions scheduled depending on course content. Presentations are suitable for newly enrolled student course material as well as recertification or ongoing certification requirements of the particular agency.

The Management of the Telecommunications Function: The Impact on Organizational Support, Planning and Training Quality

John Willems, Eastern Illinois University, USA; Karen Ketler, Eastern Illinois University, USA

This article reports the results of a survey of marketing managers in order to obtain information from the end user about the impact of the management structure of the telecommunications function on 1) the importance of the function within the organization, 2) the formalization of planning practices and 3) the quality of training on thirty issues. While the information systems manager was the most common form of management of the telecommunication function, the organizations with a distinct telecommunications manager reported greater satisfaction with top management support and a more formalized telecommunications planning and implementation process than the other organizations. The respondents from the organizations with a telecommunications manager also indicated better telecommunications training (although still somewhat unsatisfactory) than the other respondents. This was especially true in the managerial issues with a long term focus such as the use of telecommunications to gain a competitive advantage, and managing innovation and technology.

Online Learning Communities: Vehicles for Collaboration in

Stephanie Woolley, University of Colorado at Denver, United States; Stacey Ludwig-Hardman, University of Colorado at Denver, United States

Learning communities are environments that encourage mutual exchange between community members to support their individual and collective learning. Learning communities are founded on the social negotiation of meaning. Collaboration is the key tenet of constructivism and small-group theory (Springer Springer, Stanne, & Donovan, 1999; Grabinger, 1995; Duffy & Jonassen, 1992) that explains the social component of learning and demonstrates that "conceptual growth comes from sharing perspectives and modifying our internal representations in response to that sharing" (Grabinger, 1995, p. 669). Online learning communities provide the means for achieving "shared creation" and "shared understanding" (Shrage, 1991, p. 40). They are an excellent tool for integrating collaboration in online learning environments. The authors' poster demonstration defines collaboration and learning communities and addresses their theoretical foundations. The authors will discuss the benefits of collaboration and learning communities in online learning environments and provide a case study of a new online learning community at Western Governors University.

The Construction of World-Wide-Web Resource for Chinese Medicine and Acupuncture

Fan Wu, China Medical College, Taiwan; Shao-Fu Huang, China Medical College, Taiwan

As the information technology makes great strides in recent years, Internet has irresistibly reached into every aspect of our daily life. With its unique capability of well-integrating text, image and video, World-Wide-Web has been pervasive in the dissemination of medical discovery, the promotion of medical education and the application of clinical medicine. The issue of capitalizing on the state-of-the-art web technology to build Chinese medicine and acupuncture multi-media web resource is well addressed in this thesis. It is organized around:

1. The largest Chinese medicine news web site domestically.
2. The Chinese-medicine-centric high resolution multi-media Video on Demand in the field of Chinese medicine.
3. The electronic journal on Chinese medicine in the field of Chinese medicine.
4. The virtual classroom with complete features on Chinese Medicine and group-learning systems.

In addition, all the relevant web sites on Chinese medicine will be listed and linked for the benefit of the public. Integrated with Chinese medicine database, this set of medical resource helps to present teachers and researchers with an informative environment surrounded by Chinese medicine data. And it gives students the chance of individual learning and the space for the development for voluntary acquisitiveness for knowledge as well as paves the way for academic exchanges and pervasion of the information on Chinese medicine.

Automatic Generation of the Optimal Tutorial-Plan in Adaptive Educational Hypermedia System

Haiyan Xu, University of Science & Technology of China, P.R.China; XueHai Zhou, University of Science & Technology of China, P.R.China; Zhenxi Zhao, University of Science & Technology of China, P.R.China

Adaptive hypermedia system provides a good framework for web-based education. An ideal adaptive educational hypermedia system adapts to different learners during the whole period of the study. Aiming at the automatic generation of the adaptive tutorial-plan, we simply introduce the architecture of the KDAEHS: an adaptive educational hypermedia system based on structural computing, propose the concept of knowledge structure graph represented by AND/OR graph and then discusses the algorithms used to obtain optimal tutorial plan. Combined with the pedagogical strategies specified by the instructors, KDAEHS generates the optimal tutorial-plan which adapts to different learners based on the knowledge structure graph and the learners' knowledge level. Every tutorial-plan is well suit to the individual learner and can help the learner to fulfill the study goal efficiently.

Virtual Reality in astronomy teaching

Yoav Yair, CET / The Open University, Israel; Rachel Mintz, CET / Tel-Aviv University, Israel; Shai Litvak, CET / Tel-Aviv University, Israel

A new 3D model of the solar system with virtual reality (VR) features. It is based on powerful scientific visualization techniques and can be used as an effective aide in astronomy teaching is presented. The model allows for a powerful learning experience, and facilitates the mental construction of three-dimensional space, where objects are varied and different, but share common features and obey the same physical principles. The learner "enters" a virtual model of the physical world, journeys through it, zooms in or out as he wishes, changes his view point and perspective, as the virtual world continues to "behave" and operate in its usual manner. The new view helps to overcome the inherent geocentric view and ensures the transition to a scientific, heliocentric view of the solar system.

