One of the most important tasks in developing an educational tool is identifying the appropriate topics. Computer technologies may or may not be well suited for all subject areas. In other words, in some cases there are no apparent advantages in using multimedia technologies for certain topics. Therefore, to use multimedia technologies for an educational program, the proper criteria for selecting topics has to be established. Although a detailed discussion of the criteria is beyond the scope of this paper, the following is a sample list: 1) topics that the instructors find hard to explain through the traditional teaching methods, 2) topics that students find hard to understand from the typical schooling method, 3) topics that are explained or learned better if visual/auditory effects are provided, 4) topics concerning 3-D shapes, 5) when computers can provide a simulated environment that the school cannot afford, 6)topics where students need to solve many exercise problems for better understanding, and 7) topics that involve many continuous and chaining steps.

Once an appropriate topic has been selected, an overall environment must be designed. At this stage, the task must be broken down into sub-problems first. Breaking down the task involves both analyzing the content of topics and selecting the proper presentation method for the topic. In the content analysis, the following three questions must be considered: a) What goals can students or users achieve by using the tool? b) How deeply are the topics dealt with in the program? and c) How much related information or knowledge is provided for improving students' understanding?

Choosing the appropriate metaphor and media types for each parameter that is relevant to the topic is another important task in this stage. Among the various media types such as text, pictures, images, sounds, animation, and videos, the most applicable types for the topic have to be selected in order to achieve the maximum effect. Furthermore, the organization of the selected media should be considered so that the users can get information efficiently.

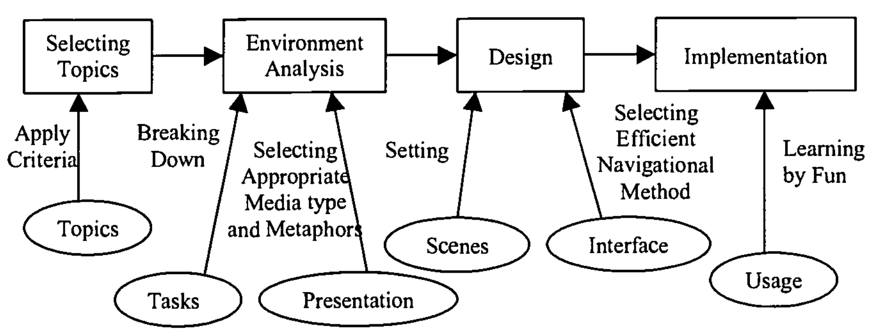

Figure 1. Development Process

The design stage follows task analysis. Setting the appropriate scenes and choosing the method of user interface must be done in this stage. Each scene must be sketched carefully according to the results of the tasks break down. A point to be considered when sketching the scenes is that each scene has to contain a proper amount of data or facts. If there is too much information in the scene, students will be stunned by the amount of information they have to digest and may lose interest. On the other hand, if there is inadequate information, the users will be busy moving from one scene to the other to find the desired information. Another point to be taken into account is the flow of the scenes. The strong coherence between consecutive scenes is necessary, of course unless the theme has changed. The smooth flow of scenes can be achieved by a well-designed user interface. An important requirement is that users must have no difficulty in navigating the program. To offer a better navigational method to users, many techniques have been invented, including task bars, hot words, dialogue boxes, and using animated icons and histories.

The final stage in developing an educational tool is the actual implementation and coding. All the plans chosen during the previous stages have to be synthesized, organized and displayed in such a way that gives the maximum effects to the users. The ultimate goal here must be that the users will enjoy what they are. By simply using a computer mouse to point and click on a particular picture, word, or button, stories and information come alive on a computer screen. The phrase "edutainment" is the buzzword for this. The explained processes are summarized as presented in [Fig. 1].

3. Synthesizing Constructivism, Cognitive Theory and Behaviorism

In developing an educational tool, a consistent educational theory is needed so that we would not digress from the initial set of goals during the entire development process. A combination of cognitive theory, behaviorism and constructivism will provide the ideal setting for the development of educational tools. The synergized theory emphasizes both accumulating personal experiences before attempting to learn a new subject and by providing enough exercise problems to enhance student's ability to apply the concept after learning it. The following characteristics from the current educational theories are identified and will be resolved into the new educational framework: 1) From cognitive theory - Habitual process of perceiving and thinking, Thought that forms association, Seek interconnection between connected ideas and individual analogies, and Awaken knowledge in long-term memory, 2) From behaviorism - Learn by doing, experiencing, and engaging in trial and error, Give repetitive stimulus and get response, Present similar stimulus material, and Give some reinforcement immediately after the response, 3) From constructivism - Constructing knowledge rather than mere memorization, Provide complex learning environment, Collaborate or cooperative learning, Examine the same material from multiple metaphor, and Invoke student's reflexivity

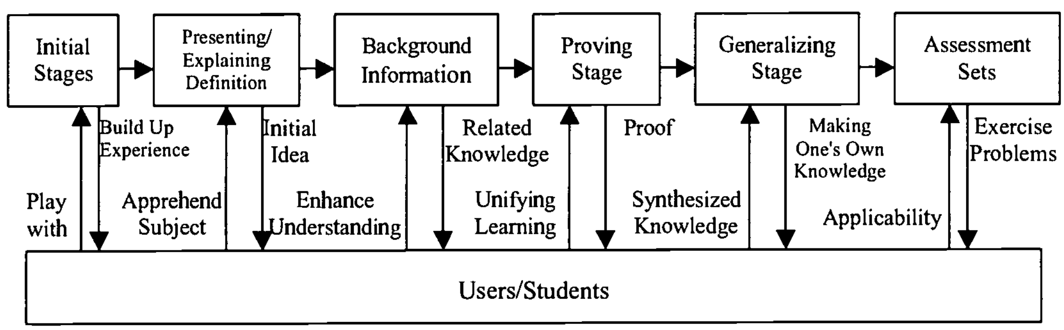

Figure 2. Steps for Developing Educational Tools for Mathematics

The tools provide the following features, which would help the students, learn mathematics step-by-step.

- Building the preliminary stage(s) at first so that the users remove the unfamiliarity from the new topic and make an experience by playing with that topic without deep touch
- Presenting/explaining the definition in order to give the students the initial idea what they are going to learn
- Giving the related background, information, and/or knowledge to enhance the students' understanding
- Doing the proof, if necessary, for the students to consolidate what they are learned systematically
- Generalizing and/or synthesizing the topic, and discussing the variations to raise the students' interest and to encourage their curiosity in the given topic
- Providing enough assessment sets for the students to know how the subject they are learning is applied to various situations

We feel that in such a framework, the designer would work closely with the educators and students in the design and implementation of the learning tool. [Fig. 2] illustrates the steps to be followed.

4. An Example: Pythagorean Numbers

At Arizona State University Multimedia Systems Laboratory, we have developed a large number of modules, each targeted to demonstrate how various technologies may be effectively utilized for delivery of learning material in the fields of mathematics, chemistry and physics. We present in detail one of the modules, namely the Pythagorean Theorem. Although this demonstration program is targeted high school students, it clearly shows that the techniques are applicable to all levels of sophistication.

4.1. Selection of Topic

The selected topic, the Pythagorean theorem, is one of the most popular theorems in trigonometry. Most students consider this theorem to be easy and memorize only one equation, $C^2 = A^2 + B^2$. However, there is much more that cannot be compacted into just one equation. In fact, this theorem represents the special case of the law of cosines which establishes the general relationship among the sides and angles of a triangle. Therefore, to understand the Pythagorean theorem, students must understand the law of cosines and possess the basic knowledge about the concepts of angles and sides of a triangle, and the triangle itself. Moreover, the proof for the theorem is not easy even to the medium level of students.

4.2. The Preliminary Stage

At this stage, the users can get the first experience of the relationships between angles and sides of a triangle simply playing with any vertices in the given figure. A brief description is given in the left upper window so that the user will know what to do at each stage. When the users move the vertex from one place to the other place on the right side of window, they can see the corresponding changes of sides, angles, and the areas of three squares that are made by each side of a triangle. They also see the changes of equations which are shown on the left lower window. Since the Pythagorean theorem comes into existence when the given triangle is a right triangle, the sound effect is added so that the users know when they have created a right triangle. The users can get a rough idea of what they are going to learn by just playing.

4.3. Presentation of the Concept and Definitions

The users are probably ready to learn the new topic after getting the first experience of the previous stage. Therefore, the formal definitions of the Pythagorean theorem and its general form "Law of Cosines" are presented and explained at this stage [Fig. 3]. The figures and their written explanation will help the users' understanding of both concepts.

4.4. Providing Background Information

The user may or may not have enough knowledge to understand the new topic. For such students, presenting the basic knowledge is a necessary step in the new teaching and learning tools for mathematics. Of course, the students who know the basic knowledge well can skip this stage and go on to the next stage directly without wasting their time. For the Pythagorean theorem, the users must know the angles and sides of the triangle and the triangle itself. Therefore, the explanation of angles and triangles are given at this stage.

At first, the users can see the general definition of an angle, the unit of measurement for an angle, and the various types of angles on the left window [Fig. 4]. After getting some basic concepts about angles, the users can pick any angle name to get the details of that particular angle. The red color is used for the text of angle names. The red colored text indicates hotwords which evoke the other events when pressed. The users can see the definition of the specific angle and its figure by pressing the angle name. On the figure, the users can play with the vertices, and see the changes in angle. The change in angle is calculated and shown on the right lower window. If the angle is out of range to the given angle type, both a written message and the sound alarm are produced.

The section for the triangle is composed similarly [Fig. 5]. The definition of the triangle and its sides are given as well as the various types of triangles. Like the angle section, the triangle names are formed as hotwords. By pressing them, the users can see the definition of the particular triangle and play with its vertices to see the changes of angles and sides. The measurements of three angles are shown, and both the written message and the sound alarm are produced when any one angle has not satisfied the condition for the particular triangle type.

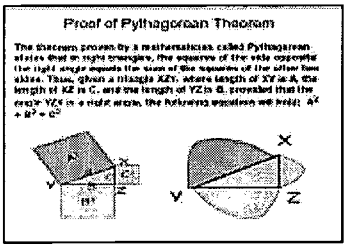

Figure 3. Presenting Definition

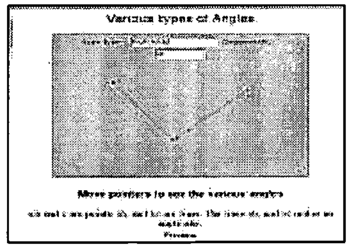

Figure 4. Background info.: Angles

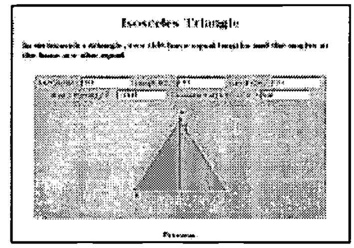

Figure 5. Background info.: Triangles

4.5. Proving Stage

Many mathematical concepts require a proof. Most students find it hard to prove a mathematical theorem because a complete understanding is needed in advance. If the visual and auditory effects can be given to each step as well as a written explanation, the users will easily understand the processes of proving theorem. For the Pythagorean theorem, the proof can be easily understood if the animation technique is used. [Fig. 6] shows the selected phases of thirteen steps for proving the theorem [Golshani, Park, Cho, and Friesen, 1997]. The users can see each phase of the proof in the right window. Its corresponding explanation is also given in written form. If the users cannot understand a certain phase, they can go back and forth until they understand thoroughly. One thing that needs attention in the figures is that the same-colored areas between the adjacent phases have the same area. Of course, the reason why they are the same is well explained within the text.

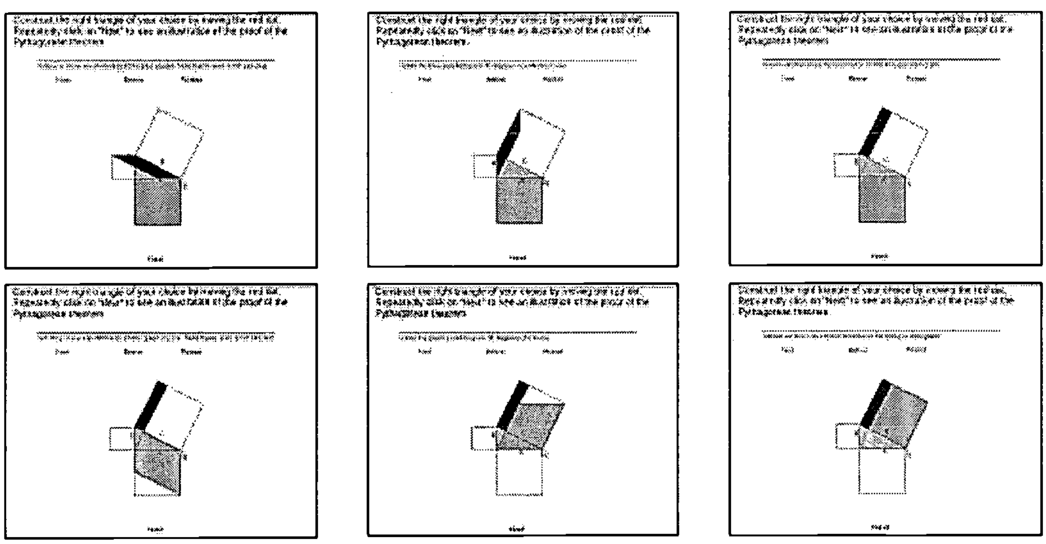

Figure 6. Animation of proof: Selected Examples of 13 Phases

4.6. Generalizations

By now, the user should be able to understand the topic completely by synthesizing all the things they have learned from the previous stages. The users can construct one solid idea about the topic. As illustrated in [Fig. 7], the student can synthesize the Pythagorean theorem by playing with any vertices. According to the movement of vertices, the areas of three squares are also changed. However, the sum of two small areas always equals the area of one big square, which satisfies the Pythagorean theorem.

In addition, we present the following extension of the Pythagorean theorem. As presented in [Fig. 8], if the user draws an arbitrary shape from any side of the given triangle, the congruent shapes are automatically drawn from the other two sides of the triangle. A simple animation shows that the area of the shape, which extends from the hypotenuse is equal to the sum of the areas of the shapes which extend from the base and height.

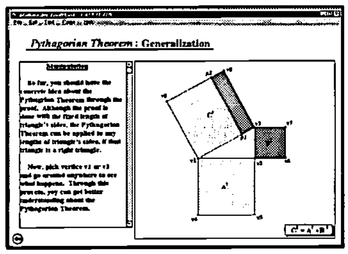

Figure 7. Synthesizing Stage

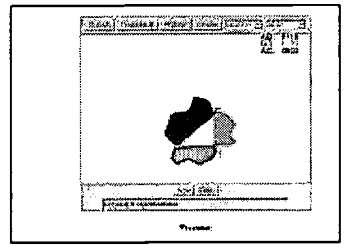

Figure 8. Variation of Pythagorean Theorem

4.7. Assessment Stage

The new teaching and learning tools for mathematics must provide a set of questions by which the student can assess his understanding of the topic. If the users understand the fundamentals of the topic, they can solve any questions and use the already acquired knowledge in practice. The exercise problems are a means to confirm how well the users understand the given topic. The users can improve their abilities through problems, which they appear with various types in the real world.

5. Conclusion

On the whole, the currently available educational tools for mathematics that are made by using computer technology are not good when used as a supplement to the traditional class. This is because there is no enough correlation between the computer scientists and the mathematics educators. This highlights the difficulty in creating of effective educational applications. This research is an attempt to engraft the computer scientist's technical background to the field of education in order to produce effective educational applications. First of all, the computer multimedia technology is fully utilized to develop new tools for teaching and learning mathematics. In addition to, the whole process of development follows the new theory that is formed by combining constructivism, cognitive theory and behaviorism. The actual implementation is performed to demonstrate how the new tools should be developed under this theory.

Abstract: Described within this paper is an adaptive hypermedia system (AHS) that utilises symbolic AI and connectionist AI to provide generic student modelling. The needs for generic tutoring systems are discussed, in terms of a system that is applicable to a multitude of teaching domains, whilst maintaining diagnostic facilities of the student. The hypermedia architecture is based on a semantic-network allowing the use of automatic reasoning to produce weighted links. A type of student model is employed to record information about the student so that the weighted links can be tailored for the student's interests. A neural network is used to grade the student into an ability level based upon their interactions with tutorials. A further neural network is used to recognise the movements students make as they browse the hypermedia and link it to tasks and abilities. This offers the potential to extract information about the student without direct dialogues.

Introduction

In the face of growing economic pressures, Leeds Metropolitan University is seeking increasingly to use educational technology and computer based learning to solve the practical problems of providing for increasing student numbers given static or decreasing resources (Willis 1994), a widespread problem shared with many other educational institutions (Sillcorn 1996). A particular interest concerns the educational use of hypermedia. This is seen as being potentially educationally valuable in that there is evidence to suggest that learning is improved when a student is allowed to follow pathways of their own choice, at their own pace and able to monitor their progress by instant feedback questions (Kibby, Mayes 1990).

A major concern, however, with the educational use of hypermedia is that of user navigation. The issue is how, on the one hand, to prevent the user from becoming overwhelmed with information and losing track of where they are going, whilst on the other hand permitting them to make the most of the facilities the hypermedia offers. One approach to remedy this is to restrict the number of links made available to the student. The concern that this might lead to an impoverished set of learning opportunities can be countered by the use of adaptive hypermedia, seeking dynamically to configure the available links as the user proceeds.

The educational importance of adaptivity

Our argument for the importance of adaptivity in an education hypermedia environment is based in part on the claim of Elsom-Cook (1989) that the perfect tutoring system should be able to slide between the two extremes of total constraint and total absence of constraint, according to the student's needs and current state of knowledge. In a similar vein, Hartley (1993), cf (Ford 1995) argues that when there is a mismatch between the strategy of the learning system and learning style of the student, performance is degraded, suggesting a need for support for different styles and viewpoints of users. With this in mind, one of our aims is to facilitate hypermedia systems with the ability to adapt to their students' needs as they progress through the systems (Mullier 1996). To this end we have developed a prototype hypermedia shell, which provides a combination of knowledge-based representations (which we refer to as "semantic hypermedia") and neural network models ("connectionist modelling").

We argue that this approach overcomes two major concerns in the domain of educational hypermedia. One is that since a hypermedia learning systems shift the responsibility for accessing and sequencing information from the teacher to the student, this may entail a cognitive overload: "The number of learning options available to learners places increased cognitive demands upon the learners that they are often unable to fulfil" (Jonassen, Grabinger 1990). A particularly important manifestation of this cognitive overload occurs when a user becomes "lost in hyperspace", not finding or being presented with the required information, a problem caused by the complexity associated with "having to know where you are in the network and how to get to some other place that you know (or think) exists in the network" (Conklin 1987). Our prototype seeks to deal with this problem essentially by making more links available to students as their knowledge of the domain is judged to be improving; in an attempt to provide the sliding scale approach advocated by Elsom-Cook, the novice user of our system is freed from much of the complexity associated with an unfamiliar system teaching an unfamiliar subject, while the more advanced student is freed from unhelpful constraints.

Dynamic linking

In order to enable to enable provision of a suitable regime of dynamic links to the student, our prototype adds to the standard hypermedia paradigm (i) a student model, (ii) a semantic network to describe the domain and (iii) a control system, the "hypermedia manager", for regulating the links offered to a given user, in the light of information from the previous two modules. The student model comprises a connectionist device for characterising a student's browsing strategies and a device for grading the student according to their ability to answer questions and complete tutorials. The semantic network (Beynon-Davies et al 1994) is a formal method of describing the domain. Its use imbues the system with the ability to perform reasoning processes drawn from the field of artificial intelligence, which in turn allows the system automatically to generate links and ascertain the student's interests. These elements are referred to collectively as "semantic hypermedia" and are described further in the following section. Finally, the hypermedia manager utilises information from the student model and the semantic hypermedia and determines which links are offered to the student, according to the student's current profile and the domain semantics.

This architecture allows three levels of dynamic linking, resulting in a highly adaptive system from the user perspective. One level of dynamic linking is provided by the semantic hypermedia element of the system. This is based on a semantic network using typed links such as is-a, has-part and kind-of (Beynon-Davies et al 1994). Production of this network is the responsibility of the domain author, but the system is able to use it to produce links between nodes in the hypermedia system automatically. It achieves this by building direct connections between nodes which are already connected indirectly via the semantic structure, and by weighting them according to the strength of the semantic relationship, construed as the number of semantic links indirectly connecting the two nodes. Weighting the links enables the system to suppress low weight links and/or dynamically tailor the displayed links to a given student in order to reduce complexity for novice students. This first level of linking is the most processor intensive, since the whole domain must be processed. However, these links are generated before a student encounters the system.

The second and third level, tailor the links to an individual and are achieved whilst the system is in use. The second level of dynamic linking requires a system to record information about the student. The student model provides information about the student's ability and their interests in terms of previous node types visited (these are stored in the Student Experience Record). The hypermedia manager uses this to modify the already present weights stored with each link. Thus the links are dynamically modified for a particular student at a particular instant in time. A third method of dynamic linking allows a human teacher to modify the link weights so as to favour certain areas of the semantic hypermedia. For example, the teacher may want the student specifically to look at a certain area of the domain. This would be accomplished by assigning a priority to certain class nodes in the semantic network. The system then increases the weight for each instance of this class, thus making it more likely to be selected.

Semantic hypermedia

The central feature here is the use of a semantic network, from which the hypermedia model that forms the basis of the student's interaction is generated. The use of a semantic network has certain advantages from the author's point of view. First, "they are natural to use, since related concepts tend to cluster together in the network...[and] ... an incompletely or inconsistently defined concept is easy to spot since a meaningful context is provided by those neighbouring concepts to which it is already linked" (Conklin 1987), cf (Beynon-Davies 1994)). Further, the use of the semantic network forces the domain author to think about how to structure each additional part of the domain and allows each subsequent part to be typed and attached to the semantic network. Again, use of a semantic network may help solve the problem of "linkitis" (Conklin 1987), whereby an author, not knowing how to link a node to an existing hypermedia network, errs on the side of caution and links nodes to other nodes that may not be relevant; this, coupled with the fact that most hypermedia systems have no facility for qualifying one particular link as more or less relevant than another, can add to the cognitive burden of the learner.

Importantly, these advantages for the domain authors translate into advantages for the users of the system. Structure in general is widely seen as important in educational hypermedia systems: "the belief that hypertext can mimic human associative networks implies that an appropriate method for structuring hypertext is to mirror the semantic network of an experienced or knowledgeable performer or expert" (Jonassen, Wang 1993). Yet more importantly from the point of view of the current project, it is the use of a semantic network that forms the basis for the automatic generation of hypertext links, by utilising automatic reasoning algorithms.

A semantic network is therefore created for a domain and substantive "content nodes" are attached to it; these content nodes are intended to provide information of potential educational value to the student and may include calls to different media drivers, eg to play a sequence of video. It is not necessary to link content nodes to other content nodes, since they are already connected indirectly through the semantic network. Additionally these indirect links provide information about the strength of the relationship between any two nodes in the resulting hypermedia system. It also provides information about how the nodes are related, in terms of the link and class types connecting them together.

Using a Solar System domain as an example, the nodes "Mars" and "Earth" can be linked by an is-a link to the class node Planet. This gives a simple knowledge base, namely the knowledge that both Mars and Earth are planets. The system can now automatically link Mars to Earth. Further direct links might be made from Phobos to Mars and from The Moon to Earth, and this would allow the system to link Phobos to The Moon, again providing a useful link without any intervention from the author. Further, links can be given a weight according to the length of the path that indirectly connects them.

Student model

The student model is made up of four sub-components:

- Browsing Pattern Recogniser (BPR)
- The Fuzzy Rule Base (FRB)
- Tutorial Supervisor (TS)
- Student Experience Record (SER)

These sub-components are described below.

The use of neural networks within the student model

Both the TS and BPR are neural network devices. We argue that the use of neural networks offers a potentially attractive way of surmounting the difficulty of recognising unclear or complex patterns (complex patterns made by a student using the hypermedia and a potentially dynamic grading of questions and students). We argue this partly on the negative grounds that the alternative, namely writing production rules to recognise these strategies, is likely to be "difficult, incomplete and non-versatile" (Mullier 1996, Tsutsui 1991). There are interesting precedents in the use of neural networks for student modelling (e.g. (Bergeron et al 1989, Tsutsui 1991, Battitti, Serra 1991), and in the current case building the neural networks could be expected to be quicker than building the equivalent symbolic AI components. Further, the resulting networks are likely to be very fast in execution and therefore ideal for real time applications (Chiu et al 1991). Other useful network properties are their pattern recognition ability on imprecise data and their potential ability to adapt to situations where a student has achieved a result by unconventional means. We maintain a compelling prima facie case for investigating their use within the student modelling provisions of our hypermedia shell.

The Tutorial Supervisor (TS)

The TS measures the ability of the student by examining the student's interactions with tutorial nodes. Such nodes may present the student with a simple question and answer session or may give the student a goal to achieve, requiring the student to browse the hypermedia and return to the tutorial node to complete the task. The results obtained from the student's interaction with a tutorial node are utilised by the TS to update its current level for the student. Clearly, it is fundamental to this that tutorial nodes are provided in the hypermedia system. Such nodes however are seen as valuable in their own right, in that simply browsing through a hypermedia system on the part of a learner may not be enough to produce any appreciable transferral of structural knowledge, and it is likely therefore to be necessary to provide exercises that explicitly test the learner's knowledge of the domain (Jonassen, Wang 1993). Tutorial nodes are essentially empty boxes into which a particular tutor can place suitable opportunities for learner interaction; they are likely therefore to be places within the hypermedia where the student is questioned about information stored in nodes elsewhere in the domain. They may make convenient points of entry into the domain, as a student is given a goal by the tutorial node, and be useful intermediate reflection and debriefing points.

The TS operates on the basis of student interactions with these tutorial nodes. It takes the student's current level (for new students this will be the lowest level), the question/tutorial's current difficulty level and the result of the interaction between the question/tutorial and the student. It outputs an updated student ability level. We argue that a specialist type of neural network (Kohonen self-organising map) is a useful means of accomplishing this, since it can adapt to different domains without the need for external intervention (unsupervised learning). Our experiments with such networks have provided results which clearly demonstrate that the network is able to adapt to different domains, where similar student levels provide different results (an expert score for one domain may be in the range of 90-100% say, whereas in another domain it may be 70-100). This on-line adaptability is only available with unsupervised neural networks.

In addition to judging the ability of students, the TS is also able to adjust the difficulty rating of questions. This is seen as valuable on the basis of the pedagogical principle that it is useful to present to a student questions at or just beyond their current ability (Bergeron et al 1989). Whilst the domain author is expected to provide an initial grading of questions and tutorials, this grading may turn out not to be appropriate in practice. The system is therefore able to examine the interactions between the population of students and the questions. If, say, the domain author grades a question as difficult, but results with students show that students of novice ability score highly with the question, then the question appears to have been graded as being harder than it actually is. If this situation occurs then the benefits of providing a student with questions at or just beyond their ability level is lost. The student may become frustrated by answering questions that are below their ability and is therefore less likely to improve their ability level (Bergeron 1989). It is therefore important to maintain an accurate level for each question and tutorial. The re-grading of questions is a gradual process, since it is unwise to alter a question's grading with respect to an interaction with just one student. The TS is able to re-grade questions dynamically and continually without making extreme judgements based upon one observation.

The Browsing Pattern Recogniser and Fuzzy Rule Base

The BPR is designed to identify movement patterns and strategies employed by the student as they move through a hypermedia domain. A number of specific hypermedia browsing strategies have been identified by empirical studies of users of hypermedia systems (McAleese 1993). Examples are pathiness, ringiness, loopiness and spikiness. Such patterns have been identified as offering the potential of providing "psychologically important information about the user" (Canter et al 1985). Recognition of the strategy being adopted by a given user during a given interaction is potentially useful to both the system and to a human tutor, but tends to be very complex (Canter et al 1985), not least because a user may adopt more than one strategy for a particular session, and may appear to be utilising different strategies at different times (Mullier 1996). The BPR seeks to provide such recognition and, because of the task's inherent complexity, adopts a neural network approach.

Once browsing patterns have been identified then the system attempts to utilise the information to determine what it is the student is doing. Such information linking browsing patterns to particular tasks does not currently exist. Therefore the system provides a unit that is capable of extracting this information as the hypermedia is used. The information linking browsing patterns to tasks and particular abilities of students is provided by the tutorial nodes and the TS respectively. Tutorial Nodes induce the student to perform a particular task as defined by the author. The student then completes the task using a browsing pattern, the system then records this information. Mapping tasks and abilities to browsing patterns in a direct manner is not suitable, since different browsing patterns may be used for similar tasks and vice versa. Instead it is necessary to pick out overall trends (generally high ability users use browsing pattern x to locate a specific piece of information, for example) over a period of prolonged exposure with many students. This is achieved by the utilisation of fuzzy logic. A Fuzzy Rule Base (FRB) is able to adapt to a complex and changing environment as the system is in use, in a similar fashion to a neural network. The important difference, however, is that the rules inside can be read and interpreted by a human. Therefore the hypermedia system shell (called Hypernet) is a hypermedia research aid, potentially capable of providing the important information describe by Canter et al (1985).

Several networks have been trained and tested on data generated from programs written to produce a rich set of simulated student browsing patterns. Results of tests of the networks have again been encouraging. For the BPR a back-propagation multi layer feed forward network has proved to be an effective network type, showing high levels of accuracy in pattern recognition. A Kohonen network, however, has also proved able to recognise browsing patterns and in addition offers the promise of detecting previously unidentified patterns.

The Student Experience Record (SER)

The SER uses an overlay model to build from a history of nodes in the semantic network visited by the student. This can be seen as a characterisation of the student's interests. This is stored for eventual use by the dynamic linking system, which seeks to tailor links more closely to the student's interests as they use the system. The overlay model records information about particular nodes in the domain. Information such as visited/unvisited indicates a student's interests. Information regarding how much a student knows about a particular concept can also be inferred from results with tutorial nodes. The SER is not covered in detail here since it draws heavily from related work (Brusilovsky 1996).

Conclusions and further work

This paper has described a novel approach to adaptive educational hypermedia. By allowing for a sliding scale of constraint, from complete constraint to total freedom, upon a student's exploration of hypermedia material (in terms of the number of links offered). The approach currently being prototyped represents a promising means of alleviating navigation difficulties whilst allowing the student to take advantage of the hypermedia material, without swamping them with too much information. The system currently exists as a proof of concept prototype in that it operates highly successfully with simulated student data, thus validating the pedagogy in this technical sense. An immediate task involves field tests of the system. A large number of students using it for an extended period is required. An important aspect is the use of the system in a range of domains, since the system is designed specifically to be applicable to a multitude of domains and its modular design facilitates the incorporation of different semantic networks.

In summary, then, the approach to adaptive educational hypermedia adopted by our prototype promises, we believe, major educational advantages. A range of interesting and important issues remain to be addressed, however. The continual need to provide for increasing numbers of students with a wide range of abilities makes continued investigation of such issues imperative.

Maintaining Information Awareness with Irwin

D. Scott McCrickard

mccricks@cc.gatech.edu

Abstract: The ongoing explosion of Internet usage has many positive effects for the educational community, but it makes it difficult to stay updated on the status of information that is important. To address this need, we created Irwin, a set of configurable information monitoring tools that endeavor to maintain a desired level of awareness for different types of information with minimal interruption to other important tasks. This paper describes Irwin and examines how four users used it over a five-month period.

Introduction

The ongoing explosion of Internet usage has many positive effects for the educational community. Email can connect colleagues separated by thousands of miles. Usenet news can allow professors and students to communicate outside of the classroom. The World Wide Web provides both essential information and much needed distractions. But with these positive effects come new problems.

Although this information is readily available, it is updated at irregular intervals, making it difficult to keep track of changes. For example, a professor may want to monitor a class newsgroup on the days leading up to an assignment due date, or a researcher may want to be updated on the score and status of a ball game on the evening before a paper due date. Another problem is that information can take a significant time to download and display. Consider the time required to download a weather report from the Web, complete with colorful icons and advertisements, at a time when a student is late for a class across campus.

People in academics often want or need to be aware of changes in the types of information in these examples, but they cannot (or should not) spend all of their time reading mail, scanning newsgroups, and surfing the Web. One solution is to use visualization and communication tools to help maintain a desired level of awareness. These tools should include an omnipresent display to allow the user to check on the status of resources with little or no effort, yet the tools must use limited screen space as the user will often want to use other applications that require significant screen space. We try to achieve a balance between these competing requirements with our Irwin information awareness system.

Irwin (Information Resource Watching In a Nutshell) is a set of tools that uses graphical, auditory, and textual communication mechanisms to help the user maintain a desired level of information awareness. This paper outlines ways in which Irwin can assist students and faculty in maintaining awareness, and it describes a field study that examines how four academicians used Irwin to maintain information awareness over a five-month period.

Irwin

Irwin (McCrickard & Rowan 1996) monitors Internet information resources and alerts the user of updates and modifications. Irwin consists of a set of *hypertools*, small reusable programs that can run simultaneously and share information. The central tool in Irwin handles the visualization and user interactions, while the remaining tools process the information from each resource and update the visualization tool when important changes occur.

The information resources monitored by Irwin can include email folders, Usenet newsgroups, Web pages, and weather data. The email and newsgroup hypertools monitor the messages in a folder or group, alerting the user when new messages arrive. The Web tool summarizes headers, lists, and hypertext links on a Web page, allowing the user to monitor news wires and hotlists. The weather tool monitors the weather conditions and forecast for a given city.

When users initially start Irwin, it tries to determine their informational interests by examining their email files and Web bookmarks. (Since users are not required to answer a list of questions at startup, they are often more likely to use Irwin.) The user can then configure both the information monitored and the way in which it is displayed after getting used to the power and flexibility of Irwin.

To show both an overview and details simultaneously, Irwin uses a *confluent zoom* display. A confluent zoom provides multiple views of a resource simultaneously with each view having a different level of granularity. With a confluent zoom, the user can see overview and details with minimal effort, and the context of the detailed views is maintained at all times by the coarser views. Since intermediate views have proven useful in graphical tools such as map browsers and medical imagery (Plaisant, Carr, & Hasegawa 1992, Plaisant, Carr, & Shneiderman 1995), we expect that the intermediate views will smooth the transition from the high-level overview to the detailed zoom view.

IMAGE NOT AVAILABLE

The image displayed here is a screenshot of Irwin. In its confluent zoom, Irwin employs an auditory cue, an icons view, a navigation bar, and several textual views. In the icons view (the leftmost view in the above image), the state of each resource is reflected by an icon. When the resource changes, the appearance of the icon changes and an auditory cue is played. If user selects an icon, the other views are updated to show information about the corresponding resource. A navigation bar (second from the left) shows a syntactic encoding of the resource contents and can be used to select the messages displayed in the textual views (the two rightmost views). Users can configure the orientation and placement of the icons with respect to the other views and can even choose to hide the other views until some event happens, e.g. an icon is clicked.

Auditory cues

Auditory cues provide a means to attract users to a change that has occurred. They may be the only way the user knows about the change if the display is obscured or not in the user's current line of sight.

We selected sounds that are distinctive but are not distracting and, most importantly, are short. Each is less than two seconds in duration, which we expect will be long enough to be noticed but not too long to become an annoyance. In our initial configuration, we tried to select sounds that were indicative of the resource; for example, a dog bark for mail (dogs always bark at the mail carrier) and a splat for news (similar to a newspaper hitting a front porch). Of course, the user can select from a list of sounds (we provide twenty) or create and use their own sounds.

Icons

Icons are used in interfaces because they provide a universal representation in a small amount of space. In a WIMP environment they can both provide information and invite the user to click to obtain more information.

IMAGE NOT AVAILABLE

The image displayed here shows several of the icons used by Irwin. Each icon is a 16-by-16-pixel bitmap that reflects the status of information resources and provides a gateway to more detailed views. The color of the icons change to reflect the recency of updates to the resource: the resource's icon is originally black, but when a resource is updated its icon changes to red. Over time, if the resource is not updated its icon color fades. It never fades entirely to black until the user clicks on it.

In addition, the bitmap itself changes based on the state of the resource. The weather icon changes its appearance to a sun, a cloud, or rain to reflect the current weather conditions, and the spider icon changes to a dead spider when its Web site is not accessible. These icons show (top to bottom) the mail, sun, rain, live Web, and dead Web bitmaps.

Navigation bar

Irwin needs a method for visualizing and navigating a list of items, such as an email address list or a list of news headers from a Web page. While a scrollbar is a widely used navigation tool, it shows little information about the content of the list. Irwin's navigation bar leverages the familiar scrollbar metaphor by providing the same basic look and functionality as a scrollbar (arrows, a trough, a thumb), but the trough space of a navigation bar is used not only for navigating the list but also for providing an overview of the contents of the list. Each item in the list is represented by a line in the trough. The thumb (the black box surrounding several graphical lines) indicates the elements that are shown in the textual listbox. To encode information about the list, we used two classes of encodings: syntactic and semantic.

A *syntactic encoding* is based only on the structure of the word being encoded. Advantages of syntactic encodings are that they require no user input and they are consistent between sessions and between users. In Irwin's syntactic encoding, a word or phrase is represented with a series of blocks of pixels, where each pixel block represents a character in the word. To differentiate between words, Irwin colors the blocks that correspond to vowels such that `a' is red, `e' is orange, `i' is yellow, `o' is green, and `u' is blue.

IMAGE NOT AVAILABLE

For example, the image displayed here shows a portion of a navigation bar representing several news postings by Annie Anton. Her login (anton) is represented by a red block, two black blocks, a green block, and a black block.

We expect the syntactic encoding to be most useful for mailing lists and newsgroups where a small number of people are responsible for a large amount of the activity. In the previous example, Annie Anton regularly posts computer jobs and internships to a local news group - by using Irwin, her postings can be identified with a glance. Also, the syntactic encoding works well for course newsgroups where the students post questions and concerns and the professor posts responses and clarifications. Since the encoding for the professor would appear quite frequently, it should be easy to recognize.

A *semantic encoding* uses information about the meaning of each list item to create the encoding. In Irwin, clusters of related items are created, and the pixel blocks for items in a cluster are identically colored. The clusters can be created automatically using the Lance-Williams dissimilarity update formula (Frakes & Baeza-Yates 1992), or the user can specify the clusters using keyword matching. The Irwin screenshot earlier in this paper showed a navigation bar using semantic encoding, where email messages are colored based on the sender group (faculty, staff, students, other).

We expect the semantic encoding will be most useful for resources with large amounts of information on a number of different topics. For example, news articles taken from a Web page can be clustered based on the topics of the articles, with the most frequently occurring topics being colored. Initially, the topics can be created automatically, then later the user may want to specify topics of interest.

We also encode the time at which the message was stamped by indenting the message according to the hour; for example, messages received at 3 PM will be indented three blocks. This is intended to group messages by arrival time, thus facilitating searches and browsing. If users know the time at which a message arrived, they can identify the range of messages in which it must fall using the navigation bar.

Textual views

Graphics alone might not show all the information necessary to understand a message - at some point a textual view will likely help. Irwin incorporates two textual views: a header list and a message view. Irwin constructs lists of headers for each resource, the senders for email and Usenet news, abbreviated headers for Web pages, and days of the week for the weather forecast. If the user selects an item from the list, the message view shows a more informative summary of the original message.

While the Irwin textual views can give the user an up-to-date peek at the contents of the monitored resource, it is not meant to replace the programs that are designed for reading, browsing, and searching the resources. To assist the user in bridging the gap between awareness and other tasks, Irwin allows the user to jump to various readers and browsers to view the resources of interest. Irwin is automatically configured to jump to a Web page using Netscape Navigator if a URL is referenced, or Irwin can be configured by the user to start or activate various email readers, news readers, Web browsers, or other programs and commands.

User reaction

While studies like our navigation bar experiment are helpful in analyzing performance for certain specific searching and identification tasks, the true test of tools, particularly for a difficult to quantify task like awareness, is the reaction of the public. By offering Irwin to users and observing how they use it, we hope to answer some of these questions.

Nine faculty members and graduate students attended a presentation and demonstration explaining how to set up and use Irwin. Seven people tried Irwin at least once, and four of those continued to use it regularly. The remainder of this section summarizes their comments. (A full report of their comments is available as well (McCrickard 1997).)

We asked those who did not use Irwin why they chose not to. Most simply did not feel like they needed such a tool. One person noted that she didn't receive much email and only rarely browsed the Web - she simply had no use for tools like Irwin. One user wanted a less passive visualization tool. He reported the he felt he did not have enough control over when the resources were checked. He seemed more interested in a typical browsing or reading tool.

All of the frequent users configured Irwin to better meet their needs, though most used it for several days first. Common resources to monitor were email, various news and sports Web sites, high traffic Usenet news groups, and the local weather.

Reaction was mixed on the use of audio. All but one user turned the audio alerts off or only used a simple beep, and the one user who did use it only used short sounds (under a second) even though Irwin provides sounds up to two seconds long. Reactions varied from "I didn't need it" to "It would drive me up the wall." While we feel that audio is not for everyone, if it is kept short and distinctive it can prove to serve its purpose for some people.
Most users did not use the navigation bar very extensively. They typically looked at Irwin only to see the most recent additions, i.e. those visible in the text boxes. One user noted that he could recognize a few patterns and occasionally would notice blocks of identical encodings together (indicating several emails or news postings by the same person) but would rarely click on them and browse them. The problem may be that the navigation bar is better suited for browsing and searching tasks than for awareness, or it may be that the users did not choose resources for which the navigation bar is best suited.

After using Irwin for several months, the users had many suggestions for resources that they wanted to monitor but could not with Irwin. The resources include Unix commands like lpq and finger and Web images like traffic and weather maps. The users wanted more flexibility over the way in which information is presented - not all resources fit in the list-based concept of the navigation bar. As we extend and improve Irwin, we are exploring new identification schemes and new communication mechanisms to allow the user to specify items of interest and to have the information delivered in the most appropriate manner.

Related Work

A significant amount of research has focused on the filtering and dissemination of information (Foltz & Dumais 1992, Frakes & Baeza-Yates 1992). However, far less work has been done in understanding how people need the information to be communicated. Many systems generate email or Web pages that still require the user to remember to check them. Other solutions have been developed for specific resources, but there is not always a direct application to a broader range of resources. We hope that the Irwin monitoring system will address these concerns by providing a configurable set of tools for monitoring interesting resources and staying aware of changes that occur to them.

The individual components of Irwin were influenced by prior research. Auditory cues have proven useful in both enhancing and replacing visual cues in user interfaces (Brown, Newsome, & Glinert 1989, Brewster 1994). Studies have shown that changing the appearance of icons can convey additional information about their use; for example, animated icons (Baecker, Small, & Mander 1991) convey more information about the functionality of tools in a tool palette than a static image. The navigation bar concept of encoding lines of data using graphical lines came from previous systems. Read wear and edit wear (Hill & Hollan 1994) represents lines of text with lines of pixels, where characteristics like length and color correspond to properties of the text such as the number of modifications. The SeeSoft (Eick, Steffen, & Sumner 1992) and RunView (McCrickard & Abowd 1996) software visualization programs represent code with lines of pixels where the length of the line can correspond to the length of the line or function, and the color can correspond to the author, module name, or last modification date. To our knowledge, our navigation bar was the first to use syntactic encodings, the first to fully leverage the scrollbar metaphor, and the first to empirically demonstrate that this type of encoding improves user performance in search and recognition tasks.

While many parts of the Irwin system have been researched individually, we feel that our true contribution comes in the integration and evaluation. We hope that the lessons we have learned have built on the work of previous researchers to provide another step towards understanding information awareness.

Conclusions and Future Work

Based on our experience with Irwin, we would like to discuss a few of the lessons we learned which should help in the future development of information awareness tools.

Irwin users were willing to sacrifice a little bit of space to increase their awareness of information resources. Even those who did not use Irwin cited reasons other than space limitations. While we do not expect that everyone will need awareness tools, it appears that there is a significant population that does.

When using Irwin, most users utilized some combination of feedback from auditory cues and icon changes to know when to check a resource. Though we provided auditory cues that were up to two seconds in duration, all of the sounds configured by our users were under one second, and most used only a simple beep. Longer sounds seem to be too distracting, and a simple visual change may suffice to maintain awareness. The navigation bar seems to be better suited for searching and browsing tasks than for general awareness, though users began to recognize a few patterns over time, and for certain situations (such as monitoring a course newsgroup or a listing of jobs) the navigation bar may yet prove to be essential.

Too often visualizations will provide complex graphical views of a data space but will make it difficult to see the actual data that is represented. Ideally, a visualization will provide a view that combines graphics and text dependent on the available space, the needs of the user, and the amount of information that needs to be shown. The confluent zoom allows the user to stay aware of the status of several resources but also to view details of a selected resource. By providing both focus and context in a compact manner, users can be free to focus more of their attention on other tasks.

Abstract: This paper reports on research engaged in the design, development and evaluation of an innovative, interactive learning tool—for Web and CD-ROM. The learning tool is the text analysis object (TAO). TAO facilitates the development of text-based extended question-and-answer problems. Using TAO, a student is able to generate a more meaningful answer by articulating their understanding rather than merely recognising the lecturer's representation, as in multiple choice questions. TAO facilitates an iterative approach to knowledge construction. Feedback to the student is determined by using a key word and key phrase search, utilising a two-tiered, hierarchical feedback mechanism—distinguishing between concepts (major ideas or principles) and details.

A formative evaluation of the TAO is reported. The examples of TAO relate to questions developed for use in undergraduate medicine. However, the TAO is applicable to many other academic disciplines where there is a need to develop more complex understanding of specific content domains.

Introduction

The use of computer-facilitated learning (CFL) for Web and CD-ROM in higher education has increased considerably in the past five years. Considerable effort (academic, financial and time) has been invested in the development of courseware. However, insufficient effort has been made to develop pedagogically sound interactive learning tools that have the potential to engage students more actively in learning. If there are to be any lasting improvements in student learning outcomes and the success of computer-facilitated learning (CFL) there is a need to:

- embed sound educational pedagogy into courseware; and
- provide interactive computer-based learning tools, which are simple for content experts to implement in a variety of learning environments supported by CFL.

The development of the Text Analysis Object (TAO) is part of a wider program being undertaken at The University of Melbourne to develop simple generic Web-based and CD-based learning and evaluation tools (Kennedy & Fritze, 1998; Kennedy & Ip, 1998). Initially, interviews with academic staff from a variety of disciplines were undertaken. Responses indicated that an interactive learning tool that could elicit student responses of more complex knowledge (rather than merely require recognition as in multiple-choice questions (MCQ)) might have the potential to enhance student learning by providing more meaningful feedback for students. The TAO is intended to facilitate an iterative approach to learning, provide meaningful feedback, and require articulation rather than recognition of knowledge. The functional aspects of the TAO include:

- a text box into which students type short, text-based answers based upon a question item;
- a software engine (one for the Web environment and a second stand-alone version for CD-ROM) to search for key words or multiple versions of a phrase or phrases defined by the lecturer or content expert;
- the ability to provide appropriate and meaningful feedback to students; and
- access to expert answers and a representative student exemplar to questions for comparison and self-evaluation purposes.

Three perspectives guided the development of TAO. These perspectives involved:
- a constructivist view of teaching and learning;
- the needs and computer literacy skills of academic staff engaged in developing courseware; and
- the requirement for a student to link anatomical knowledge to a clinical perspective.

The pedagogical perspective adopted derived from a theoretical framework that links what is known about sound educational practice with the design of computer-based learning tools (design elements) for incorporation into computer-facilitated learning environments or interactive multimedia (Kennedy & McNaught, 1997). The analysis of text from student-generated answers was designed to engage students more actively in the learning process—a move away from the click-and-browse interface of many current CFL offerings. Initially, the feedback mechanism for the TAO was established by interviews with academic staff. The final mechanism was determined after meetings with student focus groups engaged applying anatomical knowledge in a clinical context. The students were in their first year of clinical practice (Year 4 of Medicine). A number of potential scenarios were constructed and a variety of feedback mechanisms evaluated. Typical comments from the students about the problems they encountered in their daily clinical practice include:

> ...the difficulty is knowing what is important and what is not important (anatomical knowledge) in making a diagnosis.
>
> I have forgotten much of what I learnt in first and second year anatomy. ... I find myself going home each night and relearning the important concepts (of anatomy).

The TAO facilitates the incorporation of feedback that links anatomical knowledge to clinical practice, and provides a numerical score (specifically requested by the students in order to establish a link to formal assessment). The feedback mechanism is intended to address the widely reported failure of students to link pre-clinical knowledge (e.g., anatomical knowledge) with the demands of being a successful clinician (Balla, 1989; Eizenberg, 1988; Eizenberg, 1991). The feedback mechanism is a key feature of the TAO, using a hierarchical structure to separate key concepts from minor details. Initially, the TAO software determines the number of key words or words or multiple versions of a phrase or phrases (as defined by the content expert) found in the text string typed in by the student. The concepts and details of the correct responses are then differentially highlighted and returned to the student. The student knows what parts of her answer are correct, and the relative importance of each correct response. The two tiers required the development of:
- TAO software to differentiate between important anatomical concepts and what were merely anatomical details (ideas not fundamental in clinical practice), and
- a model for writing questions which focused on anatomical concepts important in clinical diagnosis.

These led to the development of a schema for writing the questions, expert and student representative answers, key words and key phrases. The schema also guided the development of the authoring environment. Figure 1 (Fig. 1) is a screen capture image of student feedback during the evaluation process. Not shown, is the video clip (a simulated patient complaining of pain in the right side of the abdomen) that accompanies the text component of the question. With TAO, video, graphics and sound may be used with any question.

TAO is intrinsically a very simple system with no built-in intelligence—a strength and a weakness. This is in contrast to other text analysis systems, for example, Latent Semantic Analysis (Landauer, Foltz, & Laham, 1998b). The Intelligent Essay Assessor (IEA) is one such tool that uses LSA—relying on the ability of the software to measure the coherence of text by comparing the degree of semantic relatedness of adjacent text segments—from parts of sentences to paragraphs (Landauer, Foltz, & Laham, 1998a).

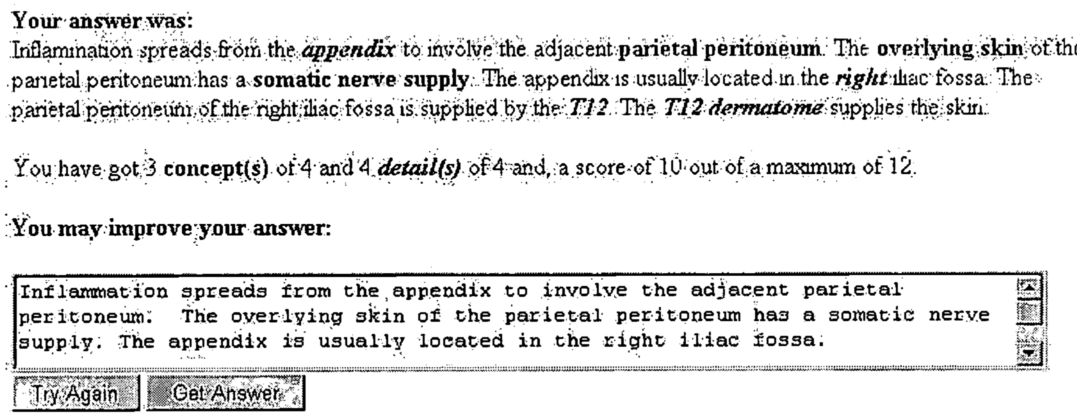

Figure 1: The Web version of TAO: Hierarchical feedback linking clinical practice and anatomical detail

The accuracy of the IEA in the grading of student essays is comparable to that of human markers. However, the training of the IEA requires a very intensive diagnostic process undertaken by experts, and access to a large number of exemplars of relevant subject material (e.g., up to 30,000 articles). The IEA makes no sense of word order, syntactic relations, or logic (Landauer *et al.*, 1998b, p. 261). In clinical diagnosis, word order and logic are critical. The TAO is designed to provide formative and (limited) summative feedback to students. It is not intended for use as an assessment tool. Student learning is enhanced by engaging students in a reflective process. In answering a question a student must address the following: How many of the major concepts have I got correct?; Are the concepts I articulated actually the ones required for a correct clinical diagnosis?; How 'good' is my answer compared to the two representative answers provided?, and, How does my answer relate to the clinical perspective presented (e.g., in the accompanying video)? TAO's strengths are:

- its relative simplicity of use by content experts,
- the ability to focus on important concepts specified by the educational needs of a particular content domain,
- the hierarchical nature of the feedback provided (concepts and details), and
- the provision for an iterative approach to learning as the student moves towards a final answer.

A content expert using TAO also has the ability to incorporate other media, video clips, graphics and sounds into a question. Video clips may be used to situate the learning in a clinical context. The major weaknesses of developing a system using TAO are the need

- to design the questions carefully, and
- a pre-emptive approach (Bain & McNaught, 1996) to appropriately express key words and phrases.

A Functional View of TAO

The basic functionality of TAO requires a:

- text field into which a student can type an answer to a question,
- software engine to analyse the student text and provide meaningful feedback,
- method of displaying an expert answer, and
- simple-to-use authoring environment.

Initially, the TAO was created as a server-side object—that is, the software engine for the tool was located on a Web-server. This decision derived from the need to have a short development time, core functionalities that could be developed quickly and tested, and a tool that could be easily maintained. Design of the Web authoring environment was inherited from the OXYGEN software engine (Ip, 1998). OXYGEN also supports Learning Evaluation Online (LEO), an online evaluation tool used in the formative evaluation of TAO (Kennedy & Ip, 1998). The second version for CD-ROM has been prototyped as a Macromedia Director® object for the project, *Demystify*—which focuses on clinical practice in undergraduate medicine.

The structure of the authoring environment was critical because the expected users of TAO are lecturers—who often have only limited computing experience. Our prior experience indicated that a forms-based approach was appropriate. The authoring environment consists of input fields for the:

- reference code for the question,
- question stem,
- key words and multiple versions of a phrase or phrases based on an important concept or concepts,
- key words and multiple versions of a phrase or phrases based on an detail or details,
- mark to be awarded for each concept (major idea) and detail (minor idea), and
- expert answer and an exemplar student answer.

Experience has shown that content experts with minimal computing skills can format questions easily for use with the TAO. The structure of each question required the:

- separation of important (clinical) concepts from (anatomical) details,
- development of a number of alternatives for key words and phrases, separated by the pipe '|' symbol, and
- organisation of the expert answer into point form which clearly showed the concepts and details (a stated requirement from the students in the focus groups).

A question used in the first formative evaluation is shown in Table 1. The CD-ROM version of TAO will be used in the *Demystify* project and the Web version in a variety of courseware in the Faculties of Medicine at The University of Melbourne and Monash University.

Formative Evaluation

Formative evaluation of the Web version has been completed. The student responses to the use of TAO were generated by the 'think-aloud' approach, researcher notes, and an online survey (Likert-style and free text response) using Learning Evaluation Online (LEO). One of the surprise results of the evaluation process was the considerable discussion, debate and collaborative effort engaged in by students in order to arrive at an answer, or succession of answers. The students found using the TAO straightforward. In each session students were asked to complete approximately half the questions (4 to 6). This led to the unusual phenomenon of the majority of students requesting to stay to complete the remaining questions at an adjacent computer (which they subsequently did). The formative evaluation indicated a strong acceptance by students of the TAO as an effective learning tool. Representative written comments from the online survey asking about the best features of TAO are:

> It is very clinically oriented which is brilliant since books do not often highlight important principles.
>
> ... the distinctions between concepts and details in the question are critical, therefore very relevant.
>
> The fact that we could type in our own answers and for the program to analyse what we got right instead of us choosing from a number of given answers.

The use of pairs of students enhanced the learning experience by promoting a collaborative approach. Students were strongly engaged in debate and argument about the inclusion or exclusion of anatomical concepts and details. Most pairs of students tended to refine the first attempt a number of times before having the response analysed. The concern expressed by some academic staff that a student would merely access the expert answer almost immediately was unfounded for two reasons.

The first reason was student motivation—when asked why they didn't look at the expert answer immediately, students stated that doing so was a 'waste of time' because it wouldn't help them learn. The second reason is more pragmatic—TAO requires a student to click on a *Submit* button before being provided access to the *Get Answer* button. A similar lack of concern was expressed in regard to the lack of a spell checking mechanism—

they believed they should know how to spell the terms. Not all comments were positive and some of these responses have resulted in changes in functionality of the TAO.

In response to 'What was the worst feature of this multimedia program?', students stated the following.

> No indication of how much is expected in answering a question.
>
> Having to sift through (expert) answers to find what you hadn't included (in your own answer).
>
> Maybe at times being too pedantic about details.

Q: 0004	In appendicitis, after initial pain has been experienced, the pain typically shifts to the right iliac fossa. Explain the anatomical basis for this	
Expert answer	Concepts: Inflammation has spread from the appendix to involve the adjacent parietal peritoneum. The parietal peritoneum and the overlying skin have a somatic nerve supply. Somatic pain is usually well localised as it is typically referred to the overlying skin.	Details: The appendix is usually located in the right iliac fossa. The parietal peritoneum of the right iliac fossa is supplied by the right twelfth thoracic spinal nerve. or T12 or subcostal nerve. The skin of the right iliac fossa is supplied by the T12 dermatome or by the right twelfth, T12, subcostal nerve
Keywords and/or phrases	Concepts parietal peritoneum somatic nerve supply| somatic nerve| somatic pain overlying skin referred pain| referred| refer	Details twelfth thoracic spinal nerve| subcostal nerve| T12| twelfth thoracic appendix T12 dermatome| dermatome right

Table 1: A template and exemplar question for using TAO

In response to 'Any more comments or suggestions for improvement?', students stated the following.

> Providing hints at second attempts and .... having a help file with a list of anatomical terms...
>
> Just enhance the text analysis flexibility– sample a wide proportion of possible answers.

In addition to the extended comments (above), the student responses to bipolar Likert-style questions were analysed. The mean responses are shown in Table 2 (Tab. 2). The responses were scored: 1, strongly disagree; 2, disagree; 3, no opinion; 4, agree; and 5, strongly agree.

Likert-style question	Mean
The TAO helped emphasise important and relevant concepts.	4.7
The TAO helped identify key concepts and provided insights.	4.6
The TAO helped provide feedback which was meaningful to me.	4.3
As a result of using this multimedia:	
I was stimulated to reflect on what is important for me to understand.	4.4
my intention to achieve an understanding of this subject was enhanced.	4.4
Overall I found this multimedia program to be worthy of extension to develop new modules with similar uses of the TAO.	4.7

Table 2: Example student responses to likert-style questions: Web-based TAO

In response to these comments two changes have been made to the TAO software engines. The mark for each question is displayed with the question stem to provide a guide for the relative complexity of the answer required. The second change is more fundamental. The TAO is to be incorporated into courseware—providing access to hints and/ or online help.

Future Development

A new collaborative project, Interactive Qualitative Questions: IQ^2, has been commenced jointly at The University of Melbourne and Monash University to develop the two versions of TAO further. The TAO is being incorporated into both Web-based and CD-ROM courseware—*Anatomedia* (designed to support the learning of anatomy), *Demystify* (which focuses on clinical practice), The Virtual Radiography Room (a simulation of radiography practice), and Gastro-intestinal Medicine courseware. In response to current student feedback a number of changes will be made. One change has already been indicated (a mark). Both versions of TAO derive from courseware based on components (Ip & Canale, 1996; Ip, Canale, Fritze, & Ji, 1997). Other changes will be:

- improvements to the authoring environment by greater integration of video and sound to provide multiple perspectives for the questions, and
- generation of each question in a separate window.

The formative and summative evaluation of student learning outcomes in both institutions for both the Web and CD-ROM versions of TAO in the four projects will continue in 1999.

Abstract: As attention becomes increasingly focused on distance education, in the public eye and within the academic community, a sense of urgency to develop on-line course offerings is taking hold among institutions that wish to be responsive to student needs (real or perceived) and that do not want to be "left behind" as peer institutions tool up for distance instruction. With the host of software tools available, adapting courses to the on-line learning environment does not pose insurmountable technical obstacles, and can be almost routine. What becomes a challenge is preserving the original value of the instructional design and adapting the pedagogical nuances of a course to best leverage the modalities of on-line instruction. This paper illustrates how a graduate level course at Teachers College, tailored for face-to-face instruction, was adapted for distant learners, and how the instructional design was captured and replicated by a web-based distance education authoring tool.

Introduction

Recently, Teachers College, Columbia University expanded the boundaries of its campus by offering on-line distance learning courses for the first time. Three graduate courses, in three different areas, were selected for this pilot initiative: Computer-Mediated Communication, The Teaching of Writing, and Instructional Design of Educational Technology. The courses, previously designed for the classroom, were adapted to on-line settings, and in the spirit of experimentation, each course adopted a different development path. We will discuss the design of the course in Instructional Design of Educational Technology, which poses several challenges to the distance format, among them, its emphasis on discussion, the importance of technology demonstrations, and the centrality of group project work. We also summarize the evolution of the CourseMaster Authoring Environment, a database-driven tool that is derived centrally from a model of distance instruction that guided the construction of the original course application.

Goals

The goals of this project were to build a reproducible distance learning model, within which rich classroom interactions among participants can be replicated, and to shed light on potential obstacles to the success of this approach. We were guided in part by our previous distance learning research that calls for a resource space, discussion space and collaboration space as components of successful computer-supported distributed learning (Bell & Meyer,1997). In the pilot course, we focussed on specific design techniques for fostering group interaction. We developed several facets of the course with community-building in mind: a student database where participants would share personal profiles; a suite of technology demonstrations and corresponding assignments aimed at getting students to share reactions to those demonstrations; a terminal project that engaged teams of students in remote collaboration; and regular discussion and chat sessions to foster and sustain whatever communal momentum had been achieved. The creation and implementation of Instructional Design Online (as the distance version came to be called) presented an opportunity to invent a web-based learning environment, adapt an onsite class to an on-line course and capture its design in a mold, thus providing a test-bed for studying learning at a distance.

Pilot Course Design: Instructional Design Online

Instructional Design of Educational Technology is a graduate class that surveys contemporary frameworks for intelligent learning environments and that engages students in designing and executing collaborative projects (e.g., an interactive web-based environment, stand-alone instructional multimedia, etc.). The class thus emphasizes learning by doing. In order to support this approach through computer-mediated instruction, the course site includes five sections, each of which can be reached by using a drop-down menu: *Information Desk*, *Course Central*, *Instructor's Corner*, *Student Lounge*, and *Help Center*. Each section has its own sub-menu for the sites located within that section.

The Information Desk includes an overview of the course, an orientation session, a course outline, and registration information. The overview offers a summary of the class and a list of required readings. The orientation is intended to welcome students, guide them into practicing tasks common to an on-line class and prepare them with the tools necessary for exploring the learning environment. Initial assignments are designed to engage students in Internet communication. Orientation assignments include viewing a video welcome from the instructors (Fig. 1) and creating a student profile.

Course Central consists of a syllabus, on-line demonstrations of educational technology, course lecture slides, and course assignments. The syllabus is divided into topic-specific modules, each including links to the corresponding lecture slides, assignments for the week and related technology demonstrations. The readings for that module are available via hypertext links to external web sites.

Web-based educational technology demonstrations represent an important element of this course. The principles and frameworks discussed in the readings can remain largely static or abstract in the absence of applications of those ideas in the form of interactive illustrations. To preserve this central aspect of the course, we adapted several works-in-progress at Teachers College for on-line viewing, including Wx-Brief (Bell, Vaughn & Reibel 1997), Aviation Story Archive (Bell, Gold & Kaplan, 1998), and the Virtual Hall of Fame (Zirkel, Bell & Gold, 1998). Each Demonstration is accessible on-line (Fig. 2) and supplemented by an assignment in which students share observations and critiques of the demonstration.

Lecture Slides are available in modules, each consisting of slides that can be navigated in succession or through direct links. Assignments are designed to encourage students to explore technology tools and Instructional Design theories, and to integrate them in discussion responses and project creations. Assignments range from regular responses to issues raised in the reading to creating interactive exemplars of concepts treated during the course.

The Student Lounge includes a database of student profiles, a meeting room and a student projects area. The Student Profiles section facilitates the distribution and sharing of individual profile and contact information. A participant database (Fig. 3) receives profile forms submitted by the student, and permits the browsing and searching of participant profiles, pictures and contact data. Profiles include direct links to student mailboxes and world wide web addresses, personal interests, and academic and professional histories. The instructors' profiles and office hours are in the Instructors' Corner. The profiles include Instructor academic background, links to personal web sites, and office hours (which are conducted face-to-face, by telephone, via text chat, or using audio conferencing).

The Meeting Room, supporting synchronous (chat) and asynchronous (bulletin board) interaction, is the primary communication area. The chat room permits live scheduled group discussions, including multiple simultaneous one-to-one private chats, about topics related to course content, assignments and group projects. Class-wide chats are transcribed and published on the course site. The discussion room supports group communication through individual message postings.

Early in the course, students are asked to form groups and to begin proposing final projects. As the semester progresses, students are asked to prepare incremental reports, such as a storyboard, documenting their progress in the final project. The Student Projects area centralizes information regarding final projects, the culminating product of the students' experience in the course. Suggestions (in the form of online technology demonstrations) are offered as potential group projects, though students are invited to propose their own ideas as well. A project database collects and publishes information about project group members, member email addresses, and project URLs, so that group members and projects are easily accessible.

Formative Evaluation

Participants

The course was offered during the spring, summer and fall semesters of 1998 and is currently in session for the spring, 1999 term. Eight students enrolled for the spring semester, 7 students for the summer, and 17 for the fall. In each semester's class, more than half of the students registered for credit. All of the students in each semester had completed or were pursuing either a Masters or Doctoral degree. Most of the students registered for credit were part-time students who work full-time as either classroom teachers or technology professionals. Several of the non-credit students were faculty at other institutions who were interested in exploring examples of distance learning courses. Students were physically situated in locations throughout the U.S. (with some international participation from Japan and Brazil).

Methods

Pre- and post-course surveys and scheduled chat interviews were used to gather qualitative information about on-line students and on-line student experiences in the pilot course. Chat sessions, discussion postings and group projects served as additional evidence documenting student performance. The objective of this formative evaluation was to learn more about how students made use of the tools we supplied with the course, the extent to which those tools furthered the students' capacity to engage in the class activities, and to explore potential research questions for further studies. The study did not attempt to measure learning outcomes beyond a qualitative assessment of their productivity as required for grading purposes. Our evaluation was guided in part by the expectation that understanding the learning needs of students is crucial to successful on-line course experiences (Reid, 1996; Warren, 1996; Willis, 1995). Pre-course surveys were aimed at gauging student backgrounds and skills and their reasons for enrolling in the course. Post-course surveys were aimed at gathering student perceptions about their experience in the course and the design of the learning environment.

Results

Computing ability and exposure to the Internet varied widely among incoming students. In each class there were individuals who reported that they did not feel confident in their computing skills, as well as others who reported that they were comfortable with a variety of computer and Internet applications. Variation in computer literacy also became evident as the semesters progressed. Many of the individuals who had expressed a lack in computing skills moved through the syllabus at a much slower rate and seemed to be less involved in group communication. There were also individuals who came in with weak computing skills and gained proficiency at a rapid rate. During one semester, a vision-impaired student participating in the course provided valuable feedback on the extent to which our course site accommodates visually-impaired students in accessing information and navigating the site.

The Discussion room was the most active component of the courses in each semester, primarily used for discussion about course assignments and scheduling. Assignment postings took on a quality that seemed to be a cross between written language and spoken conversation, with ideas expressed in a blending of informal and formal language styles. A large proportion of the postings in the discussion threads were responses to assignments or questions from the Instructor or Teaching Assistant. Students did not begin to initiate spontaneous postings until later in the semester. The discussion room was not used for dialog with other students until the Instructor suggested that students respond to the postings of other students. Once this suggestion was made, peer-to-peer interaction became more frequent and substantive.

Statements from students indicate that communication among students also took place via private email messages and by telephone. While much of the communication from the Instructor and Teaching Assistant occurred in the public communication space, spontaneous communication from students to instructors usually took place in private email or telephone messages. Email messages and telephone calls from students to the Instructor or TA were primarily about administrative and technical issues, such as course credit, and only occasionally contained content related communication. Instances of project related mail and phone calls did occur just before the final projects were due during the spring and summer semesters.

Students in the spring and summer semesters did not frequently meet in the Chat Room unless the Instructor had scheduled the chat. Students in the fall course appeared to be making more use of the Chat Room for peer-to-peer communication. One fall semester group met in the Chat Room for several hours a week. The main differences between groups in the fall course and groups in the spring and summer appeared to be group size (the fall class had larger groups) and individual computing ability (the fall class had more individuals with strong computing ability). In each term, the Chat Room was used on just one occasion as an entire class (time-zone differences caused scheduling difficulties). Not all of the students attended the scheduled chats. For the participants who did attend, these sessions were productive. Several students mentioned that Chat Room discussions were most like the communication that takes place in the classroom. All of the Chat participants spontaneously shared thoughts and ideas.

Not all of the individuals in the spring and summer courses completed a final group project. The group projects that were completed were of high quality. There had been some concern about whether students in the on-line class would have access to the same materials as students in the classroom, such as commercial, licensed authoring software, so it was decided that on-line student projects would be created with publicly available materials. Despite the potential difference in student resources, the on-line students' final project was comparable to final projects created by students in the classroom. Students in both online and in classroom courses produced original technology-based learning environments that showed some integration of theories discussed in the course.

Student comments suggested that they appreciated the variety of delivery methods and information resources provided, such as lecture notes, public readings and discussion threads. However, they also expressed frustration in accessing these resources. Several students mentioned that they had consistently had connectivity problems and problems during chat sessions and in downloading plug-ins and other course information. Advanced components took too long to download or made their computer crash. These students indicated that much of the problem was with their hardware. Suggestions were made to make graphics, video and other hard to access information available through other means. Generally, the comments acknowledged the importance of speedy and reliable connections and up-to-date hardware. Also, based on the comments made during the final chat session in which students were directly queried (in the absence of the instructor), students appeared overwhelmed by the technical requirements combined with the content of the course. These students did not feel that their knowledge of computer technology supported their learning needs and suggested a hands-on prerequisite, which would enable students to learn the technology apart from the content. All students who have completed the course thus far responded that they would consider taking another distance learning course.

Discussion

Our exploratory findings provide some information about the needs of distance learners, how our design functions in practice, and how to focus our future research efforts. While many distance courses are promoted to provide flexibility and convenience, they may in fact be more time consuming than classroom courses, depending upon the skill level and resources of individual participants and the quantity of participants. For students who were not comfortable with Internet communication or had inadequate resources, downloading data and keeping up with communication was more time consuming than they had expected. It is clear when examining both student needs and instructional design that explicit information regarding minimum and suggested hardware and software requirements be made available to students.

There appear to be both similarities and differences in student participation in classroom and distance learning environments. Similarly to on-site classes, students who were not taking the course for credit were not as active as students who were enrolled for credit. In contrast to on-site classes, students in the on-line class did not seem as accountable for their work. On-line students did not complete all of the assignments and did not attend all the scheduled meetings. Overall, the on-line students in this class required more guidance and imperatives. On-line students did not seem as self-disciplined, perhaps because they did not have physical access to the Instructor or Teaching Assistant. Despite the challenges involved in this on-line setting, students were able to utilize the tools, navigate and participate within the learning environment. Most students more than sufficiently completed the entire course on-line.

These preliminary studies have been helpful in our efforts to develop more systematic means of investigation. Based on student comments and student participation in the spring and summer courses, a new set of database-driven pre-course and post-course surveys was developed and distributed in the fall semester online and classroom courses. Survey questions are designed to capture information regarding student skill level, reasons for taking the course, predictions about the learning outcomes and challenges in on-line courses versus the learning outcomes and challenges of students in classroom courses, and perceptions of student-professor and student-student relationships. Questions in the new surveys invite both open-ended (as in previous surveys) answers and precalculated answers (based on open-ended answers from previous semesters). The overall goal of this new addition to the design of the course is to provide an improved structure for examining on-line student learning, evaluating course design, discovering student perceptions about on-line learning in comparison to classroom learning and gathering preliminary evidence about whether or not intimacy levels among individuals within a distance learning environment are different than intimacy levels among students in a classroom environment.

Bringing the Model to Life

Upon building what proved to be an effective course design given current technological conditions, we then successfully crafted CourseMaster (Fig. 4) by abstracting the original course and implementing that abstracted model as a set of relationally-linked database templates. The result is a sophisticated courseware authoring tool that not only renders the course production process less mechanically burdensome, but also adheres to (and derives its power from) this specific design model. Because it is created in a fully web-compliant database environment, CourseMaster can be used remotely by authors, and design commitments are immediately reflected in the materials published on the web. We can now create a new on-line course modeled on this design, within any subject area, with relative ease.

CourseMaster presents us with three research opportunities. First, comparisons can be made using the same design among different content areas. Second, aspects of group interaction across all content areas and design frameworks can be explored with the use of survey evaluation databases. Third, questions can be asked about instructional design in terms of particular on-line learning components, such as chats, discussion rooms and visual aids, by building identical courses that vary only in terms of the use of particular components.

Conclusion

One common deficiency among distance instruction materials we have encountered is the absence of an explicit instructional approach (Bell & Meyer, 1997). This paper described a distance courseware design in which we adopted a pedagogy that emphasizes peer interaction and group collaboration. An overall objective of this research is to develop frameworks for distance course design, appropriate for given subject domains, that preserve the positive elements of face-to-face instructional designs while introducing new strategies that take advantage of the properties of desktop telecommunication and web-based interchange. Our experiences with the design of Instructional Design Online have suggested some positive aspects of on-line distance learning and have indicated some directions for future research and course development. A principal conclusion is that successful distance learning must be at least as (if not more) firmly grounded in communication as traditional classroom instruction. Our success with the use of student profiles, collaborative project work, and extensive discussion lend supports to the claim that distance learning is effective to the degree that it creates and maintains learning communities that support knowledge construction. The emergence of collaborative tools that allow students to create and refine knowledge artifacts on-line is encouraging (Harasim, Calvert & Groeneboer, 1996). Web-based communications technologies will no doubt continue to evolve to support more real time communication and a more seamless interface among communication, collaboration, and information-gathering resources (Harasim, 1990). Flexible tools, such as CourseMaster, that help course designers to organize their information and incorporate emerging communication and collaborative learning tools support an extension beyond the current model of an HTML template for didactic presentation, toward virtual communities of learning.

CHANGES IN STUDENT ATTITUDES IN A COMPUTER ENRICHED ACADEMIC ENVIRONMENT: REPORT FROM A LONGITUDINAL CASE STUDY

Ananda Mitra
Department of Communication
Wake Forest University
USA
ananda@wfu.edu

Abstract: This paper reports that longitudinal exposure to a computerized enriched learning environment might not necessarily change the attitudes toward computer enhanced learning unless the development of the computerized enriched environment is supplemented by the fact that every member in the environment is provided with the tools for connecting with the environment. In this study, students without the tool never felt the empowerment of access and so they continued to maintain either a negative attitude, or did not alter their attitudes in a positive way even when placed in a networked and computer enriched environment. On the other hand, the students who entered the environment with a personal laptop computer and felt immediately connected to the environment.

INTRODUCTION

Based on the existing evidence on the use of computers in the higher education environment and in view of the increasing trend of all-out computer enrichment programs in academic institutions we pose the following question: 1.What are the changes in attitudes towards the use of computers in a higher education environment that is computer enriched? This question attempts to address the way in which wide-scale and long-term exposure to a computer enriched environment can alter the overall attitude towards the application of technology in higher education. As has been argued elsewhere, it is, however, important to acknowledge the context within which the technology is being applied (Ashley, 1992; Ahola-Sidaway, 1990; Bender, 1995; Fey, 1993; Goulet, 1994; Hettinger, 1995; Mitra, 1994; Mitra and Hullett, 1997).

METHODS AND SAMPLE

The study was designed as a longitudinal survey spanning five years with the first year being the baseline year. In the Fall of 1995, Wake Forest University entered into a partnership with IBM to make the institution computer enriched. In this case, the process of enrichment involved several different initiatives including extensive networking of student residence halls, classrooms, the library and most office buildings as well as providing all incoming students (beginning the Fall of 1996) with an IBM ThinkPad computer. This strategy ensured that by Fall of 2000 every student at the University would be equipped with mobile computing that would provide easy access to a local area network and then the Internet. When this decision was ratified, a survey design study was also initiated to track the changes in the way the different elements of the institution (faculty, staff, students, etc.) react to the computer enrichment. This analysis reports from three years of the study to answer the two questions posed earlier.

The survey design utilized a questionnaire that was constructed after extensive use of focus group discussions to explore and uncover the various issues surrounding the computer enrichment process at the University. Focus groups were conducted with students who belonged to the "ThinkPad Program" (henceforth referred to as the Program) as well as the students who were not direct beneficiaries of the Program but could utilize the connectivity and technology advancements in the classrooms. A survey instrument was developed and was used in the Fall of 1995 when only 100 pilot students were part of the

Program, in Spring 1997 when all the First Year students were part of the Program and in Spring 1998 when all First and Second Year students were part of the Program. The three administrations thus covered the 1995-1996 school year (henceforth referred to as Year 1), the 1996-1997 school year (Year 2) and the 1997-1998 school year (Year 3). Given the way the enrichment process was designed, Year 1 included only 100 pilot students who had a personal ThinkPad and the University was barely networked. In Year 2, nearly 90% of the university was networked and all the Freshmen and 100 Sophomores had ThinkPads and the Juniors and Seniors did not have personal standardized mobile computers issued by the University (such students who were not a part of the ThinkPad program is referred to as "legacy" students later in the paper). Finally, in Year 3 all Freshmen, all Sophomores and 100 Juniors owned ThinkPads while the remaining Juniors and all Seniors were considered legacy students. The overall composition of the three groups are summarized in Table 1.

Table 1: Composition of the samples for Years 1, 2 and 3

GENDER	Year 1	Year 2	Year 3
Male	53%	43%	43%
Female	47%	57%	57%

Other	11%	N/A	N/A

* The Seniors were not sampled in the Year 3 survey

Note: The N/A in Columns 2 and 3 refers to the fact that the question was not asked in Years 2 and 3

RESULTS

An ONEWAY-Anova measure was used to test for differences between groups and Scheffe's post-hoc test for homogeneity was utilized to identify the specific groups that were significantly different. The results indicate that there were more significant difference in attitude between Year 1 and Year 2 as compared to Year 2 and Year 3. As shown in Table 2, the results show that there are significant differences in the way the students expressed.

Table 2: Changes in attitude mean of all students from Year 1 to Year 3

Item	Year 1	Year 2	Year 3
Use of technology makes learning easier	3.5 (1391)	3.4 (469)	3.5 (271)
I prefer to take classes where I can get to use a computer	2.9 (1392)	2.9 (474)	3.0 (271)
I feel comfortable using a computer	3.6* (1392)	3.8* (469)	4.0* (271)
I have a certain apprehension about computer use	2.8* (1388)	2.4* (469)	2.2 (270)
Computers in teaching makes the learning impersonal	3.2* (1392)	2.9* (472)	2.7* (271)
Computer use increases the college work load	3.1 (1392)	3.0 (474)	3.0 (271)
Computers are effective for communicating wit faculty	3.3* (1400)	3.6* (472)	3.8* (271)
Communicating with professors by e-mail is generally gratifying	3.4* (1396)	3.7* (472)	3.9* (272)
Computers enable me to interact more with professors	3.0* (1393)	3.4* (464)	4.3* (266)

These differences include:

1. increasing comfort with the use of computers,
2. felt increasingly less apprehensive with the use of computers,
3. were less concerned that computers in teaching was making the teaching process too impersonal,
4. felt that computers enabled them to interact more with teachers,
5. felt that computers were effective for communicating with teachers about non-course related material,
6. felt that communicating with professors with e-mail was generally gratifying.

The question of attitude change was also explored by comparing specific groups of students and the changes/differences in their attitudes toward the use of computers in education. The first comparison was conducted between the Year 1 first year students, the Year 2 sophomore students and the Year 3 juniors. This group represents the legacy students who entered the University at the time when the enrichment initiative began. They did not feel the impact of the Program but were exposed to the changing technological ambience of the University. They had the opportunity to reap the benefits of a standardized computer network on campus. At the same time, they were exposed to an altering pedagogic condition where the faculty were increasingly "computerizing" the curriculum and introducing the use of computer mediated communication as a significant element of their teaching process. The groups were compared using an ONEWAY-Anova and the Scheffe's post-hoc test of homogeneity. The results indicate that the Year 2 Sophomores, and Year 3 Juniors felt that the use of computers did not make the learning process easier. The Year 1 Freshmen reported a mean of 3.6 (n=449) in responding to the item, "increased use of technology makes learning easier," while the Year 2 Sophomores reported a mean of 3.2 (n=110) and the Year 3 juniors reported a mean of 3.1 (n=48). While the responses of the Year 2 Sophomores and Year 3 Juniors were not significantly different, both of those means were significantly different from the mean response of the Year 1 Freshmen ($p<0.05$). At the same time, the Year 3 Juniors expressed a significantly more positive feeling that computers enables them to interact with their teachers, reporting a mean of 4.2 (n=48), as compared to the means of 3.2 (n=107) for the Year 2 Sophomores and the mean of 3.2 (n=448) for the Year 1 Freshmen.

Another comparison was conducted between the Year 2 Freshmen and all the other Year 2 students. This test represented a comparison between the ThinkPad students and the legacy students in Year 2. The comparison was conducted with the use of a t-test statistic with Levine's test of equality of variance. Significant differences ($p<0.05$) were observed here with,

1. the ThinkPad students feeling that the introduction of computers makes learning easier,
2. the ThinkPad students preferring to take classes where they could use the computer,
3. the legacy students feeling that computers can make the learning process too impersonal,
4. the ThinkPad students feeling that computers are effective for communicating with faculty about non-course related work,
5. the ThinkPad students feeling that communicating with teachers by e-mail is generally gratifying and
6. the ThinkPad students perceiving that computers enable them to interact more with teachers.

There were, thus, several instances where there were significant differences between the first group of ThinkPad students and all the legacy students.

While these tests represent the differences between legacy and ThinkPad students, it was also considered important to compare similar groups of ThinkPad students. The first test included an independent sample t-test with Levine's test for equality of variance. The Year 2 Freshmen, who composed the first batch of ThinkPad students was compared to the Year 3 Sophomores who represented the same group after a year's exposure to computerized instruction as well as after one year's use of the ThinkPad. There was only one significant difference observed in this comparison with the Year 3 Sophomores reporting a mean of 4.3 (n=71) in response to the item, "computers enable me to interact more with teachers," as compared to the mean of 3.7 (n=166) for the Year 1 Freshmen. A similar comparison between the Year 2 Freshmen and the Year 3 Freshmen revealed that the only significant difference between the first and second batch of ThinkPad students was that the second batch felt that computers enabled them to interact with teachers more than the first batch of ThinkPad students. The second group reported a mean of 4.3 (n=139) as compared to the Year 1 Freshmen who reported a mean of 3.7 (n=166). At the same time, the Year 3 Freshmen were not significantly different on any attitude measure from the Year 3 Sophomores. There were thus significant differences in attitude over the three years as well as across different groups of students over the three years. The specific areas of difference are summarized in Table 3.

Table 3: Summary of Findings

Significant changes in attitude for all students

Attitude Items	Pilot year to First year of computerization (1st batch of TP students on campus)	First year of computerization to second year of computerization (2nd batch of TP students on campus)
I feel comfortable using a computer	More comfortable	More comfortable
I have a certain apprehension about computer use	Less apprehensive	No Change
Computers in teaching makes the learning impersonal	Less concerned	Less concerned
Computers enable me to interact more with professors	More enabling	More enabling
Computers are effective for communicating wit faculty	More effective	More effective
Communicating with professors by e-mail is generally gratifying	More gratifying	More gratifying

Significant changes in attitude for legacy students

Attitude Items	Pilot year to First year of computerization (1st batch of TP students on campus)	First year of computerization to second year of computerization (2nd batch of TP students on campus)
Use of technology makes learning easier	Less easy	No Change
Computers enable me to interact more with professors	No Change	More enabling

Significant Changes in attitude of ThinkPad students

Attitude Items	First year of computerization to second year of computerization (2nd batch of TP students on campus)
Computers enable me to interact more with professors	More enabling

Significant differences between ThinkPad and legacy students observed in Year 2

Attitude Items	ThinkPad Students	Legacy Students
Use of technology makes learning easier	More easy	Less easy
I prefer to take classes where I can get to use a computer	More preferable	Less preferable
Computers in teaching makes the learning impersonal	Less concerned	More concerned
Computers enable me to interact more with professors	More enabling	Less enabling
Communicating with professors by e-mail is generally gratifying	More gratifying	Less gratifying

Significant differences between first batch of ThinkPad students and second batch of ThinkPad students observed in Year 3

Attitude Items	First batch	Second batch
Computers enable me to interact more with professors	Less enabling	More enabling

LONGITUDINAL PERSPECTIVES

Our results suggest that all the three elements - attitudes towards computers in general, the role of computers in teaching and the way computers facilitate the communication process - tend to become more favorable as an institution makes itself computer enriched. As demonstrated in the case of the overall student body composed of the legacy and the ThinkPad students, there is indication to suggest that the mix of students tended to become more positive towards the way in which computers could impact their college experience. Overall, the students became more comfortable with technology, were less apprehensive toward computers and were less concerned that the introduction of computers in teaching could make the learning process too impersonal. Indeed, the overall student body agreed that computers can positively impact the way in which students and teachers can interact and such interactions can be quite gratifying. The overall student body were not overly concerned over the ways in which computers could alter the learning process, and student opinion about the effects of computers on college workload did not change with exposure. In many ways, the general student body composed of the students with personal machines and those without the machines all felt that the computer was an expected and "natural" development in the pedagogic process and thus the students expressed a desire to use computers in classes. Even if the students did not change their opinion about the way in which computers can make leaning "easier," they appeared to agree with the statement that computers could make learning easier. Over the length of the study, the students felt that the use of computer in the college environment can be perceived to make the process of learning easier.

CROSS-SECTIONAL PERSPECTIVES

The cross-sectional perspective looks at the findings from the point of view of differences between the students in any particular year, or the differences between students of similar characteristics over a couple of years. This analysis demonstrates that the legacy students are less favorable than the ThinkPad students in nearly every attitude towards computer aided instruction. The legacy students who realized that they would not benefit from the enrichment that they were witnessing around them were expectedly more concerned about the utility of the technology in the teaching environment and less convinced that computers will significantly alter the ways in which teachers and students can communicate. The ThinkPad students on the other hand were more interested in being able to use computers in every class and were far more convinced that the technology will make learning and teaching better. This fundamental difference in attitude between the ThinkPad students and legacy students is also reflected in their patterns of computer use. The ThinkPad students used the Internet more and used the computer more for electronic mail with teachers. This difference in patterns of use is consistent with the differences in attitude as well. Overall, the ThinkPad students appear to be far more positively predisposed towards computers and thus approach computer enhanced pedagogy in a more positive way.

CONCLUSIONS

A key finding that emerge from this data is that longitudinal exposure to a computerized enriched learning environment might not necessarily change the attitudes toward computer enhanced learning unless the development of the computerized enriched environment is supplemented by the fact that every member in the environment is provided with the tools for connecting with the environment. This conclusion reaffirms a classical definition of the networked organization where it is assumed that every member of the networked organization has equal and democratic access to the network (Sproull and Kiesler, 1992). In this study, the legacy students are those who never felt the empowerment of access and so they continued to maintain either a negative attitude, or did not alter their attitudes in a positive way even when placed in a networked and computer enriched environment. On the other hand, the ThinkPad students entered the environment with a personal laptop computer and felt immediately connected to the environment. Indeed the academic atmosphere was getting increasingly designed and customized for the ThinkPad students and fitting in there was not a challenge to them.

Finally, this study addresses the question of effects of computer enrichment in teaching in a circumvented way. In stead of attempting to measure learning from traditional perspectives of grades and test scores, we have measured the way in which students perceive the changes brought forth in the learning environment with the introduction of computers. There is evidence in the data that the ThinkPad students considered the computer enriched environment to positively transform the learning space. The ThinkPad students also demonstrate that they are using the technology more for learning-related tasks. The legacy students, on the other hand, do not demonstrate these tendencies. Thus a positive attitude and increasing utilization of the tool by the ThinkPad students would suggest that the computer enrichment has a series of positive outcomes on the attitudes toward learning and the process of learning which in turn can have a positive outcome on learning itself. Some evidence for this claim is also found in the fact that the institutional research data indicate that the ThinkPad students of Year 1 and Year 2 have some of the highest grade point averages in several years and have the highest retention rate in several years. While it would be naïve to claim that computer enrichment is the "cause" for these trends, it would also be incorrect to discount the evidence about GPAs and not relate it to the process of computer enrichment. In many ways, the definitive answer about the effects on learning is still being debated, but the results here suggest that a networked institution where the students have easy access can foster a more positive attitude toward the use of technology in teaching and learning.

Abstract: This presentation reports on an effort to create a hypermedia supported learning environment using problem-based learning for middle school students in the subject matter area of space science. The objectives of the program are to promote problem-solving skills, to facilitate learning of science through hypermedia supported cognitive tools, and to encourage collaborative learning. The paper discusses the design and development of the learning environment and cognitive tools provided. It also outlines a research agenda for conducting research studies using the environment.

Introduction

Enhancing students' higher order thinking skills has been a major challenge for educators. For years, educators have been trying to find ways to create learning environments that can encourage students to be active learners and develop problem-solving skills. The newly devised Texas Essential Knowledge and Skills, based upon the national educational standards, places more emphasis on the integration of different disciplines and knowledge. It states that "In Grade 6, the study of science includes conducting field and laboratory investigations using scientific methods, analyzing data, making informed decisions, and using tools... to collect, analyze, and record information. Students also use computers and information technology tools to support scientific investigations." This is a very important objective to achieve. However, little instructional materials are currently available to meet such a challenge.

The project to be presented is primarily concerned with these important educational issues and approaches them by investigating how to use hypermedia technology and problem-based learning to enhance higher order thinking skills for six graders. This is a research and development project in that the need for conducting it is based upon the current literature and research in education and instructional technology. Research has been an integral part of the development both as formative and summative evaluations. This presentation will focus on the design and development of the project.

Theoretical Assumptions

Educational literature indicates that problem-based learning is an effective way to meet the challenge of enhancing students' higher order skills. Problem-based learning (PBL) is an instructional approach that exemplifies authentic learning and emphasizes solving problems in rich contexts. Though originally developed in medical education, it has been subsequently applied to a wide variety of professional schools including business and law. Recently, there is a growing interest among educators in using PBL in the K-12 setting. In problem-based learning, students are given a problem replete with all the complexities typically found in real world situations, and work collaboratively to develop a solution. PBL provides students an opportunity to develop skills in problem definition and problem solving, to reflect on their own learning, and to develop a deep understanding of the content domain (Cognition and Technology Group at Vanderbilt, 1992; Lajoie, 1993; Jacobson & Spiro, 1995).

Three implementations of problem-based learning are of particular interest to this project. The anchored instruction by the Cognition and Technology Group at Vanderbilt used video-based scenarios to anchor instruction in authentic problem-solving tasks (Cognition and Technology Group at Vanderbilt, 1992). Schank's goal-based scenarios use computer simulations to embed learning in problem-solving activities (Schank, Fano, Jona, & Bell, 1993). Cognitive flexibility theory by Rand Spiro emphasizes learning from multiple perspectives in ill-structured domains (Spiro & Jehng, 1990). Though approached in different ways, all three implementations deal with solving complex problems in authentic situations, and emphasize the importance of learner-centered activities.

Educational literature has demonstrated the benefits of problem-based learning to enhance students' thinking skills (Boud & Feletti, 1991; Cognition and Technology Group at Vanderbilt, 1992; Stepien, Gallagher, & Workman, 1993). However, research has also shown that the implementation of PBL in the classroom is a challenging and complex task for both teachers and students. Learning in a PBL environment is a challenge to the students because it requires their active participation in a self-directed manner. The development of a solution plan requires learners to sift through vast amount of information, distinguishing that which is pertinent from that which is not. Learners need to be able to generate and evaluate their problem-solving goals, and organize their knowledge in ways that facilitate development of a solution. Teaching in PBL is also a challenge because teachers must not only be familiar with the PBL approach and the skills needed to teach with it, but also must be able to provide necessary and often "just-in-time" support tailored to individual and small group needs. Effective implementation of PBL requires necessary scaffolding (Koschmann, Kelson, Feltovich, & Barrows, 1996). This can be an overwhelming task in K-12 classrooms, where learners may have limited self-directed learning skills and classes may be large.

The purpose of this project is to create a hypermedia-supported problem-based learning environment for sixth-graders. Through research and development, it is our intention to investigate and understand in what ways the hypermedia technology can be used to share the responsibilities of the teachers to provide necessary and "just-in-time" scaffolding to support students' learning in PBL environments.

Program Description

Designed for six graders, the hypermedia program developed, Alien Rescue, utilizes video, audio, animation, text, and graphics to create simulations in which students will encounter problems in a rich context and engage in scientific inquiries. The simulation begins with the arrival in Earth orbit of a group of six species of aliens fleeing the destruction of their own planetary system. Their ship was damaged during their voyage, and except for their engines and computer databases, little of their technology continues to function. In order to survive, they must find new homes on worlds which can support them. Having picked up Earth broadcasts, the aliens learned our languages with the intention of asking for our help to relocate to worlds in our solar system. However, when their life support failed completely, the aliens could only complete a distress message to be sent once they reached Earth orbit, then entered a state of suspended animation, where they must remain until they are safely relocated to suitable worlds. This science fiction premise takes students to a newly operational international space station where they become part of a worldwide effort to rescue alien life forms.

Students are asked to take on the role of junior scientists working with experts aboard the space station to determine the most suitable relocation site for each alien species. To solve the problem, students must engage in a variety of activities. They must learn about the aliens and identify the basic needs of each species. They must then investigate the planets and moons of our solar system, searching them for possible matches with the needs of the aliens. Students gather this information by performing searches within a database on our solar system and launching probes that they have constructed to gather the additional information not available through the existing databases. They must also engage in collaborative planning and decision-making as they determine how to use the resources of the solar system effectively.

In the course of developing a solution plan, students learn about both our solar system, and the tools and procedures scientists use to gather that information. The hypermedia program allows students to have access to all the tools and information needed to develop a solution plan, but the program is structured in such a way as to not suggest what that solution should be. Students are encouraged to explore the virtual space station as they determine for themselves the information they need and the process they will use to develop a solution plan.

Design Features

The program incorporates design features that are supported by problem-based learning and hypermedia research. These features include: (1) situating the problem in a rich context and allowing learners to engage in scientific inquiries as experts do; (2) presenting the problem with its complexity, yet providing tools to support students in working with complexity; (3) providing information in multimedia formats to allow dynamic and interactive presentations that address different learning styles and student needs; (4) providing experts' guidance from multiple perspectives to facilitate knowledge acquisition and transfer; and (5) emphasizing the interrelated nature of knowledge through hypertextual nodes and links.

Specifically, The program provides a range of cognitive tools to scaffold students' problem-solving process. The tools are provided through the main environment of the program, the international space station, and through the imaginative goggles students are wearing wherever they go in the environment. The tools are in two categories: (1) information presentation and (2) knowledge construction (see Table 1). With the tools provided in the information presentation category, students are required to locate helpful resources, search and research existing knowledge databases, select relevant information, and make effective decisions. With the tools available in the knowledge construction category, students are to collect new data, interpret and organize data, build the rationale for their decisions and present their solution plan. Expert modeling and coaching for problem generation and problem solving is provided by expert demonstrating how to use the tools and stories illustrating how similar problems were solved by scientists. The scripts for such video clips were developed by examining how students used an earlier version of the program without modeling, noting their sources of difficulty, then providing modeling to support them.

Tool Category	Tool Name	Tool Function
Information Presentation	Conference Room	Students receive video messages from Earth in the conference room. These messages provide details about the problem situation and help to direct student activity. These messages help to maintain the impression that students are part of a scientific community, where coordinated efforts and frequent communication are essential components of problem solving.
	Alien Computer	Because the alien ship is damaged, scientists decide to move the alien computer to the space station. It contains information about the aliens: their physiology, technology, homeworlds, and history. However, early in the program students learn that the aliens had insufficient time to complete the translation of their computer database, so only a limited amount of information is available. Students must sift through the information to identify the needs of each alien species.
	Charts	A variety of charts are provided which are designed to scaffold students' efforts to organize their data and make decisions.
	Solar System Database	This contains information about our sun, the nine planets, and ten of the moons in our solar system. Information useful to solving the problem is provided, but the database is structured in such a way as not to suggest which pieces of information are relevant to the problem or what the best solution to the problem might be. The database includes pictures that students can bookmark for later retrieval.

	Messages	Periodically through the program, students receive video email. These messages are recorded in text form in the message tool for students to review as they deem necessary.
	Mission Database	Students can review information on five landmark probe missions to see how scientists designed probes to collect specific types of data in the past.
Knowledge Construction	Probe Builder	The Probe Builder contains lists and descriptions of real scientific equipment used in both past and future probe missions to investigate other worlds in our solar system. Students construct probes by making choices within four categories: probe type, communication, power source, and instruments. Budgetary constraints force students to consider their choices carefully and make compromises.
	Launch Room	Students review the probes they have built in the Probe Builder, and decide which ones to actually send in the Launch Room. Only probes that are launched show up in the Control Room, where data from them is displayed.
	Control Room	Raw data collected by the probes are displayed in the Control Room. Students must interpret this data in order to turn it into information that they can use to develop their solution. As in all probe missions, malfunctions are possible, and poor planning can result in mission failure.
	Notebook	Students use their notebook to collect and organize information useful in solving the problem. Students can create numerous sections within their notebook to help them organize their notes. The notebook was deliberately designed not to allow students to cut and paste information contained in the rest of the program, meaning that students must type their own notes based on what they think is important enough to record. A second function of the notebook is the bookmarks feature. Students can drag pictures and video from any part of the program to their notebook. These media elements are bookmarked for later review and possible use in presentations.
	Presentation Tool	A typical assignment for students to be given within *Alien Rescue* is to create a presentation on a decision they made and their rationale for that decision. The presentation tool permits students to create a series of slides using media they have bookmarked and notes from their notebook. Students choose from a number of slide templates, meaning that slides are fast and easy to make.

Table 1. Hypermedia-Supported Cognitive tools

Development

The development of the project follows a model based upon practice in the multimedia industry and current literature in instructional technology. This four-phase model has the following phases: (1) planning, (2) designing, (3) production and (4) evaluation (Liu, Jones, & Hemstreet, 1998). Testing and revision is an on-going process both from the teachers and the students. So far the production of this project has drawn expertise from various fields which include instructional design, hypermedia research, astronomy, graphic design, multimedia programming, video and audio, and writing. It is a collaborative effort by the Instructional Technology Program, the Institute for Technology and Learning, the Astronomy Department, and the McDonald Observatory at University of Texas - Austin.

Research Agenda

Both formative and summative evaluations are integral parts of the project. Two phases of formative evaluations have been conducted, one with a small group of sixth-graders for an informal evaluation, and one with a larger group for a formal evaluation. The purpose of these evaluations was to understand how the target audience reacted to the program and what improvements needed to be made. Based upon these evaluations, revisions have been made. The improvement of the program is an on-going process, however. In addition to program improvement, research is currently underway. Present and future research studies will investigate the research issues:

- the effect of the hypermedia-supported cognitive tools on students' achievement and their problem-solving skills,
- the relationship between the use of hypermedia-supported cognitive tools and students' achievement
- the possible differential effects of the project on students with different abilities,
- the effect of using expert stories on students' achievement,
- the change of students' epistemological beliefs as a result of using the program.

In this presentation, we will share the design and development of the project, demonstrate the program and outline the research agenda.

Abstract: The Interactive Nano-Visualization in Science and Engineering Education (IN-VSEE) project provides the first real-time interface for remote operation of Scanning Probe Microscopy (SPM) over the World Wide Web for educational and training purposes. In addition to providing "live remote control" of Nobel prize-winning microscopy techniques for doing discovery based learning of our material nanoworld, novel and highly interactive learning modules are being developed for diverse material systems which demonstrate the interdisciplinary nature of nanotechnology. IN-VSEE brings the excitement of research using cutting-edge technology to upper-level high school and first-year college students and teachers.

Introduction

Advances in science and technology have led to the design and manufacture of materials and devices of increasingly smaller dimensions. Engineering techniques have already surpassed the limits of resolution afforded by the naked eye. Since the 1960's device sizes have rapidly decreased from millimeter (10^{-3}) to micrometer (10^{-6}) and now approaching the nanometer (10^{-9}) scales. They may possibly decrease to atomic scale, measured in the angstrom (10^{-10})! Working at the nanometer scale has become a reality as scientists and engineers strive to exploit miniaturization techniques and technologies for the future. These nanotechnologies are envisioned to become the manufacturing reality in the next millenium. In an effort to introduce the fascinating nanoworld, Arizona State University has become a leader in the use of Scanning Probe Microscopes in research and education. The Interactive Nano-Visualization in Science and Engineering Education (IN-VSEE) project, led by ASU is a consortium of university, community college, and high school teachers, as well as industrial scientists and science museum educators. The IN-VSEE team has developed the first interface for remote operation of Scanning Probe Microscopy (SPM) over the World Wide Web (WWW) to promote education and training to prepare students for careers in the emerging nanotechnologies. The primary goals of IN-VSEE are to:

- convey the excitement of nanoscience and nanotechnology, promote student-initiated learning and increase interest in science and engineering careers
- teach fundamental concepts in science and engineering using visualization techniques to help students learn and integrate difficult concepts more effectively
- provide students with the capability to routinely explore materials in three dimensions with resolutions at the nanoscale and even down to the atomic scale
- demonstrate the feasibility of using the WWW for remote operation of sophisticated research-grade laboratory instrumentation that can be used directly in the classroom.

The IN-VSEE project is working to accomplish these goals by:

- creating a user-friendly interface for 'SPM Live!' remote SPM experimentation
- developing cross-discipline interactive instructional modules which provide key material science and engineering concepts
- providing an 'invitation' to explore the nanoworld via 'SPM Live!'
- highlighting the interdisciplinary nature of nanotechnology
- working with teachers to provide an introduction to the technology, as well as the use of this technology in teaching
- obtaining and cataloging exciting images of materials using the Nobel prize-winning SPM coupled with other advanced surface characterization instruments.

To date, IN-VSEE has succeeded in developing a WWW user friendly interface for remote control of a scanning probe microscope which is located on the Arizona State University Main campus. Additionally, 17 instructional modules are in the review phase of development. Three teacher workshops have been held and a two-day workshop is scheduled for August 1999. Accompanying the modules is a comprehensive image bank, accessible through the IN-VSEE Web site, of micrographs and nanographs created using various microscopies.

Remote SPM

The computer science task force of IN-VSEE has succeeded in creating a WWW interface to remotely control the scanning probe microscope from any on-line classroom in the world. Figure 1 shows the Remote operator interface page for SPM Live! From this page the remote operator can control the instrument, while others can

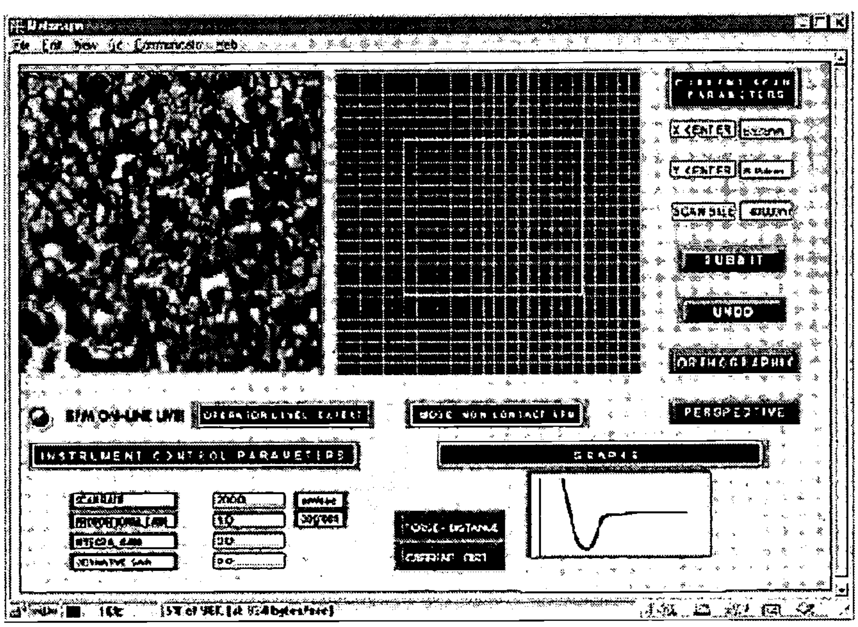

Figure 1: SPM Live! WWW Interface

participate in the same experiment using the observers' page. A chat-dialog box allows synchronous interaction between the operator, observers and IN-VSEE staff at the microscope site. Thus, students and scientists can discuss the image being viewed. Another window on the web page provides real-time video of the instrument and the IN-VSEE laboratory in order to personalize the viewing experience. The controller interface allows many of the same capabilities as the actual instrument, including zoom and rotation.

Instructional Modules

One specific aim of the educational modules is to provide a bridge between the 'virtual classroom' and laboratory. The modules provide a roadmap for students on how to design and conduct experiments, with the end goal of stimulating interest in remote operation of the SPM. The instructional modules center around a common theme of understanding and manipulation of natural and man-made materials. The module topics selected utilize interactive, discovery-based learning activities to introduce or reinforce applied material concepts within various disciplines and among various material classes over a wide range in scale. The interactive IN-VSEE modules provide:

- reinforcement and integration of key concepts and fundamental principles that are taught in high school and lower division college science, math and engineering curricula
- prospective users on the methodologies of experimental design and encouragement to formulate original experiments for remote SPM instrumentation on the web, through SPM Live!
- students with a flavor of research
- teachers with topics designed to meet national science education standards.

Figure 2: Connections made within each module. A material's atomic structure, properties, processing and performance are all related at the nano-level, as well as the macro-level.

The IN-VSEE instructional module task force has developed a module template to facilitate module development and provide consistency between modules. The module structure uses a discovery environment to provide background and relevance to the use of the SPM Live! remote instrument. Figure 2 represents the unifying concept reinforced in each module: that structure, properties, processing and performance of materials are intimately linked at all levels of scale. The standardized user interface and layout includes an attention grabber, and a navigation panel with a menu of topics and links. These topics and links include:

- real world applications
- FAQ's and trivia questions
- core material of text in images
- key concepts
- SPM relevant to the module, SPM Live!

The uniform structure of the modules facilitates ease-of-use between modules. The generic module template will also assist in development of future modules. Figure 3 shows a sample module interface.

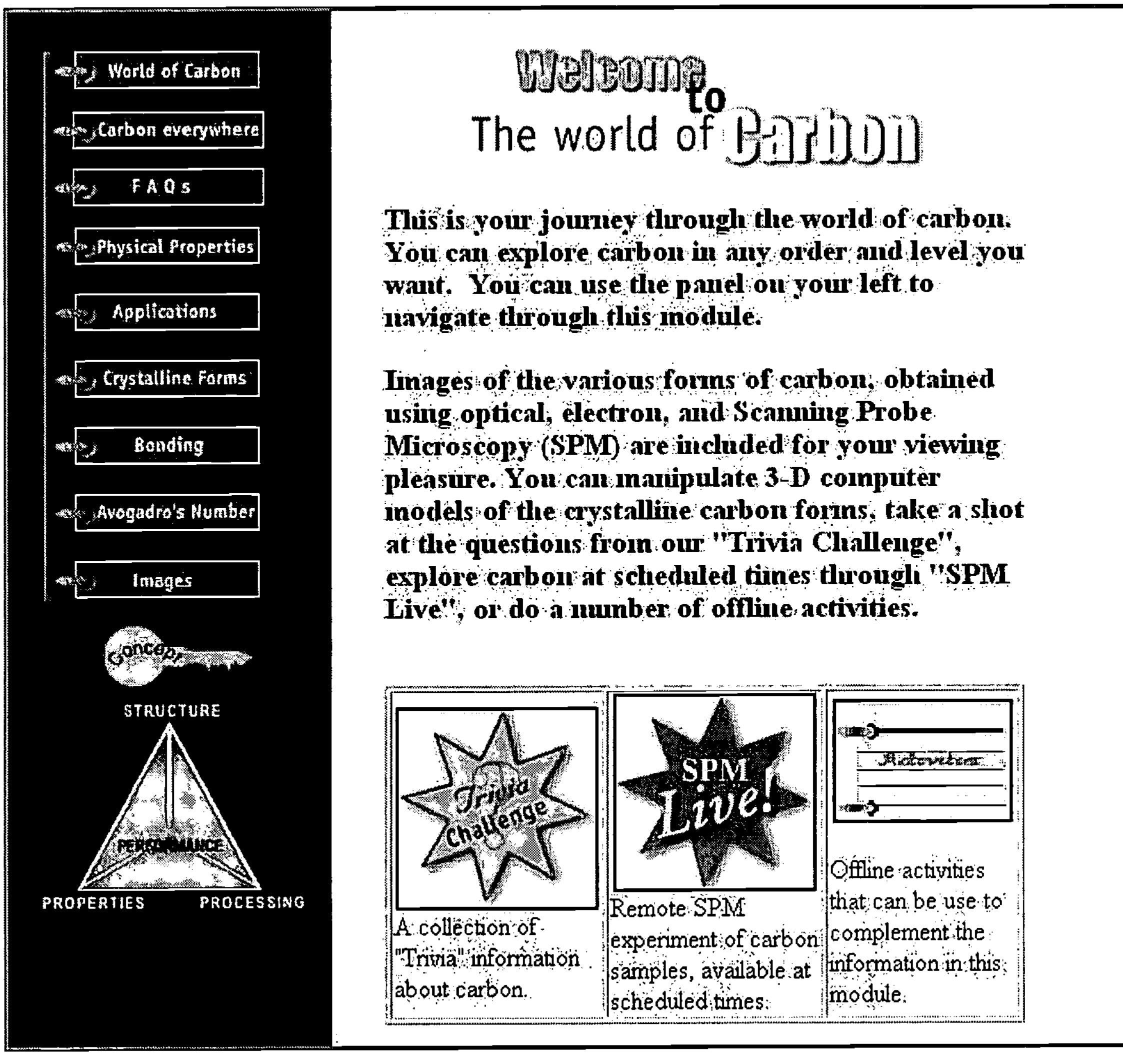

Figure 3: Instructional module interface. All modules use a standardized navigation system for consistency between the 17 modules.

Table 1 lists the titles of the 17 modules currently under development. The IN-VSEE team is beta testing modules in remote classroom demonstrations at Chandler-Gilbert Community College, Scottsdale Community College and Glendale Community College. Additionally, teachers will evaluate modules at the August workshop.

9. The World of Liquid Crystals	

Table 1: Modules currently under development

Teachers' Workshops

The purpose of the teachers' workshops is twofold. First, teacher-training is provided to help teachers develop confidence in using this state-of-the-art technology. Second, discussions and brainstorming sessions with the IN-VSEE team are designed to assist teachers in exploring ways they can best use this technology to enhance their educational objectives. The first teachers' workshop in October 1997, focused on the use of image processing in the classroom. Image processing provides a dynamic, hands-on way to incorporate microscopy images in the classroom. (Greenberg et al. 1993) It also provides links to real world applications of microscopy. In this workshop teachers also provided feedback about the "Allotropes of Carbon" module. The second teachers' workshop in July 1998, focused on ways to overcome barriers to using remote SPM, instructional modules, and microscopy images in the classroom. The upcoming two-day teachers' workshop, scheduled for August 1999, will focus on hands-on activities and beta-testing of instructional modules, especially the "Making Sense of Size And Scale" and the "Theory and Virtual Operation of SPM" modules which are considered the keystone modules for providing background to students in understanding the nanoscale.

Image Bank

Also available on the IN-VSEE Web site is a database of more than 400 SPM and other related microscopy images. These are images collected by the IN-VSEE team during classroom demonstrations and experimentation, as well as images provided by other scientists at Arizona State University. The images come from a wide variety of microscopy techniques including Scanning Electron Microscopy, Scanning Tunneling Microscopy, Atomic Force Microscopy, Magnetic Force Microscopy, along with more traditional Optical Microscopy, and macroscopic photographs. Learning activities utilizing the images beyond the instructional modules are also being generated.

Conclusions

IN-VSEE has pioneered the effort creating a user friendly interface for remote operation of research-grade laboratory instruments i.e., the Scanning Probe Microscope for educational purposes. To provide a firm foundation for students and teachers about SPM experimentation, 17 instructional modules are being developed. These modules are currently being beta-tested. Additionally, a 'virtual' SPM is being developed for the web site to provide students practice using SPM equipment prior to doing their own experiments with SPM Live! Teacher workshops in the past and future, focus on providing teachers with training to use the technology to enhance instruction in their classroom. A database of images is available for downloading to use off line or for activities on-line. This project makes available state-of-the-art, Nobel prize-winning research tools available to students anywhere via the Internet. These powerful tools intrigue students in the process of scientific investigation and the exciting field of nanotechnology. IN-VSEE also provides resources which can expand cross-discipline curricula of any school on-line!

Abstract: This paper presents Colt, a system for the development of applications that support close collaboration between two or more users. The Colt system has three parts: a design methodology, a software toolkit, and additional tools for visualization and analysis. The software toolkit includes computational objects that support simultaneous manipulations from multiple users. We define and illustrate "Cooperatively Controlled Objects" (CCOs) and we discuss their design and development. Finally, a color matching activity is presented as an example of a collaborative activity that was built using Colt and CCOs.

Introduction

Developing applications to support synchronous collaboration by two or more users involves special challenges. An application designer needs to anticipate the interaction between the user and the computer as well as the interactions between the users. The designer also needs system support for development of software that accepts simultaneous input from multiple users on the same machine. The Colt system is designed to address both of these needs.

Colt is comprised of three parts, a design methodology, a software toolkit, and visualization and analysis tools. The design methodology is based on a series of questions to aid developers in the creative process of planning a collaborative activity. The toolkit supports the implementation of collaborative programs by providing a shell application, a hierarchy of "cooperatively controlled objects" (CCOs), and support for input from multiple users. CCOs are designed to support close collaboration among the users of a computer program. Each CCO contains a mechanism to record a history of how users cooperatively controlled the objects. The visualization and analysis tools present different views of the object histories. These tools can be employed after program testing to determine if the implementation meets the original design criteria. Colt is unique in its support for the development of co-present simultaneous computer based activities. Our motivation for developing Colt is described in detail in (Bricker98). Rather than cover all three parts of the Colt system, this paper describes only the software toolkit component.

The Cooperatively Controlled Object

Many common non-computer activities contain elements of highly synchronized cooperation. Some activities are done collaboratively purely for the social enjoyment. Some are done because they are easier to complete with additional help. Unfortunately, most desktop computers today are designed to accommodate input from one user at a time. Groups who wish to collaborate using one computer are forced to share control awkwardly through a single mouse and keyboard. Social and physical conflicts over these input devices may arise since current operating systems and application software only support a single input stream. One solution to the conflict problem is to provide a separate physical device for each user. Many video game systems, such as the Super Nintendo Entertainment System (SNES), do support multiple joysticks. However, the multi-user games for these systems often employ either a turn-taking mechanism, or simultaneous competitive play. The

risk in enforcing turn-taking is that inactive users will lose focus on the task. The risk in supporting simultaneous competitive play is that it does not appeal to many people, particularly young girls. Colt was developed to support simultaneous collaborative interactions in order to address these issues. One of the goals of this research is to define a class of interesting objects that helps to keep the users focused during collaborative activities.

Cooperatively Controlled Objects Defined

In object-oriented terminology, an object contains state and has behavior. A *controlled object* is an object containing methods that allow one or more users to manipulate properties of that object. Typically these properties are manipulated directly through input devices such as mice, joysticks, keyboards, etc. A *cooperatively controlled object* (CCO) is a controlled object that is designed to be manipulated simultaneously by more than one user based on certain relationships that hold between user inputs and components of the CCO.