Uncovering cognitive processes in discourse synthesis using hypermedia

Shu Ching Yang, National Sun Yat-Sen University, Taiwan ROC

An exploratory study was undertaken to uncover the cognitive process of discourse synthesis within a hypermedia learning environment. The focus was on learners' discourse synthesis behavior and the problem solving strategies they employed using the Perseus database. The data for the study was transcribed from tape recordings of the 'thinking aloud' protocols as the learners attempted to work on their tasks. All protocols were transcribed verbatim and categorized according to each strategies content. A functional taxonomy were developed to characterize the cognitive operations and thinking processes of the learners' interactions with Perseus. The proposed taxonomy characterizes their cognitive engagement within hypermedia from a broader context. It is a multifaceted construct which entails thick cognition with many highly correlated factors. The study is concluded with practical and theoretical concerns emerging out of this focus on discourse synthesis within hypermedia.

Integrating Technology Into the Curriculum

Rosanne Yost, University of South Dakota, USA; Ray Thompson, University of South Dakota, USA

This session describes a teacher education course designed to help K-12 educators integrate technology into their curriculums. The Technology for Training and Development (TTD) Division at the University of South Dakota has developed the course by using the same curriculum planning process that the course is designed to teach. The overall goal of TTD 782: Technology Integration, is to help teachers develop an understanding of the potential for technology to transform school curriculum so that it is student centered and future orientated. As the professors have modeled the curriculum planning process they teach to their students they have themselves become better at using technology. The benefits to both teacher educators and classroom teachers have included classrooms where active learning occurs and where students gain some control over there own learning. A variety of learning styles and needs are now being met as teachers and students learn "how to learn" together.

Using Web Resources to Enhance the Interdisciplinary Nature of Freshman Preceptorial Course

Kesheng Yu, Union College, USA

The purpose of this poster is to demonstrate the design and development of the web-based set of materials designed to help instructors become familiar with topics or readings in which the preceptors' group has little expertise. The focus of Freshman Preceptorial is on cultural difference and on contemporary issues seen in historical or philosophical perspective. Three Freshman Preceptorial projects were funded in 1998 and 1999. While two of these projects are still in the progress, the Resources for Teaching the Bible are finished. This website is designed for faculty teaching and students taking Freshman Preceptorial, though others are certainly welcome to use it. While the demonstration of the design and development of the web resources, the effect of web resources on Freshman Preceptorial course and student attitude toward the use of the web resources would be discussed as well. The URL for the web site: http://www.union.edu/RESOURCES/curriculum/fpbible/

Development of an Virtual University Online Course Using an Interprofessional Approach to Teach Qualitative Research

Cheryl Zaccagnini, Shippensburg University, US; Denise Anderson, Shippensburg University, US; Kent Chrisman, Shippensburg University, US

Using an interprofessional approach, a qualitative research course was designed and taught as a virtual university course. Professors from the disciplines of early childhood, special education, and social work developed a qualitative research online course to utilize virtual university resources to reach graduate and undergraduate students at distant education sites. It was developed to implement the course as an interactive research course with web-based programming and video conferencing sites to enhance the quality of the course and to provide sufficient web-based content but most importantly to create an atmosphere of communication and connectedness with the professors and students at other sites. Syllabi was developed using a team teaching approach with access to the professors via video conferencing, e-mail, and web-based instruction. Formative and summative evaluation results indicate that teaching qualitative research through virtual university resources can be an effective alternative.

Going the Distance:Offering Design Curriculum in the University of Utah's Distance Learning MFA in Directing/Theatre Education

David Zemmels, University of Utah, USA

In the fall of 1999, the University of Utah's Department of Theatre, in collaboration with Sundance Institute/Sundance Theatre Lab admitted the first cohort to its pilot distance learning MFA in Directing/Theatre Education. The intent of this session is to provide an overview of the pilot program—its underpinnings, its infrastructure—and examine one solution to offering a theatrical design course within the parameters set by the program. Demonstration and examples of assignments and delivery methods will help conference participants envision ways to use distance learning technologies as part of program development at their home sites.

Merging Fine and Performing Art with Digital Technology:An Exploration of the University of Utah's Arts Technology Certificate Program

David Zemmels, University of Utah, USA

Successfully integrating traditional forms of artistic expression with digital technology is an ongoing challenge in the fine and performing arts. In the 21st Century, digital art forms will likely become even more important. Computer technology has become a pervasive and necessary aspect of the arts, whether you are a music therapist, art historian, actor, musician, designer, photographer, or painter. This past fall, the University of Utah's College of Fine Arts began the Arts Technology Certificate Program, an interdisciplinary pilot program offering classes in digital technology as a tool for artistic expression across all art forms. The intent of this session is to provide an overview of the pilot program and the methods and strategies used to implement it, and to showcase representative examples of student work. Demonstration participants will also explore ways to integrate digital technology curriculum as part of program development at their home sites.

Comprehensive Examinations via e-mail

David Zimmerman, James Madison University, USA

This paper will examine the electronic administration of the written comprehensive examination for the Masters Degree in School Library Media Services from James Madison University. Prior to the fall semester, 1998, all students traveled to the main campus in Harrisonburg, Virginia to take the three hour exam. Beginning in November, 1998, four students were sent the exam via e-mail and returned their responses via the same method. The following paper will include a comparison of the two methods of administration, the results of a seven-item questionnaire and a review of the James Madison University Honor System.