Each CCO is assumed to have a set of components or "properties." Each property may take on one of a possibly infinite number of values. In the physical world some properties, like the location of a spot on the floor, may have an infinite number of possible values. We will assume that the computer representation is simplified with a finite set of discrete values.

A control mechanism for a CCO provides a means for a group of users to provide a value for one or for several (or even all) of the properties of the CCO. The control mechanism for a property in a CCO can be described as a function:

$$V = f((v_1, v_2, \ldots, v_n), (u_1, u_2, \ldots, u_m)),$$

where V is the output, or new value of the property, each v_i is the input value of the properties on which this function depends, and each u_j is the input-device state corresponding to the multiple users simultaneously manipulating the object. By providing functions for each of the CCO's modifiable properties, a complete control mechanism for the CCO can be specified.

Fine-grained sharing (FGS) is a previously studied approach for defining one class of CCO (Shen92). In FGS, an object is expressed in terms of its properties, each of which is controlled by one of the users. Although fine-grained sharing can offer users a clear delineation of responsibility and control for shared objects, it lacks the ability to compel tight cooperation among the users. Users who work on separate pieces of a "shared" document do not necessarily coordinate in real time. Instead the work is done asynchronously and are the users not forced to synchronize their activities to the same degree that one does in musical performance, dance, three-legged races, and the like. Our goal is to compel users to interact synchronously. CCOs support close collaboration though complex interactions with objects by adopting a more general framework than fine-grained sharing.

Specifying the types of interactions

Developers need to specify how closely the users in a collaborative activity should work together. In order to assist in the specification of the users' interactions, we have developed a sub-classification of synchronous activity based on how simultaneously the users interact with a screen object. An *asynchronous cooperative interaction* is one in which two or more users work independently on a task, then synchronize or coordinate their work by delivering information through messages such as conversation, snail mail or email. Participants of this type of cooperative interaction may not expect an immediate response from questions or requests. A *required asynchronous cooperative interaction* is one in which each user must complete their part of the activity before the other user may proceed. An example of this type of interaction in the real world is two people trying to go through a doorway that can only fit one person at a time.

A *synchronous cooperative interaction*, on the other hand, is one in which two or more users interact on the same task in real-time. Phone calls and text chat are examples of synchronous cooperative interactions. Often, the users in a text chat session take turns in writing (the reader will wait for the writer to complete a thought before responding), but they may also type at the same time. In this case a chat writer is not guaranteed that the other user(s) are focused on the current thread of conversation, but they are working *simultaneously*. A *required* simultaneous interaction is one in which the users must manipulate an object at the same time in order to make any progress on the activity. An example of this is two people attempting to lift a heavy piece of furniture, such as a piano. An *encouraged* simultaneous interaction is one in which the users do not have to manipulate objects at the same time, but doing so will allow them to complete the task more easily or in a shorter amount of time. Furthermore, their progress may be hampered (slower) if the interactions are not simultaneous. Moving a heavy object where no lifting is required is an example of this type of interaction.

User Interface Issues for CCOs

A number of interface issues must be taken into consideration when writing software to support two or more people working in a synchronous collaborative situation. If users are to manipulate a single object simultaneously, each user must have access to her or his own device to input their modifications. It is possible, if the users are co-located and using a single display, to use an off-the-shelf computer system with one mouse and one keyboard. However, this typically causes frustration because of either an unintuitive interface or a contention for the mouse or keyboard. Obvious solutions include having the users interact over a network, or to support multiple input devices on a single machine, similar to MultiIn (Bricker98).

Apart from the hardware, the software should indicate objects each user may access. Also, some indication should be given to all users as to which user currently has possession or is controlling each object in the shared space. Color usually affords a reasonable sign of object ownership, particularly if the color matches that of the owner's cursor.

The Colt Software Toolkit

There are many toolkits designed to support computer-based collaboration. These toolkits facilitate the development of cooperative software by providing abstractions for more difficult concepts in programming groupware applications, such as how to maintain synchronization of the objects or views of objects, and users dynamically joining and leaving sessions. Most of the existing toolkits, such as Rendevous (Hill93), GroupKit (Gutwin95), and Habanero (NCSA98) support synchronous cooperation over a network. There are also a number of collaborative systems that encourage communication at a distance through common objects (Gutwin95), tasks (Hill93) or physical situations (Bier91). Groupkit, in particular, uses indicators such as telepointers and other "awareness widgets" to indicate to others (working at distant locations) where a user is working on the screen. These systems permit cooperation, but the activities in which they are used do not require the users to work on a task simultaneously or to communicate frequently. Furthermore, none of these systems support co-present interactions..

Colt was designed to facilitate the rapid prototyping of applications in which users need to work simultaneously and interact frequently. Colt's toolkit includes the Collaborative Object-based Application Program Interface (CO-API) hierarchy of Cooperatively Controlled Objects and the ColImage application shell with support for various multiple-user input solutions. The overall architecture for the Colt system is show in Figure 1.

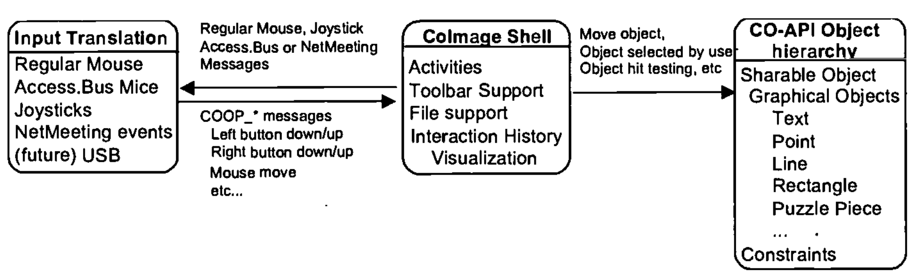

Figure 1. The Colt toolkit system architecture.

As input is delivered to the ColImage shell window, it is diverted to the Input Translation subsystem (ITS). This subsystem translates the input-device dependent event messages into input-device-independent Colt event messages. Colt messages include information about position, button state, and the user associated with the message. The activities implemented in the ColImage shell respond to the device-independent messages. The movement and location of each device is mapped to a separate color-coded cursor on the screen.

Based on the location and the owner of a cursor, the activity software can determine which objects to manipulate and if that user may manipulate that object, respectively. In particular, if a user attempts to manipulate an object he does not own the object will not allow that user to control the object, and the attempt to control the object is ignored. The CCOs in the CO-API do not respond directly to the input events, they only respond to changes to object properties.

The CO-API

The CO-API is comprised of a number parts: a hierarchy of cooperatively controlled objects (including object necessary for specifying access and recording a history of events) event, a constraint system, and tools for viewing and transforming bitmapped images.

Cooperatively controlled objects are implemented in our software environment as reusable C++ classes, and they thereby can inherit state and behavior. CCOs derive the ability for sharing from access control lists similar to (Shen92). Other properties of a CCO include location, size, orientation, coordinate system, display parameters, and color. An object will ignore attempts to change a property by users who do not have the proper privileges (as dictated by access control lists). In order to track when the users cooperatively control objects, each object in the CO-API can also store information regarding the users' changes to an object, or *actions*, in what we call a *history of actions*. The information stored for each action will vary depending on how the object is manipulated, but typically includes the changed property and the new value, which user effected the change, when the change occurred and how long it took. The history of actions may be saved and analyzed after the activity is completed. This information may be restored at a later time for evaluation purposes. The interface for an activity can be designed to include visualizations that aid the analysis of measured quantities such as the number of interactions on an object, the total time of each interaction, how the interactions overlapped, or the order in which the users interacted.

In addition to the object hierarchy, the Colt system includes a *Constraint Manager* that keeps a list of constraints currently used in the Colt system. Each constraint contains a list of input objects, or objects that may affect other objects in the system, and a list of output objects, or objects which are affected by changes to other objects. At this time, only one-way functional constraints are handled.

The CoImage Shell

We support development of collaborative activities using CCOs by providing an application shell that handles the operations, such as handling input from toolbars, and saving and restoring files, which are shared by all activities built in the environment.

As in (Bricker95), the activities supported by Colt allow each user to own an input device and corresponding colored cursor on the screen. The color of the cursor identifies its user. Objects are displayed in a user's color if only they are permitted to manipulate that object. For example, a tool on the toolbar is outlined with the user's color if they are permitted to use that tool. If two users may select a tool, it is outlined with both of the users' colors. The design and implementation of an activity defines how the tools in the toolbar are used. Some tools simply set the value of a property for an object, while others may change a mode for the whole activity. Depending on the design of the activity, a user's cursor may change shape to indicate that a user just selected an instance of a particular tool.

The CoImage shell also supports saving and restoring data in a number of formats. The shell includes methods that save the state of an activity as a binary data file so that a user can continue at a later date. The shell also includes separate methods for saving a history file in a tab delimited text format. This format permits an experimenter to visually read the data or analyze it using another program such as a spreadsheet. A copy of the data is also written in a binary CoImage data file format whenever the text version is written to disk. The CoImage shell can also save image data in the standard Microsoft Windows bitmap format, and in a format that can be read by a World Wide Web (WWW) browser.

The CoImage shell also includes methods that read and write a text-based problem description file. A problem description includes an initial state, goal states or criterion the users are expected to reach, any constraints enforced on the users in reaching that goal, and a possible scoring criteria. The current implementation of the shell contains methods that can be overridden by an activity developer to read and write problem description files. Most activities implemented with Colt to date support a problem file that contains the number of users, the initial state of the program, a text description of the goal state(s) that can be presented to the user, and the scoring criterion.

The Input Translation Subsystem

The input translation subsystem (ITS) was developed to abstract away the details of any specific input device. Device dependent input events delivered to the ColImage shell are diverted to the ITS, where they are translated into input-device independent messages. These Colt messages include information about the mouse position, the state of the mouse buttons, and the user associated with the message. Thus, the application developer only needs to respond to the one set of messages.

The system requirements for the toolkit are Pentium based PC platforms running Microsoft Windows 3.1 or Windows 95. For the co-present, single display situation, we currently support the Access.Bus multiple input system from Computer Access Technology Corporation for Windows 3.1 and Microsoft Sidewinder™ Game Pads for Windows 95. The ColImage Shell supports distance collaboration with Microsoft NetMeeting™ conferencing technology. NetMeeting supports audio, video, file and data transfer, as well as a rudimentary sharing (turn-taking) mechanism for single-user applications that are not designed to be manipulated simultaneously.

Activities that employ cooperative control

We have developed a number of activities that employ CCOs using the Colt system that include a Collaborative "Drawing" Activity, based on the Etch-a-Sketch toy developed by Ohio Arts, a collaborative puzzle activity, a coordination game based on a game where two people each use a chopstick to pick up a "bean," and a color matching activity. These first three of these activities are described in detail in (Baker97 and Bricker98).

The Color Matcher activity, as described in (Bricker95), was originally implemented in Microsoft's Visual Basic with the MultiIn system to support the Access.Bus multiple input devices. MultiIn can only be used under Windows 3.1, and we wished to conduct a user study on a version of this activity under Windows 95 (for more information on the user study, see (Bricker98)). The original version of the Color Matcher activity took an undergraduate student approximately ten weeks to implement. The re-implementation of the activity using Colt took the author only a few days. This version included an interface that mirrored the original version as well as a new CCO method for selecting the users' color, shown in Figure 2. In this activity, the users' color is set according to the color of a selected pixel in a bitmapped image (e.g., a palette). The pixel location is set by the location of the centroid of a triangle. Each user controls the vertex of the triangle that is colored to correspond to the color of their cursor. Although it would be impractical to have a bitmapped image of a full 24 bit color palette, the Windows 256 color palette affords a reasonable approximation for the purposes of the activity. The users' color in the Colt/CCO version of the activity is scored in the same way as the original application – based on the distance from the target color in RGB color space.

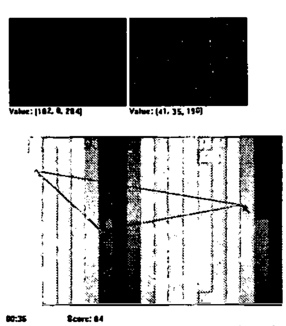

Figure 2. The Color Matcher activity user interface.

Conclusions and Future Work

We have presented the toolkit part of the Colt System, as well as a collaborative activity that was built using it. The software toolkit includes Cooperatively Controlled Objects, which generalize fine-grained shared objects in being manipulated by more complicated, higher degree-of-freedom methods. .

The Colt system was tested in the development of the drawing, jigsaw, and chopstick activities. Further testing needs to be done with developers to improve the system. There are many enhancements we'd like to add to the software toolkit, including adding support for other types of multiple input devices, such as via the Universal Serial Bus, and support for multi-way constraints. The CCOs designed to date can also be ported to other platforms, such as Java, support distance collaboration in WWW based activities. We also wish to continue to expand the CCOs in CO-API to support other types of collaborative interactions and activities. Colt could be used to implement collaborative versions of popular games such as: Tetris™, where one person controls side-to-side motion while the other controls rotation. Additionally, CCOs could be used in 3D virtual worlds, or first-person perspective games such as Doom™. An example of a CCO in such a game is a cooperatively controlled latch on a door where users may be required, encouraged, discouraged or forbidden from manipulating the latch at the same time.

Knowledge Organizations Resulting from Pairs' Problem-Solving Versus Information Gathering Activities

Jeanne Weidner*

University of California at Berkeley, 94720, USA

Abstract: We examined the externalized knowledge structures elicited from subjects who used the multimedia program *BrainStorm: An Interactive Neuroanatomy Atlas* under two contexts. In the problem-solving context, student pairs were asked to solve a clinical case resulting from cranial nerve injury. In the second, information-gathering context, student pairs were given traditional questions to answer about these cranial nerves. We assessed student knowledge using individual pre- and post-tests, and concept-based Pathfinder Networks (PFNETS), and surveyed students' opinions of the contexts. Although the survey seemed to indicate a preference for the problem-based context, the preference was not universal, and only marginally significant. The information gathering context yielded higher gain scores, and generated PFNETS more similar to the instructors' relative to the results from the problem-solving context. In addition, students who were in pairs with at least one graduate student were more likely to yield higher post-test scores and PFNETS that resembled the instructors' networks.

The Role of Technology for Problem-Based Learning

Computer technology may prove to be an important ally in support of PBL, and may help to alleviate several of the shortcomings associated with it. By providing an authoritative source that is readily available (theoretically) at any time, it allows an instructor to provide more one-on-one attention to those students who require it, thus potentially lowering the cost of the time-intensive aspects of PBL. It may also be used to alleviate the occasional problems regarding structured feedback that are sometimes associated with PBL; this readily available source of information might reduce the frustration that some students feel when trying to solve problems in a PBL environment. In addition, computer programs, to varying degrees, can be used independently or collaboratively, both in and out of classrooms. Both Linn (1992) and Okada and Simon (1997) recommend the use of student pairs as an effective alternative to group learning that incorporates the advantages of group learning, while minimizing its disadvantages. The latter reported that pairs of subjects were more successful than individuals while interacting with a computer simulated genetics laboratory during a discovery activity. White and Frederiksen (1998) report that collaborating with a higher-achieving partner while engaging in reflective activities may significantly improve the performance of lower achieving students. Just this type of effective combination can occur in heterogenous pairs of students engaged in problem based learning.

Very few, if any, studies have investigated how multimedia use in a problem-based format may differ from its use in the service of more traditional school tasks--such as information gathering--with regard to measures of problem solving ability, domain knowledge, and knowledge organization, etc. The paucity of research in this area, in part, motivated the present study.

The Utility of Pathfinder Associative Networks

One of the characteristics of PBL that accounts for the advantages attributed to it may be the way resultant knowledge is organized (Norman & Schmidt, 1992). This conjecture has support from Durso, Rea, and Dayton (1994), who used Pathfinder Associative Networks ("PFNETS"; Schvaneveldt, 1990) to measure the knowledge organizations of subjects solving an insight problem, relative to those who were given the information as a story (rather than as a problem to solve). Pathfinder networks reflect general conceptual proximities that are empirically derived from subjects' ratings of the relatedness of pairs of terms. Each network representation (PFNET) yields a "concept map" of a subject's knowledge organization (e.g., Figure 1). Durso, et al. (1994) report that people who solved an insight problem had a significantly different knowledge organization, as measured by PFNETS, than did those who (a) did not solve it or (b) were presented with the information in a non-problem format.

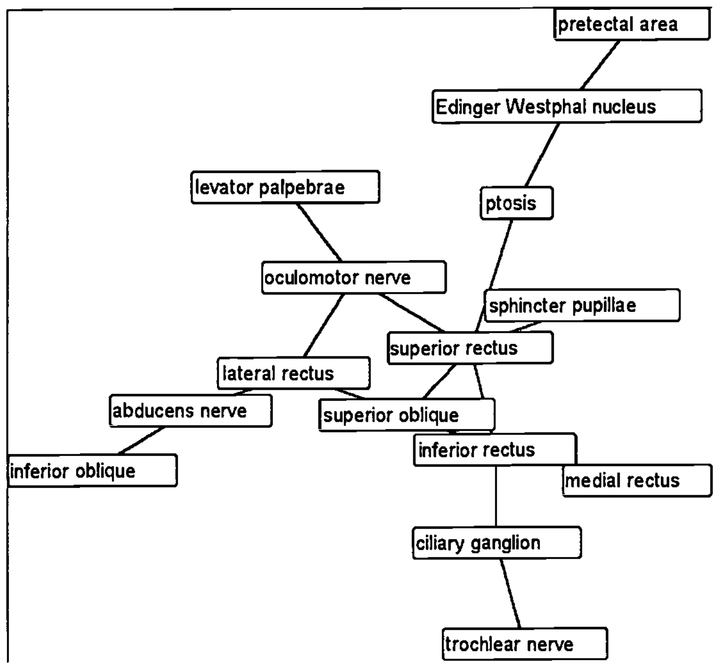

Figure 1. A student's PFNET for Exercise 1.

Additionally, Goldsmith and Johnson (1990) used PFNETS to assess the knowledge structures of students over the course of learning in a conventional statistics classroom–and to compare the students' structures with those of the instructors, over time. They found that the knowledge representations as generated by Pathfinder offered a useful assessment of classroom learning and that the correlation between a student's structure and an instructor's was a good index of how much the student learned about the domain of study.

Results

Pre- and Post-Tests

Paired sample t-tests revealed significant score differences between the set of corresponding pre-test and post-test items for all combinations of exercises and context (*p's* $< .005$, see Table 1). The difference in the means on the (full) post-tests between the two exercises indicates Exercise 2 was more difficult, in terms of proportion correct (Exercise 1 = .74; Exercise 2 =.54; $p< .001$), but the context in which students learned the material had no effect on these post-test scores (PS=.62; IG = .66). However, the information gathering context yielded higher gain scores than the problem solving context when both exercises are combined (PS gain = .15; IG gain = .23; $p=.06$; marginally significant). Additionally, analyses of the post-test item scores by type of question (recall, analysis, or integration) or topic (anatomy, function, or symptoms) revealed no significant context-based differences in score.

Exercise	Context	Pre-Test Mean	Post-Test Items Mean	Mean Difference Gain	SD	Paired T-test	*p* value
1	PS	0.68	0.83	0.15	0.13	3.854	.003
	IG	0.67	0.89	0.22	0.12	6.000	.000
2	PS	0.41	0.57	0.16	0.16	4.528	.001
	IG	0.42	0.67	0.25	0.25	4.672	.001
Overall		0.55	0.74	0.19	0.14	9.048	.000

Table 2. Correlations of Student and Instructor PFNETS by Problem Solving and Information Gathering Contexts

Pathfinder Networks

Student pathfinder networks (PFNETS) were compared to instructors' PFNETS on both individual-instructor and a combined-instructor (averaged) bases. A significant difference among the correlations and instructional contexts was found for Exercise 1 regarding the major instructor for the course (Instructor 3 in Table 2). In this case, students who learned the material in the information gathering context produced PFNETS that yielded higher correlations with that instructor's PFNET than those learning in the problem solving context (.50 vs. .36; $p<.005$). Two additional experts (Instructors 2 and 4 in Table 2) yielded a marginally significant result for Exercise 1 ($p=.094$ *and* $.055$). More generally, a Wilcoxon Signed Ranks Test showed that overall, the information gathering PFNETS correlated more highly with instructor PFNETS than did the problem-solving PFNETS (Z= -2.395; $p=.017$). Comparisons among the instructors' PFNETS revealed significant correlations for every comparison (*r's* ranging from .40 to .93; $p<0.01$). In addition, we observed a significant meta-correlation between students' post-test scores and their PFNET correlations with the instructors. For both exercises, students who scored higher on the post-test had generally significantly higher PFNET correlations with the instructors' PFNETS (*meta-r's* ranged from .33 to .85; see Table 3).

Exercise	Instructor	1	2	3	4	5	Combined
1	Post-Test	.77*	.59*	.83*	.68*	.85*	.83*
2	Post-Test	.61*	.33	.50*	.54*	.58*	.55*

Table 3. Pearson (Meta-)Correlations of Post-test Performance with Student/Instructor PFNETS Correlations (*significant at the .001 level; 1-tailed).

Pair Composition

Across both exercises, pair composition had significant effects on student performance, both on the post-test score proportions and on student/instructor PFNET correlations (see Table 4). Although there were no differences in the pre-test scores of undergraduates based on pair membership, those who were paired with graduate students performed better on the outcome measures (i.e., both gain-scores and PFNET correlations) than their counterparts who were paired with fellow undergraduates (see Table 5). In fact, graduate students in mixed pairs also benefitted more from the mixing when comparing their PFNET correlations with the instructors' relative to those in graduate-graduate pairs (r=.60 vs .50; $p < .05$).

Exercise	Measure	Undergrads	Grads	Mixed	F	Significance
1	Post-Test Score	.64	.76	.79	4.850	.020
	PFNETS Correlation	.32	.54	.60	13.634	.000
2	Post-Test Score	.44	.59	.58	3.988	.036
	PFNET Correlation	.34	.49	.45	5.737	.011
Overall	Post-Test Score	.54	.68	.69	4.526	.017
	PFNET Correlation	.32	.49	.57	18.002	.000

Table 4. Differences in Pair Performances based on Composition. "Score" indicates mean proportion of correct answers, and "Correlation" indicates comparison with experts' combined PFNETS.

	Measure	Homogenous Pairs	Mixed Pairs	F	Significance
Undergrads	Pre-Test Score	.48	.49	.002	.969
	Gain-Score	.14	.30	4.742	.045
	PFNET Correlation	.33	.53	16.402	.001
Graduates	Pre-Test Score	.59	.59	.003	.956
	Gain-Score	.19	.20	.044	.836
	PFNET Correlation	.50	.60	4.437	.046

Table 5. Graduate and Undergraduate Performance Based on Pair Membership. "Score" indicates mean proportion of correct answers, and "Correlation" indicates comparison with experts' combined PFNETS.

Survey/Questionnaire

On the questionnaire that elicited student opinions about the relative merits of each of the tasks, students agreed that both methods (1) helped in comprehending and remembering the material, (2) allowed for success in accomplishing the task, and (3) should be incorporated as regular course activities. Fourteen of the 26 items yielded statistically significant findings. Students were more likely to agree that problem-solving, rather than information gathering, a) contributed to the integration of the material, b) promoted reflection, c) provided insight into applications, d) supported collaboration, e) required the use of prior knowledge, f) piqued curiosity, g) encouraged deep understanding, h) provided contextual meaning, i) helped to better understand the lab, j) prompted additional questions, k) provided relevance, and l) was a meaningful activity (all p's $< .05$). Conversely, students were more likely to agree that information gathering, rather than problem-solving encouraged both rote memorization and attention to detail (p's $< .05$). However, while students seemed to prefer, in general, the problem-solving method, this finding was only marginally significant on a five point scale (in which 5= "strongly agree" and 1= "strongly disagree": PS mean =3.55, IG mean=2.77; $p=.108$).

With regard to their opinions about the multimedia program, 63% of students disagreed or strongly disagreed–while only one student agreed–with the statement, "Learning this material could have just as easily been done by using a textbook." Indeed, 82% agreed or strongly agreed (with no one in disagreement) with the statement, "The program provided support that would be difficult to obtain through other methods."

On the survey questions that elicited their attitudes about working on each of the tasks, students were more likely to agree that they enjoyed the problem assignment (relative to the IG assignment), and were interested, motivated, and involved in the problem. Still, although 79% of respondents disagreed or strongly disagreed with the statement, "The questions were too difficult to answer using the program," significantly fewer (59%) disagreed that "the problem was too difficult to answer using the program" (5 point scale: IG = 2.23, PS = 2.59, $t= -2.16$, $p < .05$). The opinion that the problem was too difficult to solve was modulated by the particular exercise; students who received the problem as their second exercise were more likely to view it as difficult (E1=2.4 vs E2=3.0;

p=.024). Students overwhelmingly agreed or strongly agreed that solving case problems encourages the integration of concepts (96%), whereas only 27% agreed that answering direct questions does so ($t=4.271$, $p<.001$).

The Crucial Roles of the Instructional Designer and the Subject Matter Expert in Multimedia Design

Abstract: This paper examines a study which developed and began testing a process to assist instructional designers in eliciting unfamiliar content from subject matter experts and in conceptualizing that content. It explored the development, trial, training and application of the "Content Production Process" (CPP). Three major insights were gained into the use of the CPP. Firstly, the novice instructional designer found that knowledge map construction was useful for assisting him to think carefully about the unfamiliar content. Secondly, the knowledge map appears to have been a useful "communication prop" for assisting the instructional designer in interacting with the subject matter experts. Thirdly, the instructional designer found that combining a "teachback" procedure with the knowledge map provided a powerful means of checking his understanding of the content against that of the expert. The CPP offers a process for improving the interviewing process in multimedia instructional design.

Nature of the Problem

Imagine attempting to design an instructional unit in an area in which you have no understanding or expertise. How would you approach the unfamiliar materials? What are your choices? You can read textbooks or reference materials or you could talk to experts in the area. Subject matter experts, however, are often busy people. How can you optimize your time spent with the subject matter expert? How can you elicit a sufficient quantity and quality of information so that instructional design is possible? What questions would you ask of the subject matter expert? This paper addresses the relationship between the instructional designer and subject matter expert and examines more particularly a possible method for eliciting and conceptualizing unfamiliar content knowledge from the subject matter expert so that efficient and effective instructional design can proceed.

Research on instructional design has not adequately addressed the conceptualization by the instructional designer of unfamiliar content as presented by a subject matter expert. Many researchers in the field of instructional design acknowledge the importance of this conceptualization (Brien & Towle, 1977; Bratton, 1981, 1983; Cram, 1981; Wallington, 1981; Rutt, 1985; Armstrong & Sherman, 1988; Morrison, 1988a; Tessmer, 1988a, 1988b; Rodriguez, Stephens & Arena, 1991; Davidove, 1993; Maple, 1994; Lee, 1994; Ingram, Heitz, Reid, Walsh & Wells, 1994; Yancey, 1996); however, only general heuristics and suggestions have been offered. There appears to have been no systematic efforts to develop a comprehensive strategy for the conceptualization and elicitation of subject matter knowledge.

This crucial skill of an instructional designer is a potential "bottleneck" for the development of instructional materials in project-based multimedia environments. For example, an instructional designer may be required to design multimedia in content areas as diverse as mining, engineering, taxation, alumina processing, beef production and medicine. It is not possible to be conversant in all of these diverse content areas, and the instructional designer must rely on subject matter experts to assist with this content. Without an effective strategy for interacting with the subject matter expert, valuable time will be lost understanding and organizing the content, hence the need for an efficient and effective method to assist in the instructional designer–subject matter expert interaction (Keppell, 1997).

Instructional Designers and Subject Matter Experts

Instructional Designer

Instructional designers tend to be process-oriented individuals as they can apply instructional design principles to a wide range of content areas. The designer usually begins by analyzing goals, needs and learner characteristics in an attempt to understand the instructional problem. The scope and content of the subject are then identified. These areas represent the "problem space" of the instructional designer. One of the designer's main jobs is to select, sequence, synthesize and summarize the content for instructional purposes and deliver the desired product. "Despite having *no content expertise,* the designer has a set of representations based on a *"design model"* which can guide the development of an effective training program" (Nelson, Magliano & Sherman, 1988, p. 32) (italics added).

The *design model* is the designer's accumulated knowledge of how instruction should be developed. It is the amalgamation of general experience, educational background and instructional experience. The design model is analogous to a script. Scripts are knowledge packages in memory which allow individuals to understand routine activities (e.g. eating in restaurants, visiting the dentist). They are prototypical or stereotypical information useful in everyday occurrences. Schank and Abelson (1977) suggest that we have hundreds of stereotypical situations coded in memory, each having idiosyncratic variations. The designer has a generic script which can be applied with variations to new instructional problems. This design model is one of the most important characteristics required by the designer in approaching a new instructional problem. The advantage of the generalized script is that it is adaptable to new instructional problems. The concept of the script suggests how a designer can approach unfamiliar content. The aim of the designer in the interaction with the subject matter expert will be to "formulate a working content structure within which the information and skills to be taught can be formed into a sequence and hierarchy" or other appropriate structure (Wallington, 1981, p. 30).

Subject Matter Expert

As the name suggests the subject matter expert (SME) or the content expert is an authority on a particular domain of knowledge from whom the designer is attempting to elicit knowledge. The SME may be the client in the business, academic or military setting. Nelson, Magliano and Sherman (1988) suggest that "experts'" knowledge structures are more highly organized and well integrated" (p. 30) than those of novices. "Experts tend to "chunk" or organize information into more highly structured patterns and to complete the task more quickly than novices. Experts also appear to represent problems differently than novices because of their superior ability to recognize patterns, infer relationships, disregard irrelevant information, and recall similar problems from past experience" (Nelson, Magliano & Sherman, 1988, p. 33). One of the SME's functions in training is to provide accurate content to the design team. In this study SME's have two roles: (1) providing a clear description and explanation of the content area being examined, and (2) assisting the designer's conceptualization by clarifying and verifying the content.

Phases of the Study

Phase 1: Development of the Process

The CPP was developed by using an eclectic approach. Ausubel's concept of "intellectual scaffolding" forms an important part of the CPP (Ausubel, 1960, 1963, 1968). When instructional designers are working with SME's their aim is to create a conceptual scaffold and then attach content elicited in the subsequent interactions with the SME. As designers create this conceptual scaffold (knowledge map) and elaborate the content they begin to conceptualize the relationships within the content. It seemed that some form of graphic organizer might be an appropriate tool for representing successive iterations of the instructional designer's attempts to conceptualize unfamiliar content, and of the various forms available the knowledge map was selected (Breuker, 1984; Dansereau, 1991a, 1991b). In addition to helping the instructional designer conceptualize unfamiliar content (Wedman, 1987), it was thought that there would emerge a second advantage of making the instructional designer's perceptions public for the subject matter expert to examine.

Phase 2: Personal Trial of the CPP

The personal trial of the CPP helped to crystallize the researcher's conceptualization of the process. Initially, it was necessary to keep pace with the SME and attempt to obtain an overview of the content area. A second phase began with the SME viewing the map and understanding the role of the instructional designer within the interaction. At this point in the interaction the SME appeared to become more cooperative and provided more detailed explanations because a certain rapport had been developed. A third phase involved both the designer and SME collaborating to achieve the goals of the interaction. The fourth phase centered on cultural understanding with the instructional designer feeling more effective in conceptualizing the content when the content could be viewed from the SME's point of view. After the trial an effort was made to formalize the process to allow it to be taught to another instructional designer.

Phase 3: Training a Novice Designer to Use the CPP

The training program addressed both the declarative and procedural knowledge required by a novice designer when working with SME's in a "real" setting. The novice designer was trained for a total of thirty-three hours in all aspects of the CPP. Personally teaching the process to John provided the researcher with the opportunity to observe the process in action and document the proceedings. John achieved competency in all aspects of the CPP as it was conceived at that point and was ready to work with SME's in a real setting. He had shown competence in both declarative and procedural knowledge in relation to the CPP.

Phase 4: Case Stories

These case stories investigated the designer–SME interaction within the real-world context of a military setting. They attempted to focus on discovery, insight and understanding from the perspectives of the designer and the SME's being studied. In this way they attempted to "illustrate conclusions to which the author ... was ... already committed" (Biddle & Anderson, 1986, p. 238). Such case stories are intended to provide new insights and understandings and "... not provide conclusions, however, that reflect evidence" (p. 238).

This case focussed on how one instructional designer aided by the CPP interacted with, elicited and conceptualized unfamiliar content. Through the process of the case it was possible to examine the situation in depth, detail and from a holistic perspective. This portrayal provided a solid basis for examining what took place in the interaction. The following important areas emerged during the case: (1) Strategies for conceptualizing the content, (2) the knowledge map as a communication prop, (3) the teachback function and the knowledge map.

Strategies for Conceptualizing the Content

Throughout the five interviews in the case John appeared to become more adaptable and flexible in his interactions with the SME's. As the interviews progressed, John's ability to react to the situation was more noticeable. He appeared more comfortable with clarifying the content when he was unsure of its meaning. In his initial interactions, John often allowed Steve (first SME) to complete a lengthy explanation before he sought clarification. In later interviews with Bob (second SME), John was able to seek more regular explanations. As John became more conversant and more confident with the interaction his questioning also became more specific.

John's preferred approach to gaining an initial understanding of the content was to obtain an overview of the area. He appeared to need to see the conceptual terrain of the content area before examining the area in more depth. This was consistent with the author's own application of the CPP. John commented that he needed to do this so that he could see the extent of the information that needed to be covered. It may represent a heuristic that designers need to use in the process of interacting with SME's.

John also found that the knowledge map was a useful tool which assisted him when wrestling with unfamiliar content and displaying the content to the SME. John suggested that the construction of the knowledge map "forced me to think about what was said" and "focuses my thinking". The use of the knowledge map appeared to assist John in thinking more carefully about the content. Holley and Dansereau (1984, p. 8) suggest that the creation of a knowledge map may force the constructor to process the content in "greater semantic depth". Furthermore, Holley and Dansereau also suggest that reorganizing the information in the form of a knowledge map may activate both the spatial and verbal processing systems, allowing the developer to gain a deeper understanding of the information.

The Knowledge Map as a Communication Prop

The use of the knowledge map in the designer–SME interview may act as a communication "prop" to improve the interpersonal nature of the interview. The interaction with the SME can sometimes be a stressful experience which may be lessened by the use of a visual prop in the form of the knowledge map. The knowledge map appeared to assist John in handling the sometimes difficult interpersonal aspects of the interview. "And it really helps me, because when you're dealing with someone who you don't really know very well ... I'm nervous ... and rather than sort of concentrating and talking to him and looking at him in the eye, I could focus attention on the map".

The knowledge map may also help to focus the attention of the SME and designer on the most important parts of the content. Accurate content on the map may not require further attention. It may not be necessary to further explore this information because the SME has verified the accuracy of the content. John used the map in this sense by check-marking accurate information on the map as it was examined by the SME. In this sense the map may act as a communication device that confirms the knowledge shared by the designer and SME. The focus of the interview can then be concerned with the areas that are most in need of attention.

The knowledge map appeared to assist both the SME and designer in recognizing *gaps* in the flow of the sequence and in the information; for example, Steve instantly recognized the absence of safety procedures in the map John had created on the C7 rifle. Likewise, once John had created the map on landmines, he himself, was able to pinpoint gaps in the information that he addressed in the subsequent iteration. McAleese (1988), in the context of developing expert systems, suggests that experts were able to recognize and pinpoint inconsistencies on a concept map.

Lambiotte, Dansereau, Cross and Reynolds (1989, p. 332) suggest that knowledge maps are "computationally efficient" in that they "facilitate faster search and recognition of relevant information" (p. 332). Efficiency is defined in terms of how the knowledge map representation assists attention focusing, knowledge assimilation and knowledge searching of new information. The presentation of the knowledge map to the SME may activate both the spatial and verbal systems thus increasing the processing efficiency of the information.

The Teachback Function and the Knowledge Map

In the initial conception of the CPP it was envisaged that the designer would stop at certain points throughout the interaction and teach the material back to the SME. This proved far too ambitious for a designer who is totally unfamiliar with a content area. It was not possible for the designer to gain sufficient familiarity with the content to teach back the material to the SME. John also felt uncomfortable with this practice. "I still think the toughest nut to crack for me is the teachback, I could just go over it and kind of lecture him, but I really felt uncomfortable doing that". Therefore it seems more reasonable to assume that the designer must concentrate on obtaining the big picture and must postpone paraphrasing and asking in-depth questions until a later point in the interaction. A great deal of reflection and problem-solving was required to develop a conceptualization of the SME's content area.

In spite of the original prediction, interspersing the teachback procedure (Gregory, 1986; Pask, 1975) in the interviews may actually interrupt the SME in the midst of an explanation and prove counterproductive to the overall goal of the elicitation process. A SME may require total concentration when explaining a complex sequence. If the instructional designer interrupts the SME, the SME may lose the train of thought and be prevented from explaining crucial information. The SME may also simply become irritated at being interrupted, thus affecting the rapport between the designer and the SME.

It would appear that the teachback procedure is more appropriately used at the beginning of a subsequent interview. With the aid of the knowledge map, John found this a powerful means of checking his understanding of the content against the expertise of the SME. John gathered the information in the interview, reflected on the content, constructed the map and then taught the material back to the SME at the beginning of each interview. This proved an effective adaptation of the CPP over what was originally conceived.

Conclusion

This study explored the development, trial, training and application of a process to elicit and conceptualize unfamiliar content. In particular the study examined the personal strategies used by the designer in handling unfamiliar content. A secondary purpose was to examine the effectiveness of the process to train designers in elicitation and conceptualization processes.

This study has examined the front-end investigation of eliciting and conceptualizing unfamiliar content by an instructional designer. The work is significant as it has carefully documented the interactions of a novice designer with SME's in a real context. The process appears promising in assisting the conceptualization of unfamiliar content and improving the designer–SME interaction. Further research needs to be undertaken with a variety of designers and SME's to determine the applicability of this process for the field of instructional design.

Epilogue—A Personal Note

Since conducting this study the researcher has employed the CPP to interact with over forty-six subject matter experts in the oil and gas industry in Canada from July 1993 to July 1994. Content areas included cementing, acidizing, fracturing, coil tubing, pipeline pigging, hydrostatic testing, vehicle inspections, nitrogen and CO_2. Comments by the SME's in relation to this process were very favourable. SME's were often puzzled by the accuracy of the information documented in the training manuals by an individual who was totally unfamiliar with the content. The operational procedures for twelve oil and gas operations relied exclusively on the input of SME's. The training materials were developed without actually observing the operations within the field setting. During 1994, I also worked with seven content experts in therapeutic massage. My role was to assist in the formulation of the curriculum. From August 1994 to February 1998 in Australia, I worked with over thirty subject matter experts in the development of multimedia training materials for industry and university-based clients. Some of these content areas included open cut coal mining, underground coal mining, automotive practices, alumina processing and engineering. This collaborative approach has proven to be successful in the completion of the technical projects. From February 1998 I have been working with medical subject matter experts at a medical school in Australia. I have utilised principles from the CPP to interact with over thirty medical experts in developing multimedia modules for use by medical students. Clients appear to "buy into" the process once they realize that their expertise drives the project. The role of the instructional designer is to filter and shape the content for the audience. My own experience in working with SME's has been favorable. In the project-driven environment in which I work, the identification and interaction with the SME is a major factor that determines the success or failure of the project. For me the CPP has continued to "work" and provide a valuable contribution to the design and development of multimedia modules.

Defining the Dimensions of a Formative Evaluation Program: A Multi-Method, Multi-Perspective Approach to the Evaluation of Multimedia.

Gregor E. Kennedy
Biomedical Multimedia Unit, Faculty Of Medicine, Dentistry and Health Sciences,
The University of Melbourne. Australia.
g.kennedy@medicine.unimelb.edu.au

Abstract: This paper details the dimensions of a formative evaluation program developed to refine and improve computer aided learning (CAL) modules in the Faculty of Medicine, Dentistry and Health Sciences at the University of Melbourne. Evaluation criteria were developed in three domains and are broadly based on the characteristics of a CAL module. The program of evaluation which has been developed incorporates a variety of perspectives and a number of data collection techniques or methodologies. The program of formative evaluation is divided into four stages and is integrated with the development cycle of a CAL module. Each stage employs a different methodology. An advantage of this program of formative evaluation is its applicability in a number of multimedia education development environments.

Introduction

A number of developments in recent years have led to the need for a more formal approach to the evaluation of multimedia technologies within the Faculty of Medicine, Dentistry and Health Sciences at the University of Melbourne. First, consistent with the University wide push to develop multimedia teaching methods in higher education, more energy has been directed into developing multimedia education packages for courses offered across the Faculty. Second, as of semester one 1999, a new problem-based curriculum was introduced for students completing a degree in Medicine at the University of Melbourne. A key feature of the new medical curriculum is the emphasis placed on computer aided learning (CAL) which is consistent with a self-directed approach to teaching and learning. This self-directed approach will complement traditional lectures and practical sessions. Seventeen multimedia education projects were undertaken in 1998 by the Faculty, the majority of which will be used to develop computer aided learning modules to support the new medical curriculum.

In order to assist with the design and development of multimedia technologies, the Biomedical Multimedia Unit (BMU) was established in the Faculty. In addition to assisting with project management, instructional design, graphic design and multimedia authoring, part of the BMU's role was to assist Faculty members with the evaluation of their multimedia projects. This paper reports on how the BMU approached the formative evaluation of multimedia technologies being developed in the Faculty and the rationale associated with it. Three evaluation dimensions were considered instrumental to an effective program of formative evaluation. These were (i) the criteria for evaluation (ii) the participants in the evaluation and (iii) the data collection techniques or methods. While many researchers have considered these dimensions more generally, it was thought that an effective program of evaluation required a more specific approach, and an articulation of the interaction between these variables. In addition, it was thought that the program of formative evaluation should be integrated with the CAL module development cycle.

Defining Evaluation Criteria

In general terms evaluation has been conceptualised as either formative or summative. Knapper (1980) has noted the debate as to whether educational evaluation should focus on the end product of instruction and its impact or effectiveness (summative evaluation) or whether evaluation should concern itself with the process of refining and improving instruction (formative evaluation). While the goals of these two approaches may, at times, be incompatible, a comprehensive program of evaluation should attempt to cover both areas. That is, it is important to attempt to refine and improve a CAL module through formative evaluation and it is also crucial to document the impact and effectiveness of a CAL module through summative evaluation once it has been produced. The focus of this paper is on the formative evaluation process and thus concerns the refinement and improvement of a CAL module.

If the aim of formative evaluation is the refinement and improvement of a CAL module, then the way in which this can be brought about must be determined. The starting point for this process is making judgements about the "quality" (Dick & Carey, 1991) or the "value" and "worth" (Guba & Lincoln, 1981) of a CAL module. Evaluators in the field of multimedia education are, as a result, faced with a question. What criteria will be used to judge the value and worth of a CAL module? Will these criteria be based on students' learning outcomes or will they be based on the characteristics of the learning module itself? Researchers have used both these sets of criteria in the formative evaluation process, but often place different degrees of emphasis on each. For example, Dick and Carey (1991) argue that while formative evaluation is aimed at revising the module and is an iterative process, it primarily concerns the "collection and interpretation of learner performance data" (p. 261). Alternatively, Hannafin and Peck (1988) have developed formative evaluation criteria based predominantly on the characteristics of the CAL and issues associated with its implementation. Others, such as Reeves and Lent (1984) present evaluation criteria based both on educational outcomes and characteristics of the CAL module.

There are a number of difficulties with restricting formative evaluation criteria solely to learning outcome measures. As will be argued below, formative evaluation of multimedia can begin before the content of instruction has reached the computer screen. Pragmatically, it may not be feasible to assess students' learning outcomes if the module is far from completion. If learning outcomes are used as formative evaluation criteria other problems emerge. If the proposed learning objectives are *not* found to be adequately met it may be difficult to determine why this is the case. That is, using this form of assessment it is difficult to determine the value of discrete features of the CAL module. Are the learning objectives not being met because of the illogical sequence of content, the poor navigation system in the module, or the inability of the module to engage the learner? This does not imply that the assessment of students' learning outcomes is not integral to the evaluation of CAL modules. Rather, it is argued that the assessment of students' learning outcomes may be more appropriately applied in the final stages of formative evaluation or during a program of summative evaluation.

An alternative to basing formative evaluation criteria on learning outcomes is basing them on the characteristics of the CAL module. If a program of formative evaluation is predominantly based on the characteristics of the CAL module, this program could lead seamlessly into a program of summative evaluation where the assessment of learning outcomes would become paramount. If it is accepted that formative evaluation can be based primarily on the characteristics of a CAL module, researchers and evaluators need to determine suitable criteria with which to judge CAL modules. These criteria should reflect the mechanisms or attributes of a CAL module which theoretically assist student learning. Numerous researchers in the past have developed such criteria based on theories and models of learning and instruction.

Criteria used to Evaluate CAL Modules in the Faculty

The criteria formed to evaluate the development and design of CAL modules in the Faculty were based on theories of learning and instruction (eg. Gagne, 1985; Hannafin & Peck, 1988; Hannafin & Reiber, 1989a, 1989b; Herrington & Oliver, 1997; Oliver & Herrington, 1995; Overbaugh, 1994; Park & Hannafin, 1993; Reigeluth, 1983; Schmidt, 1993: Shuell, 1980) and the criteria researchers have used to evaluate multimedia programs in the past (Hannafin & Peck, 1988; Kearsley 1985; Reeves & Harmon, 1994; Schueckler & Shuell, 1989; Shuell & Schueckler, 1989). Primary and common features which emerged from this literature review were taken to form the formative evaluation criteria. These features were classified into three general domains: Instructional and Conceptual Design, Interface and Graphic Design and User Attitudes and Affect.

A review of the characteristics of the specific sub-criteria contained in each of these three evaluation domains is presented elsewhere (Kennedy, Petrovic & Keppell, 1998), however, a summary is presented below. Five sub-criteria are contained in the domain of Instructional and Conceptual Design: introductory objectives and directions, navigation and orientation, interactivity, sequencing and structure, and consistency between learning objectives and content of instruction. The sub-criteria in the domain of Interface and Graphic Design were initially organised by the primary features of the interface; namely, colour, text, structure and sound, animations and graphics. Each of these interface components is evaluated through general questions relating to issues such as useability, consistency and clarity. Other than this more general evaluation, specific principles of "best practice" were determined for each component of the interface on the basis of previous research. The degree to which particular CAL modules conform to these notions of "best practice" is also evaluated. The final domain, User Attitudes and Affect, incorporated aspects of the first two domains. Evaluation centres on student users and asks them to evaluate aspects of Instructional and Conceptual Design and Interface and Graphic Design. In addition, users are asked to evaluate modules more generally, commenting on criteria such as effectiveness, usefulness, enjoyability, appeal, user-friendliness, relevancy and engagement

Methodology of Evaluation

Once the formative evaluation criteria were determined a method of evaluation needed to be decided upon. Within the field of education, a considerable amount has been written on the methodology associated with formative evaluation generally, and of multimedia in particular (see Alexander & Hedberg, 1998; Dick & Carey, 1991; Draper, 1995, 1997; Flagg, 1990; Guba & Lincoln, 1981; Hannafin & Peck, 1988; Knapper, 1980; Reeves, 1989, 1993a, 1993b; Reeves & Lent, 1984; Wills & McNaught, 1996). From a review of this literature the methodology associated with formative evaluation was seen to have two key components: the individuals who participate in the evaluation and the data collection techniques employed.

Evaluation Participants

It is generally recognised that the participants in formative evaluation can be "experts" and potential "users" (Dick & Carey, 1991; Flagg, 1990; Hannafin & Peck, 1988; Reeves, 1993b; Reeves & Lent, 1984). Flagg (1990) categorised experts into four areas including subject matter, media, design, and utilization experts. Similarly, Reeves (1993b) argued that experts such as content or subject matter experts, instructional experts and teachers and trainers can all provide valuable and unique contributions to the development of a CAL module. In an educational setting "users" are usually thought of as students who will eventually complete the module.

There were a number of reasons to consider a variety of perspectives in the formative evaluation process. First, it seemed that some criteria could not be reliably evaluated by users while others could not be reliably reflected upon by experts. For example, it is unlikely that a content expert, who has invested much time and effort in creating a multimedia module, will indicate that the module contains a lot of distracting or irrelevant information. Similarly, it may be difficult for a student to judge how the structure and content of the module enhanced the communication of the learning objectives. The second reason to evaluate CAL modules from a variety of perspectives was the advantage of highlighting any disparities which exist between the perceptions of CAL module users and content experts or developers. Some researchers have remarked that educational and content experts may agree that a particular feature of a CAL module is worthwhile only to find that the same feature is seen to be irrelevant, distracting or confusing for the learner (Reeves, 1993b). For these reasons it was decided that the program of formative evaluation in the Faculty would include four perspectives: those of content experts, graphic design experts, educational experts and CAL module users.

Evaluation Data Collection Techniques

Just as evaluators have suggested a variety of perspectives in the evaluation process, a number of data collection techniques have also been advocated. Dick and Carey (1991) suggest the use of one-to-one trials, small group trials and field trials as evaluation procedures. Reeves and Lent (1994) on the other hand argue that formative evaluation should be based on internal reviews and operational testing involving questionnaires, expert review, observation and interviews. It is important to use a variety of measures or data collection techniques in the process of evaluation. This enables evaluators to obtain an indication of the validity of the assessment of constructs through the processes of triangulation and bracketing. Often this process will aid in the interpretation of evaluation results.

However, before a decision can be made about the type of methodology to be employed, a number of pragmatic issues needed to be considered. Reeves and Lent (1984) noted that "Unfortunately, few CBI development projects have the budget or time-line to spend large amounts of money and time on these [evaluation] procedures" (p. 195). Commonly formative evaluation is constrained by the availability of time and money. An additional constraint in the current context was the availability of students for evaluation. Due to the large number of multimedia projects being developed in the Faculty, CAL module users were regarded as a scarce resource. The developers of the program of evaluation were wary of over-evaluating students, and in the long term, undermining the reliability of their responses. There was a need, therefore, to develop a method of formative evaluation which accommodated these restrictions yet produced data which was able to assist in the refinement and improvement of the CAL modules being developed. Keeping these constraints in mind, four means of data collection were determined for the current program of formative evaluation: expert review, questionnaire, focus group and observation.

Stages of Formative Evaluation

The program of formative evaluation was divided into four stages. These stages were integrated with the development cycle of a CAL module (see Figure 1). It should be noted from Figure 1 that the four stages of evaluation overlap and that as a module approaches the beta version in the development cycle an initial assessment of users' learning outcomes would begin. A number of evaluation resources have been developed to be used in the evaluation program, including qualitative and quantitative template questionnaires and checklists (Kennedy, 1998). There is a reliance on questionnaires and expert review as the major form of data collection as these are the most cost-effective and convenient forms of data collection. Rather than being prescriptive to Faculty staff about the use evaluation resources, an array of resources was developed to account for different evaluation questions and methodologies.

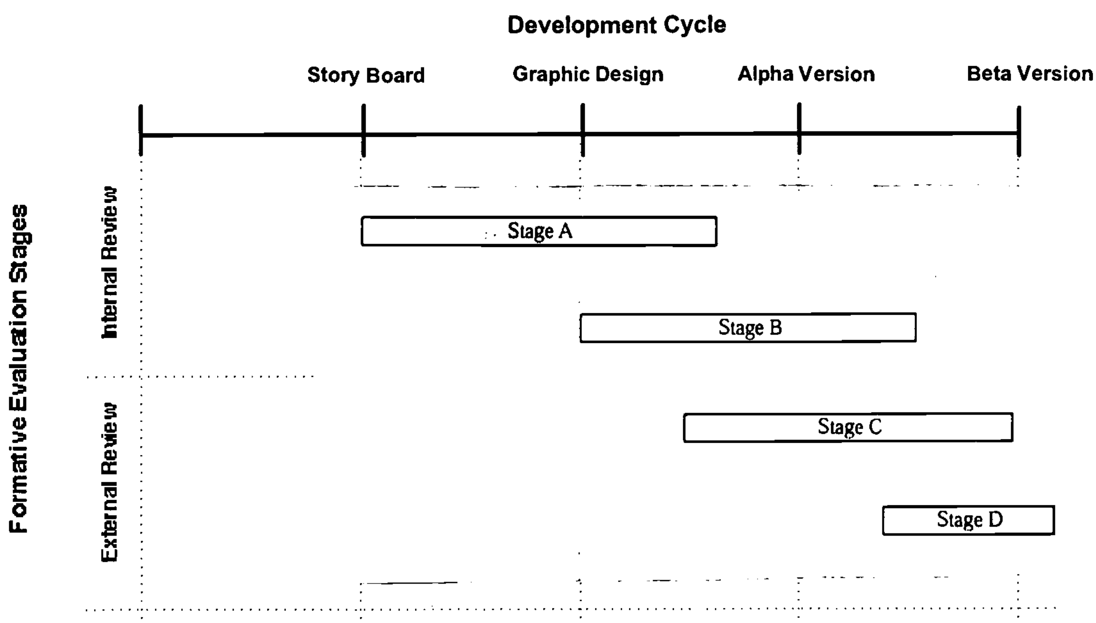

Figure 1: The stages of the proposed formative evaluation program integrated with the CAL module development cycle.

The first two stages of the program of evaluation (Stages A and B) consist of internal reviews of instructional and conceptual design and interface and graphic design. These reviews are both formal (written reports) and informal (verbal discussion and feedback) and are carried out by content experts, graphic design experts and instructional designers associated with the module's development. Stage C is the most extensive stage of the program of formative evaluation and incorporates both instructional and conceptual design and interface and graphic design. Reviews are conducted externally (that is, by individuals not associated with the module's development) and from a number of perspectives (content experts, graphic design experts, instructional designers and student users). In the final stage (Stage D) the domain of User Attitudes and Affect is evaluated and is restricted to the perspectives of student users. Three forms of data collection are used in this stage (questionnaire, focus group and observation).

Implications and Applications

The utility of the proposed program of formative evaluation lies in the fact that it is not dependent on the content area of a particular learning module, and therefore may be easily applied in any context where educational software is being developed. The criteria for evaluation, rather than being based on students' learning outcomes, are based on the characteristics of CAL modules. This allows the program to be easily transferred to other educational contexts. While the program of evaluation was developed to evaluate a number of CAL modules across a variety of disciplines, it should be noted that it can also be applied by smaller development teams. The program of formative evaluation outlined above provides a solid foundation for the development of a commensurate program of summative evaluation. It is hoped that when used together these evaluation programs will foster the development of educationally effective CAL modules.

Alternate Teaching Models for Non-Classroom-Based Instruction

Emery S. Martindale
University of West Florida
11000 University Parkway Bldg 85 Room 160
Pensacola, FL 32514
martindale@uwf.edu

Abstract: This paper attempts to justify the need for the use of alternative teaching models in non-classroom-based instruction (NCBI). Disproportionally high drop-out and failure rates, along with unnecessary constraints from behavioral teaching models necessitate the examination of alternative models. Social models such as small group discussion and information processing models such as concept attainment may more effectively utilize new delivery methods such as the World Wide Web. More research using these teaching models may aid instructional designers in selecting the most appropriate instructional model for a particular audience and instructional problem.

Introduction

As the United States moves from an economy based on manufacturing to one based on information, the need for information-literate employees is rapidly growing. Public education is currently under scrutiny from business and industry, and is being criticized for being slow-moving and overly conservative, particularly in terms of implementing computer technology. Commercial institutions expect the same productivity gains in education that have occurred in business. Computer instruction and the Internet in particular has been widely promoted as the ultimate instructional tool to replace schools and teachers (Perelman, 1994). Some promoters of computers and networks in education believe that traditional classroom-based instruction will become unnecessary as computers become less expensive and more ubiquitous. More research on non-traditional educational methods is certainly in order in response to cries for educational reform.

Non-classroom-based instruction (NCBI) can be defined as any planned learning environment that is not designed to occur in the traditional classroom. NCBI includes all forms of distance education, as well as campus-based self-paced courses and other self-paced learning environments. This type of instruction is becoming much more common, particularly due to the growth of computer networks (Harasim, 1995). With the rapid expansion of NCBI there is a need to examine its effectiveness in terms of instructional design. A primary method of evaluating various forms of NCBI lies in the examination of the teaching model employed in the design of the instruction.

Teaching models are approaches to teaching with underlying theoretical support that are designed to bring about a particular type of learning (Joyce, 1992). Joyce groups the various teaching models into "families" based on the learning theories from which the models have been derived. A learning theory can be defined as a set of principles and observations derived from research that support a hypothesis of how learning takes place (Ormrod, 1995). Models for delivery have been constructed around the tenets of certain learning theories. According to Joyce (1992), teaching models can be grouped into four "families". These families include behavioral models, social models, information-processing models, and personal models. Following is a brief summary of three of these families of teaching models. Personal models will not be discussed as they are beyond the scope of this paper.

Behavioral Teaching Models

On the foundation of the work of Skinner, a large number of approaches to learning have been developed, each taking advantage of the human being's ability to modify behavior in response to tasks and feedback. These models are used in a wide variety of applications, from teaching information to changing habits, decreasing phobias, and learning to control one's own behavior.

One of the important applications of behavioral systems theory is in the development of systems that enable learning tasks to be regulated according to the progress of the learners and which teach students to pace themselves for optimal performance. Often these systems organize material to be learned in small sequenced instructional modules that are presented to the students with assessments of learning embedded in them (Joyce, 1992). Some of these behaviorally-based teaching models include mastery learning, direct instruction, contingency management, and self-training through simulation.

Social Teaching Models

These teaching models capitalize on our nature as social creatures to further learning and to expand our ability to relate productively to one another. The models range from the simple processes or organizing students to work together to elaborate models that teach democratic social organization and the analysis of major social problems and critical social values and issues. The social models of teaching are constructed to take advantage of the "synergy" phenomenon -- the collective energy generated by group work. The simplest forms of cooperative learning organize students to help one another respond to the cognitive and social tasks presented to them. More advanced models prepare students for life in a democratic society -- an idea developed by Dewey (1916).

Many developers of the social models believe not only that they have developed important additions to the storehouse of models but also that the current state of affairs -- teacher-dominated recitation -- is actually counter-productive for individuals and society by depressing learning rates, creating an unnatural and even antisocial climate, and failing to provide opportunities for young people to maximize their potential through cooperation. Current social teaching models to be considered include partners in learning (dyads), cooperative learning, role playing, and jurisprudential inquiry (Joyce, 1992).

Information Processing Teaching Models

Information processing theory is concerned with how humans acquire, process, and remember information. This is contrasted with behaviorism's concern with measurable behavior change and lack of concern over mental events or cognition. A number of teaching models seek to discover these mental events and create effective environments for processing information (Pressley, 1995).

These models are designed to increase students' ability to seek and master information, organize it, build and test hypotheses, and apply what they are learning in their independent reading and writing and their exploration of themselves and the world about them. Some of these models induce the students to collect information and build concepts. Others teach them to profit from direct instruction through readings, lectures, and instructional systems. Some of the information processing models include thinking inductively, concept attainment, memorization, advance organizers, and inquiry training (Joyce, 1992).

Teaching Models for NCBI

The preceding teaching models have been widely used in traditional classroom-based educational environments. However, many instructional situations and opportunities exist outside the school classroom. These instructional situations, identified as non-classroom-based instruction (NCBI) operate outside of traditional face-to-face interaction with an instructor, so alternative delivery methods must be considered. NCBI has been and is currently being delivered via print, radio, television, and computer network. Following is a discussion of the teaching models employed within these delivery methods.

NCBI Delivered via Print

NCBI consists of distance education courses as well as school or campus-based self-paced courses. Distance education, traditionally defined, is an environment in which instructor and audience are separated by time or distance or both. While NCBI may seem to be a recent phenomenon, print-based correspondence courses have been in existence for over 150 years (Holmberg, 1996). These early examples of NCBI consisted of courses offered through newspapers and through printed mailings using the postal service. Print-based correspondence courses are still used today although they are now commonly combined with electronically-delivered material (Moore, 1995).

Print-delivered NCBI has traditionally relied upon behaviorally-based teaching models, particularly direct instruction and mastery learning (see Price, 1996). The common design uses short modules of instructional content followed by a self-test and then a formal assessment, most often using techniques that require low-level processing, such as multiple choice tests, matching, and filling in blanks. Course objectives are stated in behavioral terms. The student may conduct an internal dialogue with the material, but has little to no interaction with a live instructor or with other students. Collaborative learning is discouraged in these instructional situations.

The most common model for print course development is the author-editor model. Authors (often professors) are contracted to write a course, which is then edited by specialists within the correspondence school or independent studies department. In most cases the correspondence material consists of units that include a statement of lesson objectives, a reading assignment, a commentary and a study guide, and a written assignment to be completed (Moore, 1993).

NCBI Delivered via Electronic Communications

Electronic communications for education also began in the 1920s with radio programs. These programs most often focused on fundamental instruction, usually in language and mathematics (Cuban, 1986). In the 1930s experimental television programs were being produced at a few pioneering universities, and programming expanded in the next few decades. These radio and television programs were not interactive, with no student feedback or discussion with the instructor. Content was commonly delivered by a "talking head" -- meaning an instructor faced the camera or microphone and delivered a prepared lecture (Cuban, 1986). This delivery method operates within artificial constraints that are not set in place by the television medium.

Satellite technology, developed in the 1960s and made cost effective in the 1980s, enabled the rapid spread of instructional television. Televised courses have now become more interactive with the deployment of distance education equipment including cameras and microphones for the students at remote and local sites as well as for the instructors. Still the teaching model most commonly used is direct instruction, with the instructor lecturing to a group of students whether in person or at a remote site (Gilbert, Temple, & Underwood, 1991).

The last ten years have seen an exponential growth of microcomputers in homes and schools in the United States (Williams, 1996). As microcomputer access has grown, so has computer-based instruction (CBI). CBI began as an outgrowth of Skinner's programmed instruction. Because of this, much of CBI has followed the drill-and-practice behavioral model (Price, 1991). The development of the CD-ROM greatly increased the storage capacity for commercial and educational software, and this increased storage has led to the creation of multimedia titles that are rich in sound, video, and animation. While these attributes in themselves do not lead to alternative teaching models, multimedia titles tend to be more learner-centered in terms of user control and non-linear progression through the material.

The distribution of Apple Computer's HyperCard authoring environment contributed to the development of hypertext and hypermedia programs in CBI. Proponents of these programs claim that they model human associative memory and thus can serve as powerful cognitive amplifiers (Conklin, 1987). Hypertext CBI is related more to information processing than behavioral models, and these types of applications have become much more prevalent with the growth of the World Wide Web.

NCBI Delivered via Computer Networks

With the widespread proliferation of personal computers and the growth of the Internet, online distance education is a rapidly growing segment of NCBI that serves as an educational alternative to traditional face-to-face instruction. The ubiquity and ease of use of the World Wide Web has led to a large expansion of online courses in higher education. In the United States, the American Open University, Nova University, and the University of Phoenix have been traditional leaders in providing distance education. These and many other universities are now offering hundreds of courses online (Lintz & Tognotti, 1996).

Computer networks offer new opportunities for collaboration in NCBI. Protocols and software tools such as e-mail, mailing lists, newsgroups, chat, and instant messaging allow several modes of interaction. Interaction modes can be classified as one-to-one, one-to-many, and many-to-many (Harasim, 1990). The Internet is a medium that removes many of the constraints of print, radio, and television delivery mediums. Communication can occur in real time or asynchronously, allowing interaction with both instructor and fellow students. Distributing material over networks is much less expensive than television production and more expedient than print correspondence. It would seem to be a superior medium for many types of instruction. But as in print correspondence and earlier electronic media in their initial years of use, network-delivered NCBI has relied primarily on behavioral teaching models, most often direct instruction and mastery learning. This is evidenced by current Web-based online course offerings (see WebLearning, 1998; Real Education, 1998).

Current Practice

Many educational institutions as well as businesses and other organizations are providing Web-based courses for students and employees. However a large segment of this non-classroom-based online coursework remains exclusively in the domain of the behavioral family of teaching models, despite evidence of the effectiveness of alternate teaching models.

The effectiveness of the current state of NCBI is under scrutiny, particularly as institutions prepare to embark upon major distance education initiatives. Drop-out rates for correspondence courses are disproportionately high (Kember, 1989). Similarly, in a pilot study the researcher found that students in a campus-based self-paced course demonstrated unusually high failure rates. The nature of NCBI places responsibility for learning upon students who may have never faced such requirements.

For behavioral teaching models there are other concerns beyond high failure and drop-out rates. In the context of an online course these models do not take advantage of the available attributes of the http protocol. These attributes include the availability of asynchronous interaction and discussion with the instructor or classmates, and hypertext associational linking between related topics. This linking may mirror the hypothesized information processes in human cognition. Behavioral models, therefore, work within artificial constraints not imposed by the http protocol.

The dominance of behavioral models in NCBI can be explained in terms of misperception and convenience. Behavioral teaching models are perceived to present low instructor demands in terms of time and design expertise. Behavioral models such as direct instruction and mastery learning seem to be simply and conveniently translated into printed or online "study guides" which lead the learner step-by-step through the particular instructional content. Often these materials are organized into instructional "modules" which can be easily assessed for effectiveness (see Price, 1996).

In order to achieve the interaction required by social and information processing teaching models, NCBI (whether print-based or Internet-based) is perceived to require greater instructor time and resources, as well as more advanced design and programming techniques. The decision to use behavioral teaching models in NCBI may therefore be based on perceived convenience rather than effectiveness and appropriateness toward reaching the instructional goal.

Teaching models from the information processing and social interaction families do not necessarily require greater instructor time or resources to implement. Alternative online course design and specialized software present an opportunity to use these models efficiently. These alternative designs need to be compared and contrasted with designs from behavioral teaching models such as direct instruction and mastery learning which currently dominate NCBI environments.

Alternative Teaching Models for NCBI

The following two teaching models are proposed as alternatives to the behavioral models widely used in NCBI. Small group discussion is from the social interaction family of models and concept attainment is from the information processing family of models.

Small Group Discussion

The challenge of the current state of affairs is to design effective NCBI using teaching models beyond simple direct instruction or mastery learning. The evidence is largely affirmative that cooperative groups do result in improved learning. Classrooms organized so that students work in pairs and larger groups, tutor each other, and share rewards are characterized by greater mastery of material than the common individual-study and recitation pattern. Also, the shared responsibility and interaction produce more positive feelings toward tasks and others, generate better intergroup relations, and result in better self-images for students with histories of poor achievement. The results generally affirm the assumptions that underlie the use of cooperative learning methods (Sharan, 1990).

Beyond traditional face-to-face instructional situations, the effectiveness of group discussion and collaboration has also been shown effective in distance education. With Internet delivery there are many cooperative learner approaches for effective instructional environments. These include online mentorships, tutor support, informal peer interaction, and expert forums. Online group learning structures include online seminars, small group discussions, learning partnerships and dyads, learning circles, and teaching and presentations by the learners. Role playing simulations, online debates, and informal chat areas are also viable instructional environments (Harasim, 1995). Many of these learner approaches can be classified as online asynchronous group instruction. Specialized network software such as the IdeaWeb (Ahern, 1992) can be used for small group discussion and collaboration in online environments as a type of computer-mediated communication (CMC). The IdeaWeb represents an opportunity to utilize the advantages of the http protocol in creating a collaborative learning environment within NCBI.

Concept Attainment

Among the information-processing models found within traditional education, the concept attainment model is a viable choice for instructional use in NCBI. The concept attainment model of instruction can be defined as the search for and listing of attributes that can be used to distinguish exemplars from non exemplars of various categories. The model requires students to compare and contrast exemplars that contain characteristics (called "attributes") of the concept with exemplars that do not contain those attributes. Exemplars are a subset of data from a data set. Positive exemplars are the subset examples that share one or more defining characteristics that are missing in the other examples. It is by comparing the positive exemplars and contrasting them with the negative ones that the concept is learned.

Learning by concept attainment involves two phases. First, the concept name is presented along with labeled examples of positive and negative exemplars. The learner integrates these exemplars and generates a hypothesis about the concept definition. The student then states a possible definition in terms of essential attributes. Secondly, the student identifies additional unlabeled examples as positive or negative exemplars of the concept. The student hypothesis and definition is either confirmed or corrected, and a correct definition of the concept is given. The student then generates more concept examples. By following this model the student learns the concepts related to the instructional content (Joyce, 1992). Using HTML, the author has previously developed concept attainment lessons for use in an NCBI environment.

Conclusion

This paper attempts to justify the need for the use of alternative teaching models in non-classroom-based instruction (NCBI). The author contends that behavioral teaching models are dominant in NCBI and that high failure and drop-out rates, along with unnecessary constraints from the behavioral models, necessitate the examination of alternative models of teaching. This paper examines two alternate teaching models: small group discussion from the social models classification, and concept attainment from the information-processing models classification. Instructional systems using these models can be asynchronous and do not necessarily require additional instructor time or resources in terms of class management. Instructional effectiveness can potentially be increased without significantly increased instructor resources. Empirical research on teaching models should be conducted to examine the level of effectiveness of these particular teaching models for NCBI. This type of research will aid course designers in selecting the most appropriate instructional model for a particular audience and instructional problem.

Abstract: This study investigated a virtual partnership between educational technology graduate students in France and Texas. The partnership was designed initially for the students to communicate their conceptions of educational technology primarily via a Web message board. We used qualitative research methods to identify the Texas students' descriptions of their participation in and reactions to the partnership and their ideas about educational technology in the U.S. The investigation tested an existing model of six design considerations for computer conferencing (grading system, grouping, collaboration, relevance, learner control, and technological preparation) and four design considerations for cross-cultural participation via communication technologies (communication and interaction, language, content, and representation form). We discovered that unless each design consideration is addressed, cross-cultural partnership via telecommunications may be unsuccessful.

Introduction

Graduate students preparing to work in the field of educational technology and multimedia subsequently find positions as administrators and faculty members in K-12 settings, community colleges and universities; and as trainers and instructional designers in the public and private sectors. Students graduating from programs in educational technology and multimedia require specialized telecommunications and multimedia skills and face an increased emphasis on international communication in their work. Romiszowski (1997) identifies critical thinking, or creative problem solving, of "paramount importance for the knowledge worker of the future and, therefore, ultimately, for the employability of the human race" (p. 33). A study of Texas employers identified multilingual skills as vital and increasingly required for success. Other requisite skills include: written and verbal presentation skills, ability to think logically, sound judgment, ability to work in multicultural teams, flexibility in adapting to change, and ethical decision making (Zey, Luedke, & Murdock, 1999). In preparation for such work, graduate students can expand their horizons about the role of educational technology and multimedia in an international arena by using the Internet to communicate and collaborate across international boundaries. In this cross-classroom partnership, graduate students in educational technology at Texas A&M University (TAMU) in the US and the University of Poitiers (UP) in France used telecommunications to share ideas on topics related to their studies.

The Project

Graduate students in educational technology at TAMU in the US and at UP in France were linked through an electronic communication exchange designed to expand participating students' conceptions about the graduate programs and the role of educational technology. The course for TAMU students began at the end of August, whereas the UP students began their course six weeks later. The TAMU students met weekly via interactive videoconference and FirstClass computer conference software to discuss topics, post assignments, and develop small group projects. The UP students, on the other hand, were in a traditional face-to-face class: lectures, labs, problem-solving using varied technologies; the course culminated with a three-month internship in a company.

The TAMU and UP educational technology instructors had collaboratively developed the partnership activities, which included: 1) development of student biographies as individual Web pages, 2) class discussions at both universities, 3) a one-hour videoconference, 4) three discussions via message boards on the Web over a six-week period among mixed groups of students, and 5) a follow-up survey. The TAMU instructor assigned 10% of her students' grades to this project, whereas the UP instructor informed his students that participation in the project was required but did not assign specific points.

The first activity was for the students to create and publish their individual biographies on the Web. The second activity, class discussions at both universities, addressed the logistics of the partnership activities, guidelines for using the Web board, and communication issues between the two universities. The third activity was a one-hour interactive videoconference, which included the instructors and nearly all of the students from both countries. The videoconference included introductions of faculty and students, and small group discussions. Each group of eight students took turns sharing backgrounds and interests with each other as well as making plans for their Web discussions. The videoconference culminated with a demonstration of the Web message board.

The fourth activity was a series of discussions on a Web message board about the roles of educational technology. The TAMU instructor developed six identical Web boards, which allow users to post new messages, reply to questions and other replies, and search for a string of characters within messages. Separate boards were built for each group of eight students, four from each university. We planned that during a six week period, the six groups would discuss three topics for two weeks each: 1) the role of educational technology at their universities; 2) the role of educational technology in their countries; and 3) the formation of their own conceptions of educational technology. Six TAMU students, one from each group, were designated to moderate the first discussion topic for their groups, thereby modeling appropriate computer conferencing behaviors for the UP students, whose coursework had only recently begun. The TAMU instructor first entered the welcome messages and instructions. Then six student moderators each entered the first set of three discussion questions regarding educational technology in the universities. During the first two-week period, each TAMU student entered at least one reply to the three-part discussion, while most students replied several times. Then they waited for responses from UP. However, only one UP student participated, replying to each of the three questions in her discussion.

The final activity was a follow-up survey administered in March 1999. The TAMU students received their surveys by email, and the UP students received theirs on paper. The survey collected demographic data, investigated conceptions about educational technology in the two countries, and sought reactions to participation in the partnership.

Methods

Participants

This partnership included TAMU in College Station, in central Texas, and the UP, in central France. Participants included 24 graduate students from TAMU and 22 from UP. With one exception, the TAMU students were enrolled in a semester-long course in educational technology earning master's or doctoral degrees in education. All 22 UP students were post-graduates in the master's degree program consisting of coursework on campus followed by internships throughout the country. The UP students, who were primarily from France and included several students from Romania, remained as a cohort throughout the year-long program.

Data Sources

The data sources included the messages from the six Web boards and the follow-up survey results from 17 TAMU students. We downloaded the messages from the six Web board discussions, and we coded the responses on the surveys. The data were coded according to T for TAMU, a student number between 1 and 24, and "s" for survey or "w" for Web board. We analyzed the data by using the constant comparative method.

Research Questions and Procedures

The initial research questions dealt with an investigation of students' conceptions of educational technology in the two countries and identification of the conceptions that were shared across borders. However, because of the lack of participation by UP students, we changed our research focus to the actual partnership experience. We investigated the following topics:

1. What were TAMU students' conceptions about educational technology?
2. How did TAMU students' describe their participation in and reactions to the partnership?

In addition, we wanted to identify key ingredients of successful cross-cultural partnerships. Therefore, after analyzing the data, we critiqued the data based on two design models, one of computer conferencing and the other of cross-cultural collaboration. Doing so allowed us to identify which factors were not addressed in the partnership and therefore may have been responsible for the failure to achieve the objectives.

Results

Based upon the existing data, we report here on findings regarding the partnership. The TAMU students reported spending approximately 1.5 hours in class discussing aspects of the partnership. The means of student hours spent on the three activities associated with the partnership follows: creating a Web-based biography (mean = .87 hours), videoconferencing (mean = 1.02 hours), and Web board discussion (mean = 1.44 hours). Therefore, the mean amount of time spent on the partnership per student was 2.42 hours. All TAMU students created a Web-based biography and participated in the Web board. Although the videoconference was held on a Saturday and was optional, 20 of the 24 TAMU students attended.

Conceptions of Educational Technology: The US Perspective

Students perceived the role of educational technology in schools, business, and government as a growing entity for facilitating learning, supporting communication, and conducting research. In schools, educational technology enhances student learning primarily through application to problem solving, a skill that they will transfer to situations outside of school. The TAMU students identified problems associated with technology in the schools. "Schools are quickly realizing how important technology has become...In many cases, however, teachers are not trained on how to use the equipment. They also may not be trained on how to integrate the technology into their teaching scheme" (T19s). Another student expressed concern that some people believe technology "could 'replace' a teacher" (T2s). In business, educational technology facilitates training of personnel, sharing of ideas through telecommunications and presentations, and providing instructional programs and testing methods. The government sponsors "public awareness and informational programs and ...is attempting to help all schools access the Internet in order for all children to have access to information and experience with technology" (T16s).

Students reported forming their ideas about educational technology by discussing issues with their classmates, professors, colleagues, and others both face-face and through listservs; reading literature in the field; experiencing educational technology hands-on; conducting research; and solving educational and technological problems. They acknowledged the importance of educational technology and maintained a positive attitude that makes them receptive to learning: "I realize more and more each day the importance of learning to use it so I can function in today's society" (T7s). They identified various elements in the popular culture that helped them shape their ideas about educational technology: television, magazines (including trade magazines), film, and videos.

The Partnership Experience: The US Perspective

The videoconference was the most popular activity of the partnership. Students enjoyed "being able to interact with people from a different culture and setting" (T11s) and "being able to SEE the French students" (T10s). One student suggested that future follow-up videoconferences should be held. Two students liked sharing biographies best of the activities, as one of them explained: "I enjoyed reading the biographies ...and finding out how their preparation was different from ours" (T22s).

TAMU students agreed that the concept of cross-cultural learning about educational technology was good but that in reality the experience was a great disappointment. The videoconference built up students' hopes that they could communicate with students in France. However, when TAMU students did not receive responses to their questions, they expressed frustration of checking the Web board frequently and finding no responses from UP.

The two TAMU students who expressed positive experience with the Web board imparted value on the process of cross-cultural communication itself. They noted the power of international dialogue, saying: "It ... forces you to...be precise in how you are saying what it is that you want to say" (T16s) and determining "the best way to organize the discussion to make it easy to follow for new users" (T22s). Both students examined their own processes and used the partnership to refine their approaches.

The TAMU students suggested that the instructors "make sure both groups are willing to follow through with what the collaboration entails" (T11s). They offered these suggestions to enhance collaboration: (a) clarify expectations to learners by setting "a minimum number of entries in a set time period" (T9s) and maintain contact with each other; (b) arrange for sufficient access to labs and equipment as well as training in using technology; and (c) enforce communication through guidance and grading of the activity.

The students felt that they had done everything possible to encourage the UP students. They suggested that the UP students demand lab time, be proactive, and make more effort to communicate. Despite limited communication, TAMU students learned from the partnership. Several students commented that a successful partnership involves careful planning and a commitment from both sides. However, one noted that "even the best planned initiative can be short-circuited by one problem - no open labs in Poiters" (T22s). Other students acknowledged the power of technology to bring people together from distant corners of the world. "In about an hour I had met a bunch of nice people on the other side of the globe. I saw their faces, their names and I heard them talking, just like if they had been in the same room with me" (T14s).

Through observations, email exchanges, and comments from the TAMU students, we identified probable reasons for the failed electronic exchange. Limited access, limited time to reply to messages, lack of understanding the power of asynchronicity or how to use the Web board, and lack of course credit for participation all led to the UP students' setting the partnership low on the priority list of course activities.

Discussion

The purpose for identifying the reasons that the partnership was ineffective for the goal of investigating cross-cultural understandings of educational technology was to provide a scholarly analysis of why this particular cross-cultural partnership did not achieve its goals. The broader purpose was to discover the key ingredients needed for successful partnerships across cultures. The literature describes cross-cultural partnerships and suggests successful designs of such partnerships via telecommunications. This literature is related to the following topics: (a) educational partnerships, (b) designing for computer conferencing, and (c) cross-cultural communication.

Educational Partnerships

The literature on university-school partnerships reveals important guidelines for successful partnerships of various types. Tushnet (1993) identifies the following characteristics of successful partnerships: a history of collaboration; addressing real problems as they occur; mutual respect for each other; and discussions with all players about the content of activities. Prior to the partnership, the TAMU and UP instructors had not shared their content or ways to use technology. Once problems such as unequal contributions by the students began to surface, the instructors failed to communicate regularly with each other and thus didn't address the problems.

Designing for Computer Conferencing

Increased use of computer-mediated communication for teaching and learning has created a developing body of literature on designing for online environments. Researchers propose six design considerations for computer conferencing: two that involve administrative design considerations--grading system and grouping--and four instructional design considerations--collaboration, relevance, learner control, and technological preparation (Cifuentes, Murphy, Segur, & Kodali, 1997). Each design considerations will be described and analyzed in terms of the partnership.

The two administrative design considerations were grading system and grouping. Research shows that student participation rates are influenced by whether participation is voluntary or required (Wells, 1992). In partnerships, grading should include a similar emphasis on both sides, and professors should collaborate on a grading scheme for all students. In this partnership, the grading emphasis was different, with the TAMU instructor assigning actual point values for participation, and the UP instructor requiring the activity but not placing point values on it. The second factor, grouping, concerns size, location of the members, and composition of the groups. Decisions about group formation are best made prior to partnership activities. The instructors were effective in establishing small groups and combining computer conferencing expertise and command of written English.

The four instructional design considerations were collaboration, relevance, learner control, and technological preparation. Collaboration involves a group created to perform a task or solve a problem together (Slavin, 1983). Romiszowski (1997) asserts that the most effective types of teaching-learning techniques to foster critical thinking skills are "experiential exercises followed by interpersonal interaction in small groups, and with facilitators to guide the group towards useful conclusions" (p. 33). Creating and playing adventure games on the Web, for example, have been found to improve foreign language skills (Vilmi & Malmi, 1996). In this study, the participants did not share a common task to be performed.

Relevance is necessary for meeting learners' needs and allowing them to profit directly. Relevance is related to authentic activities, the "ordinary practices of the culture" (Brown, Collins, & Duguid, 1989). Romiszowski (1997) recommends several authentic activities: small-group discussions, simulation games, project-based work, and collaborative problem-solving activities. The TAMU-UP partnership might have benefited from doing shared tasks in small groups rather than discussing educational technology.

Learner control is typically characterized by learners making choices in the pacing, sequence, and selection of instructional materials. Giving learners control over their learning environment is empowering, as Cifuentes et al. (1997) noted in regard to pre-service teachers who were allowed to co-moderate their own conferences. Had the students in the partnership between TAMU and UP been given the opportunity to select their own discussion moderators and share the moderating responsibilities between sites, they might have felt more empowered.

Technological preparation is imperative in helping students be competent with the technology. Hillman, Willis, and Gunawardena (1994) assert that "user-interface interaction" is critical, particularly with high technology communication devices. They suggest methods that foster comfort with a new technology like having students play with the tools in a game-like activity before using the tools for course content. The emphasis on technological preparation and uses of telecommunications should be similar at both sites. The TAMU students had been using computer conferencing for eight weeks by the time of the videoconference, whereas UP students hadn't used telecommunications other than the Web.

As Cifuentes et al. explain, "The design concern for including collaboration and relevance is to provide a social learning context in which students can work productively with each other and internalize their own individual learning. Similarly, student motivation can be ensured by allowing some learner control in the design. Finally, adequate technological preparation empowers students to successfully complete the tasks associated with computer conferencing (1997, p. 186).

Cross-cultural Communication

While the six design considerations were tested with university students in the US, they may also be appropriate for cross-cultural partnerships. Collis and Remmers (1997) report that at least four issues are related to effective cross-cultural Web design: communication and interaction; language; content; and representation form. These four issues, when interfaced with the six design considerations, may hold the key to successful cross-cultural partnerships. First, communication and interaction are easily misinterpreted across cultures. For example, in cross-cultural contexts more communication and interaction are not necessarily better than less, and well-structured communication, moderated by an individual with standing, may be preferable for wider audiences. In the TAMU-UP partnership, the two instructors could moderate the discussions themselves. Second, because language includes verbal and non-verbal communication, those developing cross-cultural sites must be sensitive to cultural differences in communication styles. Issues pertaining to selection of language(s), translation by multilingual people, and communication protocols all present potential problems. Combining nationalities in project-based learning, such as building Web sites together in teams, could enhance the learning environment. Perhaps both TAMU and UP instructors could incorporate project-based learning projects. Third, partnership leaders must choose course content where the cross-cultural aspects are of minimal relevance or are integral to the content. Like the previous example, developing a Web site in multi-cultural teams may provide a more level playing field. Fourth, representation form needs to be considered in relation to the use of visualizations to replace or supplement text. Visual resources, while becoming more widely used due to multimedia advances, are subject to potential cross-cultural misinterpretation. For instance, only the UP students had access to multimedia in developing their Web biographies; if all participants were able to be creative, the bios would seem less one-sided.

Conclusion

This investigation was based on TAMU students' conceptions of educational technology and their explanations for the failed partnership. The investigation led to the verification of two existing models that explicate key design and cross-cultural considerations for use in cross-classroom and international environments. The first model provides six design considerations: grading system, grouping, collaboration, relevance, learner control, and technological preparation (Cifuentes et al., 1997). The second model provides four cross-cultural considerations: communication and interaction; language; content; and representation form (Collis & Remmers, 1997). Determining the delicate balance between and among these factors, particularly in cross-cultural settings, will pave the way for identifying key pedagogical techniques in making meaning. This study demonstrates the power of networking learners from across the world to learn about and from the perspectives of each other. A TAMU student summed up the experience by acknowledging that "instructional technology is world-wide, not just here in America. We have become a global society and every country is facing similar technological issues" (T7s).

Abstract: Multimedia enables novel ways of representing information, most strikingly as animations, but we lack good detailed accounts of its value for learning. The main study reported here investigates the value of animation for students aged thirteen and fourteen, learning the principles of cardiac circulation. The study compared the effects of media type, paper-based diagram versus computer-based animation, and of design of the learning task, structured versus open, in a 2 x 2 design. Learning was measured by completion of a diagram of blood flow through the heart. Statistical analysis showed a significant overall effect of task design but not of media type. Further analysis, however, showed that the animation produced distinctive kinds of errors and a second study looked in more detail at the effects of working with an animation. Results suggest it has the effect of making learners over-confident but can ultimately provide some benefits over static formats.

Introduction

The arrival of multimedia provides new ways of representing information through different media formats, such as, text, audio, graphics. Advances in technology have enabled diagrammatic representation in alternative forms, such as animation. Multimedia also provides the opportunity for innovative ways of interacting with information, not available with traditional media formats. A pervasive assumption is that the more complex and varied the technology the better the interaction and the better the learning. Large et. al. (1994) claims "It is frequently claimed by... producers (and emphasised by reviewers) that multimedia capabilities enhance educational value" (p.528). However, there is no body of empirical evidence that this assumption is generally valid.

Multimedia can be seen as a particular form of external representation, such as diagrams, which supports external cognition (Zhang and Norman 1994). Diagrams can be used to convey "whole processes and structures, often at great levels of complexity" (Winn 1987, p.153), and may reduce cognitive processing, as many important aspects for comprehension are perceptually available in the diagram and do not need to be worked out (Larkin and Simon 1987). Diagrams should, therefore, facilitate understanding, as information is more explicit and requires less inferencing. It has also been noted that different representational formats of the same structure "can activate completely different processes" (Zhang and Norman 1994 p.118). Different processes in turn may result in different conceptual understanding. Thus, the representational format may be critical in the way comprehension is actualised.

Advances in graphical technology provide the facility for dynamic processes to be represented in animated as well as static form, with the assumption that the ability of an animation to show motion more explicitly should be beneficial for learning. However, research investigating both animated and static diagrams, shows no comprehensive evidence of improved understanding, suggesting that provision of a moving image does not necessarily facilitate overall conceptual understanding. Several researchers have postulated the complexities of processing dynamic illustration and multimedia (e.g. Kaiser et. al. 1992, Hoogeveen 1997, Large et. al. 1994, Stenning 1998). This research suggests that animation may be problematic for comprehension for several reasons: use of animation on diagrams results in an unmanageable possible increase of perceptually available information, especially where multidimensional dynamics are involved (e.g. Kaiser et al 1992); use of multimedia representations can result in cognitive /memory overload due to too much information (Kaiser et.al. 1992), due to problems in having to integrate multiple representations not always simultaneously available on the screen (Rogers and Scaife 1997, Hoogeveen 1997). Interestingly, Kaiser et al. (1992) found that where only one dimension of the dynamic information was present then animation facilitated accurate observation. This suggests that 'parsing' of dynamic events is important in facilitating correct dynamical judgement.

To investigate the cognitive value of graphical representations this study uses the 'Cognitive Interactivity' framework developed by Scaife and Rogers (1996). This emphasises the interplay between internal and external representations on cognition (i) how new information is integrated with existing knowledge and re-represented and (ii) the identification of the cognitive benefits and costs of particular forms of representations identifying the properties of external representations in terms of their computational offloading - the ways in which different forms constrain the amount of cognitive effort required to solve informationally equivalent problems. An example is the way that different graphical forms of representations of the same information will limit the kind of inferences that are likely to be made, thus guiding thinking towards the concept to be acquired.

Study 1

The aim of this study was to investigate pupil learning from diagrams using either a static or animated format. Diagrammatic representation of blood flow through the heart was used in both CD ROM and paper format, to compare animated with static representation of the concept. As CD ROM presentation allows pupils more freedom in exploring information, whereas formal teaching situations use specific task questions, two different forms of task presentation were used. In the open task pupils were asked to use the diagram to find out: how the blood flows in through and out of the heart; about blood that is rich in oxygen, and blood that has less oxygen and about the different chambers of the heart, and structured. In the structured task pupils were given a worksheet with specific aspects for them to investigate designed collaboratively with a teacher. Thus, the effect of different formats of the same graphical representation and different task presentations on conceptual understanding of a dynamic process were investigated. Participants were taken from two community colleges and one comprehensive school in Sussex. No pupils had completed formal teaching on cardiac circulation.

Method

One hundred and twelve pupils aged thirteen and fourteen, from two Sussex community colleges participated in the study. Fifty three were male (mean age = 13 years 10 months; sd=3.2 months), and 59 were female (mean age = 13 years 11 months; sd=3.6 months). The independent variables were media format (CD ROM or static) and task type (open or structured). The dependent variable was the test score. A pilot study was undertaken to ensure that information was appropriate and to formulate task instructions and the test. In the main study half of the participants worked with information using the computer (animated) the other half worked with the paper (static) format. Half of each of these groups worked from the 'open' task, the other half used the structured worksheet. All participants worked for fifteen minutes on their allocated task, followed immediately by the test. Time allocation was decided as a combination of ensuring adequate time for collecting necessary information and restrictions from school curriculum activities. The teacher allocated pupils who worked well together into pairs.

Animated condition: The 'heart' section of 'What's the Secret?' CD ROM from 3M Learning Software was used. The programme covered varying aspects about the heart, including animated video presentation of blood flow. Information needed for overall understanding was found in separate parts of the programme. Pupils were guided to the relevant areas prior to beginning their own investigations, due to time restrictions, and pupils could ask for guidance during the task if they were unable to find the information they needed. Participants worked in pairs for fifteen minutes, prior to completing individual assessments.

Static condition: Three sequential static colour printed diagrams were taken from the heart section of 'What's the Secret' CD ROM. This design ensured coverage of information was apparently equivalent to the CD

IMAGE NOT AVAILABLE

Figure 1: Example of test diagram.

ROM information needed to complete the test. One class was given the 'open' task, the other used the structured worksheet. Participants worked with the information in pairs for fifteen minutes, prior to completing individual assessments.

Post test: This consisted of a black and white version of the diagram taken from the CD ROM. Pupils had to complete the diagram within five minutes, the task being to use arrows to show where the blood enters, flows through, and leaves the heart, using conventional colouration, a blue pen for deoxygenated blood and a red pen for oxygenated blood. Pupils were also required to put the following eight labels - 'to body', 'from body', 'to lungs', 'from lungs', 'right atrium', 'left atrium', 'right ventricle', 'left ventricle' - in the appropriate places (see fig1). Use of information and notes was not permitted for the test.

Results

Scoring Method

Four different aspects of the diagram, relating appropriately to the task and the structured work sheet, were chosen for analysis. One point was allocated for each of the following; (i) oxygenated and deoxygenated blood represented in separate sides of the heart; (ii) depicting different types of blood in the correct sides; (iii) correct labelling using all eight labels; (iv) correct depiction of direction of blood flow using arrows, or from labelling if arrows were not used. Subjects could therefore receive a score from 0 to 4. An interobserver reliability score of 95% was achieved.

The data were analysed to determine whether media presentation or task type affected learning about blood flow through the heart, and to determine the kinds of inferences made from the diagrams. The data are presented in three sections: analyses of the effects of both variables on the overall test score; analyses of the effects of variables on selected areas of the test from which scores were obtained; and analyses of errors made.

1. Analysis of both variables on the overall test score. A two way independent analysis of variance (ANOVA) was performed on the test scores. No significant main effect of media format was found. There was a significant main effect of task type ($F=5.08$; df =1,1; $p<0.02$), Scheffe ($p< 0.0215$); those using a structured worksheet performed significantly better than those using an open task, regardless of media presentation. No interaction was found between the two variables.

2. Analysis of the effects of variables on selected areas of the test A series of two-tailed chi-square analyses were performed separately on the four selected parts of the test to determine whether media presentation or task type affected performance in particular areas of the test. No significant differences were shown in any section: Blood in separate sides, chi-square 0.017, d.f = 1, not significant; Blood in correct sides, chi-square = 0.013, d.f = 1, not significant; Labels, chi-square = 0.505, d.f = 1, not significant; Directionality, chi-square = 0.108, d.f = 1, not significant.

3. Analysis of errors made. Despite the absence of overall significant differences, an inspection of individual scores showed that pupils made more errors with labelling and direction of blood flow. Analysis on these aspects revealed differences in errors of interpretation of blood flow. The two most noteworthy errors were; showing blood to flow into the heart deoxygenated but to flow out oxygenated or vice versa; and perceiving the blood to enter the heart through the ventricles and leave via the atria. A chi-square was performed to determine whether pupil interpretations were affected by the two independent variables, and was found to be significant for 'in deoxygenated/out oxygenated' (chi-square = 6.00; d.f = 1; Fisher exact $p<0.0222$), and approaching significance for 'blood entry through ventricles' (chi-square = 4.03; d.f = 1; Fisher exact $p<0.0608$).

Discussion

The results showed no significant difference in overall test performance between computer and paper diagrams. However, significant differences of task type were evident. As diagrams contain large amounts of information in one representation the learner must decide which aspects are important and in which order to 'read' information. Sequencing the information may reduce confusion and enable focus of attention on relevant aspects. The worksheet may have provided this by guiding pupils to specifically focus on smaller components of information and to order salient related pieces of information.

Although analysis of accurate depiction of each of the four chosen aspects showed no significant differences, pupils in all conditions made most errors with blood flow and labelling. This suggests that these concepts were less clear from the diagrams or were more conceptually complex to grasp. Analysis of these aspects in terms of errors made showed significant differences across conditions. Representation of blood flowing into the heart oxygenated and out deoxygenated, or vice versa was more prevalent in the animated condition. This seems to attribute to the heart a similar functional role as the lungs. Depiction of blood flowing in via the ventricles and out via the atria was predominant in the static condition.

These findings may be explained by aspects of graphical representation, in particular re-representation and computational offloading (Scaife and Rogers 1996). Re-representation: the results suggest that different representations not only influence whether problem solving is easier or more difficult, but also generate different understanding, confirming that different representational formats of a common structure "can activate completely different processes" (Zhang and Norman 1994, p.118). In this study the animated version shows simultaneous movement of all aspects of blood flow. Multidimensional dynamics are not sequenced into separate dynamical processes (as advocated by Kaiser et. al. 1992), and result in a confused presentation of movement. Thus, 'direction' could be misconstrued as blood flowing in one colour and out another colour, resulting in the confusion of oxygenated in, deoxygenated out. The static diagram did not explicitly show direction of blood flow, which had to be inferred from the labels (fig.1). Without attendance to these labels direction could also be misconstrued.

Computational offloading; overall, improved understanding of the circulation in the heart was not apparent from the use of animation, supporting evidence that multidimensional problems are not aided by animation (Kaiser et. al. 1992). Too much movement of different parts and different types of blood made it difficult to see where each element was going and what each part was doing. Pupils made comments such as 'stop moving' and used the diagram in stationary format to work out the blood flow. Although use of animation may be assumed to increase perceptually available information thus reducing cognitive processing, cognitive effort and 'working out' of dynamics may be reduced to such a degree that learning is ineffectual.

Although animation may be more explicit "our perceptual appreciations do not spontaneously form the basis of our conceptual understanding of dynamics" (Kaiser et. al. 1992, p.686). Anderson (1995) proposes that conceptual knowledge is based on the meaning of a representation. Errors in pupil learning suggest that comprehension of the function of the heart or reasoning behind the blood flow was lacking. This information was not explicit in the information in either presentation format, therefore the meaning of the representation was not evident. If 'meaning' is important in overall conceptual understanding then awareness of the rationale behind the concept may constrain certain aspects of the process. Knowing the function of the heart, or each part of the heart, would serve to constrain the inferences or information gleaned from the diagram. For example, if the function of the ventricles to 'pump' blood out of the heart is made explicit, then this constrains the way that the blood is likely to flow, consequently affecting diagram interpretation. The context and function of a represented structure may critically influence the effectiveness of a graphical representation. Not only may it be important to investigate the external graphical constraints (Scaife and Rogers 1996) of a representation, but also the internal cognitive constraints.

These aspects confirm cited complexities of animation and multimedia. Stenning (1998) suggests that such complexity may be a result of the following characteristics of animation; i) evanescence, the problem of memory load is enhanced by the 'transient form' of animation, which means that all sequences of movement need to be held in memory to integrate with new pieces of information to understand the process; ii) control, the evanescent form means that learners are unable reaccess pieces of information as they are no longer perceptually available. Learners therefore have no control over what information is viewed, or for how long, as information is continuously passing by. Large et al (1994) proposes that "animation improves performance when used as an interactive dynamic, continuously changing *depending on subject input*" (p. 527, emphasis added); iii) expressiveness; Animation demands a more expressive representation, as all aspects of a process must be shown simultaneously, making focus on one aspect difficult. So: how do pupils work with animated and static representations. Do these properties of animation complicate learning? Do static diagrams give clearer understanding?

Study 2

Study 1 demonstrated that different representational formats of the same process result in different understanding, and suggests that learning a dynamic concept is not necessarily facilitated by animation alone, comprehension being dependent on other factors. Study 2 set out to examine more specifically the differences in ways that pupils worked with animation and static diagrams of blood flow, which parts they found hard or easy to understand, and investigate cited claims about animation.

Method

Twenty two pupils aged 13 and 14 years (mean age = 14 years 1 month) participated in the study. Thirteen were male and nine female. This study used verbal protocols of pupils working in pairs (as allocated by the teacher) either with a computer presented animated diagram or with a static paper diagram. All participants worked with the researcher for approximately half an hour on their allocated information, but those using the static diagram were also given an opportunity to briefly work with the animated version, to investigate any further information. All sessions with pupils were video-recorded.

Animated condition: The same CD ROM programme was used as in study 1, but pupils worked only with the animated diagram. Text information was obscured and introduced only if pupils found it too difficult to retrieve information from the diagram alone. Pupils interacted with the programme only by clicking to view the animation again.

Static paper condition: This consisted of a single diagram from study 1, initially without accompanying text. Pupils were provided with pens to make notes on the information if they chose. One of each pair was given a few minutes to study the diagram alone. Time allowed was dependent on the individual pupil, but generally did not exceed five minutes. Pupil 1 was then required to explain to pupil 2 what the diagram was showing. The interview proceeded differently with each pair according to the information relayed back from the pupils. Pupils participated in discussions between themselves. The researcher intervened only when pupils were unable to glean any more information, by asking open questions or more specific questions depending on pupil progress.

Results and Discussion

Preliminary analysis confirms previous caution that animation, can be, as in this case, too complex - being too fast, lacking in learner control, and impeding attention focus, and suggests that animation alone may be insufficient to aid comprehensive learning of a dynamic process. Animation appeared to generate artificially high confidence levels, increasing complexity and preventing learners from paying appropriate attention to the information. For example, children refused the opportunity to view the animation more than once despite evidence of miscomprehension. This suggests that animation provides inappropriate computational offloading precluding the possibility of effective learning, by giving the learner false certainty of gained knowledge. Only when learners had to explain the process or were asked specific questions, were they aware of their lack of understanding. Externalisation of knowledge may be an important part of the learning process (Chi 1998), with diagrammatic learning as well as textual. Only one pupil was able to give a full description of blood flow after initial viewing. Two pairs made inaccurate interpretations of flow, perceiving blood flowing in one colour but flowing out the other. This suggests that they perceived oxygen exchange taking place inside the heart. Moreover, these pupils stated that the function of the heart was to 'clean the blood' i.e. to oxygenate the blood. This equates with errors found in study 1, also suggesting that meaning and interpretation of a representation may be related.

Inability to focus attention was apparent when pupils were asked questions about specific aspects. For example, all pupils primarily focused on blood flow. After one more viewing four of the pairs noticed the heart contracting. No pupils spontaneously noticed valve action and had to be specifically directed to this component. Even then three pairs needed to watch the animation twice more to procure appropriate information. Pupils themselves expressed difficulty with focusing, suggesting that directing attention to pertinent pieces of information is important. With each viewing of the animation pupils were able to explain blood flow in more detail, and combine this information with contraction and valve action. Thus, they appear to take in small amounts of information at one time, gradually combining their knowledge with previous pieces of information, which highlights the importance of parsing or sequencing knowledge acquisition.

Despite some disadvantages, animation may provide benefits over use of static diagrams alone. When attention was focused and pupils were directed, animation imparted more information about the dynamics of the system than pupils could obtain from a static diagram, for example, they could construct clearer models about how the valves worked and how the heart 'pumped'. However, in both of these studies interaction with information was severely limited. Future research is continuing to investigate the effects of different levels of interaction with such diagrams on learning, for example, slowing down the animation, stopping facilities, focusing attention on salient aspects of information in an appropriate order, the effect of construction and simulation on comprehension of such a system. This research will also investigate pertinent aspects of learning, such as the effects of externalisation by interacting with information.

Abstract: In this paper, we describe our efforts to introduce desktop videoconferencing into schools. Our particular project focus is the support of distributed collaborative learning between K-12 science classrooms. We outline an educational argument for the use of videoconferencing and go on to present a case study of the educational videoconferencing experiences in our project. We particularly identify and describe the kinds of technical difficulties that can be encountered and the way we overcame most of these problems. Once the students began to use the technology meaningfully to support inter-school collaborative learning a whole host of interesting educational, organizational and other issues began to emerge. We highlight the most important of these issues. Finally, we consider some of the issues influencing teacher acceptance of videoconferencing.

Introductio

We consider K-12 education to be an important but largely unexplored area for the application of collaborative technology. Videoconferencing has been around for over three decades but in that time it has enjoyed little commercial success or widespread acceptance. In this paper, we report on our efforts to introduce low-cost Internet-based desktop videoconferencing (DVC) into K-12 science classrooms as a basis for Computer Supported Collaborative Learning (CSCL). Desktop videoconferencing does *not* use specially equipped rooms or studios to facilitate telelectures; it uses the desktop personal computer as the basis for synchronous multimedia communication with remote others. There has been little published research into the introduction, use, and acceptance of DVC to support distributed collaborative learning in and between K-12 classrooms. Most research in the general area of educational videoconferencing has concentrated on distance education (usually at university level). We make a clear distinction between CSCL and distance education. Whereas, CSCL emphasizes supporting peer interaction, distance education is more concerned with supporting instructor-student interaction. CSCL is a relatively new area, and those working in this area are still involved in the process of defining its boundaries (Bannon 1995). It includes collaborative learning *through* a computer, *around* a computer, and even *with* a computer. Our project focus, and the focus of this paper, is on collaborative learning through networked-computers, but because most classroom computers have multiple users, there is usually also an element of collaboration around a computer involved.

The Educational Value of Videoconferencing

We believe there are sound educational reasons for incorporating desktop videoconferencing into everyday classroom activities. Over the last decade or so, there has been a growing awareness of the link between learning and context. Learning is now widely seen as inherently social and taking place within a community of learners (Brown & Campione 1996). Individual cognitive development is largely shaped and determined by the characteristics and potential of the various communities of which one is a member and by the role or identity one assumes within these communities. Unfortunately, the kinds of mental activities encouraged, developed, and valued in school communities appear to be quite different from those valued outside of school (Resnick 1987). If we consider schools as communities of practice, the primary practice appears to be schooling (i.e. activities and skills that only have meaning within schools). Cognition outside of schools is typically socially distributed, linked closely to tool manipulation, situation specific, and involves contextualized reasoning or reflection in action. In contrast, school-developed knowledge and skills are rarely capable of being meaningfully applied in other contexts. In other words, school learning is often inauthentic.

Communication technology and associated activities afford the opportunity to "virtually" extend school-based communities of learning (Eales & Byrd 1997). Authentic activities are often collaborative and children benefit when their learning involves meaningful interaction with their peers. Learning can also be enhanced when children engage in learning activities with students of other ages. With younger children, they reinforce their own learning through having to articulate and demonstrate their knowledge, while with older children, they receive assistance from a more advanced learner's perspective. School-based educational activities can also be stimulated and enhanced by contact with domain experts from outside the school system, for example, scientists, mathematicians, or writers. These representatives of real-world communities of practice not only provide expert advice, they also act as role models and guides. Generally, "outsiders", experts, local community members, or parents can be a source of authentic influence on school practices, which can help to develop more meaningful and robust cognitive abilities among students.

Various technologies, such as the World Wide Web, e-mail, and interactive chat can contribute to extending learning communities. But videoconferencing, particularly in its support of social presence (Short et al 1976) and mutual knowledge (Krauss & Fussell 1990), may be a uniquely suited technology for extending the learning boundaries of the classroom. Daly-Jones et al. (1998) found that when more than one person is at each end of a conference, video makes a significant difference to the fluency of interaction and awareness of remote partners. However, the effective use of videoconferencing in authentic collaborative learning situations still remains a largely unexplored area. Our project seeks to contribute to the development of understanding in this area.

Early Experiences with Videoconferencing

The context for our investigation is a large interdisciplinary project group from Virginia Tech and the Montgomery County Public Schools (Virginia) supported by a major award from the U. S. National Science Foundation. The *Learning in Networked Communities* (LiNC) project seeks to leverage the network infrastructure brought to the County by the *Blacksburg Electronic Village* (BEV) (Carroll & Rosson 1996). A recent report (Elswick 1998) describes Blacksburg as "America's most wired town", with 60% of residents and 70% of businesses currently on-line. As part of the infrastructure support for the BEV, all the schools in the county are connected to the Internet by T1 ethernet lines (capable of transmitting data at around 1.5 million bps).

Our particular interest is the development of network support for middle and high school science education with a special emphasis on collaborative learning. Apart from our interest in educational videoconferencing we have also undertaken extensive research into the participatory design of educational software and the development of Java-based tools for collaborative learning. The project members include four science teachers from four different schools, two high schools and two middle schools. One of the high schools and one of the middle schools are together on the same campus in a rural part of the county. The other two schools are in the Town of Blacksburg and are approximately one mile (1.6 km) apart. The distance between the rural and the town schools is approximately 12 miles (19 km). DVC has been used to support a variety of different interactions, including *peer interactions* between students at different middle schools, *cross-age interactions* between middle school students and high or elementary school students, and *expert or mentor interactions* between middle school students and non-teacher adult mentors.

Our videoconferencing experiences in the LiNC project can be divided into two quite clearly defined phases. Our early experiences (phase 1), although they demonstrated a potential interest from teachers and students were dogged by technical problems. Our later experiences (phase 2) have demonstrated that most of the technical problems can be solved allowing us to begin to study the educational, organizational and other implications of videoconferencing in the classroom.

Our early experiences using videoconferencing in the classroom demonstrated the potential of the technology but also highlighted a number of significant problems. On the one hand, students were highly motivated towards videoconferencing and the teachers felt that it was a positive educational experience, while on the other hand, technical problems abounded and clearly interfered with the quality of the educational experience. These conflicting reactions are summed up by the comments from one middle school student:

> "Videoconferencing is a lot of fun. It's almost like sitting in the same room with the person that you're talking to. But I do think that it could be better. Not only the computer, but things like volume or the background noise, the speed at which the sight and sound come, and the amount of time we were on the computer."

Reliability Problems - Our early videoconferencing sessions between students at different schools often involved a number of system crashes. We had tested the hardware, software, and educational activities beforehand in the classrooms, but a condition that only occurred during actual school classes caused the computers to crash. After every crash, the computers would have to be "hard-rebooted", that is, turned off and then turned on again. Quite apart from the obvious loss of time (around 5 minutes) involved in every crash and reconnection, such incidents severely disrupted the flow of communication and concentration of the students. On this particular system, the first indication of an impending crash was the freezing of the received video image, the audio connection would be lost a short time afterwards. This allowed just enough time for the students to transmit a distress message usually along the lines of "your faces are frozen". Not surprisingly the students' reactions to system breakdowns were disappointment and disillusionment. During one of the breaks in communication caused by a crash, one high school student said to another, *"I think it would be easier to go over there in person."*

Audio Problems - Audio quality was a constant problem. Quality was variable but usually poor. Sometimes a system crash resulted in better audio quality when reconnection was achieved. The particular videoconferencing system we were using lacked any way of adjusting the audio levels. Getting closer to the speakers and microphone (as well as shouting) became the only method of varying the levels of sent or received audio. Audio levels were such a constant problem that many of the groups assigned a "designated listener" to press their ear against one of the computer speakers and then relay the incoming audio to the other students in the group. Another response to poor audio quality was to move communication to the chat (text) channel. Unfortunately, classrooms appear to be inherently noisy places often with poor acoustic properties. Unlike audio quality, the quality of the video did not seem to be an important issue for the students.

The "Do You See What I See" (DYSWIS) Problem - Activities between students using videoconferencing often involve coordinated use of applications running on the two computers. In the particular system we were using there was no way for one group of students to see or control what was on the other group's computer screen. This leads to a common situation where one group has to describe to the other group just what they should have on their screen. In reply the other group then has to try to describe what they actually have on their screen. Students were often not familiar with the names of programs or the terms for screen features (e.g., icon, dialog box). In such circumstances a common reaction is to pick up the camera and point it at the screen.

Camera Framing Problems - The standard desktop videoconference cameras are naturally built for office use. If a camera is placed on the top of the computer monitor, it captures the image of a seated user quite well. However, in the classroom, computers often have two, three, or more users. Students, either by design or accident, start to disappear from the transmitted video image as the communication session progresses. Sometimes, all that can be seen of a group of students is perhaps an ear and an elbow.

Overcoming the Technical Problems

Our early experiences using desktop videoconferencing in the classroom were often depressing and frustrating for students, teachers, and researchers alike. Clearly, without project motivation there was little likelihood of the teachers incorporating videoconferencing into their normal educational practices. However, these early experiences did allow us to clearly identify the principal practical problems related to using this technology in classrooms. Before we began the second phase of videoconferencing we tested a number of different videoconferencing programs, cameras, video capture cards, and microphones in different settings. Each of the four classrooms in the project is now equipped with 5 computers (200Mhz Pentium PC's). Three of the computers in each classroom are equipped for desktop videoconferencing. This involves the fitting of a video capture card and the provision of a camera, a microphone, and videoconferencing software (Microsoft NetMeeting 2.1). We also have computers at the university equipped for videoconferencing. These can be used for communication between experts or mentors at the university and the classrooms, or for project personnel to communicate with teachers. Most of our videoconferencing has been point-to-point, but we are currently experimenting with multi-point conferences in some instances.

The audio quality and audio control in our second phase DVC system has been extremely good. However, classrooms can still be noisy places and background noise is still a problem. To address this problem we have provided inexpensive unidirectional microphones with a very short effective pick-up range. The disadvantages of these microphones are that they have to be held in the hand close to the mouth. This reduces the ability for someone using the microphone to control the computer with two hands. It also means that whoever holds the microphone can monopolize the communication. On the other hand these small inexpensive microphones are remarkably effective at cutting out background noise.

The "Do You See What I See" problem has also been solved by the DVC software we are now using. Students can now share any application with other students, for example, show them web pages or word processing documents. Students can also collaborate while using an application, which means that control can pass back and forth between the collaborating parties. Students also use the collaborative whiteboard and text chat, and pass information between schools by point-to-point file transfer.

The only technical problem that still remains an issue is camera framing. While most of the groups have 3 or 4 members the number of students appearing in the video window is typically around 1.25. Ideally we would like a wide-angle camera that can still sit on the top of the monitor (the only logical place to position the camera). We have experimented with the use of the video image from our wide-angle video cameras used for data capture as feed into the DVC transmitted video image. This tends not to provide very much detail and can not of course be considered a permanent solution. We continue to experiment with different cameras and camera positions in an attempt to improve this situation. We have also experimented with a hand-held camera for close-ups of student models and other physical objects. This involves an additional camera on a long cable connected to the computer via a switch-box, allowing students to switch between the monitor-mounted camera and the hand-held camera.

Computer systems used in schools have to be more than just reliable; they need to be robust to withstand intentional and unintentional misuse by students. The revised hardware-software combination used for videoconferencing in phase 2 of the LiNC project has proved to be remarkably reliable and robust and has solved most of the previous technical problems. System crashes are now extremely rare. Students now quite happily use DVC with little support or intervention from project personnel, and confidence in DVC technology has even developed among the teachers again.

Beyond the Technical Problems

Our initial phase 1 videoconferencing experiences in the project forced us to focus on the various technical problems. In phase 2 of the project the technology has now become largely transparent for the students allowing them to concentrate on their education activities. Below a certain technical threshold the student discourse appeared to be mainly concerned with the technology itself, but above this threshold users concentrated on the tasks in hand. The significant reduction in technical problems has allowed us to begin to focus on the many interesting educational, organizational and other issues now emerging from the project. We highlight some of the most immediately apparent issues in this section.

Around the same time that we changed the videoconferencing technology, the teachers involved in the project initiated a change in educational direction. Previously, our use of technology in the classroom had primarily focused on one-off "experimental" situations occurring every few months. The teachers felt that an ongoing collaborative project-based approach would provide a more meaningful basis for considering the introduction of videoconferencing and other network-based tools into the classrooms.

Educational Issues

Student motivation is an important factor in education. Most students involved in our project show a considerable interest in videoconferencing in the classroom. However, some students show an active interest in videoconferencing (they want to start communicating as soon as possible) whereas other students are only passively interested (they like to observe but not take part in the interaction).

Perhaps the most significant educational issue to emerge from our introduction of DVC into the classroom was that many of the most active and competent DVC users were what might be termed "average" students. The experienced teachers in the project first highlighted this characteristic of videoconferencing. These students are often hampered in school activities by poor literacy skills. For example, one middle school student when asked which method of communication he preferred replied: *"The video [DVC], because you actually get a chance to see and talk to the person rather than spending a lot of time typing."* Videoconferencing introduces a new form of communication into the classroom which requires new skills. Many of those that demonstrated competency in this area were students who normally do not get the opportunity to excel in the classroom. Student motivation developed during videoconferencing also appeared to be transferred to areas where literacy skills are more central. For example, students coordinated videoconferencing sessions via e-mail messages and presented their final project reports in the form of web pages.

Not all students are comfortable with videoconferencing. Most of our videoconferencing sessions involved middle school students. These students are around 13 years old and this can be a difficult time, particularly with regard to concerns about self-image. One feels that, ideally, many students would like to be able to see and hear the students at the other end of the connection without being seen or heard themselves. We observed one particular videoconferencing session between two middle school groups where self-consciousness was very much in evidence. This was the first time this group had experienced videoconferencing. In a session that lasted approximately 20 minutes, the monitor-mounted camera was moved 19 times by the students. The camera view was usually moved away from the person doing the moving. Students also made comments, such as "get the camera away from me". Students in this group also showed audio self-consciousness. The microphone changed hands at least 27 times during this session. It was also offered to other students on many more occasions but refused. Side comments during the session included: "What? Someone else speak to them", "I don't understand Southern accents", and "I don't want it [the microphone] give it to her". In addition, we also observed many examples of nervous behavior, including adjusting hair, covering the mouth, and giggling. On other occasions we have observed videoconferences where students move communication to the text chat channel apparently to deliberately avoid talking into the microphone. One of the most common ways that groups seem to deal with this self consciousness issue is to designate one student to act as spokesperson for the group. The whole issue of student attraction and fear towards videoconferencing needs further investigation.

Organizational Issues

We have found that the educational value of videoconferencing is highly dependent on the suitability of the collaborators and the underlying basis for the collaboration. You cannot just connect people together and expect them to meaningfully collaborate. One of our student projects involved a group of students at one school building the arm of a working robot and another group at a different school building the mobile base. Clearly such an activity requires that the two groups actively collaborate. The development of such *collaboration-dependent activities* can have a positive influence on the perceived educational value of DVC.

Three obvious coordination problems are immediately apparent:

1. Teachers need to establish contact with remote others (teachers or experts) who can organize/provide meaningful educational interactions for their students. These contacts not only have to be educationally compatible, they also need compatible videoconferencing facilities.
2. Assuming teachers have been able to make contact with suitable others, they then have to negotiate a basis or a context for the use of videoconferencing in their respective educational practices. This is no simple process. Teachers, even those teaching the same subject to the same age students, have very different teaching styles and related practices.
3. Time is very important in middle and high schools. Classes change according to the clock. We have found that even in the same county, schools may have different time slots for the classes throughout the day. Trying to organize a time when groups from two different locations can take part in synchronous communication can be extremely difficult.

In the LiNC project, these coordination issues have been less apparent because the project itself has provided a basis and a structure for coordination between the various teachers.

Does DVC have a Future in K-12 Education?

We see desktop videoconferencing as a valuable educational tool particularly suitable for supporting distributed collaborative learning between schools and between schools and the community. However, teachers have a considerable amount of autonomy in their own classrooms and any kind of significant educational reform, including the widespread acceptance of new technology, is notoriously difficult. Our studies suggest that desktop videoconferencing supports distributed collaborative learning surprisingly well. Even though the technology was presumably developed with office environments in mind. However, the suitability of the technology and the high motivation levels amongst students does not guarantee that DVC will be widely accepted in schools. We have described the possible technical problems in some detail and have gone on to suggest some of the organizational issues that also need to be surmounted. Our experiences suggest that desktop videoconferencing can make a significant and special contribution to learning in schools, however, there are many factors that may hinder the widespread acceptance of this technology.

National Science Foundation, under the Networking Infrastructure for Education program. We wish to particularly thank the other members of the project.

Customizing the Web

Two Tools for Individual and Collaborative Use of Hypermedia Course Material

Abstract: It seems desirable that learners do not only passively browse through course material, but are also able to actively work with it by adding own material, annotating existing documents, creating own views of the material and exchanging documents with fellow learners. We have developed two tools that allow for such active individual and collaborative use of course material. "Semantic Spaces" allow learners to organize hypermedia documents according to their individual view while not interfering with the "real" link structure of the course material. These spaces are represented as maps and serve for orientation as well as navigation purposes. A collaborative virtual environment has been developed to allow for synchronous as well as asynchronous multi-user collaboration. Both concepts have been implemented and tested as prototypes that can be easily integrated into standard or advanced web technology. An evaluation will yield first results by the beginning of 1999.

1 Introduction

The World Wide Web has become one of the major ways to distribute course material to students. However, this material is usually only available for browsing purposes. While the original idea of hypertext allowed readers to take an active role in the creation and extension of hypertext documents (cf. Bush 1945, Nelson 1980), the World Wide Web has ignored this concept. Material presented on standard web servers is usually static in the sense that readers cannot actively work with it: Because links are embedded into the documents and are always visible to everybody, readers are not allowed to link from existing documents to material that they feel is important for the learning context, nor can they annotate existing documents. Also, restructuring of existing material is only possible in very simple ways (by bookmarking) or by writing own documents that are external to the server. While with advanced technologies like, e.g., Hyperwave (cf. Maurer 1996) some of these restrictions have been removed, the problem of allowing the learner to create their own view to existing material has not been solved.

We believe this problem to be closely related to navigation and orientation problems in hypertexts that have often been reported (see, e.g., Conklin 1987) and are of particular importance in learning contexts where learners have to construct knowledge from large bodies of material presented to them. Semantic Spaces allow users to create their own maps of the hypermedia material, thus documenting their individual understanding of the information space. Objects recorded on the map can be connected to the "real" objects of the hypermedia system. When users move through the material, their current position can be visualized in the Semantic Space. First experiments with mock-ups suggest that users get a better overview of the hypermedia material and have a better sense of orientation. A tool that allows creating, modifying and sharing of Semantic Spaces has been implemented as a prototype and is currently being tested. An evaluation and further developments are planned for 1999.

While this tool may help learners to work with hypermedia course material individually, collaboration between fellow learners is one major aspect in teaching and learning processes. When learning with hypermedia systems in a collaborative environment, students need to communicate their position and their understanding of the documents to each others in order to start a dialogue about the material provided by the system. Thus, learners should be supported in sharing perspectives on course material (cf. Wan & Johnson 1994). Norman (Norman 1994) reports that special tools are needed for communicating the current position and knowledge of the structure of the material used: "Pointing out" the user's current position or sharing their knowledge with other people is impossible without shared knowledge of the structure of the system. In the project sTEAM, we have developed such a tool as a client-server application that is based on a MUD (multi-user dungeon) environment. Learners may meet in "rooms" within that system and share documents as well as discuss topics, thereby implementing asynchronous as well as synchronous cooperation facilities. A prototype is currently being evaluated.

In the next section we will shortly discuss the possibilities and problems of creating individual views on course material and cooperating with fellow learners when working with standard tools. We will also discuss features of more advanced learning environments. The following two sections will then describe the two approaches of individualization and cooperation of web based material and compare them to related work. The prototypes will be described. The last section will summarize the main results and describe the plans for further development and evaluation of the tools.

2 Working actively and collaboratively with documents

Many hypermedia systems under development today are used in education. The most promising aspects of hypermedia use are in our opinion (Keil-Slawik, Klemme & Selke 1996):

- the integration of all materials used in the learning process;
- the availability of these materials for all forms and phases of learning, without the need to use different media in different situations;
- hypermedia's capability of being a repository for all learning situations, with the option of reusing hypermedia units in different situations and contexts.

Hypermedia systems for this purpose need to accommodate large and frequently changing bodies of documents. This requires powerful tools allowing users to move through the hypermedia system, interact with it and other users, and customize it for their personal needs.

While today we see more and more courses offering material via the World Wide Web, it was already in 1993 that Ben Shneiderman coined the phrase of "education by engagement and construction" (Shneiderman 1993). He stressed the fact, that students on the one hand have to interact with the material—which means not just clicking and hopping from page to another—and on the other hand need to interact with each others. Also, in the development of the Intermedia system the developers state that "hypertext systems that support multiple users allow researchers, professors, and students to communicate and collaborate with one another within the context of a body of scholarly material" (Yankelovich et al. 1988, p. 81). This is definitely a potential of hypermedia systems, the importance of which is obvious from a constructivist viewpoint. However, we find little of that in the courses we nowadays see on the web.

This is mainly due to the fact that the World Wide Web in fact is mainly used for the mere distribution of documents. Because of the Web's and HTML's architecture, the material can only be read. Students are not able to create personal hyperlinks or organize the documents in an individual manner apart from setting bookmarks, a technique that—according to questionnaires to our students—is heavily used by learners. For security reasons, many universities do not even allow students to publish their own documents on the faculty's web server. Annotations to documents were possible with Mosaic, a browser popular in the old days of the web. However, users could only create annotations on a per-document basis in an additional file. With the Netscape and Microsoft browsers becoming more prominent, the situation became even worse since these browsers do not support annotations at all. As a consequence, the Web often serves as a printing-on-demand device for text documents. Cooperation is also only possible in a very limited way: by sending documents or links to other users.

These limited capabilities suggest the use of more advanced web servers like, e.g., Hyperwave (see Maurer 1996) that allow users to actively work with documents (cf. Brennecke, Schwolle & Selke 1997). As compared to traditional Web servers, Hyperwave offers several important advantages. The sophisticated user management and integrated management of access rights makes it possible to establish a private area for each student where they can file their own documents and create a personal view of the available documents. With Hyperwave's concept of collections different views can be created without installing real copies of documents. In combination with the integrated link management, links always point to the most recent version of a document even when the material has been revised. However, these views are still more or less lists of links. A graphical representation of the document set can either be produced with a "local map" of links (see next section) or hand-crafted clickable images that are difficult to maintain.

Hyperwave also offers limited cooperation functionality through access rights. Users can decide who is granted read or write access to their documents. Other systems coming from the CSCW area, such as Lotus Notes, offer sophisticated workflow mechanisms. However, collaboration in learning contexts is usually very different from cooperative processes in a company, as both, the formation of groups of learners and the collaboration based on documents, are rather informal. Also, groups only exist for a very short period of time and members may join or leave within very short time intervals. For this reason, the systems mentioned so far are only of limited use in collaborative learning environments. In the web, there is no relation between the documents and the people working with them: E.g., it is not possible to obtain any information about people who have read a particular document.

3 Individualization of course material: Semantic Spaces

It has been claimed that link structures in hypermedia systems map well onto users' cognitive structures (Jonassen 1986). However, this hypothesis is questioned by many experts in the field (see, e.g., Duffy & Knuth 1990). The link structure itself is based on the syntactic structure, i.e. the interrelationships defined on the document space by hyperlinks. This must not be confused with the semantic structure of the contents of hypermedia documents, i.e. the interrelationships of the concepts presented, since these are in most cases not the same (Whalley 1990, p. 63).

The insight into these structures is particular to a user and cannot easily be transferred to others. Specifically non-experts need help finding out about the concepts covered in the documents and they are not necessarily interested in the form of presentation as represented in the link structure. In particular, users new to a subject have problems discovering the underlying structures and finding their way through the material. Understanding of a subject area develops gradually. Users continuously extend their models as they find more information. These models are different from the relationships explicated by nodes and links in the hypermedia material, so the students' model can be completely wrong and will (hopefully) be corrected later.

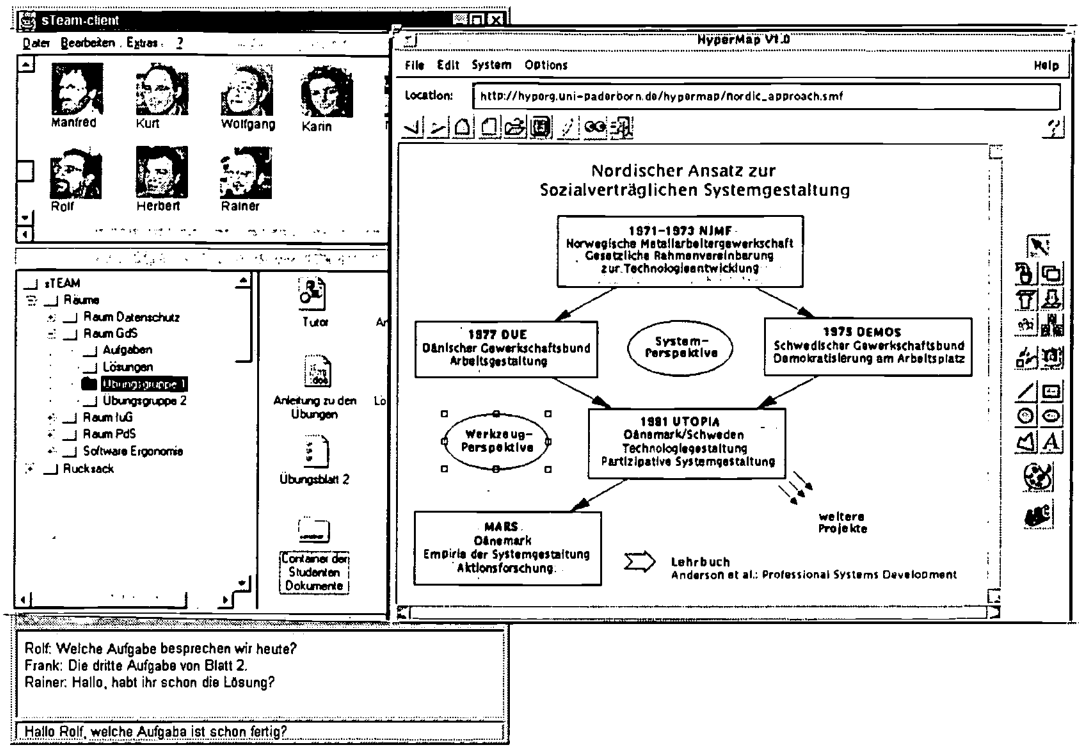
These problems of individualization and orientation are amplified in large interwoven hypermedia systems such as the World Wide Web, which span huge numbers of hosts and reference material of different contexts. In order to make efficient use of a hypermedia system, a consistent hypermedia working environment needs to be provided to the learners. It should offer tools for information selection, navigation through the system, and documenting the findings and results. Utting and Yankelovich (Utting & Yankelovich 1989) described and tested different tools such as local and global maps for solving navigational problems. However, the proposed tools proved either to be insufficient in scope or too complex to be understood and efficiently handled by the users.

Semantic Spaces may help to overcome these problems. A Semantic Space is a two- or three-dimensional map that represents the user's individual understanding of the information space. It is closely intertwined with the objects of the hypermedia systems and serves as a tool for the active exploration of hypermedia systems. As users move through the hypermedia system, they enter concepts and relationships that they think are significant into the map. The concepts displayed in a Semantic Space are thus not necessarily related to the nodes and links in the hypertext, but represent the user's current knowledge and understanding of the system. Users can therefore explicitly document their personal understanding of the part of the system they have explored.

Items and links in the Semantic Space can be created interactively by naming the concept and target document or by dragging a document icon into the map, automatically connecting the object in the Semantic Space with the documents. The interrelationships between the concepts in the Semantic Space and the documents of the "real" hypermedia system are maintained by specially labelled bi-directional hyperlinks connecting concept and document. With the help of these links, the position of the user within the hypermedia system can be visualised in the current Semantic Space when the user moves through the hypermedia system. They will be altered, moved or deleted as the process of understanding continues. A set of tools, similar to those of standard desktop environments, for grouping, moving, deleting, etc. provide for quick and direct manipulation. Additional drawing and writing tools allow for annotation and graphical markup (arrows, boxes, etc.).

By creating maps of their own, users can develop and visualize a spatial understanding of the hypermedia system. This intensifies the users' involvement and can thus foster their understanding of the overall context (Shneiderman 1993). The general layout of the map remains persistent until the users decide to change it because it no longer represents their understanding of the document space. The maps themselves are also documents within the hypermedia system. They can be inter-linked with the other documents or be referenced by other Semantic Spaces, thus creating a mesh or, if required, hierarchy of maps. Since they are persistent over time and can be shared with other users, they can be used in group learning situations to assemble and document the group's common knowledge of the information space. Furthermore, they can provide starting points for the further exploration of the system. Collaborative design of Semantic Spaces may thus foster understanding and learning in groups.

A tool for the creation and usage of Semantic Spaces has been implemented on top of the hypermedia system Hyperwave using a combination of Java and JavaScript. Users can use their standard Netscape browser to retrieve



documents from the hypermedia system. A separate map viewer communicates with the Navigator windows indicating changes in location. By selecting an element in a map the user may also cause the browser to display the corresponding document.

The concept of Semantic Spaces is described in more detail in (Klemme, Kuhnert & Selke 1998). In supporting constructive navigation in hypermedia systems, they are similar to the NESTOR system (Zeiliger 1998). Whereas in NESTOR there is an automatic generation based on the user's activities, in Semantic Spaces the users explicitly have to create their own visualization. Evaluations may show if there are significant advantages in either of the approaches. Semantic Spaces may also be compared to concept maps (Kremer 1997). However, they do not impose any rules on how to represent objects and relationships. Also, while providing an abstraction from the underlying hypermedia database, Semantic Spaces still serve as navigational and orientational means by providing location feedback.

4 Collaborative Virtual Environments: sTEAM

With the emergence of local area networks and the massive growth of the Internet, communication games on these networks, the so-called MUDs (multi user dungeons), were developed. While many of these are text-oriented, recent games of this type also support graphical user interfaces. MUDs are based on real-time communication and interaction of multiple users moving through a "virtual world" which is organized in "rooms" or "places". MUDs are based on a client-server architecture, allowing players with different computer systems to participate in these games from different places. MUDs are on the one hand multi-user capable, on the other hand authorised players, the so-called wizards, can restrict access to the game. They can grant or deny access to specific rooms to a certain group of players and can also extend the "world". In such games direct communication and interaction in real time are the main goals. Groups of players can communicate directly and influence each others in their game actions, while the communication flow is unrestricted. Since the architecture of MUDs is open, the games can be modified and adapted to new situations during the current session even while the system is running. So at any time during the game new situations can be created, with which the groups of players have to cope. A number of "serious" applications—usually called "collaborative virtual environments" (CVE)—have been developed on top of this architecture (see, e.g., Donath 1995).

Our goal was to combine the advantages of classical MUDs and Hypermedia database systems with each others, allowing users to share documents in a virtual world and to communicate with other users while working with certain documents (see Bollmeyer 1997). The system developed is called sTEAM and uses the paradigm of virtual rooms representing a document space. People can meet in virtual rooms, interchange documents and communicate with each others. The rooms can be seen as areas of interest or as given topics of a lecture. In these areas the stored objects are files, which all have some topic or subject in common. Exits connecting different rooms represent hyperlinks. The big advantage of this connecting technique is that they represent a semantic context without having to represent a planar layout of rooms that can be represented by a planar map.

Among the system's major new aspects are its abilities for easily constructing new rooms. As virtual rooms can be created by any user on-the-fly, document collections can be structured easily and personally or collaboratively by the students. For example, when students discuss different approaches to a certain topic during a tutorial or lecture on, say, user interface design, they can create a new room and meet there. They may then search for examples of different user interfaces on the web and collect these (as hyperlinks or as copies of the documents) in this new room. After they finished their work they could either leave this room and make it accessible for other students interested in the same topic, or take just a few objects to their private rooms and delete this temporarily needed room again.

Groups of students and teachers can thus build their individual and cooperative learning spaces. Hypermedia documents can be transported easily between the various rooms. Messages and attachments can readily be stored in such learning places and, most important, the learners may meet in groups within the system. The system may either be used within a scenario where students meet "in real life", using the rooms in the way described, or within a scenario where students do not meet and make use of the integrated facilities enabling them to synchronously communicate with each others. Currently, only a text-based chat tool is integrated, but audio or video connections may be implemented in the future. Thus, collaboration is enhanced through a powerful CSCW system regardless of whether people meet in the same place or work from different places.

The sTEAM system currently exists as a prototype consisting of a client written in Java and a web server implemented in the MUDs own object-oriented programming-language LPC using the Dworkins Generic Driver (DGD), a modified well-known MUD server. This system allows runtime modifications of all objects in the environment. To create their individual environment inside sTEAM, the user can employ the pre-defined objects, derive their own objects from existing ones, or create new ones by implementing them in LPC. Many different new objects may be created during a long term use of the system.

All sTEAM objects are stored on the server. Currently, all data management is covered by the sTEAM server. Using an interface that is currently under development, it will be possible to connect sTEAM to a database in the future, thus allowing the use of multimedia documents stored in that database or of hypermedia objects stored on a Hyperwave server. Thereby, sTEAM can easily be integrated into existing web environments. All objects like hypertexts, images, links, users etc. have a number of common attributes that are used to control the details about objects such as name, access rights, owner, creation date, expiration date etc. and methods. In addition, some objects have special attributes and methods such as an associated MIME-Type and a download method for documents or a method "talk to" for user objects. Users can also add their own generic attributes to objects. By default, the user object has a virtual container object, that can be seen as a "suitcase" that the user carries along. Any objects they want to take along, even exits, can be stored in this suitcase and stay there until taken out. sTEAM features a sophisticated security scheme resembling that of Hyperwave with one significant difference: User groups can be defined by any user, as they are just objects on the server which have attributes. Just as rooms, user groups can thus be created on-the-fly. So, if some team of students decides that they are a group which needs to share access rights, they create a group object.

The client deals as the interface between the user and the functionality given by the server and has to be easy-to-use and platform independent. The last requirement was the reason for its implementation in Java. In order to create an easy-to-use interface we restricted the view of the virtual environment to a simple 2d-representation. The view is made up of three areas, showing the users currently in this room, the interior of the room, i.e. the objects including exits to other rooms, and the communication area. Here, the user can type text to chat and talk or communicate in other text based ways. All of these objects, even the users, are subject to direct manipulation. E.g., you can "talk to" other users, "download" documents, or move to other rooms with just a mouse click on the respective object. More sophisticated functions including creation of new objects and file upload can be accessed by menus.

According to the view presented above we are developing sTEAM under two main aspects. As a first goal, sTEAM will serve as a research platform for studying new forms of cooperation and collaboration between students. sTEAM closes the gap between classical information and communication technology allowing the users to actively structure their document space while setting up communication channels between them. As a second aspect, the flexible design allows the fast and easy creation of special clients to study questions of human computer interaction or new forms of collaboration technology.

5 Conclusion

We have described two concepts for individual and collaborative use of hypermedia course material. Semantic Spaces allow learners to organize hypermedia documents according to their individual needs. These spaces serve as means of orientation and navigation. A collaborative virtual environment called sTEAM establishes a virtual working environment in which groups can meet to work on certain topic areas. Social contacts between students can thus be augmented by the system. Both systems have been implemented as prototypes and will consequently be evaluated. Future plans include the integration of Semantic Spaces and sTEAM to allow for an easy transition between individual and group learning processes.

Abstract: The Multibook project of the Darmstadt University of Technology builds a webbased adaptive hypermedia teaching and learning environment for multimedia and communication technology. Hereby, the demands of diverse user groups, user levels and especially of diverse learning strategies are taken into account. Besides information gained from the interaction with the user, the system uses standardized content relations and meta-information to adaptively compile a selection from the set of available information units. A subset of the meta-information represents the compiled lesson on a high level and is presented to the learner as a dynamically generated table of contents.

1. Motivation

"Imagine everything is available and tied together. Grand visions come to mind of what things will be like when 'it's all there and linked'. The thought of that great body of material calls to us, calls to us like an ocean. ...' But that ocean of universal hypertext is not enough: we want free sailing on it."[10]

So why should we restrict this demanded freedom of navigation? There are many applications where it makes sense to guide the user to a certain amount. One of these are learning environments. If the use of such a system is supposed to lead to an intersubjectively measurable learning effect, it must be guaranteed that the user has seen/learnt certain parts of information, and doesn't get completely lost on his/her way. Hence the decision where to go cannot be entirely up to the user.

The solution we are going for is to offer a special form of guided tours comparable to those of a classical hypermedia system. It's our concern to build a system, in which we can generate tours dynamically. We offer these guided tours to the user in form of tables of contents, that structures a relevant subset of the material. We see this as a suitable way to overcome the gap between a linear ordered text and free navigation.

2. Related Work

Recently, ideas from intelligent tutoring systems (ITS) and from hypermedia have been brought together opening the field of adaptive hypermedia. This synthesis responds to the specific strengths and weaknesses of both approaches. ITS [1],[4],[15] provide a high level of guidance in learning, they model and control the entire learning process in great detail. A domain model representing all facts of the field that are to be learnt, usually forms the background for a model of the learner's knowledge and knowledge acquisition. Free exploration by the learner does not play an important role in ITS, the navigation decisions are very much up to the system. As discussed in [6], most of the existing ITS systems are environments for coding and testing a specific programming language. Furthermore, users often need considerable time for learning how to use an ITS, because the development of an intuitive user interface for ITS systems seems to be a very difficult task. Hypertext and hypermedia systems exploit the nature of different media such as text, pictures, audio, video or simulations as a medium for making differentiated statements and communicating less structured knowledge. In addition, a hypermedia system offers more than predefined learning paths - by selecting different nodes in different order, the individual learners produce a multitude of paths through the material. The drawback of these systems is that the learning process cannot be controlled in a well defined way. This results in insufficient guidance. In particular when used for educational purposes, hypermedia systems are striving for a higher degree of control [7],[3]. We regard as decisive the step of adding conceptual information on top of the hypermedia chunks, being the basis for their intelligent selection and sequencing. Connecting the concepts with semantic rather than didactic relations that would already imply sequences or dependencies among the concepts [2] provides yet a higher degree of flexibility - this way, the concept space lends itself to realizing different learning strategies and goals but also to tasks like information retrieval.

The Interbook project is a well known adaptive hypermedia system, which also makes use of a concept space, called domain model [8]. Interbook supports navigation through the lesson with adaptive annotation, showing the type and the educational state ("ready to be learnt", "recommended", "not ready to be learnt") of each offered link. Interbook is based on the domain modelling approach of ELM-ART, a WWW version of ELM-PE, that is currently one of the most advanced intelligent learning environments for programming. In the online description of Interbook the term "I3-textbooks" (integrated + interactive + intelligent textbook) is suggested for approaches which integrate on-line representation of learning material with the interactivity of problem solving environments and intelligence of ITS. In this sense, the Multibook project can be seen as a specific type of an I3-textbook, although our application domain brings along some different problems which requires slightly different approaches and techniques, which we will describe in the remainder of this article.

3. Multibook

3.1 Constraints and Requirements

The content of the Multibook system, currently being developed at the TU Darmstadt, is the printed book "Multimedia: Computing, Communications & Applications" by Ralf Steinmetz and Klara Nahrstedt consisting of about 1200 pages, and a selection of Java applets [13]. The aim of Multibook is to have individual views on this material according to the needs and preferences of the individual users. A linear, printed book does not satisfy these requirements: It does not adapt flexibly to the level of difficulty, the learning aim, the learning strategy and the media preferences of the specific user. Apart from that, many aspects of multimedia technology can be explained better using motion and interactivity. A pure hypertext or hypermedia system does not satisfy these requirements either. A hypertext is static, in that the text is either heavily linked and there is a suitable path through it for every user - then the user might be confused by the number of possibilities and not be able to find this path. Or there are only a few links, then it will probably not satisfy the demands of each individual user. An ITS system does satisfy these requirements, but these systems only work in areas which are highly structured, such as Mathematics and especially programming languages. The level of control and the detailed knowledge of the state of the user can't be achieved in our subject domain. To formally model everything that can be said about multimedia in texts or images would not be a feasible approach. Also the extent and the extensibility of our material and the amount of text describing it are constraints which make it impossible to guide the user in such a controlled way.

3.2 Approach

The Multibook system has multiple facets: it provides an intelligent testing environment for the user, offers search facilities for a direct access, etc. In this article, however, we will focus on the main task: To find and to propose a suitable path, hence a suitable composed lesson. To be able to acomplish this, the content and meta information concerning the content must be represented in a formal way, that enables the system to operate on it. As a result the system can play the role of a guide for the user. In order to find a suitable path, the system makes use of a user profile and of the meta information. In the beginning, the profile is filled with the demands and preferences of the learner. There are two spaces in which the knowledge base is modelled: a domain model, which we call the ConceptSpace, and the MediaBrickSpace, where knowledge is represented in small modular pieces of text, in images etc. The concepts and the actual content are therefore separated. The ConceptSpace represents the domain, the MediaBrickSpace is a set of possible explanations of this domain. The concepts are comparable to possible chapter headings and are interconnected by semantic relations. There are different possibilities to choose a set of relations. The granularity of the model relates to the fact that we are interested in roughly structuring the domain rather than completely representing all facts. In the vocabulary of Knowledge Engineering, this makes our ConceptSpace a terminological rather than a axiomatic ontology [12]. We are aware of the benefits that the extended use of verb concepts, and the expression of a greater variety of facts they allow, could have for our domain. However, the current model is, for simplicity reasons, mainly built around noun concepts [5]. Semantic relations strongly guide the composition of lessons but do not predetermine a unique set of topics and the order of these, to make application of different learning strategies possible

In the following we will describe in an exemplary way the rules that operate on the different categories of the profile and on the relations in the ConceptSpace to compile a adequate outline for a lesson.

The rules which are responsible for choosing the global structure of the lesson use the semantic relations corresponding to the learning aim. Note that these rules are not a hardwired part of the system. At this stage, we

modeled some rather straightforward didactic rules ourselves, later we want to give the domain experts working with the system the possibility to specifiy their own rules. Examples for rules using the semantic relations: In his/her profile, the user is characterized as a student learning for exams. In this case the system will search for concepts which are related to the chosen topic by the relations "uses", "part_of" and "is_a".The selection of the topics has to be coordinated with their order arising from the chosen learning strategy, e.g., hierachical: Definition - broader term- component - application. In other cases the selection of the topics uses, on a small scale, inferences on the ConceptSpace. Example: The topic is related to another by the relation "problem". Then the system would most probably find a concept representing a solution for this problem among the more specific concepts (i.e. one that is connected by a "is_a" relation). The lessons are finally put together by combining a set of media bricks. They can be in form of text or other multimedia elements such as images, graphics, video and audio streams and - with the main focus - animations realized as Java applets. Also these multimedia elements satisfy the requirements of modularity. This requires that the format of the media bricks enables the system to describe the content, grade of detail, and the underlying pedagogical concept of the media brick. Thus it is possible to integrate a media brick in a lesson, independent of the kind of media. Particular emphasis of our work lies on the issue of coherence [14]. When a user of a hypertext does not have the possibility to choose the pages, i.e. he/she cannot establish the relation between the parts of the lesson by himself/herself, he/she is more likely to expect a coherent lesson, a lesson where the relations between the parts are obvious, although they are put together by someone else. For this purpose the media bricks are not only linked to the corresponding concept but also interconnected in the MediaBrickSpace by rhetorical relations based on the Rhetorical Structure Theory [9] [11]. Examples for such rhetorical relations are "deepen" or "explain". It is a major task of the system, to make this relations explicit.
In general, the rules for building the lesson out of the relevant media bricks, have to use the rhetorical relations and the characteristic of the media bricks, in order to match the users level of difficulty, media preferences and coherence expectations. Simultaneously, they have to work off the structure of the lesson compiled earlier and to fulfil the demands of the user's learning strategy. Note that the learning strategy requires rules working on both spaces. These goals are not always easily harmonized: The system will, for instance tend to select as the next media brick one that is connected to the current one but also one that is connected to the next topic in the planned structure.

4. A Table of Contents for each User!

As an example how we overcome the gap between free navigation and static guidance by using the meta-information described above, we suggest a dynamically generated table of contents. Dynamically generated tables of contents combine the best of both worlds: The interests of the user are made manifest by the outline, the structure, of the lesson. This task can be achieved by applying the user profile instead of constraining the user to choose the media bricks by himself/herself. As with a guided tour the lessons are coherent, and more security is given to a sensible course of text/media. Rules working on the ConceptSpace are responsible for creating the outline according to the user profile; rules working on the MediaBrickSpace are responsible for the coherence of the lesson.

4.1 Tables of Contents

Tables of contents, what are they and what function do they have? Generally, a table of contents is the rough structure of lessons. Any kind of table of contents is motivated by semantic relations. A table of contents gives the reader an overview of the lessons and shows the view the author has of the subject.Therefore we can consider the table of contents as a path through a net of concepts. We observe that not every path can serve as a table of contents, nor does every structure of a topic make sense. Obviously some proven patterns occur quite often. These characterize a sensible structure for texts. We give three examples:
A structure based on *part_of* relations:

1. Media Server
    - 1.1. Disc Controller
    - 1.2. Storage Management
    - 1.3. File System
        - 1.3.1. Allocation Table
        - 1.3.2. Access Control
    - 1.4. Memory Management

The subchapters describe the components of a media server, the sections of "File System" represent the components

of a file system.
A structure based on *is_a* relations:

1. Image Compression
   1.1. JPEG
   1.2. PNG
   1.3. TIFF

Here the subchapters are examples of the topic of the chapter.
A structure based on *proceeds* relations:

1. JPEG
   1.1. Picture Preparation
   1.2. Picture Processing
   1.3. Quantization
   1.4. Entropy Encoding

The structure of these view follows the order of the process itself.
The structure in each of these three examples is a paths, that is a tree, even leading to multiple trees or forests. It is not necessary that the structure is based only on one kind of relation, hybrid composition can also be observed quite often. There are several reasons why it makes sense to provide explicit guiding for the user in the form of a table of contents:

1. A user in a learning environment has to learn certain topics, if he/she wants it or not.
2. The user may not have the necessary overview of the area to choose the relevant concepts.
3. The user is not able to compose a lesson according to a learning strategy by himself/herself.
4. The knowledge base is too broad to be managed effectively without help from the system. The system can select and combine the media bricks faster and more efficiently than the user.
5. A table of contents offers the user some sort of orientation. He/She can see exactly where he/she is and to which context the current topic belongs.

In the Multibook system there are also situations where "classical" free navigation is the appropriate strategy: The user selects the topics being relevant for him/her from a net of content objects, which is a simplified version of the ConceptSpace where the relations are omitted. The net offers the user an overview of the area with connections between the topics beyond the linear order of a table of contents in a printed book and many hypertext systems. The user can choose the topics without working on the media bricks, thus simplifying the complexity of the knowledge bases.

4.2 Dynamic Table of Contents

Since the aim of the Multibook system is to be adaptive to the needs and preferences of the specific user we need more than just one table of contents: We need a table of contents for each single user. This cannot be obtained by having several static tables of contents. If the set of media bricks would bc static we could precompute every possible way through the material. This means, every possible learning strategy etc., could be realized and presented to the user. But since our system is open for extensions of both ConceptSpace and MediaBrickSpace including media bricks from external sources, we must be able to generate the tours through the material dynamically for every user. Our system is able to fulfil this task because of the partition into ConceptSpace and MediaBrick Space. The concepts/topics are modelled separately from the descriptions, therefore every concept can be picked up to be the main topic. The semantic relations which allow the diverse structuring of the topics make it possible to tell the difference between sensible and senseless structures, i.e. table of contents. The ConceptSpace with its manifold semantic relations is a starting point for different and meaningful ways to construct tables of contents. Topics which are chapter headings in one lesson can be subchapters in another.

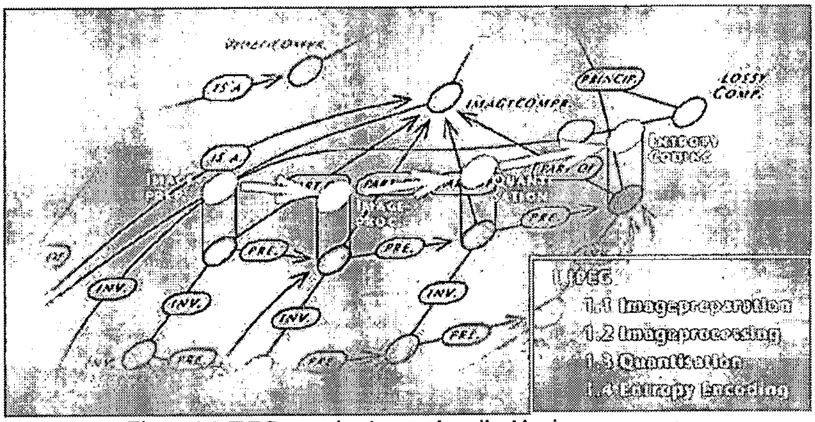

Figure 1.1 JPEG as main chapter described by its components

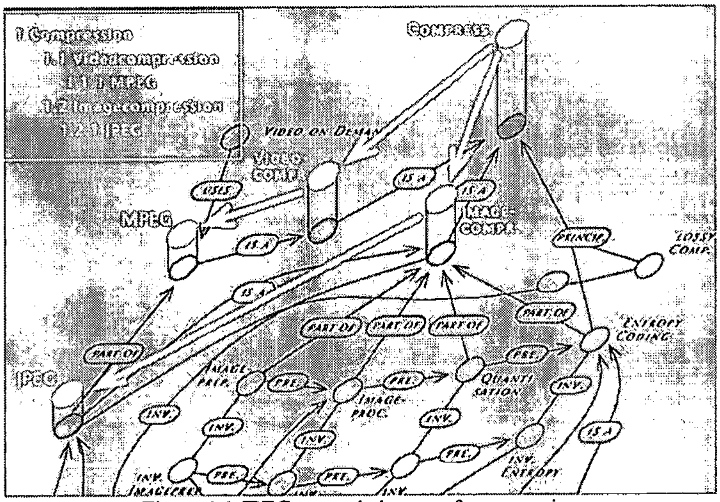

Figure 1.1 JPEG as a subchapter of compression

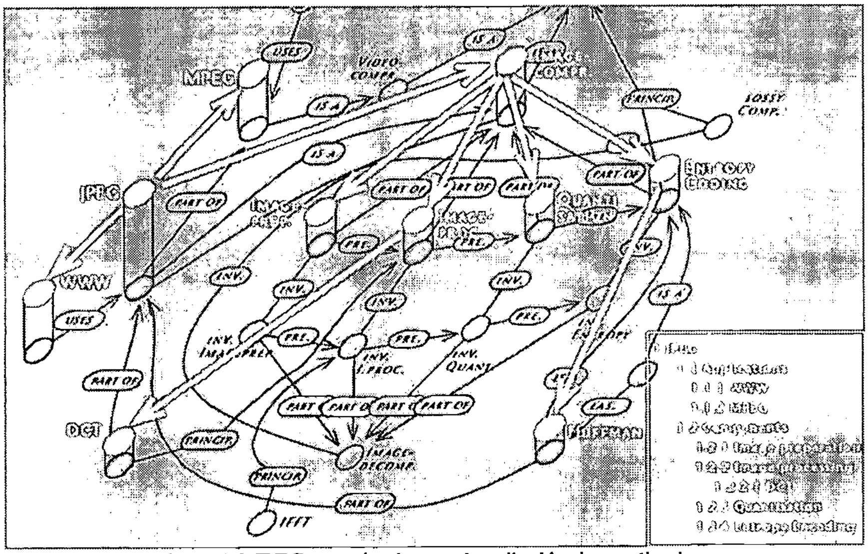

Figure 1.3 JPEG as main chapter described by its applications

BEST COPY AVAILABLE

In Figure 1 different views of the complex JPEG are shown. The topics selected for the outline are highlighted in the figures. In Figure 1.1 JPEG is defined by its componenents, in Figure 1.2 JPEG is a subchapter of Compression and is explained in the context of MPEG. In Figure 1.3 JPEG is the main topic of the chapter and is described first by its applications where MPEG is mentioned, then in detail by its components

5. Conclusions and Outlook

The learning strategies we have implemented so far (problem oriented vs. hierachical) are exemplary. Our aim is not to prove whether a certain strategy is under certain circumstances better than another. We rather want to provide a tool for educationalists to conduct these kind of experiments. They can test their theories about learning strategies by applying their research results to our system. The system is flexible for changing the rules in both spaces which are responsible for composing the lessons. As we only recently finished a prototype of our system, an empirical evaluation is now on its way: In a broad field trial at the end of this year with the students of our institute, we will investigate to what extent the individual tables of contents help to navigate on a hypermedia system. A major problem which needs further investigation is how to produce the media bricks. To write a text in a modular way is quite unaccustomed, also a deeper understanding of the relations is necessary to bind new media bricks in the MediaBrickSpace.

Acknowledgements

The authors would like to thank the Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie (BMBF) which partially funded the research project and the Volkswagen Stiftung. We owe also thank to our colleagues Abdulmotaleb El-Saddik, Martin Wessner, Rüdiger Pfister and especially to Jörg Haake for their helpful comments.

email: {*scm6rm, dave*}*@cs.cf.ac.uk*

Abstract

The automatic assessment of coursework can have significant advantages, especially when dealing with large class sizes. Several automated marking systems have been developed in recent years [BBF93, BBF+94a, BBF+94b, LJ95, TR96], the Ceilidh system probably the most popular and significant. All the systems have basically required the user to manually submit prepared pieces of coursework to the system. In many the cases this is perfect method for submission of coursework. However, with the possibilities offered with internet connections alternative methods where the coursework may be marked directly over internet. This is especially necessary if the coursework involves testing some networking component (*e.g.* Are Web page links (URLs) valid and working, or do CGI scripts operate properly). This paper addresses the practical issues involved in supporting the provision of such a system. The system is demonstrated with implementations of marking students Web Pages for HTML content and Perl/CGI scripts for dynamic correctness and syntax. However, we emphasise that general principles of using the internet as means for automated coursework assessment and general practical solutions to this problem are presented.

1 Introduction

The automatic assessment of coursework can have significant advantages, especially when dealing with large class sizes. It is evident that not all pieces of coursework can be adequately assessed by computer. However, with careful consideration and design of questions a wide variety of topics can be tested. Several automated marking systems have been developed in recent years [BBF93, BBF+94a, BBF+94b, LJ95, TR96], the Ceilidh system probably the most popular and significant. All the systems have basically required the user to manually submit prepared pieces of coursework to the system. In many the cases this is perfect method for submission of coursework. However, with the possibilities offered with internet (or other network) connections alternative methods where the coursework is placed on web pages or specified directories and the work is marked over the network. This is especially necessary if the coursework involves testing some networking component (*e.g.* Are Web page links (URLs) valid and working, or do CGI scripts operate properly when called over the Web).

The provision of automatic assessment can offer enhanced possibilities both for self-study and for class administration. Some of these possibilities are listed below:

- A large number of exercises can be assembled, which students attempt and submit interactively via the courseware. These exercises are then marked by computer and the marks returned to the students. In many cases, the marks can be returned almost immediately. Breakdowns of the marks can usually be supplied — thereby providing additional feedback to the students. Model solutions can also be provided. Many more exercises can be attempted and submitted by students than is possible using conventional lecture techniques — and, of course, this method is suitable for distance learning. The burden of course administration is also significantly reduced.
- Similar submission and marking procedures can be adopted for *assessed* exercises. Additional (electronic) gathering of marks is easily facilitated.

*This project was funded by a Nuffield Undergraduate Research Bursary (Grant No. AT/100/98/0433)

- Checking for plagiarism can be more comprehensive and consistent.

Clearly different methods of assessment and submission are required for different disciplines.

In recent years, the Ceilidh automatic program marking system has been a popular, stand-alone means of supporting a wide variety of programming language courses [BBF93, BBF+94a, BBF+94b]). We have used Ceilidh extensively for C programming courses at our institution for many years. Current research, we are undertaking, is investigating the possibility of utilising advanced Ceilidh features to enhance the marking process described in this paper. Ceilidh is now quite widely used in many programming and software engineering courses — both in the UK and overseas. In addition to administering coursework submission and marking, the full Ceilidh system also supports lecture notes. Unfortunately, the lecture support structure does not fit in with our philosophy of delivering courseware over the WWW, which has always been a major aim of the courseware we have developed [Mar95, Mar98a, Mar98b, MH96a, MH96b, MH97]. However, the automated coursework marking tools are extremely powerful. We have (for the C course) provided an integrated Web-based courseware environment that called upon Ceilidh's facilities for marking students' programs. Essentially a Web form interface has been provided for students to submit their programs. A similar system is now provided by the original Ceilidh developers (see http://www.cs.nott.ac.uk/~ceilidh/).

Other relevant systems for automated program assessment include PASS [TR96] which has addressed wider issues of syntax and grammar analysis of submitted (C) programs and BOSS [LJ95] which has provided a user-friendly interface for online submission and supports several programming based courses.

However, the submission mechanism over the Web is not always ideal. We have found from our experiences with C coursework online submission that it is cumbersome for students to develop their programs externally of the courseware the ensure that work correctly (compiling, debugging, test runs) and then submit by essentially cutting and pasting the source code into a Web-based form. More importantly in order to assess that certain pieces of coursework work according to specification they may actually need to test to run over a network. A system is there required, with many general applications, which in networked based and user simply provide solutions to pieces of coursework by placing on a Web-page or in a directory which can be accessed via a network. A few systems for assessing the validity of HTML for Web Browser Support[Add98] and generally interpreting HTML[CAS98, EWS98] have also appeared on the WWW recently.

The principle aim of this paper is an investigation into the practical issues involved in supporting the provision of such a system. The system is demonstrated with implementations of marking students Web Pages for HTML content and CGI/Perl scripts. However, general principles of using the internet as means for automated coursework assessment and general practical solutions to this problem are presented.

2 The Assessed Coursework — Internet Computing

With over 100 students taking the Internet Computing (Year 1, BSc Course), an alternative to 'marking by hand' was required. Several assessed exercises of coursework to test students understanding of other internet concepts such as searching, ftp and email[Mar98b]. However the major piece of assessed coursework involved developing a Web page and writing some CGI/Perl programs with a HTML form interface. By careful consideration of the web page content and CGI-based tasks it was possible to devise effective exercises that could be marked online.

Students were set specific tasks to achieve in HTML for their Web page, such as having to include certain HTML formatting including images, and Web links on their Web pages. For example students were requested to put their name, college address *etc.* in certain font styles and formats, and to include an image of themselves. Students were also required to find and provide (external) links to web pages that address a particular topic. By choosing topics that have an abundance of web pages devoted to the topic (VRML, Perl and Video were used this year) one can ensure that students can easily find such pages on the Web. Also it is not unreasonable to assume that Web pages should include the topic name in Web page headers, title or main text which can easily be searched for to verify the relevance of the Web page.

CGI programming exercises were devised such that they have a specified input and output. Therefore the CGI scripts can be called via a Perl script with arguments specified within the URL and the output checked by Perl pattern matching. The content of the Perl source may also be checked. The CGI programming exercises that were currently set involved producing a simple online calculator or image browser in Perl which were automatically marked. The marking system developed is modular and other exercises are planned as alternatives in the near future.

3 Assessing Web Page and CGI Programming Exercises

As mentioned above students were set specific Web programming tasks to achieve using HTML and CGI/Perl. Basically the marking system involves scanning the students' Web pages to verify content and links by simple pattern matching. Web links can be verified by following the URL given and checking if the Web link exists and if the content is valid. Links to the CGI/Perl exercise were also identified and followed. The CGI/Perl programs were then analysed for dynamic (runtime) correctness and syntax. Marks are accumulated by the system as set criteria are met. A configuration file for each exercise is used to set the appropriate mark values for each task. The system is implemented using Perl.

3.1 Restrictions Imposed by Current System

In order to achieve the above automated marking some (not unreasonable) restrictions have had to be applied. These restriction do not pose and real limit to our system and can be enforced as part of the exercise as described below:

- Students Exercise Home page must have specified location and content — All students have allocated web space which can be easily accessed in a methodical manner (*e.g.* http://www.cs.cf.ac.uk/User/Student_Name). Therefore a student class list is assembled offline and this list is read by the marking system. For each student in turn the system accesses their web space and searches for a prescribed web page (*exercise.html* for example). The student web page location, system configurations and exercise names are input variables to the system. In order that the CGI programming exercises may be located these must also be specified. Since the students have been asked to produce a HTML page that must adhere to certain criteria this insistence of providing links can be readily into incorporated this part of the assessment.

  Other systems [Add98, CAS98, EWS98] for more general assessment of HTML. In the future we intend to incorporate some of these ideas into our system to make it more robust and general. Our system implements a very simple method of parsing the HTML that basically verifies that all HTML tags match up and then checks for specific criteria above to mark the page.

- Student CGI program links must have specified name and method of parameter passing — In order for the link to be found from the exercise page the exercise must have a link that contains a specified name link (*e.g. Perl exercise 1*). CGI programs must also adhere to the standard get/post methods of parameter passing.

- Student CGI programs must have (or be designed to produce) standard output — In order to mark the program dynamically the exercises need to be designed so that specific output is produced which can easily be marked. This is basically a similar requirement to the Ceilidh and other program marking systems. The dynamic output part of the marking scheme is essentially achieved by pattern matching using regular expression. We use the powerful built in regular expression capabilities of Perl to perform our dynamic marking of programs.

3.2 The Automated Marking System

We now outline the basic algorithms for the modules that perform the marking of the HTML and CGI/perl scripts:

Configuration and Main Module(Fig. 1) — This module basically reads various configuration files, sets up the appropriate Web links to students' web pages, calls the appropriate HTML/CGI marking modules and finally assembles the final marking statistics. Having assembled various web links it is relatively straightforward to download web page source to internal structures in the main module using the standard Perl *UserAgent* package[Per98].

HTML Marking Module(Fig. 2) — Students are instructed (as part of the exercise requirement) to constrict a web page of specified content and of a specified name. The exercise page is therefore downloaded, stored internally in the module and then assessed for style and content. Not that we are not marking general HTML style but marking a page against a prescribed format. The format

```
For each student in class do
  begin
    Build home page link
    Get Home page
    Find exercise 1 (HTML)
    Download Exercise 1 page
    Mark HTML page style and content
    Find CGI/Perl exercise links
    Download HTML Form exercise page
    Mark CGI/Perl exercise
  end
```

Figure 1: Main HTML and CGI marking algorithm

is designed so as to give students some individuality to their page design. Some general HTML page style is checked such as overall page length (no more than 1.5 pages) and that the number of images and size of the page downloaded (including image size) is not too large (30 Kbytes). Web page tags are identified and matched according to the specified requirements. Students are also required to find and provide (external) links to web pages that address a particular topic (*e.g.* VRML, Perl and Video). Web links are found in the HTML exercise page, checked for keywords matching respective topics and the the web link downloaded. The downloaded web page was then searched for occurrences of the keyword. Thus, we can test and mark for the validity of the Web link and the relevance of the web page to the topic.

```
Parse HTML:
   Count number of lines, estimate page length
   Check HTML tags mark according to exercise criteria

Parse graphics:
   Find image tags in page
   Download images in turn
   Check number of images vs size of files

Parse URLs:
   For each line of page
     Check for keyword/URL link
     Download URL link page
     Check URL for Keyword in Title, Header, Main text
```

Figure 2: HTML marking algorithm

CGI/Perl Marking Module(Fig. 3) — Links to the CGI/Perl scripts must be specified from the exercise home page. The link to a HTML form interface is found, downloaded and then parsed to establish the name and URL of the associated Perl script and the name/value pair parameter passing format. The Perl program is then marked in two ways:

- The Perl program is run over the Internet to check that it can run as a CGI script — The URL of the Perl is formed and the argument list is formed from the name/value pair list and appended as an explicit call (*e.g.* http://my_perl_url/my_perl_cgi?name1=value1). The output of the perl script is marked for dynamic correctness.
- The Perl source code is downloaded and code is more rigourously tested for dynamic correctness and syntax in a similar fashion to the Ceilidh system[BBF93, BBF+94a, BBF+94b]. Several test runs against set test data are performed. Marks are awarded and accumulated for passing each test. The precise weighting for each mark is specified by a configuration variable for the test and reflects the appropriate level of the test.The Perl syntax is check by using the Perl *warning diagnostic* command line option (`perl -w`). In reality our implementation is a simple version of Ceilidh's more powerful syntax and error checking. The `perl -w` command performs a UNIX *lint* (line interpreter) type checking enabling us to check for program errors, unused variables *etc.* This diagnostic checking process generates many standard error messages which can be tested for (simple pattern matching). Marks are deducted for the each error found which are again preconfigured and reflect the appropriate severity of the error.

```
Main:
Begin
Analyse HTML form source for:
    name/value pair structure
    find Perl script name and URL

Download Perl script source
If Perl file in CGI directory
   Test_script_over_internet
Analyse_Perl_script
End of Main

Test_script_over_internet:
   Construct Perl calling structure from name/value pair and Perl script URL
   Execute Perl script over the internet
   Analyse feedback for correct answer

Analyse_Perl_script:
   Analyse for dynamic correctness:
      Run script with a variety of input test data
      Analyse output for correct answer
      Mark accordingly
   Analyse script syntax and efficiency:
      Run perl script locally with -w option
      Parse output for error messages
      (Syntax, unused variables etc)
      deduct marks accordingly for respective errors
```

Figure 3: Form/CGI marking algorithm

4 Conclusions and Summary

The system has been implemented and tested on test user web pages and last year's Internet Computing class. The basic framework and approach has been demonstrated to work. The system is still however basic. The biggest limitation is that only a small number of exercise modules have been developed — 1 specific HTML and 2 Perl marking. However, the system has been designed to be modular and it is a simple task to develop new modules. New module development is currently in progress. One limitation in the Perl marking program is that small customised Perl modules need to be developed to mark each CGI/Perl programming exercise. This is because each exercise may have different form interface requirements and there is a need to test each program over a CGI network and locally. From the lessons learned so far an extras level of generalisation of this process may lead to a more streamlined and simpler approach to Perl program assessment module development. We are currently investigating means of achieving this. We have used the Ceilidh automated programming marking system [BBF93] in other courses. Currently, we are developing scripts so that Ceilidh may be used to assist in a more formal assessment of Perl programming style (and, maybe, HTML) programs. We also intend to incorporate more general HTML assessment ideas [Add98, CAS98, EWS98] into our system.

In summary we have outlined a system that is novel in that it is attempting to assess coursework over the Internet which may lead to an alternative means of submission than current systems. Furthermore, such a system is requirement when internetworking skills need to be tested. We have addressed the practical issues involved in supporting the provision of such a system and demonstrated the system with implementations of marking students Web Pages for HTML content and Perl/CGI scripts for dynamic correctness and syntax. However, we believe that the basic approach has outlined general principles of using the Internet as means for automated coursework assessment.

The Internet Computing course is available on the Web at the URL:
`http://www.cs.cf.ac.uk/Dave/Internet/` and anyone interested in obtaining the marking system should contact the authors by email.

Acknowledgements

We would like to express sincere thanks to the Nuffield Foundation for supporting this research. We would also like to thank our computer systems guru Robert Evans for helping us with many system programming problems and for supplying us with test user web space.

Constructive "Noise in the Channel": Effects of Controversial Forwarded E-mail in a College Residential and Virtual Community

Richard Holeton
Residential Computing
Stanford University
United States
holeton@stanford.edu

Abstract: As part of a case study of electronic community building in a college freshman dorm, discussion list messages were analyzed quantitatively and qualitatively. Messages were categorized by social purpose (housekeeping, social dialogue, or critical dialogue) and as either forwarded messages or original messages. Forwarded messages included jokes, polemics about politics or social issues, and electronic chain letters deemed offensive by some participants – e-mail forms that, along with metadiscussion, have been widely perceived as distractions and impediments to serious online discussion. A series of discussion threads about gender issues, however, reveals that such "noise in the channel" can frequently lead to constructive critical dialogue, both online and offline, in the context of a residential student community.

Introduction

Many studies have analyzed electronic newsgroups, scholarly mailing lists, and other discussion groups as virtual communities (e.g., Rheingold 1994; Herring 1996). Other studies have looked at classroom uses of computer-mediated communication (CMC) and its effects on learning communities (e.g., Cooper & Selfe 1990; Harris & Wambeam 1996; Colomb & Simutis 1996). Only recently, however – in new contexts such as fully-wired college dorms -- have we had the chance to study the interplay between virtual and face-to-face community in residence-based communities. What are the social effects and potentialities of CMC when participants also live and study together? Critics fear that students who spend more and more time in front of computer screens – even "talking" to their teachers, classmates, and dormmates online instead of in person – are becoming more isolated. According to the *New York Times*, "Some scholars say 'plug per pillow' campuses are undermining the ideal of a residential college" (Gabriel 1996). Former hacker-turned technology critic Clifford Stoll says, "We're turning colleges into cubicle-directed electronic experience and denying the importance of learning to work closely with other students and professors, and developing social adeptness" (qtd. in Gabriel 1996).

For such critics, the whole idea of a dorm e-mail discussion list would seem to be antisocial or, at best, superfluous. But as I have argued elsewhere, the fears of Stoll and others are based on dubious either-or and zero-sum assumptions, the faulty notion that computer activities and community-building activities must be mutually exclusive (Holeton 1997). On the contrary, residents of the dorm I studied used their discussion list in highly social ways and even found the list more valuable than traditional or face-to-face media for purposes such as discussing social and political issues. Their live dorm programs and their hallway and dinner discussions often complemented the e-mail list, and vice-versa (Holeton 1997). In this kind of hybrid residential-virtual community, participants share dorm hallways and lounges, bathrooms, mealtimes, social events, and intramural sports teams as well as the electronic discussion space. With the familiarity and intimacy that are missing from distance-based virtual communities, we should not only expect less rudeness or flaming online but we should also question previous assumptions about forwarded e-mail trivia, chain letters, and metadiscussion – in particular the widespread perception that "in written communication these messages constitute noise in the channel that interrupts discourse" (Korenman & Wyatt 1996, p. 239). The poor reputation of metadiscussion in virtual communities is encapsulated in a widely-distributed e-mail joke entitled "How many Internet mail list subscribers does it take to change a light bulb?" Answer: 1,331:

> 1 to change the light bulb and to post to the mail list that the light bulb has been changed
> 14 to share similar experiences of changing light bulbs and how the light bulb could have been

changed differently
7 to caution about the dangers of changing light bulbs
27 to point out spelling/grammar errors in posts about changing light bulbs
53 to flame the spell checkers
156 to write to the list administrator complaining about the light bulb discussion and its inappropriateness to this mail list....
[etc.; about fifteen additional categories of responses typically follow]

Must forwarded messages, inane or offensive jokes, and metadiscussion serve only as time-wasting distractions, irritants, and bandwidth hogs? To what extent, instead, can they function as constructive discussion prompts or make positive contributions to residential and virtual community building?

About the Study

Rinconada House, Wilbur Hall, is an all-freshman dorm of 94 students (including 5 upperclass residence staff) at Stanford University, where during the 1990s all dorms were wired with in-room ethernet connections to complement networked residence computer clusters. The study is based on a complete archive of over 1200 messages posted to the dorm e-mail list for the academic year 1995-96. Rinconada's history includes the use of dorm e-mail discussion lists for a number of years and its 1993 claim as the first college dorm with a home page on the web. My wife and I served as Rinconada's Resident Fellows, faculty leaders of the residence staff who live in an adjacent cottage, from 1990 to 1997, and thus – especially where qualitative judgments are made -- I am necessarily a participant-observer in the study. All the house residents, including the staff, were subscribed to the discussion list. The full study, including data from which this paper is derived, is available on the web at *http://www.stanford.edu/~holeton/wired-pages/wired-main.html*.

The messages were broadly categorized according to three larger social purposes, which suggest a rough hierarchy from lower-order to higher-order uses of CMC:

1. *Housekeeping* (lost and found, arranging meeting times, etc.)
2. *Social dialogue* (publicizing dorm or university events and programs, sharing outside interests, relieving stress, etc.)
3. *Critical dialogue* (discussing social, political, academic, or intellectual matters; discussing dorm community issues or controversies; etc.)[1]

Generally speaking, critical dialogue is the type of discussion encouraged in academia, where matters of social or intellectual importance are negotiated in a reasoned, collegial way, and its inherent value in learning communities will be presumed. Metadiscussion -- discussion about the medium itself or how the list should be used, or "talk about talk" (Korenman & Wyatt 1996, p. 238) – was classified as critical dialogue. Messages were also categorized as either (a) forwarded messages or (b) original messages or replies. Forwarded messages are those passed on to the list by members but whose content originated from a person or organization outside the group (the list was closed to unsolicited junk e-mail or direct "spam" from Internet mass-mailers). In the many cases where forwarded content was framed by the sender's own commentary, I made a judgment about whether the primary content of the message was the forwarded material or the original material.

After measuring the various proportions of these message categories, I analyzed the relationship between forwarded messages and sustained threads of the higher-order, critical dialogue. I also considered the effects, in my observation, on the face-to-face community. My discussion focuses on the most sustained critical dialogue of the year, a series of related threads about gender issues that comprised dozens of messages and lasted most of autumn quarter.

Findings and Discussion

In addition to the numerous political calls to action, urban legends, electronic chain letters, Top Ten lists, and jokes that have proliferated on the Internet, a whole genre of undergraduate e-mail humor has

[1] In designing these categories I was influenced by Ziv's "Taxonomy of Communicative Purposes" (Ziv 1996, Table 2, p. 247).

developed as college students got online throughout the 1990s. Typical titles in this genre include "50 things to tell your professor when you turn your exam in late" and "100 ways to torture your roommate." A more insidious subgenre includes material, often with humorous intent, deemed offensive by women, men, specific ethnic groups, gay or lesbian people, or other social groups. These messages are widely forwarded among college students around the world, and the Rinconada list was no exception.

In terms of larger social purpose, from lower-order to higher-order uses of CMC, 13% of the total messages in 1995-96 were classified as *housekeeping*, 57% as *social dialogue*, and 30% as *critical dialogue*. One-quarter (n=306 out of 1244 or 24.6%) of the total messages were classified as forwarded messages. The vast majority of forwarded messages fell into the *social dialogue* category (and more specifically, the sub-categories "Sharing outside interests" or "Relieving stress"). Of the 711 *social dialogue* messages, 269 or nearly 38% were forwarded messages. See Figure 1.

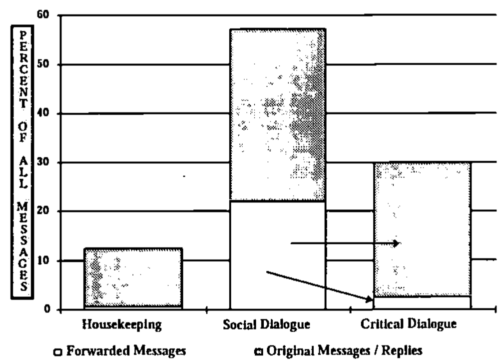

Figure 1: Proportions of Forwarded Messages by Social Purpose. The two arrows indicate that forwarded messages in the *social dialogue* category frequently led to *critical dialogue* messages or to "answering" forwards.

The majority of this busy traffic in forwarded messages were ignored by other participants, so initially we might be tempted to view them, as others have, as "noise in the channel." Anecdotally, some residents reported being put off by common Internet banalities such as those described above. On the other hand, I would argue that there is some inherent value, in a diverse educational community, in participants being exposed to one another's range of interests and passions as reflected in forwarded e-mail messages. Further, a lack of online response doesn't necessarily mean that a joke or piece of trivia wasn't appreciated or didn't provide some needed levity. Residents frequently made offline responses to online chatter, a phenomenon that should be studied further as a potential contributor to community building. Online, some participants answered forwards, playfully or seriously, with another forwarded message taking an alternate or opposing view. For example, a jocular list entitled "How to tell if you're a Republican" would be answered by an equally-jocular "How to tell if you're a Democrat." Sometimes this kind of sparring led to a substantive discussion thread when participants framed their answering forward with extensive editorial comments.

Although many forwarded messages went unanswered, *the most sustained threads of critical dialogue that developed over the year all began as reactions to forwarded messages.* As we might expect, the most controversial or inflammatory messages – those with the most loaded social or political content of interest to undergraduates – evoked the most reaction, including forwards about sex, rape, neo-Nazis, and free speech. The remarkably constructive quality of the dorm's reactions to these prompts, which dispute the claims of pessimists that virtual communities are inevitably being broken down by "flamers, cranks, fetishists and monomaniacs" (Chapman 1995), is revealed especially in the autumn-long discussion threads about gender issues.

Subject: I'm disgusted (fwd)

In October, 1995, an infamously misogynistic e-mail originating at Cornell University called "Top 75 reasons why women (bitches) should not have freedom of speech" was widely disseminated at colleges. It evoked a furor that made national headlines (e.g. Grunwald 1995). Some of the more politely-phrased "reasons" included, "If she's in the kitchen like she should be, no one can hear her anyway" (no. 2), "If she can't speak, she can't cry rape" (no. 38), and "Only one set of lips should be moving at a time" (no. 43). Phyllis[1] forwarded the message to the Rinconada list with the subject header "I'm disgusted," initiating a month-long discussion thread.

Vigorous metadiscussion about the appropriateness of posting the "75 reasons" message to the list ranged from Duncan's plea to "think twice before passing this kind of thing on" to defenses of freedom of speech. The staff did not intervene in this discussion but purposely let residents negotiate norms for the e-mail list, attempt to establish shared values, and, hopefully, assert collaborative ownership of this electronic space. Their initial success is indicated by Adelle's assessment of the metadiscussion (i.e., meta-metadiscussion?): "It was nice that for once people expressed their ideas about e-mail without becoming rude or over personal. I guess people are starting to become more considerate of others over the e-mail. What was so hard about doing this?"

The "four players of Cornell" who composed the controversial message (and even put their real names on it) got flamed from far and wide, issued apologies, and faced disciplinary charges. Meanwhile at Stanford on the Rinconada list, Gregory started a serious discussion of gender issues by objecting to how such incidents reinforce negative stereotypes about men. Several other men participated thoughtfully in this thread. For example, Duncan wrote, "On behalf of my gender I would like to emphasize that the majority of men do not think this way about women, that many find it sick that some people actually perpetrate such filth, and that the guys who wrote this in the first place are probably loving every angry response that they receive."

Subject: Re: Something Serious To Think About (fwd)

Less than two weeks after the "75 reasons" forward, an e-mail chain letter originally called "YOUR PARENTS WERE RIGHT ABOUT THIS ONE" was forwarded to the list by Mona with the new subject header "Something Serious To Think About." Interestingly, Faith had previously sent this message only to the women of the dorm, and now Mona prefaced her posting with explicit appeals to her male dormmates for a continuation of reasoned discussion:

> To all the women of the dorm, sorry for cluttering up your e-mail with a repeated message, but I wanted to send this to the guys, and this was way easier. Guys, please don't take this as an attack on males, cuz it's not. I just thought it was an important message for the state of the world we live in, regardless of gender. Faith was great enough to send this to all the girls, and I thought there might be guys in the dorm who would appreciate it as well (for male/female friends, for themselves, or just as a reminder that you can't trust everyone in this world, unfortunately).

Mona concluded her persuasive preface with gender-neutral appeals to dorm spirit and Stanford spirit ("Rinc Rules and Weenies Got Roasted!" -- a reference to the recent Big Game football victory over Cal-Berkeley). The forwarded narrative itself depicts a generic date rate ("He knocks on the door. She doesn't really know him well, but her friends party with him often. So, she smiles and settles back onto her bed as he walks in...."), offers moral lessons ("we all learned in kindergarten – ask before taking, and don't touch what isn't yours"), and exhorts readers to spread the word:

> This is a chain letter. Send one to the people you care about, or are afraid of. In any school, in any country. Please write the name of your school at the bottom, and place an X beside it if someone you know has been a victim of assault or rape. [A long list of colleges and universities marked with Xs follows.]

In response, the previous thread about male stereotyping evolved into a discussion about rape, with extensive contributions from Gregory, Ronald, Buff, Betty, and others. Gregory and Ronald argued that the generic date rape in the narrative grossly oversimplified what can be a complex series of miscommunications.

[1] All names are pseudonyms.

Buff sent a four-page self-described "treatise" on rape rebutting Gregory's and Ronald's arguments, Ronald sent a rebuttal to the rebuttal, and so on. Six days into the thread, Betty tried to get the discussion refocused on basic feelings and human communication, suggesting that the argument had gotten too analytical and theoretical – a classic example of what some have identified as a female communication style (e.g., Tannen 1994) contrasted with the male "agonistic," warlike debate style (Ong 1981):

> I think it's fine to analyze all the little points of the law and of ethics on a theoretical level, but it seems to me that the real issue here is a lot more broad. It's about respect and communication. You should respect yourself enough to both voice your desires or concerns and then respect your partner enough to ask about their feelings and listen to their response.

Subject: 75 REASONS. PLEASE FORWARD. (fwd)

Yet another forwarded message – "75 Reasons Why Angry Cornell Women (Your Worst Nightmare) Are Exercising Their Freedom of Speech," a reply to the original inflammatory "75 reasons" list – re-ignited the gender threads again in early December. It was posted by Carolyn, Rinconada's Residence Computer Coordinator (RCC), an upperclass member of the residence staff. The Cornell women's message cited a number of statistics from the Women's Action Collective, establishing a scholarly tone. Some men on the Rinconada list, such as King, reacted defensively: "Men are often depicted as villains that suppress and abuse women.... I want to question the validity of some of the statistics given in the message." Ronald questioned the Women's Action Collective's statistics by offering his own research and citations from the *Western Journal of Medicine*, *The New Republic*, and other sources, as in a formal academic paper. And Betty and Clarisse challenged the men with a thread called "Could we just forget semantics for a minute?"

In a virtual *touché* that seemed to go largely under-appreciated by the men, Clarisse connected the political discussion about gender directly to the dorm face-to-face community, chastising the "guys" for referring to Carolyn, the RCC, as "The Computer Lady." Although Clarisse qualified her objection as a "random thing," it wasn't random at all, because of course Carolyn had posted the Cornell women's rebuttal.

Along with Carolyn, the rest of the residence staff had many opportunities to make similar connections between the virtual and the residential community. We organized formal residential education programs with gender themes, such as a consciousness-raising exercise led by the Resident Assistants called "Gender Alliances." Not surprisingly, numerous conversations at meals and late at night in the hallways extended and complemented the online discussions. Such conversations fed back into the e-mail discussion list as more participants got involved; 60% of the dorm's residents participated in critical dialogue threads at one time or another.

Moreover, the value of all this online discussion about gender issues was by no means limited to those who did most of the "talking." A survey I conducted near the end of the year showed that even those who participated little online were active as *readers* of the list and thought it was very useful for discussion of social and political issues. These so-called "lurkers" were not necessarily inactive in the face-to-face community – and vice-versa, the most active e-mail participants were not all similarly active in physical dorm activities (Holeton 1997). Thus, online interaction and offline interaction together offered residents more, often mutually reinforcing ways of communicating, exploring and negotiating ideas, and getting to know one another. In these complex and sometimes surprising ways, the "four players of Cornell," the "Angry Cornell Women," and the purveyors of other chain letters and forwarded messages helped enhance, rather than diminish, the community experience at Rinconada House.

Conclusions

A dorm e-mail discussion list or other electronic discussion space can be very useful for the kinds of critical dialogue encouraged in academia. At least in this higher education context, the kinds of forwarded e-mail trivia, controversial messages, and metadiscussion that have disrupted other virtual communities need not preclude higher-order uses of CMC. Messages forwarded by participants from outsiders, even if annoying, preachy, or distasteful, can prompt substantive discussion and serve as valuable tools for building community. On the Rinconada 1995-96 e-mail list, the most engaging and successful critical dialogue threads of the year started as reactions to controversial forwarded messages.

With the proliferation and specialization of e-mail lists in the late 1990s, some college dorms have begun separating discussion lists from announcement-only lists. This kind of strategy for filtering out forwarded messages might result in missed opportunities for higher-order electronic discussion and associated benefits for the community.

Hybrid virtual-residential communities like today's fully-networked college dorms, where residents have a good deal at stake in their relationships both online and offline, will become increasingly common in the near future. Teachers, residential educators, list administrators, and others with experience in such hybrid communities should continue to explore the effects and best uses of electronic discussion and other emerging technologies.

Keys to the Culture: Factors in Successful DL Implementation

Dr. Robert Fulkerth, Assistant Professor
School of Technology and Industry
Golden Gate University
San Francisco CA 94105 (USA)
bfulkerth@ggu.edu

Abstract: Distance Learning has become a standard practice in educational institutions. This paper describes an action -oriented approach to that enables anyone, from faculty members to administrators, to become effective change agents for DL. Five factors are discussed:

a. Understanding your Institution: change agents understand their institution, often by taking an outside view.
b. Designing for "Fit": successful DL efforts are aligned with an institution's processes, from curriculum changes to the strategic plans and objectives of stakeholders at all levels.
c. Designing for Quality; Faculty as Intellectual Capital: utilizing the faculty throughout the DL implementation process can create faculty buy-in. Faculty also can provide a perspective on the delivery technology chosen.
d. Designing for Accreditation: as more programs move online, it is necessary to be aware of the expectations of accrediting organizations.
Designing for Integration and Acceptance: activities that smooth the way for DL acceptance inside the school are informational activities, publishing, clarifying intellectual ownership, and providing a technology development center.

Introduction

As Distance Learning continues to become a mainstream educational practice, schools are addressing it less as an innovation and more as a challenge to existing institutional cultures. Those who first taught DL classes and designed delivery systems are now becoming spokespersons and advocates to those in their schools who feel threatened, are not convinced, or are simply not interested.

However, the appearance of online courses, certificates and degrees, many blessed by traditionally-oriented accrediting bodies, is creating a new land rush: rather than the question Should we Go Online, the question in many schools has been jump-started to How Quickly Can We Get There? Acceptance by accreditors, combined with the ubiquity of the World Wide Web and other online course presentation and management tools, is creating a race to mount online programs of all sorts.

Such rapid changes can create tension in the culture of institutions. Instead of the meandering pace of change that schools are used to, Distance Learning has seemingly appeared in the US without precedent or warning (its worldwide history notwithstanding), elbowing aside accepted practices of development and delivery. As well, DL is refocusing debate on issues such as intellectual property, course ownership and faculty workloads.

Fortunately, the knowledge level of decision-makers is on the rise. We're moving from the notion of solitary faculty members designing online courses to an awareness that viable distance programs involve interactive, long-term efforts among diverse institutional constituencies.

This paper discusses an action-oriented approach for DL advocates and change agents to use as they integrate quality-oriented distance delivery courses and programs into an existing school world. After presenting 3 potential DL scenarios, the following issues are discussed:

Understanding your Institution
Designing for "Fit"
Designing for Quality; Faculty as Intellectual Capital
Designing for Accreditation
Designing for Integration and Acceptance

Scenarios

a. One or a few faculty members create and present courses online, probably in a bulletin board, email, or perhaps World Wide Web environment.
   This leads to . . .

b. The school begins to support the development and presentation of courses, certificates and (increasingly) degrees online, in varied delivery modes. There may be some support, but efforts are still by individuals or small groups.

c. The school, recognizing the sea change and the potential that distance education represents, builds multifaceted distance delivery into its mission and its long-and-short-term strategic planning. Distance technologies and development are line items in the budget. The institution does not immediately buy into one delivery mode, but understands that tools and approaches continue to evolve. Faculty and development staffs are adequately supported in development and research, and, in return, they operate with reasonable performance expectations. Developers are encouraged to understand and use not only the "new traditional" technologies (conferencing, Web and Web-enhanced), but emerging technologies.

"C" is very probably fantasy. It's more than likely that you and your institution are at a middle point, with perhaps some distance education implementation in place, probably not enough staff and budgetary support, and an undifferentiated sense of urgency at the administrative level that DL programs need to be developed and implemented.

Theoretically, strategic planning drives institutional activities. In reality, projects that are successful tend to be incorporated into strategic planning after the fact, depending on the degree of their success and the fit they find in a given institution. With that in mind, let's discuss a number of activities (and thought processes) at several levels that can help the change agent move her or his institution toward successful DL planning and integration. First, we need to revisit our institutional culture.

Understanding your Institution

Why is understanding your institution important? The development process may be driven by the DL bandwagon, but it's still directed by the many well-known dynamics of organizational change. These forces (resistance, withholding support, differences in expectations between decision-makers and implementers, conflicts among constituents, a "show me" attitude) are well known and must be recognized to be effectively addressed. Since any culture tends to be invisible to those within it, the change agent who is a member of an institutional community should first step back and take a look at his or her school, with, as the comedian Gallagher says, "new eyes."

Designing for Fit

A subsequent step is to develop meta-objectives for the distance program. Consider the institution's mission and existing programs, and position DL to align with them. This is a fundamental step in creating a long-term support dynamic. Work with stakeholders at all levels, from Board of Trustees members to staff, if possible.

Position any existing DL courses and programs in such a way that they correlate with the emerging objectives of the institutional effort. Ideally, this sort of strategic planning should be addressed before nuts-and-bolts development begins, but in practice, development frequently involves aligning any new programs with an institution's existing culture. Regardless of the situation, the change agent should focus on growing the distance program both within the institutional culture and with an eye toward development and marketing avenues.

Developing for Quality; Faculty as Intellectual Capital

For long term credibility and success, courses and programs should be of the highest quality. Institutional and programmatic quality descriptors may grow out of DL planning, but faculty members should be at the front line of quality at the course content and presentation level. Faculty represent the intellectual and educational capital of the institution, and their contributions should be nurtured and protected as much as possible.

While faculty members are an important resource, they may resist becoming involved with DL for many reasons. An important conflict that invariably arises is the traditional notion that intellectual capital resides with the individual instructor, and is usually manifested in the face-to-face classroom. Expanding this paradigm to fit teaching in the largely unknown territory of virtual space is a complex issue, and it encapsulates other questions of course ownership and intellectual property. Working supportively with faculty is important. It will help resolve such issues, and will demonstrate to the body of faculty members that their contributions to the integrity of the institution are understood and valued.

Another benefit of this perspective is that an intellectual capital approach to planning and design can help forestall the inevitable temptation to choose technology delivery mode over course/program content. If the institution first settles on a delivery mode and provider, (which administrators will tend to do) then content delivery, along with the entire look and feel of your institutional program, will be constrained by the system that is chosen.

If institutional constraints do make it necessary to choose a standardized delivery system, be sure to engage faculty members and developers in understanding how the system allows for the use of technology features as they evolve. Currently, audio/video, web interfaces and the incorporation of course management, multimedia production and presentation are features that are supported by some systems, and not by others. In the near future, any substantial delivery system will have to support video conferencing, interactive database access, streaming media, multimedia, QT/AVI audio/video and World Wide Web access, and users will have to know how to incorporate them into content and course presentation.

Implementing a flexible system is important for another reason. Whatever delivery system is chosen, it will become a traditional organizational entity, which will then resist subsequent intrusions of new technologies and ideas.

Developing for Accreditation

Designing for quality implies attention to translating courses and programs into online environments, not only to attract students but also to maintain standards that will satisfy your school's accrediting body.

Accreditation standards for online programs are still a murky issue, although standards are emerging, and completely online certificates and degrees are appearing. Since institutional accreditation is frequently involved, DL developers should be in close contact with the school's accrediting body. The Western Association of Schools and Colleges, for example, currently allows programs to offer up to 50% of courses in existing programs via online delivery modes before accreditation review is called for. At that point, incremental changes or proposals for online programs must go before the Substantive Change committee for scrutiny. (These requirements are in flux, and may have changed by the time this is published)

Designing for Integration and Acceptance

This concluding section discusses a number of activities and processes that can be undertaken on an ongoing basis. These are some of the "little things" that will, in the long run, help you to open doors for DL development, and that will grow credibility.

• Work toward incorporating DL into the university's administrative and financial structure. There should be distinct budget lines for DL support, delivery and design. The DL entity should have representation on faculty and institutional governance bodies, and should report institutionally at the Vice President level.

• Develop a communication process that shares information and invites involvement from the university community. Giving community members ready access to information about development will encourage awareness and buy-in.

Newsletters, flyers, memos and in-house press releases are effective, but more impact will be created by using the technology itself as a primary communication vehicle, perhaps via an institutional Intranet , groupware activities or an electronic bulletin board. A good introductory use of such technology is newsgroups, or perhaps designing online textbook order forms that faculty are expected to use.

• Implement a user Development Center. Whatever form such a center takes, it should be equipped with high-end technology tools sufficient to allow DL developers to experiment, practice and apply technology ideas. Technological and pedagogical support should be provided. Such a center will have practical application, but the real impact will be its demonstration of the school's commitment to Distance Learning.

• Promote ongoing faculty involvement and ownership of course materials.
Placing courses online for the first time usually involves moving existing content to text-based online activities. This is time consuming but relatively easy, and a traditional course can be translated to a reasonably effective online course this way.

Ideally, this first time translation is only the first step in growing a sophisticated online course that utilizes the many technology tools available. Faculty should be involved (and supported) in course development over time. If ownership and subsequent development of online courses are handed off to the distance learning entity as soon as a course is transferred, then quality may flag, because the interest and expertise of the primary instructor will be lost.

• DL practitioners should be encouraged to demonstrate, present and publish, in both local and larger venues.

• Encourage early adopters and innovators, wherever they are found. They are role models for others, and they will continue to demonstrate how technology can be used in obvious and less-than-obvious ways. If they are involved in development or if they use the Development Center, not only their discoveries but also their processes for using technology can be codified and shared with others.

• Share progress internally and in the public community. This can mean providing copy for student and faculty newspapers as well as local media. Schools are notoriously memo-centric, so non-traditional venues for sharing successes should be chosen to ensure attention.

• Value and use technology innovation wherever it is found and whoever provides it. Technology, concept and content skills may be found everywhere in a school community. Integrate the skills and efforts of those innovators into DL program development.

Conclusion

Finding keys to unlock a school's culture is a difficult challenge, particularly when changes are occurring quickly, under the impetus of external pressure. College teachers, staff and administrators who believe in DL are finding that they have to quickly develop and apply new skills outside the envelope of their normal job descriptions. Any expertise they develop has to quickly be shared with colleagues, in order to make cultural changes happen. But Distance Learning, whether we think of it as a new paradigm or one of many extensions of the old, is clearly broadening educational horizons. Advocates for Distance learning who understand its potential can provide the leadership to move their colleagues and schools toward successful integration of this exciting new educational opportunity.

Virtual Reality in Engineering Instruction:
In Search of the Best Learning Procedures

Abstract: The present study describes a prototypal system for machine tools teaching in a Virtual Reality environment integrated with hypermedia. The goal is to lead students not only to understand the structure and functioning of the lathe, but also to use such a machine. To reach this, the prototype tries to foster conceptual changes in students' mental models and to increase students' control over the learning process. A series of experimental tests have been carried out to assess the educational validity of the instructional tool which has been devised. The aim of the first phase of the project was to assess whether students could use easily the virtual lathe and to verify what they learn about such a machine. The purpose of the second phase was to focus on some critical aspects of the learning process activated by using the virtual lathe in order to realize which are the instructional procedures which give the best learning outcomes.

Current Needs in Engineering Instruction

There are many multimedia teaching aids available for engineering education. However, the problems currently encountered in the use of such instructional tools account for the computer packages' reduced interactivity, for the impossibility of on-line assessment of students' competence levels and of relevant feedback, for the difficulty to integrate the presentation of notions and concepts with the active exploration that software allows, and so on. Furthermore, educational packages often lack of user friendliness, are not always adapted to the needs of either teachers or learners, the networking is rarely sufficient, and traditional pedagogical methods have certain difficulties in integrating the contributions of didactic multimedia. In addition, the products designed and distributed are seldom modular, open-ended, and sufficiently flexible to fill the different goals of the users. Finally, there have been few attempts to validate experimentally the efficacy of computer-assisted courses.

To devise better products for teaching and learning scientific and technological topics, collaboration among Information Technology engineers, didactics experts, cognitive psychologists, and software developers is needed. In this way users will have validated products available along with technical and pedagogical assistance from specialised institutions.

In order to reach this goal, accurate researches are requested, particularly in three fields:

- in the cognitive sciences field, to the extent that it is in particular a question of increasing the pertinence of the trainee model by observing and reconstructing students' spontaneous learning process;

- in the information science field, in order to improve traceability and guidance of individual activities or joint-solving training pursued by the student;
- in the expert systems and artificial intelligence field, to allow the creation of innovative telematic procedures which can amplify the range of their use.

The results of this research will favour the definition of a new pedagogical approach which will be more individualized and interactive both for students and for teachers. More precisely, at the service of didactic innovation, the instructional tools to be devised should allow personalised training and the learner's activity should be privileged by favouring an immediate evaluation of his or her actions, among other things, as well as the apprehension of all the information available in the learning environment. In other words, the development of didactic frameworks corresponding to the students' customised requirements, either in person or remotely, in different teaching contexts are needed. Moreover, a methodology for these innovative practices based on interaction, tracing and intelligent guidance to improve every student's performance should be shared. For example, new teacher-training methods and the elaboration of new learning situations which call on games, exercises, interactivity and problem solving should be developed. Further innovations targeted are the adaptability of the media to different contents, cultural environments and cognitive profiles.

The purpose of the project described in this paper is to present an instructional tool to be used in engineering education which integrates hypermedia and virtual reality and to discuss the results of some experimental investigations aimed at evaluating its pertinence and at assessing which are the best procedures to train students. The long-term goal of the project is to produce, thanks to the progress achieved both in software tools and in learning devices, an high-quality course to disseminate innovative methods for engineering teaching accessible to the greatest number and at reduced cost.

The Virtual Factory

The possibility to use a Virtual Reality system for teaching and/or training surely offers a series of advantages: learning efficacy, safety in the interaction (because the knowledge objects are virtual) and cheapness of didactic mission (because the computer system replaces the didactic equipment and the machinery, generally existing in the technical/scientific laboratories). The efficacy of the didactic mission increases because with Virtual Reality it is possible to integrate, but not to replace, the traditional knowledge processes, based on a symbolic-reconstructive approach (for example, using books, language or logic connections), with the natural knowledge process based on a perceptive-motor approach. Finally, Virtual Reality in the field of engineering is thought to make easy learning and training in using machine tools; it utilizes different teaching techniques thanks to different didactic paths depending on the kind of user (student, worker) and on his/her cultural and vocational level. The representation techniques of Virtual Reality allow to model all elements, that are the objects of lessons, at different complexity stages, to foster a progressive learning of the subjects.

On these grounds, the project aims to realize a prototypal system to teach the utilization of machine tools through a desktop Virtual Reality-hypermedia integrated environment. The prototype regards a manual centre lathe [Boer et al. 1997]. It will allow, on one hand, to implement in a virtual environment typical exercises of a manufacturing laboratory, eventually performable with the aid of the hypermedia environment, and, on the other hand, to set a graphic computer network that is able to share interactively the same synthetic environment. The virtual lathe is addressed to students that attend the last three years of technical-industrial schools and engineering faculty courses. This application could easily be introduced in the industry (maintenance courses, NC-machine tools programming, products marketing).

The prototypal system consists of a traditional centre lathe (fundamental machine tool, both historically and industrially, mainly dedicated to the machining of cylindrical workpieces), in the virtual environment, and of the master environment, which contains technical information and didactic instructions. The two environments have been integrated to work together.

The project is based upon a logical structure called A.I.A.D.I. (Italian acronym of "Direct and Indirect Learning Integrated Environment"). It consists of two main environments (Virtual Reality and hypermedia), plus a third environment which has the function of introducing the student into the system and of allowing to choose among some proposed alternatives, regarding the type of exercise and the learning modality.

The lathe consists of a set of components (structures, piece supports, parts for the information transfer and control) that receive power, data, and materials with the goal to modify their physical characteristic by a sequence of operations. From the operative point of view, the machine tool presents some mechanical components that are in relative movement and therefore it is necessary to define their own kinematics characteristics and their movement synchronization according to the specific operation. A set of technological parameters comes into play; these, if rightly fixed and linked, allow the reaching of the productive goal.

The *Virtual Reality environment* allows to learn the machine tool (declarative knowledge) and to learn its use (procedural knowledge) within a realistic situation, performing practical operations, both physical (i.e., piece positioning on machine tool and cutting tool movement) and conceptual (i.e., choice of cutting tool from the virtual store, choice of cutting speed). First the lathe has to be prepared with the necessary accessories; then all the necessary parameters have to be set; finally, the user can perform the assigned task according to the drawing previously showed. The virtual machine gives a feedback at each step.

The design of the *hypermedia environment* is based on the concept of "structured approach"; it may reduce the risk of "getting lost in hyperspace", that is not to know how to go back to the starting point and the risk of obtaining a so called "spaghetti document", that is a document containing a lot of pages, each one with a short piece of information, which doesn't let the user learn effectively the concept. The chosen model for this application is called HDM+ (Hypermedia Design Model). The hypermedia environment represents the knowledge store/manager of the system and is comparable with the role of teacher. It lets the student learn through texts, pictures, movies, graphical simulations, and Virtual Reality or real situation demos. It is subdivided into three logical parts: glossary, hypermedia, and simulation. The student can access the hypermedia environment on his request; the structure of the student-computer interaction is open-ended. Five different kinds of lesson are implemented in the system: theoretical, demonstration, guided practicing, free practicing, and examination; student is allowed to choose the kind of lesson and change it at any time. *Theoretical lesson* is worked out only in the hypermedia environment: the system explains the information related to the chosen item. In the same environment the *demonstration lesson* is available; it consists of two demos related to the chosen manufacturing cycle. In the *guided practicing* the student performs the manufacturing cycle step by step under suggestions and control of the system; each step consists of three phases: "what to do", "how to do", and "to do". In the *free practicing* the student performs the chosen task in the Virtual Reality environment and he or she can take information from the hypermedia environment, and the system shows the results at the end of job or stops the lesson if mistakes occur. Finally, the *examination lesson*, is similar to the previous kind of lesson except the hypermedia environment is inaccessible.

The prototypal system has been realized on a personal computer (Pentium processor, 32MB RAM) using VRT 4-00 Superscape, for the implementation of the virtual environment, and Multimedia Toolbook 4.00 for the realization of the hypermedia environment.

An Experimental Study

Aim

A pilot study demonstrated that the machine prototype enables students to learn what a lathe is and how it works. The next step of the project was to devise the best procedure to train students. As far as this need was concerned, a critical question to be addressed was: is it better that students begin their training by navigating the virtual lathe or by facing the hypermedia? This was crucial in order to identify the relevant steps of the learning process in which students have to be engaged.

To answer the above mentioned question, an experiment was carried out by analyzing a specific learning situation, that is, the set up of the lathe.

Method

Three groups of novice university students were assigned to the following learning conditions:

Virtual Reality - Lathe = participants navigated freely the virtual lathe before reading hypertextual information;
Virtual Reality - Neutral = participants navigated freely a virtual environment (a room) with no connection with the lathe before reading hypertextual information;
Hypermedia = participants read the hypertext about the lathe without having navigated the virtual environment before.

Indices were obtained from the students:
- by observing their behavior
- by administering questionnaires about:
 . computer using skills
 . naive representation of the lathe
 . knowledge presented through the hypermedia
 . the role of Virtual Reality in education

The sequences of tasks for each group were the following:

A) Virtual Reality - Lathe condition
- computer using skills questionnaire
- questionnaire about the representation of the lathe (1)
- free navigation of the virtual lathe
- questionnaire about the representation of the lathe (2)
- experience with hypermedia
- questionnaire about hypermedia information
- set up of the lathe in the virtual environment
- questionnaire about the representation of the lathe (3)
- questionnaire about the role of Virtual Reality in education

B) Virtual Reality - Neutral condition
- computer using skills questionnaire
- questionnaire about the representation of the lathe (1)
- free navigation of the virtual room
- questionnaire about the representation of the lathe (2)
- experience with hypermedia
- questionnaire about hypermedia information
- set up of the lathe in the virtual environment
- questionnaire about the representation of the lathe (3)
- questionnaire about the role of Virtual Reality in education

C) Hypermedia condition
- computer using skills questionnaire
- questionnaire about the representation of the lathe (1)
- experience with hypermedia
- questionnaire about hypermedia information
- set up of the lathe in the virtual environment
- questionnaire about the representation of the lathe (3)
- questionnaire about the role of Virtual Reality in education

Instruments employed in the investigation can be shortly described as follows.
a) The *computer using skills questionnaire* asked students about their knowledge and previous experience with Information Technology; some abilities concerning computer use were assessed through self-evaluation.
b) The *questionnaire about the representation of the lathe* focused on some critical questions. For example, students were asked to describe a lathe, to explain how it works, to list the kinds of manufactured good for which it can be employed, why it may be dangerous, which abilities are requested to use it. The same questionnaire was administered twice (in the Hypermedia condition) or three times (in the Virtual Reality condition).

c) The *questionnaire about hypermedia information* consisted of open questions about specific aspects of the structure and functioning of the lathe which were explained in the hypermedia environment.

d) The *questionnaire about the role of Virtual Reality in education* reported a list of 24 statements, such as "Virtual Reality requires to plan actions", "Virtual reality is good for intuitive people", "Virtual Reality yields incidental learning". Students had to rate on a 5-point scale their agreement with each statement.

Operations required to the students during the experiments were the following.

a) *Free navigation of the virtual environment*: basic instructions for navigation were provided and exemplified; then students were trained in exploring virtual environment by allowing them to navigate ad libitum the Virtual Reality prototype.

b) *Experience with hypermedia*: students could navigate the hypertext about the lathe in order to achieve competence to carry out the set up of the lathe.

c) *Set up of the lathe in the virtual environment*: students employed the virtual machine tool to set it up. Students' behavior was observed and categorized.

Results

Responses given to the *computer using skills questionnaire* showed that familiarity with computer and ability levels were equally distributed between the three groups of participants and that the subsequent behavior during the experience with the virtual lathe did not depended on the variables measured by this questionnaire.

Responses given to the *questionnaire about the representation of the lathe* were converted into scores; the highest was the score, the highest was the quality of the answer. Data indicated that at the beginning of the experiment both the Virtual Reality and the Hypermedia students had no adequate notions about what a lathe is and how it works.

After the free navigation of the virtual lathe, Virtual Reality - Lathe students learned some core concepts about the lathe.

Knowledge presented through hypermedia was acquired by the three groups in the same manner; in fact, the analysis of the responses given to the *questionnaire about hypermedia information* revealed no differences between the three groups of learners.

No differences between the three conditions during the set up of the lathe performed in the virtual environment emerged also by the observation of the students' behavior.

At the end of experience Virtual Reality - Lathe students showed a higher increase in the adequacy of their conception of the lathe (measured by the *questionnaire about the representation of the lathe*) as compared to the Virtual Reality - Neutral and Hypermedia students

Conclusions

The main findings of the experiment can be summarized as follows:

- the virtual lathe prototype can be used to teach what is a lathe and how such a machine works;
- the integration of Virtual Reality and hypermedia allows novice students with no previous training in engineering to understand the essential feature of the lathe;
- improvements in both declarative and procedural knowledge emerged after a short experience with the virtual lathe prototype;
- the initial naive representation of the lathe is restructured thanks to the experience in the virtual environment and a more relevant notion is acquired after the free navigation.
- learning is enhanced when the exploration of the virtual lathe precedes the presentation of the hypertextual information.

Further Developments

On the ground of the experimental work that has been carried out, the final part of the project aims to elaborate and ensure the distribution of a multimedia and virtual reality training tool validated on the basis of a full-scale evaluation of the cognitive processes involved. This product focus above all on customized teaching and the personal attitude for active self-training; its intention is to establish an interactive environment for each learner which favors the immediate evaluation of his or her activities, as well as providing information accessible locally or at a distance within a given context by multiplying the interpersonal communications possibilities thanks to the electronic network. It also imply that teachers must receive appropriate training which leads them to the most effective mastery possible of flexible, open-ended software packages and reinforce their role as pedagogical project initiators and mediators, indispensable in the progress of the training process.

Reduce Web-Based Classroom Management Efforts by Refining Collaborative Learning Strategies

Chih-Kai Chang
Department of Management Information Science
Lunghwa Institute of Technology
TaoYuan, Taiwan
chihkai@mail.lhit.edu.tw

Abstract: When a Web-based classroom teacher manages a Web-based distance learning system, there can be a substantial burden of preparation work. Hence, an instructor needs a Web site manager to help him/her use tools to manage the Web-based classroom. In fact, some of the more tedious work can be avoided by using proper collaborative learning strategies. To use collaborative learning strategies on Web, a Web-based classroom teacher can use advanced technology for managing learners' portfolios, controlling learning flow, and constructing collaborative learning activities; and he/she can also refine existing collaborative learning strategies, which reduce the requirements of the advanced technology. Furthermore, refining existing collaborative learning strategies can make it easier to implement them in a Web-based classroom. Although there are methodologies for constructing a Web-based collaborative learning system, none specifically address the possibility of refining collaborative learning strategies to work with Web features. The paper surveys some notable collaborative learning strategies as well as proposing guidelines and recommendations for how a Web-based classroom teacher can refine those strategies for use in a Web-based classroom through our technical perspective.

Introduction

"Issues of determining which strategies and how they are used in classrooms, as well as matching proven strategies to classroom needs and measures of intervention fidelity, are targeted as primary areas in need of research." (Gunter & Denny, 1996) Traditionally, an instructor manages a classroom by proper strategies. The properties of strategies that an instructor uses to manage a classroom include group, activity, agenda, role, responsibility, interdependence, etc. Those strategies are called classroom management strategies. Many educators agree that using collaborative learning strategies can reduce an instructor's efforts in classroom management. At the same time, collaborative learning strategies are also required to implement a Web-based distance learning environment to promote learning motivation and learning performance (Leidner, & Fuller, 1997). Hence, guidelines are necessary for an instructor's training needs in using collaborative learning strategies on the Web (Sherry & Morse, 1996). However, in order to construct a Web-based environment for collaborative learning, an instructor must make great efforts to solve technical problems of using Web features for collaborative requirements.

To construct a Web environment for collaborative learning, an instructor first needs to explore the various possible collaborative learning strategies and extract their common characteristics. Then, an instructor may want to see comparisons between the characteristics of collaborative learning strategies and features of the Web. For instance, an instructor may want to know the answers to questions such as 'Are existing Web technologies sufficient for developing a virtual space for collaborative learning?', 'What are the efforts required for an instructor to manage the Web-based classroom after constructing it?', 'Which kind of collaborative learning strategies are most effective on the Web?', 'Does using collaborative learning strategies in a Web classroom work as well as in a traditional classroom?', and etc.. However, both instructor and Web site manager have no guidelines about the relations between the technological efforts and their effectiveness before constructing a Web-based collaborative learning environment. Thus, there should be reports to depict the relationships between technological efforts and collaborative learning strategies from both technical and pedagogical perspectives. Thereafter, a distance learning instructor can coordinate with a Web site manager to construct an effective Web-based classroom with less effort.

The features for a collaborative learning strategy include heterogeneous grouping, interdependence, individual accountability, and group processing (Warschauer, 1997). An instructor may ask the Web site manager to construct all of these features on the Web-based classroom. For instance, an instructor may want to use Team Game Tournament (TGT) collaborative learning strategies. However, a Web server is inherently passive, without a grouping mechanism, so that it is very difficult to construct collaborative learning activities. This problem is called the learning activity construction problem. Furthermore, a TGT strategy must control learning flow among learning activities for its regrouping requirements. That problem is called the learning flow management problem. Besides, the logs of a Web server can not provide enough information for an instructor of the Web-based classroom to make evaluations. That is called the portfolio management problem. To solve those problems from a purely technical perspective, our previous research used active database, workflow, and data cube technology to enhance the capability of a Web server (Chang & Chen, 1997; Chang et al., 1998).

Frequently asked questions about our previous research are "Is so much efforts always needed for a Web site manager to satisfy an instructor's requirements?", or "Does an Web site manager need to construct all features of existing collaborative learning strategies for an instructor to begin practicing collaborative learning activities on the Web?". In fact, the Web site manager's burden can be greatly reduced if the instructor can make an agreement about learning strategies with learners. Hence, the Web site manager can temporarily ignore that requirement and put more effort on other more important requirements. To reduce the Web site manger's efforts, three aspects of an instructor's requirements for using collaborative learning strategies on Web should be considered for refinements.

First, an instructor using a Web-based distance learning system has the difficulty of constructing collaborative learning activities because the Web system does not support role assigning, and learners' behavior recording. If an instructor wants to heterogeneously group learners in a Web-based classroom, the instructor needs to know 'how was a learner's learning performance previously?'; 'Which kind of role is suitable for a learner?'; 'What is the capability of a role, called individual accountability, for a learner in a heterogeneous group?', and so on. The present Web system can neither answer those questions by retrieving information from the large amount of logs, nor endow learners with a role. Hence, a Web site manager may be asked to develop programs for retrieving meaning from the logs of an existing Web-server. These issues are referred as the *heterogeneous grouping* requirements for constructing activities. However, a teacher will have difficulty in constructing a collaborative learning activity because the Web does not support a collaborative style of working. The teacher must arrange the style of collaborative work and define what a group member can do. Furthermore, an instructor should be able to reuse previous learning activities to construct other learning activities. These are referred to *specification and regulation* problems in the activity construction.

Second, an instructor does not have effective tools to control the learning flow to allow learners' interdependence. Some works of previous studies have attempted to manage the learning flow of a learner on the Web, for instance the Guided Tour for Courseware (Hauck, 1996) and Footsteps for a Quiz Activity (Nicol, Smeaton, & Slater, 1995). Those works devised mechanisms for generating dynamic hyperlinks or views of a Web site to help the Web site manger to manage learners' learning flow for collaborative learning. Thus, the Web site manager can easily generate a Web page with specific learning flows instead of rewriting a Web page while instructors modify the collaborative learning strategies. However, that kind of solution requires a workflow mechanism and Web site manager who is skilled at transferring the learning flow of a collaborative learning strategy into the workflow. Furthermore, certain kind of learning flows are difficult to transfer into the workflow mechanism. These issues are called *interdependence* requirements for managing learning flow. A teacher must maintain the progress of an activity because network tools can not automate the agenda of an activity. In addition, progress in agenda of an activity may depend on certain tasks that learners must finish. However, an instructor can not always monitor the progression of a collaborative learning activity. These are called *automating schedule* problems of the learning flow issues.

Third, to analyze a learner's behaviors, an instructor must make a great effort to find pedagogical meanings in the large volume of learners' records. Recording and diagnosing learners' behavior is tedious work for an instructor in a distance learning environment; especially to analyze the interaction patterns of collaborative learning. Although learners' behavior records may have been properly recorded and analyzed, an instructor can not easily determine the group processing from learners' portfolios to refine grouping strategies or learning flow of the collaborative learning strategy. This issue may be called the *group processing* requirements for portfolio management. Consequently, there should be a mechanism for completely recording group processes in a collaborative learning activity. The mechanism should be able to represent all the used data, including generated and navigated. We call this issue the *recording and analyzing* problem of the portfolio management issues.

In other words, a Web site manager or a distance learning instructor must make great effort to construct and manage the additional components of a Web server due to the properties of collaborative learning strategies.

To reduce management efforts for collaborative learning on Web, this paper proposes guidelines for refining collaborative learning strategies to ease the heterogeneous grouping, interdependence, and group processing requirements. Although the proposed guidelines are not generally applicable to all collaborative learning strategies, they do extend our previous research. The point here is that the Web site manager does not have to remember, or be bothered with intricate, yet irrelevant, information; he can remain focused on the validation task at hand. Hence, the Web-based collaborative learning environment will be more easily constructed by a Web site manager and managed by a distance learning instructor.

An illustrative example and guidelines

It is assumed that an instructor would like to construct a collaborative learning strategy, for this example TGT(Team Game Tournament), on Web. The three steps of one round for the TGT collaborative learning strategy are: (1) divide learners into heterogeneous groups for collaboration, (2) regroup learners into tournament for the honor of their own groups, (3) return to their own group for reflection. A learner will get his/her points for his/her group, which is determined in step one, in order of his/her performance in a tournament group. In next round, learners will be assigned to suitable tournament group according their performance in last round. Hence, learners will help each other in the first step to get points for their own group. The purpose of step two is to let every learner have the opportunity to get points for their own group because step two assigns learners to a groups of learners with similar levels. The last step enables learners to reflect on their behavior by returning to their own group and discussing their performance with collaborative partners.

A Web site manager should first construct the required learning activities for TGT, that is discussion activity and tournament activity. For instance, the discussion activity needs heterogeneous learners to help each other learning. Initially, the distance learning instructor should divide learners into heterogeneous groups according their previous learning performance. Thereafter, the Web site manager should develop mechanism for heterogeneous grouping, such as behavior recording, online testing, and so on. Furthermore, the Web site manager has to endow learners with suitable capabilities in an activity, that is the concept of role. Then, the agenda of the collaborative learning activity should be defined and obeyed. A Web site manager has to develop or use additional tools to satisfy the requirements for constructing activities because Web features do not innately include the functionality for constructing activities. In summary, a distance learning instructor may ask the Web site manager to be responsible for the following tasks: (1) Constructing the role mechanism in a collaborative learning activity, (2) Automating and coordinating the agenda for every group in the learning activity, (3) Learners' portfolio analysis. All the above tasks are very complex for implementation on the Web. Hence, it may not be best to directly transform the collaborative learning strategies in a classroom to a Web-based learning environment.

The following sections depict the guidelines for refining collaborative learning strategies to reduce the complexity of implementing them on Web. First, the role mechanism in a collaborative learning activity can be replaced by embedding autonomic systems in the collaborative learning strategies. Then, group moderators can help coordinate the learning flow among groups. Finally, embedding a feedback role can help instructors to determine the group processes in collaborative learning activities.

Autonomic systems instead of role mechanism

In practice, an instructor can reduce both construction and management efforts by embedding autonomic systems into a collaborative learning strategy. For instance, learners can divide themselves into heterogeneous group by ranking each other. An instructor can ask every learner to give a score to the other learners, who are ever in the same discussion activity or tournament activity, as the source for ranking. Instead of providing a mechanism for online testing, the Web site manager just provides the functionality for learners to rank the learning performance of each other. Furthermore, heterogeneous grouping requires a learner's background information, such as race, first language, majority, etc. Most of the information can not be easily collected by distance learning instructors, but learners will know the background of each other and will reveal the knowledge through the ranking function.

The autonomic system should consider the following function:

- Ranking. This functionality of the autonomic system can be used for heterogeneous grouping because the ranking results will categorize learners. For instance, an instructor may ask learners to rank each other from degree A to D about their mastery of a specific topic. Then, the instructor can use the ranking results to group learners. An instructor needs to ask learners to rank only their partners in a group or a competing group because a learner can not know the learning degrees of others that he/she never contacted. The instructor can normalize the ranking results to suit the required number of members in a group if the ranking results are presented in a percentage form.
- Voting. The functionality of the voting mechanism is similar with the ranking functionality, but the purpose of voting functionality is to choose the most suitable learner for a specific role from a group according personal characteristics. Instead of assigning roles to learners, this issue lets learners recommend someone for a role. Hence, the instructor or Web site manager need not make efforts to arrange every learner to his/her suitable role. For instance, the moderator is one of the roles in the discussion activity of the TGT strategy. Because a moderator should be responsible for maintaining the agenda in time and coordinating with other moderators, learners should vote for a learner with proper characteristics to play this role.
- Accountability. This functionality means that a learner's role determines his/her capabilities. In general, the collaborative learning system has to determine what a role does something (Chang & Chen 1997). The instructor can design daily routines for each role to maintain. Consequently, every learner should be responsible for some tasks that can only be executed by the capabilities of his/her playing role.

Consequently, both a Web site manager's burden and an instructor's Web-based classroom management efforts can be reduced by the aforementioned autonomic functionality.

Moderator coordination supports learning flow management

Subsequently, a Web site manager should determine the learning flow among learning activities according to the learning flow of TGT strategy. In other words, the Web site manager should develop a mechanism to coordinate learners of an activity with other learners of the same activity. For instance, the group that first finishes the discussion activity has to wait for other groups. In our previous research, this interdependent relationship is called and-join learning flow, which means that the subsequent learning activity is activated only after all the prior learning activities are finished. And-join is one of the learning flow types that the instructor or Web site manager should make efforts to control. Hence, we previously presented a model for the instructor to depict the learning flow in the requiring collaborative learning strategy, as well as a methodology for the Web site manager to manage the learning flow based on workflow technology (Chang & Chen, 1998).

The requirements of managing learning flows for collaborative learning includes regrouping learners, learning activity coordination, and maintaining strategy constraints. After a collaborative learning activity is finished, learners of the previous learning activity may be arranged into different groups, a process called regrouping learners. For instance, learners in the same discussion group of the TGT strategy will be distributed to different tournament groups. Some collaborative learning strategies need to construct the interdependence relationships among learning activities; hence learning activity coordination is necessary. For instance, in the TGT strategy the tournament activity can not start until all previous discussion activities are finished. Sometimes the collaborative learning strategy should be modified before being applied to some situations, which is called maintaining strategy constraints. For instance, an instructor can not directly use the TGT strategy on thirteen learners because the number of learners can not be exactly grouped.

In addition to using a technical perspective, a distance learning instructor can reduce gaps between the requirements of managing learning flow and workflow technology by adding a coordinate subsystem into his/her collaborative learning strategy. Hence, the requirements for learning flow management can be largely reduced by the coordination of learners play a specific role in every group. If the moderator of the group can notify other moderators of other groups, the Web site manager can ignore the and-join learning flow and make more efforts to manage other kind of learning flow. The moderator of the notified group must agree to reply to the notification after finishing the current learning activity. Similarly, moderators can handle the or-join learning flow requirements, which means that the subsequent learning activity is activated by coordinating agenda if one of the previous learning activities is finished. Consequently, learners are interdependent because they should notify or wait for the notification to do something in the learning flow.

Learners' assessments support evaluating group processing

Finally, the Web site manager must record learners' behavior and learning performance during an activity to permit the heterogeneous grouping and learning flow managing requirements in next stage. Although a Web server can provide system log files, such as learners' access records, a distance learning instructor requires a report with pedagogical meaning. Hence, the Web site manager has to develop or use tools for monitoring, managing, and mining learners' portfolios. Furthermore, the Web site manager should provide a friendly interface for an instructor to understand the generated reports. The purpose of the friendly interface, called multidimensional analysis in our previous works, is to demonstrate reports in any style asked by instructors. However, the issues observed by an instructor are dynamic and can rarely be predicts. Hence, we use the data cube technology to support the Web site manager providing report service to instructors.

A distance learning instructor can help to reduce the Web site manager's portfolio management efforts by refining the collaborative learning strategies. In our opinion, there are other ways to support an instructor recording learners' behavior, analyzing behavior records, and making decisions. These additional guidelines include daybook, moderators' comments, and learners' questionnaires.

- A distance learning instructor can first design a daybook according the pedagogical issues that he/she wants to observe. One specific role of any learning activity should take the accountability to write down the events related to the items, which is defined by the instructor, in the daybook. Hence, a distance learning instructor can review the key processes of collaborative learning by reviewing the daybook that is written by the student with a specific role. Furthermore, the workload of the Web site manager is reduced by developing tools to help the instructor design the daybook instead of developing methodology to retrieve pedagogical meaning from learners' behavior records. Although we proposed in previous research a methodology to solve the learners' portfolios management issue by data cube and multidimensional analysis technology, the Web site manager can not master those skills over the short term.
- Moderators' comments can be used to indicate possible directions for behavior records analysis because a moderator will realize the problems in his/her group. A distance learning instructor can easily get the moderators' comments either by periodic email or a Web page for feedback. Hence, a distance learning instructor can avoid using the cube operations for multidimensional analysis but get the same requiring results.
- The results of learners' questionnaires can be used to verify moderators' comments. Furthermore, a distance learning instructor needs not reconstruct the collaborative learning processes before making decisions using the verification from learners' questionnaires results. Consequently, the instructor can free the Web site manager from the tedious tasks of computing cube visualization.

To sum up, an instructor may expect simply transfer existing collaborative learning strategy into the Web format and get similar effects on learners. From the perspective of the instructor, four features should be implemented on the Web, that is heterogeneous grouping, interdependence, individual accountability, and group processing. From the perspective of the Web-site manager, the collaborative learning strategies will involve technical requirements including activity, learning flow, and portfolio management. As in the examples mentioned above, an instructor can motivate learners' autonomic behavior by refining collaborative learning strategies to reduce classroom management efforts and technical requirements. Table 1 illustrates the relationships among learners' types of autonomic behavior, collaborative learning strategies, and ways to reduce technical requirements.

Technical requirements	Characteristics of collaborative learning strategy	Suggested refinements
Assign group	Heterogeneous grouping	Ranking
Assign role		Voting
Endow capability	Individual accountability	Accountability
Agenda	Interdependence	Notifying others
Automate agenda		Notified by others
Repository for behavior records	Group processing	Designing daybook and Appending daybook

Multidimensional analysis		Moderators' comments and learners' questionnaires

Table 1: Relationships between technical requirements and refinements of collaborative learning strategies.

Conclusions

This paper provides guidelines for a Web site manager to coordinate with a distance learning instructor for refining collaborative learning strategy. Consequently, the refined collaborative learning strategy will reduce the Web site manager's efforts in constructing the collaborative environment on the Web, and also reduce the distance learning instructor's efforts in managing the virtual classroom on the Web. This paper also briefly introduces the required technology and the method of constructing a Web-based collaborative learning system from our previous research. However, that purely technical solution for constructing Web-based collaborative learning environment would be a burden for the Web site manager due to its tedious technical tasks. Based on the characteristics of collaborative learning strategy, we present guidelines for refining collaborative learning strategies from our technical perspective. A collaborative learning example, the Team Game Tournament, is used to illustrate how the guidelines reduce the work needed for implementation. Hence, a distance learning instructor can use existing collaborative learning strategies and shape them to be suitable for implementation on the Web with relatively little effort. Most important of all, the guidelines indicate the directions for the instructor and Web site manager to achieve a common grand point of constructing a Web-based collaborative learning environment.

E-mail:jehng@src.ncu.edu.tw

Abstract: This paper describes a study that examined how an Internet telecommunications tool, EdPsy Web, was used to support a pre-service teacher training course at the level of higher education has changed the quality of social and intellectual interactions that were different from what has happened in a traditional classroom setting. Findings of the study showed that students had seen the value of and demonstrated a positive attitude toward network learning after using Edpsy Web to create discourses. When assignments were delivered in an electronic form, students were motivated to see and compare what other students had accomplished and thus were more aware of what they had achieved. This network learning environment provides more opportunity for collaborative thinking and knowledge sharing. The analysis of electronic discourse explicitly demonstrated the multiple thread nature of electronic message interactions. In general, this network-enhanced classroom setting offered an alternative pattern of interaction which differed from the traditional face-to-face setting in some ways, but not all.

Introduction

There has been dynamic growth in the utilization of Internet telecommnications in the area of higher education. Researchers have indicated that the utilization of telecommunications technology in education will have significant impacts on instructional activities (Roberts, Blakeslee, Brown, & Lenk, 1990). When compared with traditional face-to-face communication, computer-mediated communication functions differently. This new medium has its own rules or patterns for managing temporal, spatial, and social aspects of interactions (Beals, 1992; Harasim, 1990; Kiesler, Siegel, & Mcauire, 1984). It allows for asynchronous interactions. Asynchonicity expands user control over the time of interaction, thereby increasing the time available to read or re-read a message in order to carefully formulate a proper response, the result being a more fruitful and thoughtful discussion around a number of interrelated topics. The record of dialogue interactions can be a rich source of ideas setting the stage for knowledge building activities. Furthermore, the place-independent feature of the telecommunications-based learning environment has the capability of linking persons from different locations for the purpose of communication. Compared to traditional face-to-face communication, asynchronous network communication operates in the absence of social context cues, such as facial expressions, eye contact, and voice intonation. Participants must make their communication clear and understandable. Transcripts of network conversations provide an explicit record of interactions for users to interpret and trace the progress of intellectual interactions. Finally, the telecommunications-based learning environment tends to reduce differences in social status and prestige, thereby providing a more egalitarian context for social interactions. This may lead to more open and spontaneous participantion. Based on its powerful capabilities of information management and unique communicative style, the telecommunications-based learning environment may have different impacts on student learning and motivation.

Facilitating collaborative interactions through computer network

Recent studies on human cognition have viewed learners as agents in a distributed cognitve system which includes physical objects, symbolic representations, people in social relationships, and features in physical situations, all of which play a part in the accomplishment of cognitive activities (Oshima, Scardamalia, & Breiter, 1996; Pea, 1993). This view of human cognition implies that learning no longer belongs to an individual enterprise, but to a joint effort made by learners and their surrounding environment. Theoretically, the classroom can be regarded as a distributed system where students, teachers, symbols and artifacts interact. The classroom discouse provides a collective zone of proximal development that supports student learning (Brown, Ash, Rutherland, Nakagawa, Gordon, & Campione, 1992).

Researchers have recognized that tools offered by computer-mediated communication (CMC) not only can increase the learner's access to information but can also faciliate knowledge building activities. Studies in the Internet-infused learning environment indicated that the utilization of telecommunication tools in teaching may influence student learning regarding science (Linn & Songer, 1991; Songer, 1996). The telecommunication-based learning environment provides a chance for students to get access to real-time resources and firsthand information. Students have greater opportunity to participate in dialogue with distributed peers. The flux of personal experiences, scientific information and expert knowledge infused into the learning environment has the potential to help students develop a rich explanatory base for learning and application of knowledge. Studies have shown that students in the network learning environment demonstrated significantly greater understanding of scientific concepts than did students in traditional classroom settings (Songer, 1996), greater motivation to interact and share ideas with other students (Ruberg, Moore, & Taylor, 1996), and more thoughtful and self-regulatory learning behaviors (Scardamalia & Bereiter, 1991).

The telecommunications tool has demonstrated potential as a medium for sustaining and expanding zones of proximal development, freeing teachers from the burden of being the sole source for transmitting knowledge and allowing the learning community to extend beyond the boundary of classroom. Studies have indicated that telecommunications techonology can faciliate thinking and help shape thought (Brown et al., 1992; Scardamalia & Breiter, 1991). Through the computer-mediated learning environment, participatory activities in which students could practice cognitive strategies, communicate understanding, clarify their positions and develop ideas with their partners are more likely to be facilitated.

Previous research made a claim that the telecommunications technology could be a powerful tool for collaborative interactions and for building a community of learners, however, few demonstrated how the mechanism underlying the process of collaborative interactions could provide opportunities to facilitate learning, and how participants were motivated to learn in the computer network environment. In viewing collaborative interactions in the telecommunications-based learning environment are essential for students to develop their understanding and experience, this research attempted to explore two problems, namely (a) did a network-enhanced classroon setting actually motivate students to interact and share knowledge? and (b) did distinct learning behaviors exhibited by students exist in a network-enhanced classroon setting? Answers to these two problems could help us not only understand how a telecommunications-based learning environment facilitates group interaction and collective knowledge building, but help develop an effective learning environment as well.

Method

The study was conducted in an instructional setting where college students interacted and discussed educational psychology problems with an Internet tool. Three key evaluation methodologies, survey, discouse analysis and message flow analysis, were used to investigate social and intellectual interactions and assess the educational value of this network-enhanced learning environment.

Participating subjects

The subjects were 58 students registered at the National Central University, Taiwan. They were from different departments and participated in an educational psychology course designed as one of the prerequisites for training pre-service teachers. There were 22 males and 36 females.

The network-enhanced learning environment

An Internet telecommunications tool called EdPsy Web was used in this study. The role and purpose of this Internet tool was not to replace but to enhance and transform existing instructional activities into more powerful ones. There were ten functions provided by Edpsy Web (Figure 1).

Participant information. Students could access information about their teacher by clicking the "Know your Teacher" button. Information regarding the teacher's educational backgrounds, research activities, and publications were avabilable for the students' reference. The tool also allowed students to access fellow students' personal information through the "Know your Classmates" button.

Instructional activities. An on-line course syllabus was available for students to consult at any time through the "Course Syllabus" button. The system also provided an on-line discussion function through the "On-line Problem Solving" button. By using this button, students could post ideas and peruse other students' opinions regarding a particular problem or issue. All written assignments could be delivered to and evaluated by the teacher electronically through the "Assignments" button. Students could use this function to see the teacher's evaluative comments as well as other students' works. The "Exchange Idea" button allowed students to exchange ideas regarding the course. The "Reference" button provided lists of reference materials relevant to the course content, such as books, journals, and brief introductions of preeminent educational psychologists.

Instructional administration. Activities regarding the course was announced and accessed through the "Announcements" button. Students could check their grades by clicking the "Check your Performance" button. Finally, students could send their suggestions regarding the course through the "Your suggestions" button.

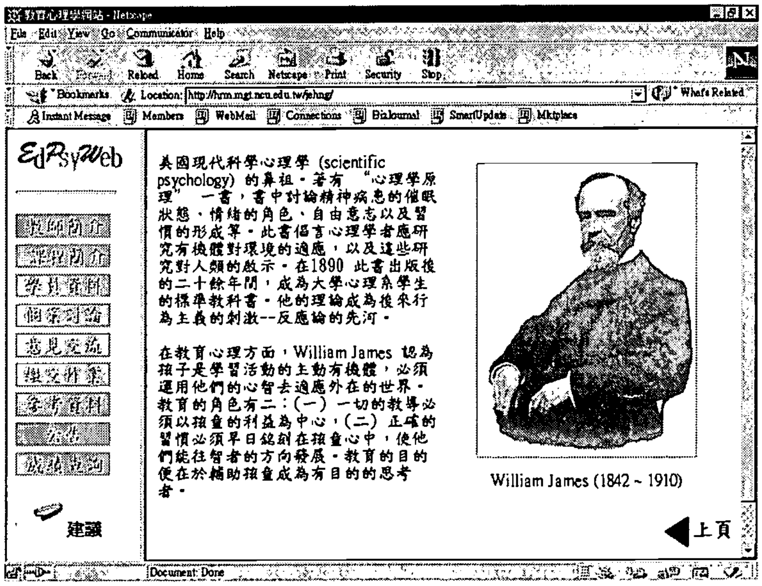

Figure 1: The Edpsy Web Internet tool.

Procedure

In order to have this functioning network community implemented successfully, the teacher managed a reliable computer network for students access and designed well-specified tasks to be accomplished by students (Riel & Levin, 1985). At the beginning of the semester, the teacher spent one week teaching students to learn to use Edpsy Web. Students were requested to enter their personal information into the system and all written assignments were transmitted to the teacher electronically.

After the mid-term exam, two on-line problem solving activities were arranged and each one lasted two weeks. Problems were posted electronically. Students were required to post their ideas and discuss solutions to the problems with their classmates using this Internet tool. They were allowed to collect information from different sources. The teacher did not take any action to moderate or intervene in student discussions. The two activities were held in two different formats commonly used in traditional classroom settings. Firstly students were requested to pose their opinions individually. The problem contained the issue of whether speed reading can really assist students to study and acquire knowledge. Secondly students were requested to study in a group. Six groups were formed and each was required to figure out opinions before posting it on EdPsy Web. The problem contained the issue of whether an objective evaluation systems could be developed to assess student learning in an ill-structured domain, such as history, geography and civics.

Data source

A post-course questionnaire was developed to assess student attitudes toward this learning experience. The questionnaire contained 21 statements with a five-point Likert scale in which 1 indicated strong disagreement, 3 neutral and 5 strong agreement. The questionnaire also included an open-ended question which would solicit the students specific opinions about EdPsy Web. Fifteen senior students who needed to participate in graduation exams dropped the second on-line problem solving activity and did not complete the questionnaire.

All student on-line behaviors were recorded by Edpsy Web, including the time and frequency they logged into the system. Students' written assignments and their ideas during the two on-line problem solving activities were all collected by the system.

Analysis and results

In response to the two research problems addressed above, our data analysis focused on four questions related to emergent learning in the Edpsy Web learning environment: (a) Did students hold a positive attitude toward learning with Edpsy Web? (b) Were students of different genders motivated differently to use Edpsy Web in relation to their prior Internet experience? (c) Did students demonstrate particular learning behaviors during the on-line problem solving activities with Edpsy Web? (d) Did on-line problem solving activities impact their understanding specific learning issues related to educational psychology?

Student attitudes and the motivational differences

Statistical analyses of students' responses on the post-course questionnaire showed that mean scores of 21 items were above 3, indicating that in many circumstances students had a positive attitude toward learning with Edpsy Web. An 2×2 ANOVA analysis of student responses was made along with two demographic variables: gender and prior Internet experience (Table 2). Results indicated that the two variables significantly determined the students' attitude toward Edpsy Web. Students who were frequent Internet users (at least 3 hours a week) tended to be more motivated and had a more positive attitude toward learning with Edpsy Web than infrequent ones (less than 3 hours a week), $F = 5.49$, $p < .05$. Males tended to have a more positive attitude than females, $F = 8.24$, $p < .05$. There was an interaction effect between the gender and the prior Internet experience variable, $F = 7.60$, $p < .05$. Females who were frequent users tended to have a more positive attitude than female infrequent users. No significant difference in attitude between male frequent and infrequent users.

		Gender	
		Male students	Female student
Internet	More than 3 hrs per week	86.09* (9.83)	94.00 (3.61)
Experience	Less than 3 hrs per week	86.63(11.72)	80.69 (11.68)

Note. Mean scores with standard deviation in parenthesis.

Table 2: Student attitudes toward learning with EdPsy Web as a function of their gender and Internet experience.

Student on-line learning behaviors

Analysis of login data can help recognize student on-line learning behaviors. The 58 students had logged into Edpsy Web for more than 950 times across 10 weeks of use. Three hundred and ninety-eight logins were clustered during the two on-line problem solving activities. Eighty-three messages were posted across these two on-line activities, of which 80 individual messages were for the first activity (average 1.38 per person) and 13 group messages for the second (average 2.17 per group). For the first activity, all students posted messages.

Impacts of on-line problem solving activities

In order to explore how the on-line problem solving activities impact student learning, transcripts of all written messages were analyzed and an attempt was made to draw up a typology of electronic messages related to the educational values they displayed. The analysis of transcripts of the first on-line problem solving activity indicated that the independence and initiative of the students in searching out different sources of information to develop their ideas during the on-line discussion. For example, one male student wrote a message drawn from his personal learning experience about speed reading:

> "... I received speed reading training while I was preparing the national extrance exam during the senior high. I really feel that speed reading training helps me read faster, but it may overlook comprehension. I also feel that I have acquired lots of knowledge about study skills from the training. Although speed reading skill can be acquired within a short period of time, but you still need to keep practicing in order to maintain the skill. In my experience, a speed reading training course provides different reading skills such as skimming by gaining control of eye movements, reading without subvocalizing, range reading technique, meta guiding with photographic memory, mind mapping, etc..."

Some of the students wrote messages to express their ideas based on their knowledge learned from the textbook. Part of them drew information from what they had learned in order to defend why speed reading can really work to facilitate quick learning of text material. Part of them drew theories to deprecate the educational value of speed reading. For example, a student drew a memory theory explaining why speed reading can not facilitate deep learning and processing information:

> "...In 1972, Craik and Lockhart proposed the theory of levels of processing in that information can be processed in human memory at either the syntactic level or the semantic level. Processing information at the syntactic level becomes superficial processing. It is difficult to keep information that is processsed at the syntactic level in the memory for a longer period of time for later retrieval. Speed reading training only

teaches students how to draw quick attention to learning materials, but does not allow time for deep information processing. Therefore, speed reading does not help individuals to retain information in the memory for a longer period of time..."

Several students got information from materials outside the course or from the Internet. The following excerpts indicated that students drew information from the Internet:

> "... Many people believe that speed reading is simply skimming or scanning materials, and that reading material slowly is the best way to subsume printed information. Such an assumption is incorrect. Skimming may be appropriate for reading new material. Surprisingly, the more quickily you read, the better you can memorize things. But it is important to comprehend what you read.
> One efficient way to read material is mind-mapping, a multi-dimentional mnemonic, in that you make use of the structure of paragraphs and their placment in the text to improve your reading efficiency, but not each word literally. For example, you just make up a memory word for the main theme of each paragraph and relate them. Reading paragraph by paragraph easily helps you understand. It is not helpful in increasing comprehension when you just read material word by word... Resources: http://www.study.com.tw/txt3.htm...."

Analysis of transcripts also found that there were no particular persons who dominated or took the lead during the dicussion. The message flow analysis indicated the number of messages issued and the number of student logins per day were significantly correlated, r = 81, $p < .000$. Interestingly, the number of student logins and messages issued dramatically jumped each Tuesday when the course was held. A similar pattern repeated in the second week of on-line activity. Obviously, the ebb and flow of messages corresponded to the ebb and flow of school activity.

Previous research on on-line discussion indicated at least three types of roles could be identified when tracing specific themes as discussants wove their way through messages: idea introducer, idea developer, idea synthesizer (Vallee, Johansen, Lipinski, & Wilson, 1974). Based on this idea, an analysis of the major role that each message played was made for the first on-line activity. As Figure 2 shows, at the initial stage of activity, students' messages mainly dealt with idea introduction and development. Some of the students' messages introduced about what speed reading is. Other students then drew certain psychological theories from textbooks to support or deprecate previously initiated ideas. As more new ideas were introduced, more students began to add information to elaborate upon those ideas during the middle stages of the activity. Almost 60% of the major role played by messages as an idea developer from day 4 to day 12. The role of idea synthesizer became more apparent at the end of the activity. As shown in Figure 2, a map was plotted. Messages sharing the same theme were clustered around each day and those clusters containing messages with the same theme were linked with lines across the duration of problem solving activity. A main idea could be elaborated into more specific ideas which later may became main ideas. The map demonstrated the "multiple thread" nature of electronic message interactions and that different ideas were being pursued in parallel (Quinn, Mehan, Levin, & Black, 1983).

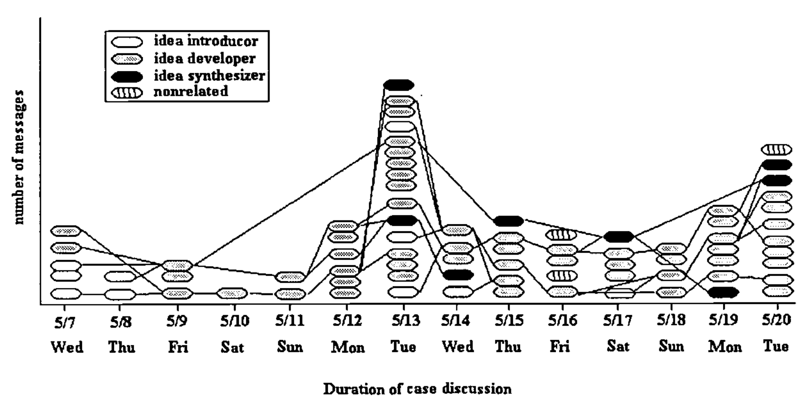

Figure 2: The multi-thread characteristics of electronic messages flow in the first problem solving task.

Discussion

Findings of the study indicated that students had a positive attitude toward network learning after they had used the Internet tool, EdPsy Web, to assist learning, social interactions, group problem solving, assisgnment delivery, and knowledge sharing. Students were highly motivated to have a system that allowed them to send their assignments electronically, to read their teacher's evaluative comments, and to compare other students' works in an electronic form. In most traditional classroom settings, students usually submit assignments to their teachers physically, and receive feedbacks from them without having opportunity to understand what they had acomplished in comparison with other students. In EdPsy Web, however, students had opportunty to see and compare what other students had performed so that they could be more sensitive to what they had achieved. This provided opportunity for students to develop a metacognitive skill to self-monitor and self-evaluate their learning behaviors which may lead to a more effective process of knowledge acquisition.

Results of this study support the hypothesis that two variables, gender and prior Internet experience, are significantly related to attitude toward this Internet tool. Since boys are exposed to computers at an earlier age and more offen than girls, they have more opportunity to use the Internet. Therefore, they are more apt to take advantage of the tool to learn. With less time exposure to the Internet, most female students were not familiar with the functions afforded by the tool so they did not fully appreciate it nor did they take advantage of it. This may have a bearing on male and female students' attitudes toward the tool.

Analysis of the on-line problem solving activity indicated that students could fully take advantage of the telecommunications tool to generate and express their ideas. According to results of our survey, students preferred the on-line problem solving activity to be held on an individual basis rather than in a group. This may indicate that students were motivated to use the tool to express their own thoughts and learned with it individually. The data explicitly showed that there was no group leader to dominate and take the lead during the on-line learning activity and all students posted their messages. Evidently, the network learning environment provided a more egalitarian climate for social and intellectual interaction.

Abstract: An interdisciplinary on-line project, connecting two high schools from diverse school districts, positively influenced student attitudes and resulted in a collaborative publication on the World Wide Web. Comparisons of the frequency distributions resulting from administration of an Attitude Survey in the form of a Likert-type scale revealed increases in positive student attitudes toward English and science, connecting the disciplines, technology, and collaborating with students of different socioeconomic and ethnic groups. Barriers to other formal statistical analyses of the data included: the unforeseen changes in population of the two classes; small sample size; and insurmountable technological problems in one of the schools. Further research is recommended to examine similar interventions.

Introduction

Making high school education work in a changing culture necessitates linking learning to life. Because of the rise in the number of problems associated with urban high schools, such as gang activity and difficulties in dealing with increasingly diverse ethnic and linguistic school populations, high school teachers have become aware of the importance of making school relevant to students' lives. Further, they are starting to recognize the need to emphasize an interdisciplinary curriculum organized around questions students consider important, rather than a strictly subject-based curriculum. A number of innovations in high school curricula integrate subject areas to make "...connections between bits of knowledge and skills from different realms, organized around [such] focusing questions..." (Clark & Agne, 1997, p. xv) as

- How does a civilization come into being?
- What does it take to solve a major environmental problem?
- What do I need to know to thrive in a technological society? (Clark & Agne, 1997, p. xv)

Students must link facts and ideas from disciplines in order to answer these questions, as well as use higher-order thinking skills, and apply abstract ideas to real problems in real situations.

In attempting to explore these and other higher order questions, the infusion of computer technology into the classroom can enhance classroom communications and resources. Computer-mediated communication, in particular, can "...virtually bring the world into the classroom, engage students in collaborative processes, enable them to access experts worldwide, and to make each student an active member of the international community." (Schrum & Berenfeld, 1997, p. 28).

The social, as well as academic benefits of using computer-mediated communication are abundant. Social barriers break down, as students from different communities, cultures, and socioeconomic classes collaborate with each other to discover answers to such important questions.

The Project

A grant from the Corporation for Public Broadcasting (1997) to encourage the infusion of technology into the curriculum enabled the collaboration among the School of Education at California State University, Dominguez Hills, and two high schools in two different districts during the 1997-98 school year. Students from the tenth-grade "Integrated Science" class at West Torrance High School in the Torrance Unified School District, collaborated with eleventh-grade English students at Manual Arts High School in the Los Angeles Unified School District, on an interdisciplinary problem-based project that involved research, inter-school communication via e-mail, creative production and publication on the World Wide Web, as well as social action.

The goal of the project was to involve students and teachers in interdisciplinary teaming and infusing computer technology into the high school curriculum. Technology provided the students with increased motivation, as they researched and wrote for a wide audience (on the Internet), and examined issues of scientific and social import. Teachers used constructivist methods that empowered their students, and provided exemplary models to be used with university credential candidates enrolled in Secondary Interdisciplinary Methods courses and/or Educational Technology courses.

The high school students, from two very socioeconomically and ethnically different schools, collaborated with one another on-line to write and do research, in order to build a home page that provided a forum for information and creative writing about scientific issues of import to humankind.

Manual Arts High School is located in the center of Los Angeles, commonly referred to as the "inner city," and West Torrance High School is located in a suburb adjacent to the city of Los Angeles. Both are considered ethnically diverse, though with different ethnic populations; Manual Arts High School is primarily Latino and Black, and West Torrance, primarily Asian and Caucasian. There is a large gap between the schools with respect to students' socioeconomic backgrounds.

The following were the objectives in the year-long project:

- to increase students' awareness and understanding of the world around them;
- to make students cognizant of the issues arising from the environment and scientific discoveries, as well as their ethical and moral implications;
- to stimulate students to explore possible solutions to moral dilemmas posed by the issues;
- to encourage students to use concepts inherent in real issues to write fiction and poetry;
- to improve students' research and writing skills;
- to motivate students to do further reading of science fiction, poetry, and material concerning the issues;
- to promote inter-school cooperation;
- to bridge the gap between socioeconomically and ethnically diverse student populations;
- to involve students, teachers, and pre-service teachers in research which makes use of computers, CD-ROMs, and the World Wide Web;
- to update equipment at both schools to complete the project;
- To stimulate discussion, further reading and exploration of social action by students and others accessing the resulting Web site; and
- To create a constructivist learning environment that supports inquiry, interdisciplinary teaming, and the integration of technology into the curriculum.

As a first step, both classes took an attitude survey (see Tab. 1) at the beginning of the project to determine how they felt about several things: studying English and science; using technology; and working with students who were different from themselves. This survey was to be administered again at the very end of the project to determine if there were any significant changes.

Next, the Integrated Science class did research both in traditional methods and on the World Wide Web to write scientific briefs on issues related to their studies, issues that have moral and ethical implications, that involve conflict, and are of serious import to humankind. Although originally conceived to involve a biology class, the issues in integrated science broadened the scope of possibilities. After brainstorming during the first few weeks of school, the Science students came up with the following:

1. Space exploration
    - Mir Space station (out of control, or having alien contact)
    - Mars Lander (discovery of life form)
    - People living in space (stations)
    - Asteroid impact Specific environmental topics
    - Effects of El Nino
    - Global warming
    - Nuclear war or nuclear accident at San Onofre
    - Ozone depletion
    - Effects of a "supernova" on Earth
2. Animals
    - Communication with dolphins
    - Communication with apes and chimpanzees
    - Effects of solar flares on the Earth

- Another ice age

3. Human physiology
   - Ebola virus
   - Curing cancer
   - diet medications

Attitude Survey
Directions: For each of the items below, write the number that best describes your opinions. There are no right or wrong answers; we are merely interested in how high school students feel about these issues. • Not at all (1) • A little (2) • Somewhat (3) • Quite a bit (4) • Very much (5)

Category	*Item*
The Disciplines	1. I think English and science are two subjects that relate to each other. 2. I think English is an important subject. 3. I enjoy English class. 4. I think science is an important subject. 5. I enjoy science classes. 6. School would make more sense if teachers from different subjects would work together to plan projects for the students. 7. Teachers from different subjects should work together to plan student projects so that the students could make more connections between the different topics they are studying. 8. Research/library skills are important in studying science. 9. Reading is important in studying science. 10. Writing is important in studying science. 11. Word processing is an important skill in studying science.
Technology	5. I feel comfortable working with computers. 6. I feel comfortable exploring the Internet/World Wide Web. 7. I feel comfortable doing using e-mail. 8. I think learning to use technology is important. 9. I think technology is useful. 10. I think learning how to communicate via e-mail is important. 11. I think learning to do teleconferencing is important. 12. I think communicating via e-mail is a useful skill. 13. I think teleconferencing is a useful skill. 14. I like working with computers/technology while I learn science and/or English.
Work Situations	6. I feel comfortable working alone on assignments in class. 7. I feel comfortable working on assignments in a small group in class. 8. I feel comfortable working with students from another class in school. 9. I feel comfortable working with students from another school. 10. I feel comfortable working with students from other neighborhoods. 11. I feel comfortable working with students from other geographical areas. 12. I feel comfortable working with students from other races and/or cultures.

Table 1: Attitude Survey

The science students then sent, via e-mail, the "scientific briefs"(see Tab. 2), which were uniform in content, to the students in the "Contemporary Composition" class at Manual Arts High School. Again through email and one videoconference (which unfortunately had to be aborted due to lack of appropriate wiring) students from both classes attempted to explore solutions to the issues, possible avenues for social action, and "what if" scenarios. The students in the English class then took the issues in the "scientific briefs," and created science fiction short stories based upon them. In preparation for the creative writing, English students did their own research, reading works of science fiction authors who have dealt with such issues.

English students edited the articles to be published on the Web site for mechanical and organizational content. Similarly, the science students edited the English students' stories for scientific accuracy. Both classes then published their works on the Internet, on a Web site provided by Manual Arts High School. After the publication of the first issue, the intent was originally to solicit contributions from students at other schools for contributions to other issues. Unfortunately, the actual amount time both classes needed to complete the steps in the project exceeded the amount estimated; therefore only the initial round of stories was published.

Scientific Brief
Issue: ____________________ Explain why this topic is an issue:
Explain the controversy over this issue:
Background: Give a brief history of this issue (When and where did it become an issue? Facts leading up the present situation.)
Current status of issue: What has been accomplished? Where are we now in relationship to this issue? Has any progress been made? What?
Possible solution(s) to this issue: ________
Suggest a "what if" for a possible story, poem, or play about this issue:

Table 2: Template for Scientific Briefs

The project Web site is *http://www.lausd.k12.ca.us/Manual_Arts_HS/CPB/Science_Fantasy.html.* A Hyperlink to the project web site is also available from the author's Home Page at California State University, Dominguez Hills, at *http://www.csudh.edu/soe/faculty/nmach.htm.*

As the culminating event, in late May there was a face-to-face meeting of both classes, together with their teachers and the university sponsor at a luncheon at California State University, Dominguez Hills. A guest speaker, Mr. Scott Greenberg, got the students involved in an interactive writing workshop. Mr. Greenberg, is a humorist, screenwriter, speaker and leadership consultant who has inspired young people across the country to overcome obstacles and achieve their dreams. Students met at the University Student Union, where they mingled over lunch. They then were put into heterogeneously composed groups in order to participate in the writing workshop.

At the end of the year, both classes again completed the attitude survey (see Tab. 1) to see if there had been any significant change in any of the variables (see Fig. 1).

Findings

In addition to administering the Attitude Survey (Tab.1) at both the beginning and end of the school year, the teachers compared student work, student journals and other classwork from fall to spring, for improved factual content and writing skills. Both high school teachers also informally compared the participating classes to their other classes with regard to student motivation and involvement, on such variables as attendance; quality of work submitted (content/writing skills); and participation in projects.

Results of the Attitude Survey are indicated in the charts in Figure 1, below, and at *http://www.csudh.edu/soe/faculty/NmachAACE/figure3.html.* Although they were from two different schools and two different subjects, the two classes were combined due to the small number of students in the sample, and for purposes of comparison between pre- and post-project attitudes. There were some students who took only the pre-test, but for one reason or another did not continue to participate in the project; they therefore were not included in the post-test. *In toto*, 39 students completed the pre-test and 33 completed the post-test. The author therefore looked at frequency distributions in the form of percentages of students who responded with specific ratings on a one-to-five point Likert scale to the various questions.

Some interesting Pre- and Post-project differences emerged when comparing the mean percentages of students' ratings in the area of technology in general. When all the items were combined in this area, numbers of students using a rating of "5" rose slightly (from 44% to 48%), though they were initially somewhat high. "Comfort Level with Computers" also showed a rise in number of students giving ratings of "4"and "5," with a corresponding decrease in those with ratings of "1," "2," and "3." Ratings of "4" for this question rose from 41% to 48%, and ratings of "5" rose from 18% to 30%. The increase is similar when looking at "Comfort Level Using E-mail," with those rating it with "5" rising from 33% to 45%. In other areas, numbers of students selecting "4" and "5" combined, for attitudes toward the disciplines, in this case English and science, as well as interdisciplinary work, showed a slight increase, rising from 57% to 61%. Similarly, more students selected these same ratings for attitudes toward working with others, particularly those from other ethnic and socioeconomic groups, with those selecting "4" or "5" combined rising from 58% to 64%.

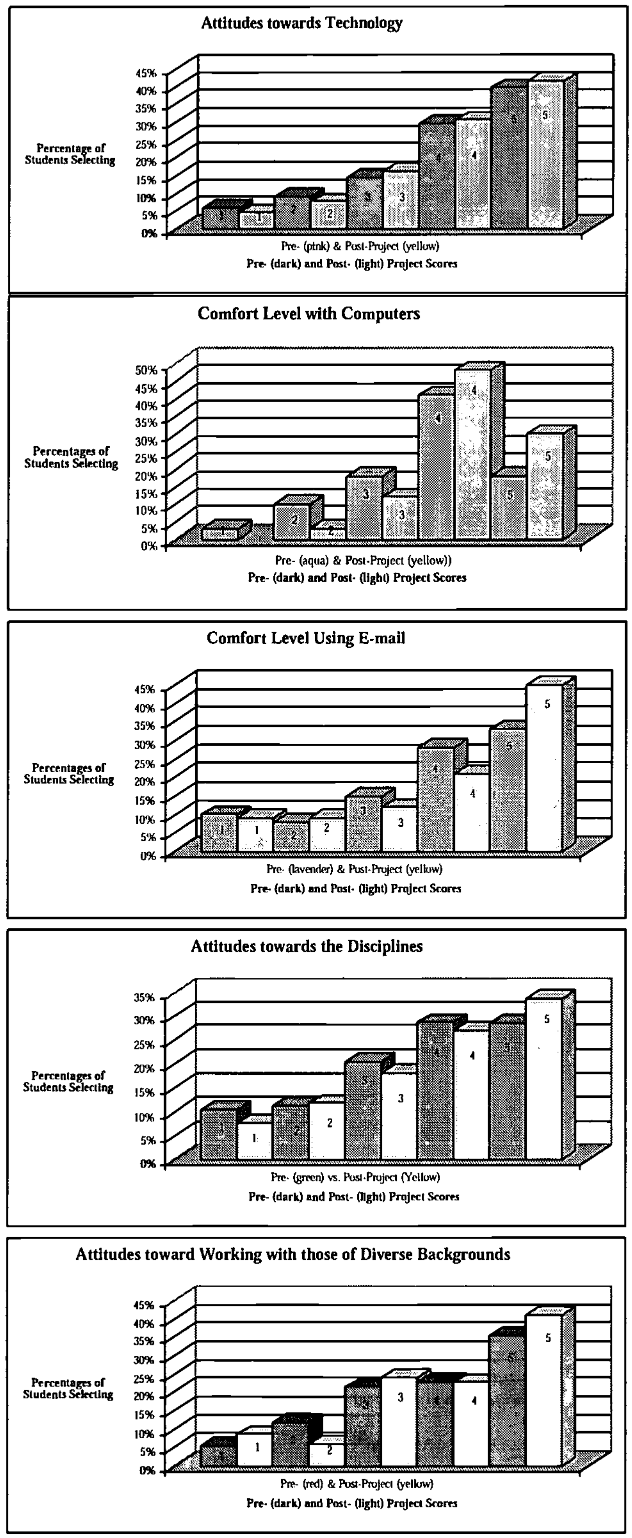

Figure 3:Bar graphs Depicting Pre- vs. Post-Project Attitudes – percentages of students responding with #1-5 on Attitude Survey (in color at *http://www.csudh.edu/soe/faculty/NmachAACE/figure3.html*)

Informal feedback from students was highly positive. Students came away from the face-to-face meeting with changed opinions of the ethnically and socioeconomically different groups than they had originally held, and increased levels of self esteem. One student actually commented that the guest speaker at the face-to-face meeting "changed her life." Both teachers in the two high schools reported higher than normal attendance on the days students were to work on the project, particularly on days when e-mail and an attempted video conference were to take place. Teachers noticed slight increases in student grades when compared with their other classes, but also a tremendous increase in student motivation, as evidenced by student attendance, small and large group participation, and submission of classwork.

Conclusions

In sum, it appears that in this project, electronic collaboration positively affected student attitudes toward English and science, connecting the disciplines, technology, and collaborating with students of different socioeconomic and ethnic groups. The increases in attitude ratings were most evident at the higher end for most categories, strongly suggesting noticeable differences in those areas. On-line communication is, after all, both color- gender-blind, thus capable of dispelling stereotypes about students from other areas, other ethnic and socioeconomic groups. To the students, the meaningful real-world connections of an interdisciplinary project, as well as the knowledge that their work would be published on a Web site, motivated them to apply themselves to the study of both English and science, and positively influenced their ability and comfort level in using technology.

Unfortunately, certain problems prevented the emergence of statistically significant findings, most notably: (1) the size differences between pre-and post-test populations of the two classes prevented stricter comparisons using raw data and t-tests to prove significance; (2) the small sample precluded making generalizations from the data collected; and (3) one school was not fully wired for Internet access, thus making it difficult to carry out the teleconference successfully.

It was ironic that it was the suburban school that was not fully wired, while the "inner city" school" was extremely well equipped. This is the reverse of what would be expected, since the inequities in school funding usually expected in the two types of schools ("inner city" *vs.* "suburban") usually have repercussions in their technological sophistication. Our "suburban" school, however, may not be representative, since it has a large working class population that has been rather conservative in defeating school bond issues. Similarly, our "inner city" school may not typify the inner city schools in Los Angeles, because of the unusual number of technology grants it has received.

Further research, with improved experimental design in such areas as using a larger population of students, comparisons with control groups and stricter controls on administration of attitude surveys, would increase the generalizability of results.

Using Analogy to Build Conceptual Understanding of Multimedia Environments

Paula Roberts
Communication and Information Studies
University of South Australia
paula.roberts@unisa.edu.au

Abstract: The web-like nature of multimedia projects differs significantly from traditional linear environments, and navigation in this new terrain relies heavily on abstract thinking, involving spatial ability. This study examined the use of a familiar analogy in assisting the conceptual understanding of hypertext and multimedia environments. The outcomes of this research suggest that familiar analogies may enhance perceptual understanding in computing novices, and encourage these students' use of the new media for academic writing.

1. Introduction

Research has shown that the use of word processors in student essay writing in secondary and higher education has brought minimal benefit, and has done little to aid the planning and revision of texts. The reasons lie chiefly in the computing technology itself. When composing text on the computer, the vision of the writing is limited to the current screen view, and preceding passages are obscured. The scrolling back and forth required to locate an earlier sentence or paragraph creates in many writers a form of cognitive motion sickness. More serious still, the writer has little chance of developing a conceptual map of the whole piece, leading to what has been described as a 'text sense' problem; that is, a lack of 'knowing' or recalling the text brought about by the difficulty of gaining a 'global perspective' of a piece of writing which is essential for its structural reform (Eklundh 1990).

These difficulties have caused many students to spurn the use of computers as writing tools, and they persist in writing their first and subsequent drafts by hand, and then use a word processor only to produce a final version of their writing. Thus the revision of previous drafts remains a surface, cosmetic process, most often without structural alterations, despite the obvious usefulness of the word processor's 'cut and paste' facilities.

Other strands of writing research have led to the design of hypertext systems which assist the cognitive mapping of writing from source documents, and which allow the planning stage of writing to proceed in non-linear fashion. However useful these systems may be, the movement from linear computer environments to the web-like, branching structures of hypertext and multimedia formats requires a conceptual leap in cognition which depends to a great extent on spatial ability. This facet of human cognition is under-developed in many students (females in particular) due to differential socialization and mathematical experiences, and is an anomaly which apparently disappears with practice (Hyde et al. 1990).

Computing educators, who understandably are caught up in the excitement of the educative potential of multimedia formats, must not take for granted a student's easy passage from the old and familiar linear formats of reading and writing to these new, non-linear presentations of information. This paper describes how the use of a familiar analogy, in this case, the format of information presentation in popular newsmagazines, has assisted students in achieving the conceptual transition from the linear to the non-linear, and, at the same time, has both improved student academic writing, and revealed to the students the narrative potential of writing in multimedia formats.

2. The use of analogy in the conceptual understanding of computer systems

Learning with computers often creates problems for students inexperienced in their use, and anxiety can develop into avoidance (Harrington et al. 1990). Familiar analogies have been used by computer designers to reduce anxiety and to increase the 'user-friendliness' of their product, for example, Apple's (and now Windows') 'drag and drop', icon-based filing system for electronic documents uses familiar analogies, in which the user drags a file to a familiar folder icon, or to a rubbish bin icon, an arrangement which is far easier to understand and use than the former PC filing method of creating directories and sub-directories.

Analogical reasoning has a long history in human cognition and scientific thought. Gentner & Jeziorski (1993) define the central idea of analogy as the mapping of knowledge from one domain (the base) into another (the target). However, in processing analogy, people implicitly focus on certain similarities and discard others. These writers cite a bright student reading the analogy, 'a cell is like a factory', and suggest she is unlikely to see a cell as constructed of masonry and steel, but more likely will consider the similarities of the processes of factories and cells, that is, the intake of resources to maintain operations and generate products.

The research literature supports the use of familiar analogies in promoting understanding of new concepts especially in novices (Hesse & Klecha 1990). Analogies act as 'advance organizers' which allow learners to 'map the new' on to familiar material, although there is a danger that the particular quality of an analogy may bias how new material is understood, and the transferability of learning may also be impeded if the analogy is insufficiently transparent.

Russon, et al. (1994) cite a small body of work relating to the use of analogies in computer education for novice learners, including Beard, et al. (1987) who found that paperwork analogies were helpful in students' understanding of simple database retrieval. Russon and his colleagues (1994) discovered that changing one aspect of computer exposure, in this case the way computer material is taught by the use of analogy, had beneficial effect on skill acquisition and the development of confidence in computer novices. These various writers identify the value of analogies in assisting learners to link new with familiar material, thereby fostering both a sense of relevance and reducing anxiety.

3. Multimedia: a conceptual approach

Douglas (1993) notes that, as an environment for reading and writing, hypertext represents an intriguing and compelling paradox, for while its content looks like the printed word, its technological apparatus places the printed word in an environment almost free of the physical constraints and characteristics traditionally associated with printed text. The problem of how the unfamiliar structure of hypertext might best be conveyed to students as they explore different ways of writing with computers suggests the need for a familiar analogy to aid the conceptual understanding of hypertext and multimedia formats.

The genre of newsmagazine writing presents itself as a powerful analogy (and conceptual tool) for understanding the complexities of these new writing environments, as well as their potential to revolutionise our traditional notions of text. Newsmagazines represent a new yet familiar form of electronic writing. Formatted with page layout software similar to that used by student writers, their structure and visual presentation allows easy analysis of the text. That these magazines are composed and typeset centrally, and then transmitted electronically to regional areas of the world for the addition of local content, is compatible with students' understanding of online communications and co-operative writing. However, it is these magazines' style of information presentation which makes them an even more effective analogy for students in their understanding of new ways of writing, and reading electronically.

The newsmagazine presents its information in fragmented but connected pieces, and departs from a text-only approach to communicate with various formats of text and graphics, a visual variety which has been created with the purpose of gaining attention and facilitating understanding. Designed to be read in trains and buses as much as in lounge rooms, the newsmagazine allows readers different entry and exit points from its stories by segmenting them into main text and commentaries. This, of course, is the nature of hypertext and multimedia presentations of information, where the reader has a similar choice.

In newsmagazines, these commentaries which exploit the facilities of page layout software, exist on a different narrative level than the main text, thus creating an illusion of web-like connections with the main story. As such, these 'layered' texts represent a powerful analogy, which aids students' understanding of the electronic construction of hypertext and multimedia environments, as well as the opportunities they present for the reader to depart from the traditional linear path of reading. These facets of newsmagazines were used as conceptual tools in the study outlined below.

4. The Study

This paper describes a study of Arts undergraduates at the University of South Australia, who, in writing with page layout software, moved beyond mere page design to exploit this software's potential for displaying the 'layering' of information. Using a newsmagazine style of writing, typified, for example, by *Time* and *Newsweek* magazines, the students took a word processed story and transformed it into a layered text which simulated a hypertext or multimedia environment.

The news-magazine genre is familar to most students who are avid consumers of magazines. *Time* and *Newsweek* magazines are known to students, (if not as well as the more 'pop culture' adolescent magazines), and are readily available. At the start of the study, the unique features of these magazines' presentation of information were analysed. For example, in a recent story on heart attacks, the *Time* magazine writers departed from their main theme of the incidence and cost to society of the prevalence of heart disease, to create various subthemes, (or layers), to the main story. One such subtheme was a list of recovery chances, based on the closeness to medical assistance at the onset of the attack. Another was a commentary on risk factors in the prevalence of heart disease, related to personality-typed individuals, while another significant section was an interview with patients who had made an excellent recovery after suffering a heart attack.

In *Time* magazine, through desktop publishing techniques, the themes in this article had been integrated on the same or adjoining pages, but were separated by textual and graphical means, such as the main columned text's weaving its way through 'islands' created by graphics and photographs, and by the separate, coloured and boxed panels of text which contained the subthemes. Here was choice for the reader, either to follow the main text through the pages to its conclusion, or to digress to the accompanying subthemes, and later, maybe, to once more resume the main story.

So, *Time* magazine presented a practical example, if in a contradictory and linear print form, of an electronically layered hypertext. That is, instead of the subthemes being hidden from view in electronic layers distant from the main text, the page layout of these articles provided a hypertextual, visual example on the one plane. In this way, this journalistic model created a conceptual analogy of hypertext for students yet to undertake projects in multimedia presentation.

The writing task undertaken by the students involved transforming into a layered text the article written by van Gelder, entitled *The Strange Case of the Electronic Lover*, which is reproduced in Dunlop & Kling (1991). Briefly, the story involves deception on the Internet. A male, New York, psychiatrist masquerades as a disabled female, Joan, and develops online, electronic relationships with a host of unsuspecting women. The motives of Alex (not his real name) for these several months of deception are uncertain. Whether Alex saw himself as an earlier *Tootsie* or *Mrs Doubtfire* and could argue some valid professional reason for his actions, or whether he sought only personal gain, remains a mystery. Certainly, Alex (in a complicated sub-plot) developed a sexual relationship with one of his new female, 'on-line' friends, and eventually was unmasked. An interesting outcome was the reaction of Alex's 'victims'. Most did not condemn him, but spoke only of the pleasure and benefit of their electronic interaction with Joan (Alex's female persona).

First the students analysed the story of the electronic lover, and its many facets became visible as layers, or stories within stories. As they set about planning the four pages allowed for their review essay, there was much to interest both male and female students, and their responses to Alex's deception were varied. Some were offended by the deception, while others were more tolerant, and these divergent opinions, interestingly, were represented not only in words but in the scanned photographs which they chose to represent Alex.

Some students created an ethical debate as the framework for their review, some highlighted gender issues, while others extended their review to the wider concerns of behaviour in global communication networks. Others, still, followed the journalistic view that here was an interesting story whose nuances could best be highlighted by the interplay of banner headlines, subheads and pullquotes with the text, and with typography and graphics chosen for visual impact, in page layout software which allowed these differing story lines to be given individal emphasis in ways not available in the linear, wordprocessed, original version of van Gelder's article.

So, page layout software allowed the composition of diverse pages, each exploiting text and graphics to construct 'commentaries' on the main story. Importantly, the students created their own fragmented, but connected, textual format, which was a hypertext, but in a single plane.

There was a significant increase in student understanding of the meanings and issues contained in the story as they wrote with software which allowed the visual representation of its various facets, and the structural planning of their review essay. Before writing electronically, the students created pencilled drafts of the layout of each of their four pages, much as an architect would make preliminary sketches of individual living or working spaces before proceeding to the formal plans of a building. Of importance here was the visual advantage of seeing discrete but connected pages of text, a view which is denied to the writer when working in the linear, medium of wordprocessing. Of great significance was the students' planning, not for the purpose of page layout only, but as an integral part of their story-telling, an element so frequently missing from the work of student writers who work with word processors.

After completing their desktop publication, the students were asked to describe how the story might have been enhanced further in a multimedia format, for example, with the use of audio/visual interviews with Alex's so called 'victims', or with ethical debates, or street interviews which would act as straw polls of citizen opinion. There was an imaginative response from these students which demonstrated not only their acknowledgement of the potential of writing in a multimedia format, but also their conceptual understanding of how this could be accomplished.

5. Conclusion

Hypertext and multimedia systems present advantages and disadvantages for readers and writers. Theoretical arguments insist that hypertext is a system which offers an absence of direction, where textual meaning can be suspended on an immediate level, thus allowing its readers to compile their own experience of the text as a whole. Such is the case with the fragmented but connected texts of the newsmagazine writing genre which allow discontinuous reading without loss of meaning. However, the problem for writers who use hypertext is the need for a conceptual, navigational map so that information might be juxtaposed without loss of meaning in an environment of transparent windows, paths and links, and one which lacks the traditional structures of chapters and closure.

The students in this study demonstrated the usefulness of page layout software in providing a pathway to the conceptual understanding of writing with multimedia, as well as their enthusiasm for writing in this format. Reluctant writers seemed better able to cope with writing smaller, but related pieces of text, and enjoyed communicating with graphics as well as text.

The outcomes of the study suggest the beneficial effect of a familiar analogy in building conceptual understanding in computing novices who are about to undertake further study and projects in the non-linear environments of hypertext and multimedia. Also suggested by this research is the potential of multimedia for writers and readers to interact more fully with the layers of information in a textual piece. Certainly, in this study there was a significant increase in student understanding of the meanings and issues contained in the story as they used software which allowed the visual representation of these layers of meaning. As well, the planning and revision processes in student academic writing were encouraged by the rough sketches made by the students, which acted as conceptual maps as well as the structural underpinning of their writing.

Abstract: This paper describes the development of a self-paced multimedia learning resource designed to facilitate the transition of graduating nurses into the workplace. The resource uses an authentic case to simulate the complexities of life in a typical hospital ward, and place graduating nurses in the role of problem-solvers. Problem solving in the simulation is based on a rich repertoire of cases and stories that have been extracted from the experiences of expert practitioners. This case-based reasoning architecture reflects a model of learning where graduating nurses are coached in the development of decision-making skills within the context of a contrived but an authentic presenting problem. Outcomes of formative evaluation carried out in a semi-structured format with individuals and small groups of nurse practitioners have revealed a positive disposition towards the resource and the approach to learning it utilises.

Educational Problem

Current practices in the preparation of nursing students for a successful transition into the workplace is reported as being ineffective. Meanwhile, the Graduate Nursing and Preceptor Programs offered by the hospitals (at least in the Australian context) to facilitate the transition of graduate nurses into the workplace are under tremendous strain. It has been suggested that in order to prepare better nursing graduates for the challenges of the workplace, there must be alternative ways of developing the decision making skills of graduating nurses *in situ*. This implies improved collaboration between the employing organizations and Nursing education institutions to develop additional strategies to formal classroom and clinical education processes that could be used by the graduating nurses in their workplace in a self-paced and self-instructional environment. Moreover, this alternative solution to the continuing concern for the successful transition of graduating nurses into the workplace had to be solidly grounded in the authentic problems and situations of their daily routines. The learning tasks had to be immediately relevant and meaningful to them, not contrived or removed from their workplace environment. The learning architecture used would be powerful if it benefited from the experiential knowledge base of practitioners.

Instructional Solution

In attempting to address this need, we developed a self-paced and self-instructional multimedia learning environment using the case based reasoning architecture. The material presented on this learning environment attempts to simulate the complexities of life in a typical hospital ward, and in so doing making the education of graduate nurses and students case-based and authentic.

Learning activities incorporated in the courseware require users to make decisions about the best course of action, and source of information regarding each case or problem. Users are also able to discuss the cases presented to them in the multimedia environment and reflect on how they might have addressed the situation. This learning architecture reflects a situated cognitive model of learning where students and graduating nurses are coached in the development of their strategies for recognizing learning opportunities and critical thinking with the help of authentic cases.

We have not recommended throwing out all the other resources and abandoning students in a welter of diverse information sources presented in this multimedia environment. On the contrary, we suggest leading students very carefully through unstructured problem situations from multiple perspectives and sources of information, providing careful instructional feedback, not only on content mastery but also on the skills of information-processing, critical thinking, and clinical decision-making.

Implications for Advances in Learning

This project proceeded from the realisation that current practices in the preparation of nursing students' successful transition to the workplace upon graduation are ineffective and deficient. Moreover, it was of the view that more of the same kind of education was not going to be very useful and argued for a radical shift in the approach to this component of nursing education. A shift which would combine powerful educational technologies and proven learning strategies to build a technology enhanced learning environment. This environment is innovative in two ways. First, it integrates powerful technology with case based reasoning in an integrated learning environment. This adds to the currently burgeoning enthusiasm in the use of interactive multimedia applications for enhancing learning and teaching effectiveness. Secondly, it comprises a significant shift away from current practices of teaching and learning towards one that is case-based. In this environment student assessment is situation-specific and as such authentic.

Theoretical Foundations

There is considerable support for the belief that learning and teaching is most efficient and effective when it is situated in realistic settings where learners are clear, not only about the reasons for learning but the context or the ecology of their learning environment. This view of learning is in contrast with the notion that subject matter content is something that can be represented in schemas stored in memory and retrieved in certain ways when needed. The foundations of these beliefs are derived from cognitive science and artificial intelligence, and trace back to Gestalt Psychology and the works of Wertheimer, Kohler, and Koffka, who were German Psychologists of the early 20th Century (Bower and Hilgard, 1981). Gestalt psychologists argued in favour of the role of *insight*, *perception* and *reflection* in the learning process as opposed to *association* based primarily on past experience, such as that proposed by Thorndike, Skinner and Pavlov (Bower and Hilgard, 1981). This philosophy of learning and teaching translates into the premise that to educate and facilitate learning we must create situations that are not only motivating and challenging, but that necessitate learning of facts, principles and procedures. One tried and tested way of doing this is through a Goal-Based Scenario (GBS).

A GBS is essentially a contrived situation in which learners assume a main role. Their "goal" as part of this role is to accomplish the mission or task associated with that main role in the scenario. In order to achieve this goal the learner will need to acquire particular skills and knowledge. *This is where the learning is taking place.* Goals in this context refer to the successful completion of the task at hand not the achievement of grades. A GBS serves to both, motivate learners and also give them the opportunity to "learn by doing". As long as a goal is of inherent interest to learners, and the skills needed to accomplish those goals are the targeted learning outcomes, we have a match and a workable GBS. The important idea here is that a GBS is organized around "performance" skills and the end result is a student who can perform the specified task.

Every aspect of human behaviour involves the pursuit of goals. Sometimes these goals are simple, like brushing your teeth to prevent decay; sometimes they are quite subconscious, like searching for similar experiences when you encounter a new experience. Sometimes they are quite complex, like trying to build high quality software to effect change in the education system. When goals are simple, we really don't think about them much. When they are subconscious we don't think about them at all. And, when they are complex, we may think about them, but find the going so rough that we hone in on the simplest ones and lose the forest for the trees.

But understanding how people pursue goals is a critical aspect of understanding cognition. For computers to really understand human stories, they need a complete model of the goals that people pursue, the plans, the use, and the complexities that arise. The issue is this. If goals underlie human behaviour to the extent that we cannot understand a story or what someone says or what someone wants, without a clear assessment of the underlying goals and the interaction of those goals, then it follows that goals are at the root of human learning. Why would anyone learn anything if not to help in the pursuit of a goal? Why would anyone try to understand anything if not because they had the goal of learning new information from what they were trying to understand? The desire to change one's knowledge base, to comprehend what is going on about you, and to learn from experience, are all pretty much different ways of saying the same thing. And, all of these are goal-directed. If goals are at the base of the human thought process, then it follows that learning must be a goal-dominated arena as well.

The intent of a Goal Based Scenario is to provide motivation, a sense of accomplishment, a support system, and a focus on skills rather than facts. Facts can be deceptive. They give the sense of knowing without the significance of knowing. Understanding why you are doing something, having a clear goal that is more than the recitation of facts, truly knowing why and wanting to know more so that one can become curious about more "whys" is what learning is all about. Goal Based Scenarios, interrupted by good telling of important cases, offer a reasonable framework for courses that are meant to be the means of education.

Learning Architecture

Perhaps the most harmful misconception people have about intelligence is that being smart comes from knowing a lot of rules. Behind this notion is the sense that reading a lot of textbooks and absorbing what they say will lead one to become an expert. While it does make sense to say that intelligence comes from knowledge, most of that knowledge in practice looks quite a bit different than what you find in a textbook. The architecture of this learning environment follows from the premise that if we are to prepare better graduate nurses for the challenges of the contemporary workplace, we must shift our focus from a content-centred to a case-based reasoning approach. The case-based reasoning approach is based on the principles of a situated cognitive model of learning (Schank, 1997, 1990; Schank and Cleary, 1995). The primary propositions of the situated cognitive model of learning are outlined by Savery and Duffy (1995) as follows:

- understanding is gained through our interactions with authentic cases and *in situ*;
- cognitive conflict is the stimulus for learning, and also determines the organization and nature of what is learned.

In this multimedia learning environment case-based reasoning is used to improve current instructional practices in the education of nurses for their transition into the workplace (see Figure 1). The intent of this model is to present students with a contrived but an authentic scenario, which offers them an opportunity to learn in a safe environment, and by making mistakes without injury to real human patients. We argue that mistakes offer real opportunities for learning when these are accompanied by timely and potent feedback. We will now describe this model in some detail.

Clinical Decision Making with Case-Based Reasoning

• Learners encounter the problem situation as they enter the learning environment. • They deal with the problem (in a safe environment) with help from experts in the form of their experiences and stories, and also documentation and other resources available in electronic form. • Their "goal" in this simulation is to develop an action plan for managing the patient's situation. • This action plan is considered at the "case conferences" where feedback is provided.		
Phase I: Case Encounter		
• Learners encounter the case at *handover* where they are explained its history and pathology.		
Phase II: Understanding Problem		
Precipitating event	**Identifying its causes**	**Managing the situation**
Learner encounters the precipitating event.	Learner seeks to locate the cause of precipitating event.	Learner attempts to manage the situation.
Phase II: Seeking Solutions		
Becoming aware	**Asking questions**	**Reasoning**
Learners listen to the stories and experiences of expert practitioners.	They ask experts questions about their work experiences.	Learners attempt to reason on the basis of the stories of experts.
Phase III: At the Case Conferences		
Raising issues	**Asking questions**	**Reasoning**
Learners explore new and related issues to the problem by reviewing sources of information.	They ask experts additional questions about their work experiences.	Learners develop their final action plan based on the stories of expert practitioners.
Phase IV: Developing an Action Plan		
• Learners submit their action plans to supervisors and receive feedback on their decision making.		

Figure 1: Clinical decision in nursing practice with case-based reasoning. The phases in the figure guide the procedure for attempting to use the repository of cases.

Case Encounter

As users enter this learning environment they are presented with a clinical case in the form of a scenario. A guide (which is always available) welcomes users and informs them of their immediate goal. In this scenario learners are required to make clinical decisions on the basis of information that is available to them. This information is presented in the form of documentation and expert knowledge (which are encapsulated as stories) to manage a crisis situation. Users begin by attending a *handover*, which is a regular event of a nurse's daily routine where relieving nurses are updated on the current situation of their patients and this is where the user encounters the case. As in a real hospital setting after *handover* the learners move on to attend to routine nursing care activities and meeting patients' needs by administering medications and ensuring patients' comfort. Soon after this users are met with a "precipitating event".

A precipitating event in this instance is an emergency situation that causes, or has the potential to cause a chain of events. It requires the learner to make complex decisions under the pressure of time. Within this learning environment though, time is not a variable because this is a contrived learning situation in which users have the opportunity to review relevant documentation and seek advice from experts if necessary, on the best practice before making decisions. This becomes the "goal" or mission of users, which is not to be confused with a "learning outcome". A learning outcome is a skill that learners will develop (such as decision making) as they seek to fulfil their goal or mission. In order to achieve this goal or mission, the first thing the learner must do is to understand the situation and control it because the situation has the potential to deteriorate, and then develop an appropriate action plan to manage the situation.

Managing the Situation

In the first instance, the learner must do everything that is necessary to manage the crisis situation before recommending an action plan. In order to do this, it is necessary that the learner *understand* the crisis, including its causes.

In this scenario the learner is presented with a situation in which Mr. George Parker (the patient) is experiencing an anaphylactic reaction to a drug administered and to which he has been previously sensitised. To diagnose this situation accurately, the learner needs to assess the patient's condition. In order to arrive at a correct diagnosis, learners can access a whole range of information including documentation on hospital procedures/protocols and video-clips of interviews with expert practitioners (experienced nurses) on appropriate procedures to follow or not to follow under such circumstances.

After diagnosis the learner must take appropriate action to manage the crisis situation by generating an action plan. But before the learner develops an action plan, they are prompted by the learning system during each step of the transaction to identify and sequence (from lists) appropriate actions that are necessary for correct diagnosis and management of the anaphylactic reaction.

For example, during diagnosis the system asks the learner, *"What would you be looking for to confirm that George Parker is at risk of an anaphylactic reaction?"* It allows the learner to choose from a list of past events or patient characteristics the appropriate triggers that would confirm that this patient is indeed at risk of an anaphylactic reaction that is about to take place. This action plan requires the learner to make decisions about prioritising and delivering care that is appropriate, given the circumstances.

Users are able to make these decisions after having listened to the experiences of expert practitioners. These experiences (reported as vignettes) are presented in the form of stories and made available to users as they make their decisions. *This is where the learning is taking place for the learner.*

In real life, nurses do not have the time in a crisis situation to consult anything because of the pressure of time associated with the situation. In this context however, they are allowed the opportunity to stop and reflect upon each possible action they can take, and seek advice and information, review the underlying pathology of the case, and policies and protocols governing such situations before including them as part of their action plan.

Reflecting at Case Conference I

When an action plan has been developed, users proceed to a case conference. This is a place where users have the opportunity to reflect upon their own action plans and that of others. There is the opportunity here to engage in collaborative negotiation of meanings, questioning, critique, and commenting on alternative approaches of care that is deemed appropriate to the case. There is the opportunity here for invoking cognitive conflict in the learner, which has the potential to lead to changing perceptions that result in learning.

Reflecting at Case Conference II

The second case conference offers an opportunity for learners to obtain feedback on their revised action plans. This has the potential to lead to further cognitive conflict for learners and lead to further questions and critique that can result in learning.

Developing an Action Plan

In the final stages, users ought to be in a position to develop an action plan that is based on informed decision making and one that is realistic and acceptable to their supervisors. By now it will be clear to users that the process of reaching this stage is more important than having the action plan accepted. The architecture of the model was designed to develop in learners clinical decision making skills. And it sought to achieve that by focusing and urging users to learn from the experiences of expert practitioners. Its expressed intent was to expose nurses to the process of clinical decision making and encourage them to make decisions on this basis so that this process is automated for them. Ultimately, within this case-based reasoning environment and through the use of critical thinking users should hone their problem solving skills and ability, in making appropriate clinical judgments concerning patient status.

Development

The development of this interactive multimedia courseware product adopted a *user-oriented* approach (Goodyear, 1995) which comprises ongoing testing and formative evaluation of the prototype by experts in multimedia courseware development, content experts and a selected sample of intended users. This multimedia environment is being developed using Asymetrix's Multimedia Toolbook™, a quasi-object-oriented, event-driven development system for Microsoft Windows™. Toolbook™ combines database functionality, text manipulation, hypertext, drawing capabilities as well as a full-featured programming language called OpenScript™ which allows the developer to program object behaviour. Toolbook™ offers all the advantages of a prototyping tool and is best suited in projects where user initiated changes need to be made during the development process.

This prototype is currently undergoing a series of iterations of progressive development. The highly modular nature of object-oriented programming allows the developer to test each object and its behavioural characteristics. This learning system contains both generic content about the diagnosis and management of anaphylaxis as well as specific procedures and protocols that are specific to St Vincent's Hospital in Toowoomba, Queensland, Australia, which has served as the reference site. Furthermore, in order to achieve the most realistic nursing clinical decision making environment possible, all participants in the video clips used in this multimedia courseware are nursing practitioners who have volunteered their time.

Procedure

Much of human reasoning is case-based rather than rule-based. When people solve problems, they are frequently reminded of previous problems they have faced in similar situations. Most people have experienced problems brought about in their daily life. For instance, you are in a queue at the ATM to withdraw money and you realise that you forgot your PIN number, you are reminded of other times you have been in similar situations. While rushing to catch a train you realise that you do not have the right change to purchase a pass from the ticket machine, you are reminded of other times when you have been similarly caught out. People constantly experience such "remindings", comparing one experience to another so as to learn from both.

Often we believe that our mind is wandering, as it seems to flit from thought to thought, leading us in directions that often seem irrelevant to our needs at the time. But the reminding process is reflective of our mind's constant search for past information to help in processing new information. In effect we are creating theories about the minute details in the world around us, trying to create a theory of banking procedures that will help us to select the right one and better function in the world. We are constantly accumulating cases and comparing those to the cases we have accumulated in an effort to understand the next case that will appear.

In line with this process, the first step in the development procedure for this project was to develop and shoot the precipitating event. The experiencing of anaphylaxis was chosen as the event because it represents a reasonably complex occurrence in a hospital as well as a common scenario in the community, for example, children receiving immunisation at the clinic, or being stung by a bug etc. Except for the patient experiencing anaphylaxis, all other participants in this video shoot were educators and health professionals. The next major task was to capture a large enough repository of the experience of nurse practitioners in the form of stories. Gathering this repository was no mean task. Interviewing, filming, and editing of these stories took up much time. Indexing of the database of these stories was an ongoing exercise.

The model of learning outlined in Figure 1 guided the development of the learning transaction. This unfolded in several phases. Within the multimedia simulation, users could move easily from activity to activity towards their ultimate goal, which was the successful management of the presenting problem. Some of these activities comprised selecting from a number of decision options, dragging and dropping them in appropriate boxes, deciding to administer a particular treatment or not, deciding to call for help or not, choosing to consult expert video clips for advisement or not, and making decisions. Resources apart from expert's stories such as procedures and other reference manuals had to be identified and collected for the reference of users.

Evaluation

Our approach to the monitoring and evaluation of the outcomes of this project was utilisation focussed. As such our focus was on the use and utility of the instructional innovation for nursing students, their lecturers, graduate nurses, and other stakeholders such as the employing institutions. Evaluation of the courseware prototype is continuing. Formative evaluation of courseware has been carried out with small groups of potential users including a small group (n=3) of subject matter experts who were asked to validate, among other things, the authenticity of anaphylaxis. A semi-structured Expert Group Checklist has been used for gathering the comments of the expert group. A semi-structured questionnaire including an Interface Rating Scale has been used to collect data from the group of potential users. A larger scale implementation evaluation of this courseware is planned. This will involve observations, focus groups and use of semi-structured questionnaires.

Results of the formative evaluation carried out so far show that:

- users found the learning program easy to use and navigate,
- the majority did not find the information overwhelming, and the content pitched at a appropriate level for the target group,
- the curriculum was well balanced.

With regards to interface design:

- users felt that the screen design was pleasing and appropriate use of graphics was made,
- the clarity of information presentation was high.

On the whole they found the program enjoyable. Subjects were asked how *interesting* did they find the material on each one of the sections on the CD? Material on the CD was itemised to include: Handover, attending to patient, listening to stories, making decisions, and preparing the report.

- The majority reported each one of these sections either interesting or very interesting.

Subjects were also asked to rate the *usefulness* to them of these same attributes.

- All of them rated these attributes either useful or very useful.

In summary, what did they like most about the multimedia-based simulation? These included simple access to different components, more interesting and retained information in comparison with reading a journal article or book, realistic presentation, interactive patient observation.

Object-oriented Instructional Design and Applications to the Web

Robby Robson, Department of Mathematics, Oregon State University, USA. Email: robby@orst.edu.

Abstract. In 1945 Vannevar Bush created a theoretical machine that constructs and stores knowledge as trails through information. This presages Web-based learning and points out that authoring and delivery environments should be based on information and knowledge constructs. Unfortunately, current Web-based learning environments are based on the manipulation of data. This approach links data rather than ideas, forces authors to think about form rather than pedagogic substance, and makes it almost impossible to extend the functionality of commercially available learning environments in new and creative ways.

An information-based approach can be realized using the object-oriented paradigm applied first to instructional design and then to the software built to support it. This note summarizes our work in this direction. We treat the problem of hyperlinks with conclusions similar to those of Hermann Maurer's Hyperwave group and illustrate how the object-oriented approach can add extensibility to on-line learning environments.

Hyperlinks, Data, and Information

When thinking about pedagogy it is useful to distinguish among *data, information,* and *knowledge.* In (Robson 1999) we illustrate these epistemological categories by looking at tabular data that is to be included in a document or lecture. The main point is that forcing an author to enter data into table cells via a GUI fixes the form in which the data is displayed. This makes it impossible to specify context sensitive rendering methods and thereby inhibits the ability of an author to think in terms of connections among ideas. Instead, the author is forced to spend time on the format used to display data. A table or graph is a means to convert data into information and the problem we encounter is that the authoring system confuses the two.

Another fundamental example of this same phenomenon is the notion of a hyperlink itself. It has been pointed out by that standard hyperlinks carry with them the same flaws that GO TO statements carry in programming languages. To quote from (Lennon & Maurer 1996),

> There is certainly no significant data model for WWW, and in many ways first generation systems may rightly be likened to novice programs that used too many GO TO statements.

Manifestations of these flaws are the prevalence of broken links, the inability of users to annotate documents, and the difficulty of creating symbolic links by traditional means. The computer science analysis of the hyperlink problem is that hyperlinks should be object-oriented instead of procedural in nature. This approach is taken by Kappe, Maurer, and Tomek in their work on the Hyperwave system developed at the Institute for Information processing and Computer supported new Media in Graz, Austria (Maurer 1999).

Whereas we agree with the Hyperwave solution, from the pedagogic perspective the underlying problem lies in the confusion of data with information. In the minds of authors, hyperlinks are symbolic and informational. For example, an instructor might wish to insert a link to a brief biography of Linus Pauling into a Web page discussing Vitamin C. The instructor may or may not have a specific biography in mind. The URL should really be "link that displays a brief biography of Linus Pauling" rather than something like http://bio.linus.pauling.edu. By hard-coding the URL of a link, information is replaced by its instantiation and becomes data. This is not what we want.

Vannevar Bush's memex machine (Bush 1945) is considered to be a visionary description of the Web (Berners-Lee, 1995). It is actually an even more visionary description of an on-line learning environment. Below is a quote from the memex article that describes the use of the machine. Note how the owner's goal is described using the words "interest" and "study", which implies a quest for knowledge, and that this knowledge is constructed by finding information (books and articles) and linking this information.

> The owner of the memex, let us say, is interested in the origin and properties of the bow and arrow. Specifically he is studying why the short Turkish bow was apparently superior to the English long bow in skirmishes of the Crusades. He has dozens of possibly pertinent books and articles in his memex. First he runs through an encyclopedia, finds an interesting but sketchy article, leaves it projected. Next, in a history, he finds another pertinent item, and ties the two together. Thus he goes, building a trail of many items. Occasionally he inserts a comment of his own, either linking it into the main trail or joining it by a side trail to a particular item. When it becomes evident that the elastic properties of available materials had a great deal to do with the bow, he branches off on a side trail which takes him through textbooks on elasticity and tables of physical constants. He inserts a page of longhand analysis of his own. Thus he builds a trail of his interest through the maze of materials available to him.

We observe in (Robson 1999) that learning is the process of acquiring or constructing knowledge and that many components of teaching deal primarily with information. As in the Vannevar Bush description, a key component is the forming of cognitive relationships among pieces of information. Yet the vast majority of current on-line educational resources, the current versions of memex, operate strictly in the data domain. In memex terms they are fixated with the physical production of the books and the fonts used for annotations.

This has many negative consequences. One is that too much effort is spent on form and format and too little on pedagogic substance. This contributes to the large cost of developing Web courses or course components at Universities (Arenson 1998 and Harapnuik et.al. 1998). Another consequence is that authors and designers cannot interact with learning environments in a language built around concepts of teaching and learning. This is typified by the need to make hard links instead of symbolic cognitive links. *But the worst effect is that teachers and authors are using technology that dictates and limits on-line pedagogic methods instead of using technology which both serves existing pedagogy and encourages the development of new instructional strategies*. We will discuss that now.

The Limits of Commercial Environments.

Confusing data with information can make more work for the author, but the real problem with the functional nature of current authoring environments is the lack of extensibility. Towards the end of Bush's memex article (Bush, 1945) he speculates that

> Wholly new forms of encyclopedias will appear, ready made with a mesh of associative trails running through them, ready to be dropped into the memex and there amplified.

The Web reflects this in its ability to integrate new sites, but the tools that exploit the Web for pedagogic purposes are limited to the functionality that the creators envisioned. To illustrate this, suppose that we are using a commercial course management system that offers all of the standard amenities: user types, quizzes, navigation, record-keeping, chat, email, and so on. Suppose further that we would like to use this on-line environment to do some new things, for example to

(A) display student progress towards a learning objective as a bar chart,
(B) pair students and have them exchange papers and critique each others papers, or
(C) have different students see different examples on the same Web page depending on their scores on a particular quiz.

These are all things we have done using the Web and that represent sound pedagogy. (A) was suggested to the author by a high school guidance counselor and was implemented in a mathematics Web site. The implementation uses nothing more complicated than an image tag with the width parameter read in from a database. (B) is something we have done using QuestWriter software developed at the author's home institution (Bogley et. al. 1996). In our implementation, the computer takes care of *all* of the management including pairing off students, delivering electronic versions of papers and comments, and sending email reminders when a student falls behind on an assignment. (C) is an example of *adaptive pages*. Adaptive pages have been implemented in a number of academically developed environments including Interbook (Interbook 1996) and QuestWriter (QuestWriter, 1998).

Despite all of this, the creators commercial environments have not included any of the functionality represented by (A), (B), or (C). It might be possible to bend the environments to implement the associated pedagogical ideas, but it would be very hard to do so neatly and impossible to truly add new functionality.

An Object-oriented Model

If our goal is to create an environment that operates on a higher level than data manipulation and that permits users or designers to add new functionality, then we need a new underlying model. In (Robson, 1999) we propose such a model. We start with an object-oriented approach to instructional design that is independent of the medium in which it is realized but works very well for the Web. At its core is the notion of a *learning object*. Examples of learning objects include "explanations", "assessments", "lectures", and "applets". Anything that an instructor or student might use as a path to learning is a candidate for a learning object. In our model the designer (or author) defines learning objects and manipulates their methods and properties. Methods might include ways of rendering an object in various media, and properties might include other objects. An important property of an object is a *relationship* to another object, often rendered as a hyperlink in the Web context. This allows us to incorporate the symbolic and cognitive notions of links discussed earlier in this note.

In (Robson, 1998) we illustrate how this object-oriented model can be implemented in a primitive way. We discuss a few Web sites with ad-hoc authoring environments built using a simple database and Web integration software (Robson & Whitesitt 1999). In these environments the author can associate an external link to the content of a page, or a learning objective to a lecture, by using a pull-down list of available links. Although this is just a first step, it brings out the underlying philosophy that the role of the author is to specify relationships among objects and not to worry about how those relations will be rendered.

Extensibility

Our primitive attempts do not illustrate the possibility of creating an *extensible* environment. We believe this is not only possible but is where the next generation of instructional management systems must go. Although we have built none of this, and therefore must admit the possibility of many hidden difficulties, it is worthwhile speculating about the shape and form of such an environment. What we envision is an environment in which every component can be accessed with full authoring and design privileges by an appropriately authenticated user. The various learning objects would be displayed graphically. Properties could be assigned from lists and sub-objects could be defined with automatic inheritance of properties.

To illustrate what could be done with this environment, start with your favorite course management system and imagine that all components are object-oriented. As an exercise, suppose we wanted to construct a new component that supports group work. We would need a way to form groups, a way to facilitate group communication, a way to give out projects, and a way to determine scores on the projects. Of these, the part that is most obviously missing is the one that forms groups of students, but we could start with the "class" object[1]. A "group" is just a "class" within a "class". We should therefore be able to suitably define a new "group" object that would inherit properties from the "class" object. This would immediately give a

[1] Most academically-oriented management systems include a notion of a "class" (a class of students, not a class in the programming sense) as a top-level construct.

"communication" property that could be realized as a chat room and/or threaded email, an "assessment" property that would allow us to give and score assignments with deadlines, and so on. The assignments associated to our new "group" object should probably be re-named "projects". We would also want to change some of the rendering properties to give the group project a distinctive look and we might want to associate text or interactive exercises to "projects". All of this could be done without much difficulty because our envisioned object-oriented authoring tool supports precisely these types of transactions.

In our own real life implementation of a limited group learning environment we relegate all management tasks to the computer. It would not be so easy to program our environment to automatically create student groups and send email reminders to non-participating members unless similar functionality was already present in our base learning environment. This points out the need for a true programming environment within an authoring environment. High-powered industrial products, for example Macromedia products, have this feature, but academically-oriented management systems generally do not. This is an issue for another time and place.

Conclusion

We have traced a path that starts with the realization that current on-line learning environments are grounded in the manipulation of data as opposed to the communication of information and construction of knowledge. As has been pointed out by the computer science community, even the hyperlink suffers from this defect. Our path takes us through some of the difficulties this causes and proposes an object-oriented approach that allows us to overcome these difficulties. The environment we propose is built around learning objects and, unlike any of which we currently know, has the potential to be extensible. Authors and designers can use it to create new on-line learning objects from old ones. Despite the fact that this journey goes back at least as far as Vannevar Bush, we feel we are just at the beginning.

Interactivity and Narrative: Strategies For Effective Learning

Roderick Sims
School of Multimedia and Information Technology
Southern Cross University, Coffs Harbour NSW 2457 Australia
rsims@scu.edu.au

Abstract: This paper investigates methods to maximise the benefits of interactivity in the context of computer-based learning applications. To achieve this, the analysis initially reviews the factors which to date have defined interactivity and some recent assessments of its impact, with a subsequent assessment of interactivity in terms of three alternative components - narrative, play and agents. Commentary on perceived problems with interactivity are also discussed. Based on this analysis, the major finding is that mutual reciprocity, a critical element of interactivity, is not manifested in applications and that the introduction of elements of narrative and play have the potential to alter the dynamic of the interactive process. Of greater impact too is the potential to integrate the interplay between designer and learner into the interactive engagement. By integrating these elements, a revised model of the interactive environment is proposed, based on mutual adaptation by designer and learner. By developing our understanding of the complexity of interacting elements which impact the interactive process, we will take another step towards a truly interactive environment.

Reassessing Interactivity

The Interactive World

Interactivity, in the context of computer-based learning, ranges from simple navigation of web-pages to immersion in interactive virtual worlds. It is often portrayed as the distinguishing factor of the new media, with the assumption that "interactivity in a computer product means that the user, not the designer, controls the sequence, the pace, and most importantly, what to look at and what to ignore" (Kristof & Satran, 1995:35). While this holds true for recreational or information-seeking activities, the value of control for educational pursuits is less clear, as there are conflicts between the value of control for new learners as well as questions regarding the overall prescriptions for control identified through research findings (Reeves, 1993).

The overall aim of this discussion is to develop a better understanding of interaction in terms of the factors which inhibit or enhance content engagement, and the communication or transfer which results in deep processing and consequential learning. When considering technology-based learning the significant factor is the engagement which takes place between the learner and the content, and the extent to which there is a change, manifested through learning, skill formation or knowledge acquisition resulting from that engagement.
However, interactivity as a determinant of effective learning has yet to be fully established, based on analysis of a range of sources including theoretical limitations, research credibility and the variety of interactive constructs. For example, Whitby (no date) describes the vision of the future home with a video wall of sports, interactive access to player profiles and holographic video-phones. While acknowledging the popular appeal of this scenario, Whitby (no date:1) questions whether people really wish to interact that way and concludes:

> *... we are rushing to implement interactive CDs, cable shows and personal electronics in the crudest ways without pausing to consider whether an improved medium will result. Storytelling and narrative lie at the heart of all successful communication. Crude, explicit, button pushing interaction breaks the spell of engagement and makes it hard to present complex information that unfolds in careful sequence.*

The problems confronting educational technology developers are clearly defined - how to develop computer-based environments to engage the learner in effective instructional communication without generating *interactive interference*? In addition, Whitby (no date) also introduces the notion that storytelling and narrative are critical determinants of communication, which is the ultimate goal for educational multimedia applications.

Interactive Challenges

In addition to the impact of internet communication in the tertiary environment, the development of stand-alone computer-based learning applications is widespread and often a critical business risk. As we continue to research and develop computer-assisted learning applications, it becomes clear that there remains much to learn about the nature of interactivity and implementing its components effectively and appropriately. In noting that complexity comes with the freedom associated with learner control, Kirsh (1997) asserts that there are additional restrictions resulting from the scripting of applications which require the user to adapt to their structure, suggesting that:

> *Since interactive interfaces ought to foster this type of coordination between improvisation and planning we need to discover better theories of what is involved in the dynamic control of inquiry, line of thought, and action more generally. We need to discover more open-ended models of coherence and narrative structure. (Kirsh, 1997:81)*

While acknowledging that one solution is to scaffold a learning environment to support rather than direct, Kirsh (1997:83) argues that an analysis of the nature of interactivity in terms of reciprocity between the two parties (designer and user) suggests that "computer interfaces are rarely interactive because the programs that drive them are rarely intelligent enough to behave as tacit partners". In this instance, as well as the observation by Whitby (no date), the concept of narrative for coherence is introduced, which Kirsh (1997) beleives might be resolved through the application of a modified decision-cycle theory.

From a different perspective, Bardini (1997) compared the concepts of *association* and *connection* in relation to interaction with hypertext and hypermedia environments, observing that most implementations to date have been associationist, extending the argument to consider the relationship of the main protagonists (agents) in the interactive process. Ascribing the process of delegation and inscription to both the designer and user, "the degree of interactivity of the interface can be seen as the relative opportunity for both user and designer to take part in the two dimensions of the representation process" (Bardini, 1997:12). While this supports the position of Kirsh (1997), it also highlights the potential of creating gulfs (Norman - cited in Booth, 1989) which might compromise mutual engagement of the user and designer - the ideal of the interface as a socially constructed narrative (Bardini, 1997).

In brief, these two observations suggest that interactivity remains an uncertain concept and that developing applications in such a way that the learner is integrated into some form of narrative may lead to implementations which reduce the gulf-potential between user and designer. However, it is also necessary to appreciate that there are many factors that contribute to effectiveness of computer-based learning. The following section reviews these dimensions, with specific emphasis on the relationship between learning theory and subsequent learning.

Learning Theory and Interactivity

To assess the relationship between learning and interactivity in a computer-based environment, it is necessary to examine the extent to which the various approaches to learning provide guidance or indices of relative and appropriate interactions to foster learning. By way of example, Craik & Lockhart (1972) suggest that the conditions of learning can affect whether surface or deep learning results. According to Kearsley (1998), the *levels of processing* approach views stimulus information as being processed at multiple levels simultaneously depending upon its characteristics, and that deeper processing will result in more being remembered. In addition, the meaning of the presentation will affect the extent to which material will be remembered; similarly the less meaning implies greater attention and therefore an interruption to the processing flow.

For the development of a learning task within this paradigm, educators are required to present information both meaningful and relevant, aiming to ensure that attention is focused on the content without interference. Transposed to a computer-based environment, the context within which the material is presented is alien, at least on the first encounter, and therefore attention can be required to de-construct the content from the interface, metaphor or context. If attention is too focused on the de-construction process, it can be argued that the consequential learning might be interrupted or de-emphasised, generating more superficial rather than deep learning. This reinforces the potential of interactivity to actually interfere with the learning process.

From a human-computer interface perspective, Booth (1989) identifies that users can have mapping difficulties when accessing computer systems (matching the information presented with their current experience), which have been described by Norman (cited in Booth, 1989) as being gulfs that prevent users from dealing easily and efficiently with computer-based tasks. The *gulf of execution* exists when the user knows what is to be achieved but does not know which physical variable to adjust or in what way to adjust them and the *gulf of evaluation* exists where the system has altered, usually as a result of the user's actions, but the user cannot easily understand the change in that system's state. The assertion by Craik & Lockhart (1989) that meaning is critical to deep processing underlies the importance of effective design of the human-computer interface if successful engagement is to occur. The interaction of the user in manipulating the system forms a precursor to their interaction with the content and thus any disturbance in the manipulation may have subsequent consequences with that engagement. This example highlights the impact one approach can have on the way we think about interactions and supports further investigation of a wider range of learning theories and paradigms to help clarify the links between interactivity and learning. However, this form of analysis is beyond the scope of the present discussion.

Interactivity and Narrative

Introduction

The overt issues faced by prospective designers, developers and implementors of educational software is often the look and feel of the product. What is often omitted is an analysis of aspects of the total interactive experience that will maximise engagement (manifested through learning, knowledge acquisition or skill development) and the overall communication of content. However, it is proposed that the frequent development in the base technology (mainframe, desk-top, on-line) have taken precedence over developing a comprehensive understanding of the means by which the technology might enhance the learning process.

As continually evolving field, educational technology is often subject to creativity and experimentation as the most legitimate means by which its potential can be realised. At the same time, there is considerable evidence to support the conclusion that we do not yet fully understand its similarity to or differences from current means of educational communication (Plowman, 1996b; Kirsch, 1997). There is no doubt that much of the development has assumed that the technology is simply an automated form of current practice, and this may in part be responsible for the often stated comment that educational technology has failed to live up to its original expectations. In other words, should the implementation of educational resources on a computer-based medium be a replication of current media, or are we dealing with a new environment that has not yet been fully explored in terms of interface to and interaction with its human users?

There is a growing body of literature and discussion which supports the latter position, through a re-assessment of the way in which we conceptualise the use of interactivity in educational multimedia applications. One of the most interesting aspects of this research is the comparison of traditional story-telling techniques (narrative and play) with those presented through the technological medium. While the complex framework which surrounds the study of narrative and story-telling should not be trivialised, in the context of the growing demand for technology-based solutions to learning, the possibilities provide a novel and refreshing perspective.

Interactive Impact

Based on the previous discussion, there is an indication that if interactivity has the potential to distract, the use of narrative may be useful. Narrative can be viewed from a simplistic context of representing a linear storyline (Plowman, 1996a); it can also be perceived in the way it is deconstructed in terms of how the story is told, the way it is received, what meanings it can have and the specific social, cultural and technological context in which it is told (Humphreys, 1997b). An extension of this analysis is the assertion that narrative enables construction of mental models of the situation and environment (Bower & Morrow, 1990). Therefore it can be predicted that narrative may assist meaning, reduce the impact of interactive interference and provide the necessary framework to promote learning amongst diverse groups of learners.

But in what way can narrative, as currently understood, relate (or integrate) with the values of an interactive world? Josephson (1997) suggests that we are still learning to define a new media literacy, and by defining it we are also creating it. If we can define an effective interactive narrative, then we can begin to project what will happen to that narrative as the audience moves from being "actively engaged on an interpretive level to actively intervening in its representation" (Humphreys, 1997a). In a comprehensive analysis of narrative and interactivity, Plowman (1996a:92) observes that

> *Narrative coherence is identified here with a lack of redundancy and a fixed sequence. Interactive multimedia (IMM) programmes challenge these traditional definitions of narrative because it can be suspended or altered at discrete decision points, the foci of interactivity, and a rearrangement of discrete elements gives rise to new text and new meanings. While the concepts of wholeness, unity and coherence of meanings are not fashionable in a post-modern world, in "educational multimedia... the notion of multiple interpretations has different implications, particularly for comprehension and cognition".*

Because these decision points represent the foci of interactivity, and a rearrangement (through branching or learner control) of discrete elements gives rise to new text and new meanings, the implication in educational multimedia of multiple interpretations becomes critical, particularly in relation to comprehension and cognition. While "narrative isn't just a shaping device: it helps us think, remember, communicate, and make sense of ourselves and the world" (Plowman, 1996a:3), when contrasted with its implementation in an interactive environment, its efficacy is uncertain. So can narrative and interactivity co-exist? Plowman (1996b) argues that interactivity is at odds with our expectations of traditional narrative forms and communication. As disruption of the narrative is strongest at the foci of interactivity, interactive multimedia development should be considered in terms of how it can be integrated into the underlying narrative. However, by examining techniques for measuring interactivity and comparing these with the basic narrative structures, the potential for the new media to combine and incorporate effective narrative was examined by Plowman (1996a) who concluded that, with young learners at least, a meaningful narrative was beneficial for learning.

In an alternate view of interactivity, Hilf (1997:7) states that "through the interrupted narrative, the learner learns more about the story and characters through their own interaction". Whereas Plowman (1996a, 1996b) recognised the negative interference potential of interactivity, Hilf (1997) declares the opposite. Clearly there are disparate views on narrative and interactivity, and their combined impact on the communication of content; whether an interactive device contributes to engagement and meaning or generates an interruption to that process is the underlying reason for considering the impact of narrative on the overall process.

In his analysis, Hilf (1997) introduces four narrative structures: linear (where the user is guided from beginning to middle to end), interrupted (where the narrative is halted while problems, tests or some other form of interaction is implemented), branching (where the user has the option to choose from a range of paths) and object-oriented (where elements within the narrative can be controlled or defined by the user, thereby impacting on other users within the system). In terms of interative learning environments, it would appear that branching narrative is termed menu selection and interrupted narrative the tutorial model in which a pre-designed sequence is interspersed with interactivity in the form of the question-response-feedback loop. The object-oriented narrative conforms to the delegation/inscription factors, at least in terms of the user (Bardini, 1997).

From Narrative to Play

So does narrative interfere with or promote engagement during an interactive learning session? The answer is likely to be both, but possibly to the detriment of the final outcome. An extension of the narrative aspects of interactivity are proposed by Humphreys (1997a). Like Plowman (1996b), she suggests that giving the audience (or user) choices can disrupt the sequence of events, affecting the final closure of the narrative. From another perspective, "as the level of interactivity increases and the amount of agency for the user structured into the piece increases, the amount of 'retelling' done decreases" (Humpherys, 1996a:6).

To provide an answer to this, Humpherys (1997b) explored the concept of play and play theory, which she suggests are closely related to narrative, and notes that to maximise audience engagement through interactivity requires consideration of agency, narrative structure, emotional engagement and construction of meaning. The consequences of this conundrum may find some solutions in play theory, which Humpherys (1997b:9) suggests can provide a "framework which accommodates the audience or user into the process of engagement with interactive media in ways that narrative theory finds difficult". While narrative is about the experience of a recounting of a story, play is the experience of enacting a story.

IMAGE NOT AVAILABLE

Figure 1: Intersection and Parallel Concepts of Interactivity

A preliminary comparison between narrative and play interactivity is represented in Fig. 1. The top sample of an interactive sequence represents a narrative regularly intersected or interrupted by an interaction whereas the bottom sample depicts a constant interaction between user and story. While play in terms of the instructional game has long been recognised as a valid model (Alessi & Trollip, 1991), the early implementations were not contextualised in narrative. By integrating play elements such as friendship, risk, problem solving, competition and creativity, Humpherys (1997b:9) suggests that "play theory offers a framework which accommodates the audience or user into the process of engagement with interactive media in ways that narrative theory finds difficult". More importantly, in the context of educational applications using multimedia, Humpherys (1997:11) speculates that "Interactivity produces for the user of media a different relationship to story. This shift in relationship may be able to be framed as a shift from narrative, as an experience of recounting a story, to play, as an experience of enacting a story".

The notion that multimedia applications for learning should focus on either narrative or play to enhance engagement implies that the interactivity provided to users must therefore be integrated in such a way that it not only provides opportunity to reinforce the specific learning objectives but also to maintain the user's participation in the story.

Multilinear Narrative

Rather than comparing the traditional linear narrative with non-linear interactive multimedia, Johnson & Olivia (no date) use the term multi-linear. This term implies a range of equally plausible paths which may be taken through the application and offer the suggestion (with respect to internet sites specifically) that beginnings and endings should be replaced with the terms entrance and exit. In discussing the relationship between the content and the medium, Johnson & Olivia (no date) cite the work of Liestol 1994:105:

> *The screen occupies a third position, between the three dimensions of space and the one dimension of time. The screen and what it presents is a manifestation of the present, between past and future. Therefore the movement from space to time and the reduction from three dimensions to one both halt at the position of the screen and its flatland of two dimensions. Obviously the design and composition of elements on the screen are of central importance to any critical study of hypermedia texts.*

This introduces a further variable to the equation of effective interaction with respect to the user having to develop the skill to either adapt to changing dimensions or to create a new dimension by which they interpret the technology interface.

Conclusion

Interactivity is often portrayed as the crucial element of the new technology, and yet recent research has demonstrated that there is still much to understand about the ways in which the interactive process facilities access to technology, especially in the context of computer-based learning applications. As Plowman (1996a:102-103) states,

> *disruption of the narrative is strongest at the foci of interactivity ... (which) should be considered in terms of how they can be integrated into the overall narrative and how they can be used as a way of stimulating interest in the unfolding narrative ... by considering the interrelationship of narrative, linearity and interactivity and their design implications we can help learners to make sense of interactive multimedia.*

And it is our challenge to develop applications which minimise the potential for interactive interference. By considering the concepts of narrative and play in association with the links between the designer and user, a model of adaptive applications which cater for both designer and user is proposed as a means to enhance the interactive process.

Architecture in the Digital Domain: A Collaborative Design Studio

Barry Jackson,
School of Architecture
New Jersey Institute of Technology
Newark, New Jersey 07102, USA
bxj2634@tesla.njit.edu

Abstract: This paper describes an interdisciplinary design studio that utilizes concepts and methodologies intended to create a comprehensive approach to the organization of building design through the merger of several techniques. These techniques include 1) collaborative learning and design, 2) using multi-tasking workstations, 3) hypertext learning modules and courseware, and 4) interdisciplinary team teaching. The studio merges the preceding teaching paradigms, building on current research and the experience of the faculty. The studio also establishes the premise that architectural design studio and engineering laboratories (structural and mechanical) will need to be organized across departmental boundaries as team oriented activities. Learning modules are being developed in a multimedia format, using analog video and hypertext. The modules are expected to be completed using digital video, allowing latitude for evolution of the material. The paper discusses the continual shift between synthetic and analytic processes in the context of problem solving. Also discussed are methods of representation, design assignments and design methods and process.

The Problem

Architects and engineers, who need to interact during their professional career in order to build any kind of complex building, are educated entirely separately. "Over the past century, increased movement toward concentration within an academic discipline has taken charge of the curriculum, as well as serving to compartmentalize the professoriate and the institution." (Landry 94) The vertical separation of disciplines occurs in most universities. This suggests a need for modification of the curriculum and teaching methods, and development of the delivery of course material. Fortunately, this comes during a period of reflection in schools of engineering and architecture when, as Mitgang suggests, there are "growing doubts over whether the traditional educational environment is preparing students for a rapidly changing world outside." While "schools remain wedded to shopworn traditions" there seems to be a growing malaise about the role of design as the centerpiece of architectural education. (Mitgang 97) Recognition of the problem also comes at a time when new teaching methods are emerging.

The problem with the vertical separation between disciplines is that students from each discipline learn to solve their part of the problem independently. This separation discourages them from understanding the relationship among the problem components. The students usually complete their projects without having the opportunity to gain insight to the trade-offs required for an optimal solution. While courses in each department include information about the other disciplines, each is taught in a manner which tends to diminish the importance of integration. Moreover, the ultimate professional relationship among the disciplines, which in the building industry consists of teams, is downplayed by the students working as individuals in their classroom experience. Research outside of the architectural and engineering professions suggest that "future work situations are likely to use a complex mixture of different information channels, including video conferencing, e-mail, small group work, and on-line searches." (Kilker & Gay 94) In other words, information and designing systems are being developed which rely on new modes of interaction, intertwining the sociological and technological aspects of the design process. These are the conceptual underpinnings of the development of a new approach.

Designing the Solution

The major effort in trying to refine elements in the curriculum (particularly in different departments) depends upon what might be termed "changing the culture" of the curriculum. To create these changes an architectural design studio/engineering laboratory, TOTAL STUDIO, is being organized comprehensively, across departmental boundaries. The course is being changed from independently organized activity to a team oriented activity. The hypothesis is that a concurrent and collaborative design environment will add to the problem-recognition and problem-solving abilities of the engineering and architecture students. In most workplaces in the building industry, problems solving and design require collaboration among members of a group. These activities require that people share information and coordinate their activities in a setting that allows for immediate interaction (Kilker & Gay 94). Although the design and production of buildings traditionally requires collaboration, the work is done serially, with drawings passing among the professions and each adding their information and recycling through the process until the project is completed. No methods of optimization are applied because of the way the design process is structured. Optimal solution spaces are closed off by the time each new part of the process is introduced. Therefore, the focus of the studio is around the activities in which the students can engage to help construct a comprehensive knowledge base necessary to design, optimize and build complex structures.

The impact of the studio is to improve the education, professional behavior and attitude of students as they prepare for various aspects of the building industry. The students have the opportunity to see how the separate courses they have taken in architecture, structural engineering, and building performance are integrated. They can observe that contemporary construction is not a simple separate, sequential process, but rather a system characterized by integration and a search for optimal solutions. When design is objectively considered as an iterative, multifaceted process, and a series of problem solving sequences, a significant paradigm shift can occur. Emphasizing this way of thinking, we discovered, is imperative because the way engineering and architecture students learn is different.

Our goal is to create a completely computer mediated environment, where students work on their designs and problems, communicate with each other both locally and at a distance, and receive courseware and criticism at the workstation. One innovative aspect of TOTAL STUDIO is that it is interdisciplinary, and has been designed from the beginning to provide the format for the perpetuation, replication and dissemination of the studio in a continually upgradeable hypertext format. The studio focus has moved away from the traditional piecemeal design methodology.

Implementing the Solution

The Underlying Pedagogy

The study of building design must be rooted in a general theory of building science in which architectural space and form, structure, and the environmental aspects of the building envelope are considered inseparably. Optimization is a complex problem to solve. "In architecture, aesthetics deals with the way buildings look: the skin, form, site, and overall image within the culture to which they belong. In engineering, technology is informed by modern science and is systems and process oriented. Controlling building environments (both actively and passively) can produce more insightful architecture when an understanding of the aesthetics of the building envelope (static) is paired with an appreciation of the technology of the building systems (dynamic)." (Greenwood et al 97) The studio focuses on the development of structural, energy and spatial intuitions and the relationship among them. Study of highly indeterminate structures is crucial for understanding building frame design. (Black and Duff 94) For energy analysis and building performance, it is preferable to analyze a skin-dominated building so that relationship of form to energy flow can be considered. One goal of the faculty is to identify projects at the appropriate scale to study these relationships. We are currently using an elementary school project which seems to have the requisite components and degree of difficulty.

Collaboration and the matrix of studio organization

Collaborative design—thus collaborative learning about a project—is a new concept for students in the studio. A very serious introduction is required to get the students working collaboratively. Collaborative learning is

"...a learning process that emphasizes group or cooperative efforts among faculty and students, active participation and interaction on the part of both students and instructors, and new knowledge that emerges from an active dialog among those who are sharing ideas and information." (Turoff 95) While group criticism and group research is a normal activity in the design studio, designing together is not. Turoff, is his years of development of computer-mediated environments at NJIT concludes that "in many learning situations it has been observed that two people working together at a computer learn more working together than either one separately. It is this ability to share the actual interactive process of 'creating the painting' that this approach entails." (Turoff 95) This suggests, as Feisel points out, that "we need to design an educational process that involves students in one another's learning and rewards mutual accomplishment." (Feisel 94) The studio adapts these concepts and builds on them.

To facilitate the collaborative idea of teaching and learning, the studio is organized around a matrix of groups and teams. Groups are defined as a number of students organized to develop techniques and learn a particular set of the task. Teams are defined as a number of students assembled to apply techniques and complete a design task. Each student is a member of one group and one team. The sets of teams and groups act as support clusters for each student. In recent semesters, the four by four matrix of teams and groups has been applied. The teams and groups for the first part of the semester are four member each. When the major design project begins the teams of four are divided into teams of two. This affords the opportunity to modify teams to improve interpersonal relationships among the members. The team organization depends heavily on the mix of students. The current mix is two architecture students working with one engineering students. Each semester slight variations on the model have to be developed to accommodate enrollment.

The Learning Groups

In theory, the learning groups should be divided among the three disciplines involved in the project: architectural design, structural design, and mechanical design. Each learning group will be led by an instructor who will develop the educational modules associated with that discipline. The members of each learning group will be responsible for learning the software packages associated with specific segments of the problem and also be encouraged to share their knowledge. As the experiment evolves, different uses of learning groups are developed. For example, last semester project research assignments were made by the learning groups; this semester software instruction is carried on in learning groups.

The Design Teams

The design teams develop the building design as a whole. During their sessions with the design instructor they work together on the development of the project, each member looking at, and engaging, the design from the perspective of their learning group and/or discipline. Architecture students and engineering students work together on the design, each naturally contributing from the point of view of their background. While it is intended that contributions to the design are made across disciplines, there has been a tendency for the engineering students to wait for the architecture students to finalize their designs before contributing their engineering expertise. Changing this attitude toward design is central to the success of the project. This year we have separated the engineering students by semester (structural engineering in the fall; mechanical engineering in the spring.)

The Simulation, Animation and Modeling Laboratory (SAML)

The studio is held in an advanced graphics computer laboratory with video equipment available for various levels of production. The laboratory has been developed with support from NJIT and the National Science Foundation (NSF) (Jackson, 97a, 97b). The computers are networked with adjacent computer laboratories and the Internet. The laboratory is also adjacent to the Multimedia Internet Delivery and Production Studio (MIDPS) which is part of the New Jersey Center for Multimedia Research (NJCMR). This provides the faculty with a set of authoring tools, and other multimedia production equipment which aids in the development of the courseware. Combined with our existing video equipment, MIDPS augments our facilities to provide webcasting.

The Four Modes of Representation

Although the studio is designed to be in a multimedia environment, an important idea is to dampen the use of the computer as the central tool. The computer is considered on equal footing with all the tools in the toolbox. This is accomplished directly through assignments which emphasize the four modes of representing architecture. The notion of multiple representations of information is central to the course and is discussed thoroughly with the students at the beginning of the semester. Narrative descriptions of initial and final concepts are required, as are short written reports on field trips and research issues. Building class site models and chipboard study models in the traditional way—especially as a comparison to the 3D computer models—is emphasized. Students learn to study their work simultaneously via the computer models and via physical models and sketches to augment their visual perception and other cognitive skills. Research suggests that students relate to what they see on the screen better if they can relate it to previous experiences. (Roberts, et al) Our experience suggests that the shifting from one mode of representation to another, while difficult for some, offers the opportunity to broaden the perceptual understanding of the design problem and its solutions. Modal shifting also prevents the students from getting mentally fatigued by working on the project from one point of view. The most difficult shift occurs between the design mode and the analytical mode.

Final student projects are presented in two ways. The first, for an oral presentation of the project before a group of critics, designs are presented on traditional 'boards' which allows computer models to be rendered, printed, and thus communicated traditionally. This also gives the students the opportunity to mix their media, drawing on strengths and skills they may have previously acquired. The second mode of presentation is on the Internet both as digital images and as VRML models. To link these two methods we have experimented with webcasting the final review, both as a means of organizing the work and disseminating innovative methods. The first webcast was merely a window into the studio. Currently we are more prepared to modify our methods of digital presentation to meet the challenges of a new media.

The Results

The studio is presently being supported through funding from the National Science Foundation as *An Interdisciplinary Virtual Laboratory for Engineering and Architecture.* The studio was offered in the academic year of 1996 and the spring of 1997 as a pilot effort, and is operating currently as a "proof of concept". The following items have been implemented: 1) collaborative learning and design, 2) computer mediated environment, and 3) interdisciplinary teaching, coursework and design. Deep within this seemingly complex learning environment outlined are elements of the traditional design studio. The semester is divided into an analysis phase and a design phase with a few short research assignments interspersed. The goal is that the whole experience can be compressed into one semester. The current two semester sequence is designed to emphasize structural issues in the fall semester and building performance issues in the spring. Development of a preliminary syllabi quickly dispatched the idea that such a holistic approach could be accomplished in one semester until some experience has been gained in the development of the delivery system. However, the organization of the three academic units involved suggests implementing the course in one semester. The difficulty of a one semester course is that there is too much to learn and apply in one semester. Learning and application can only take place if the students have the proper preparation prior to enrolling in the course. Effecting one element of the curriculum is one thing; creating a downward ripple effect is another matter.

Collaborative learning

From the faculty point of view dividing the class into teams has two major effects: 1) on the downside, it increases management time to continually monitor the interpersonal problems which occur as people adjust to working together; 2) on the upside, it reduces the number of critiques and increases the time available for each critique. Moreover, it increases the students' effective working time because they need to manage each other and spend time in the studio discussing the problem and working together. In general, students are very favorable toward collaboration. Exit interviews and course evaluations indicate a strong interest in learning to work together.

The computer-mediated environment

The multimedia material is currently under development. Our project had access to adjacent mutlimedia projects and have benefited from that synergy.(Bengu 95; Bengu & Swart 97) The computer-mediated environment works as follows: Course material created on the word processor is converted to HTML, edited to add dynamic elements, stored on the server, accessed, displayed and disseminated through the browser. This provides the student and others continual access to all of the course material as it is posted and modified. Dissemination of course materials becomes seamless. Remote access and email allow the team members to work at a distance. The NJIT library catalog is also available at the workstation so that references to books and articles can be located immediately by the student.

We have found that it is imperative that faculty take a hands on approach to imparting computer skills. Comments from the students indicate they are more confident in the instructors who are hands on and display their skills directly rather than those who are more aloof and directive in their approach. The experience of the last few semesters suggests that teaching small groups of students detailed methods of access to the computer systems diffuse information among the students more rapidly than imparting the information to the whole class in a formal setting. The students learn more quickly in informal settings in which they are able to communicate directly with their peers. Research by Roberts et al also suggest that of the critical variables for productive learning, "the most important is the faculty's pedagogical style in their direct teaching and the student interest in the subject. The faculty must be sensitive to both the need to empower students exploration by providing them with the skills they need to explore... through direct teaching as well as allowing and encouraging students to do their own exploring." (Roberts et al) This requires continual observation of the skill acquisition of the students.

Problems

The development of TOTAL STUDIO is an evolving effort. The imprimatur of NSF funding has been a great aid to fostering collaboration among the academic units. A review of the four semesters of experience have yielded the following findings: 1) students are slow to conceptualize the multitasking potential of their workstations, and therefore under utilize the potential of the UNIX environment, 2) there are only a finite number of teaching hours in a studio and having to spend time teaching software subtracts from the time used for teaching principles of design, and giving individual design criticism, and 3) engineering students and architecture students organize their work and their thought processes in an entirely different manner which will require further analysis and adjustment on the part of the faculty.

While working on teams is generally not part of the studio culture, most teams have operated successfully in recent semesters. The reason for lack of success in teamwork seems to be based on the conflict in personality, differences in work ethic and habits, the lack of experience in working on teams, and a mismatch in skill levels between team members. In anonymous evaluations, the students commented that "I liked the team thing as an idea. It didn't work out for me though because I had a hard time with my partners. I do think in the future, team design is a good idea." Or "Groups of peopled helped but caused many disagreements which slowed down progress. Although the thought of putting people together was a good one." The extended history of the studio as a collaborative one aids in the development of teamwork because it generally excludes students who might undermine the concept.

Conclusion

The metaphor, changing the culture of the curriculum, may seem slightly pedantic; however, methods of teaching have been passed from generation to generation in the most unquestioning manner. New technologies, as precursors of changing methods, are often resisted. The efforts to change, sometimes abetted by the layers of accrediting organizations, are held back by the 'viscosity' in the organization. Creating a change that evolves, rather than changes abruptly, gives the results an opportunity to become integral to the culture and reaffirmed by tradition. Our team of faculty expect criticism from our colleagues, from professional organizations with long standing paradigms and vocabularies holding antithetical views, and even from the students. We are abetted by the support of outside funding, and the interest of professional organizations, both of which add an imprimatur to our efforts. At the core of our activity is the goal of helping to "lead the professional to a future of greater relevance and responsibility." (Mitgang 97 p. 124)

Abstract: In this paper we present a multimedia-based system that facilitates teaching chemistry to pupils of Hellenic (Greek) high schools over a LAN. The system uses a variety of multimedia objects. An important aspect of the system is the central control the teacher can have over some aspects of a lesson. So, the teacher can enable the section to be taught and disable the rest ones, and design and deliver on-line tests to the pupils. The pupils are then able to submit their answers to a central database. This is achieved by using dynamic hyperlinking implemented as remote SQL queries over a LAN.

1. Introduction

Over the past few years, new technologies have been used in producing educational tools. The use of multimedia technology has given a great impetus to the training evolution in education. Multimedia systems provide an integrated environment for the creation, storage and presentation of a variety of media types (e.g. text, graphics, video and audio) enabling the development of a great number of successful prototype educational applications (Hopper 1990), (Fox 1991), (Narasimhalu & Christodoulakis 1991), (Faconti 1994).

In most cases, information technology is concerned with heterogeneous data both static and dynamic. Existing LAN (Local Area Network) development tools support efficient solutions for the integration of multimedia interfaces (static information) and database systems (mainly dynamic information) with impressive results (Narasimhalu & Christodoulakis 1991).

Today in Hellas (Greece), computer technology (e.g. multimedia systems) is not extensively used for educational purposes in subjects other than informatics in Secondary Education. When used, it is usually done on stand alone computer systems. However, due to recent introduction of LANs in computer labs in Hellenic high schools (Garofalakis et al. 1998), the need for educational software that exploits LAN capabilities has been arisen.

This paper presents the architecture of an interactive multimedia-based environment to be used as an assistant for teaching chemistry in a classroom over a LAN. It incorporates a multimedia application, for manipulating static information, and a relational database, dealing with dynamic information. These two components intercommunicate via an application server over a LAN. The end-users (teacher and pupils) can access corresponding available information (static and dynamic). The static information resides in the multimedia

* The order of the authors is alphabetical.

application and is to be used during a chemistry course. The dynamic information is related to the tests designed and delivered by the teacher and the answers given by the pupils and resides in the database.

The paper is organised as follows. Section 2 presents the abstract architecture and design aspects of the system. Its functionality and interaction with the users are discussed in section 3. Section 4 deals with the implementation aspects of the system, while the last section, Section 5, presents the conclusions drawn and directions for further work.

2. System Description

The system is composed of three basic components (see Fig. 1), the *multimedia application*, the *application server* and the *relational database*. The multimedia application (front-end) interacts with the human users and the administrator of the system. The application server acts as an intermediate between the multimedia application and the database by conveying queries from the former to the latter over a LAN. The database (back-end) accepts data from various sources (mainly dynamic information), processes it, stores the results and pipes it to the front-end, when requested.

The system topology is illustrated in Fig. 2, where the front-end and the back-end of the system are indicated. The database resides on the central PC of the LAN (server), whereas a copy of the multimedia application and the application server exists on each of the rest PCs (clients).

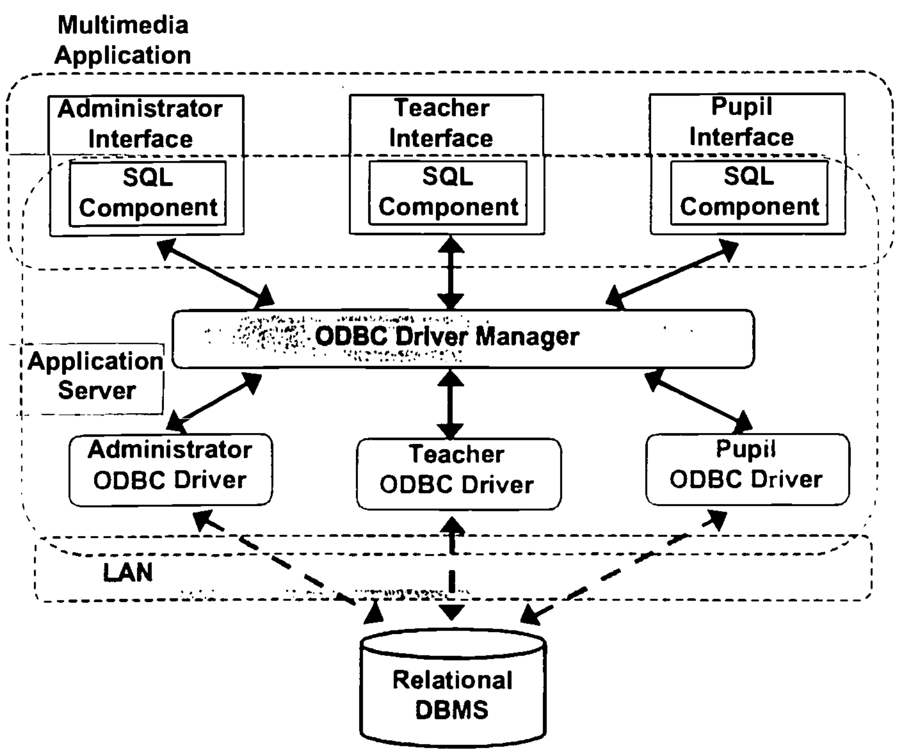

Figure 1: The architecture of the system

2.1 Multimedia application

The static information provided by the system is included in the multimedia application and presented in a variety of ways, such as hypertext, special sounds, appropriate images and animations, hypermedia object, educational games or quizzes, video recordings of real chemical experiments and interactive simulated chemical experiments. Every screen follows one of some predefined presentation screen patterns. Common to all, on the top area of the screen the logo of the application, at its left, and the title of the specific section or subsection, at its right, lies. Also, at the bottom of the screen, there are several buttons (or options) facilitating the interaction between the user and the application. The main content is displayed at the central area of the screen, the active screen (see Fig.3).

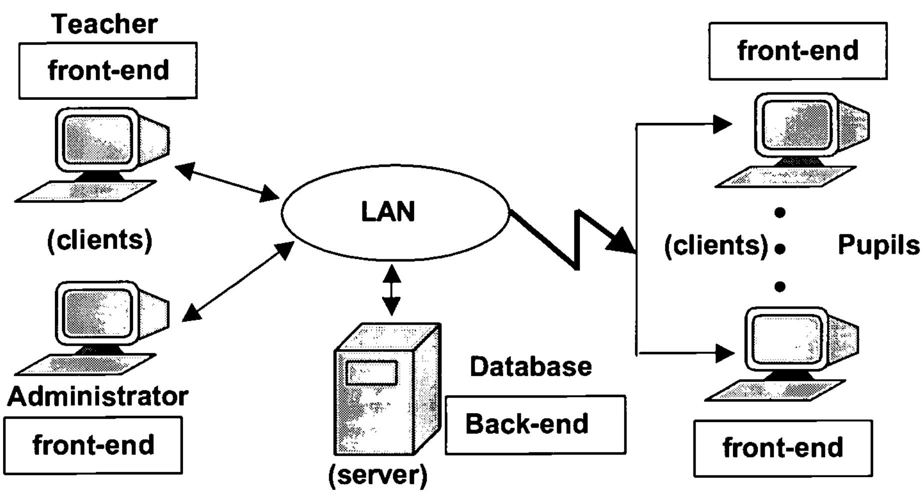

Figure 2: The topology of the system

Figure 3: A screen for topic selection in a subsection

Navigation scheme is a mixture of the hierarchical and linear models. The content is distributed in sections, subsections and topics. Its topic comprises a series of screens containing information in any combination of the above mentioned ways of presentation. The user determines the presentation flow in a degree, by using hot area selections as well as buttons. For example, in Fig. 3 there are three hot (selection) areas, one for each of the three topics. On-line help is available, usually via messages at the bottom of the active screen, where necessary, thus making use of the system as simple as possible to even a novice user.

There are different components of the interface of the system (front-end), related to the administrator and the end-users (teacher and pupils) of the system. These components are related to the user views, described in section 3. The interface of the multimedia application allows use of both the static and the dynamic information. Access to dynamic information is achieved via *dynamic hyperlinking*. That is, links to objects are defined not as local references but as remote queries to the database. This means that some hyperlinks are established dynamically, at run-time, assuming that the information is structured appropriately in the database. This reduces the cost of static hyperlinking and results in ease of tailoring, since it permits data/schema update and evolution (needed for on-line applications) via the database. In addition, it makes the presentation stable, since the hyperlinked objects are subject to the integrity control of the database.

Dynamic information concerns a) activation of the section to be taught and deactivation of the rest ones, b) creation, modification and selection of multiple-choice type questions for each section to form a test, c) storage of the answers of the pupils to the test and d) access authorisation checking.

2.2 Application Server

The Application Server comprises the ODBC Driver Manager, the SQL components and the ODBC drivers. SQL queries to the database are directed via the ODBC Driver Manager to the corresponding ODBC driver and then to the database. ODBC Driver Manager is necessary in case we have more than one ODBC driver for each of the administrator, the teacher and the pupil. This happens when we have more than one database or database partition. In case we have a single database, ODBC manager degenerates to direct connections of the ODBC drivers to the corresponding SQL componenents.

The three components of the SQL server, that are related to the user views (section 3), are as follows:

- **SQL component for the administrator:**
  This component is responsible for the security of the system, since it enables the administrator to establish passwords for the pupils and the teacher. The passwords are stored in the database. It also deals with database updates.
- **SQL component for the teacher:**
  This component allows the teacher to take control over some aspects of a lesson. The teacher can enable the section to be taught and disable the rest ones. Also, it allows the teacher to handle the set of the test questions. He/she can insert new questions, modify existing ones, delete old ones and select a subset of them to set up a particular test.
- **SQL component for the pupils:**
  This component is responsible for checking pupil identification, by examining their particulars, like name and password. Also, it has the task of on-line delivering the test designed by the teacher. Finally, it is responsible for recording the answers of the pupils in the database.

It is the last two components where dynamic hyperlinking is mainly used.

3. User Views

We can distinguish four different ways information can be viewed, that is four basic views, as far as the users are concerned:

- **General view:** In the general view, the user can access all available chemical information by navigating through the sections, subsections and the topics of the multimedia application. For this purpose, the screen is divided into hot spots (specific regions) for every section or subsection and the user can select a specific region and access the related information (Fig. 3).
- **Administrator view:** In the administrator view, the user can establish passwords for the users of the system and update information in the database.

- **Teacher view:** In the teacher view, the user is able to specify the content of a lesson, design and insert new questions in the question set, select a subset of the existing questions and deliver it to the pupils and view their answers.
- **Pupil view:** In the pupil view, the user can identify himself/herself to the system and answer to the test questions that have been delivered by the teacher.

The administrator of the system can use only the administrator view. The teacher can use the teacher view, the general view and the pupil view, whereas the pupil can use the general view and the pupil view. A third person can use only the general view.

4. Implementation aspects

The system, in the form of an advanced prototype, has been developed under the Windows 95 operating system and has been tested on a variety of workstations. The multimedia application was developed using the Macromedia Authorware and Macromedia Afterburner authoring tools that use icon-based scripting. Some additional code was written using Visual Basic.

The database application was developed using the Access RDBMS. The image format is BMP while the videos are formatted as AVI and compressed using the Intel Indeo(R) Video R3.2(32) encoder. The animations are formatted as AVI files as well. Finally, any sounds were digitised and compressed into WAV files.

The application that handles the communication between the user interface and the database comprises a number of SQL components. In particular we used the ODBC functions (ODBCOpen, ODBCClose and ODBCExecute) that Authorware offers for opening a database, closing a database and executing insertions, deletions and updates respectively. These functions are called via calculated icons. Dynamic hyperlinking is implemented by connecting Authorware parameters to database items.

5. Conclusions and further work

In this paper we present the architectural aspects of a multimedia–based system that facilitates teaching chemistry over a LAN to high school pupils. It enables a high level computer-based teacher-pupil interaction using multimedia and hypermedia technology.

An important feature of our system is the use of dynamic hyperlinking, which facilitates on-line control in some aspects of a lesson by the teacher. The teacher can disable all irrelevant sections, so that the pupils cannot "play around" the application, but concentrate on the specific section. Also, the teacher can design new questions, review or delete old ones and select which questions will form a test for a certain lesson. All these are done from a unified user interface, offering different views to different users.

We intend to improve our system in two directions. One concerns extension of the flexibility of the teacher, in making changes to the content of the application other than to questions, such as to text, images, videos etc, in a predefined way. To this end, object-oriented database and authoring technologies may be used (Thuraishngham 1992). The other concerns use of the application over the Internet, additionally equipped with teleconference capabilities to provide a kind of a virtual high school class (see e.g. Hiltz & Wellman 1997). To this end, a number of technical problems should be solved (Wilson 1994).

Abstract: Educational hypermedia authoring process remains as a critical point. This kind of application can assume different formats depending on the chosen learning focus. To build a system of patterns, we analyzed contemporary theories and drew two hypermedia categories: exploratory discovery and guided navigation. We identified the main modeling problems related to the formats and write corresponding solution, using design patterns concepts. We are finishing and refining the patterns and describing others to compose a system of patterns for educational hypermedia modeling.

1. Introduction

Building hypermedia-based educational applications is not easy. Besides a multidisciplinary team, an educational application must reflect the chosen educational goals and the learning environment. Learning environment must be specified *a priori* in educational software life cycle, and it mirrors an educational philosophy and the elected learning theory. However, expert educators and hypermedia designers never build their new applications from scratch. They usually reuse successful ideas they have used in the past. In traditional model of education, pedagogical strategies and goals are imposed by designers. Now, Constructivism is in the front end of the education, and designers can not impose a specific learning model but allow students to construct their own knowledge. While traditional instructional design is based on a linear and hierarchical relationship, new instructional design aims to allow students to select and develop their own strategies, searching for new knowledge domains. Our research is to develop patterns for modeling educational hypermedia applications, considering that instructional technologies are now centered in the process, looking forward for interactive learning environments creation. Intended goal is to obtain a satisfactory formal level, so it can be reused by teachers and hypermedia designers.

This paper presents a set of navigational patterns for helping educational hypermedia designers. The work is organized as following: section 2 briefly discusses learning theoretical foundations to construct educational hypermedia scenarios; section 3 shows how to minimize problems met in developing educational application, using concepts of design patterns. Conclusions and future works are pointed out in the last section.

2. Learning Theoretical Foundations

In the nineties, changes in education focus can be pointed as a remarkable fact. The challenge, today, is to design computational environment to support the knowledge construction, instead of continuing to develop software based on contents memorization and repeatness. The breaking up with overshot issues has brought out important impacts on educational software. New instructional design encapsulates hypermedia features, as the non linear format and the free choice of navigational paths.
Moreover, educational hypermedia can adopt different pedagogical formats, such as impromptu discovery, free exploratory discovery, guided navigation and navigation over enchained sequences of information. To support these formats, learning and methodological guidelines must be available to help designers' work.

[1] This paper has been partially funded by CYTED- Sub- project VII - SHMI

Learning theories reflect dichotomous visions of how the learning process happens. On one extreme, there are the closed approaches, such as the Behaviorism viewpoint and, on the other extreme, there are the opened approaches, such as the Socio-Interactionism. Between them, we can outline Gagné's Neo-Behaviorism and Piaget and Bruner's Constructivism.

Behaviorists consider individuals a passive organism, governed by external environment stimulus. Learning is a permanent change in a specific behavior. Behavior is only what can be externally observed and measured, and it only changes facing reinforce contingencies.

Neo-Behaviorist theory also considers the learning an external behavior, which can be observed and generate permanent changes. Moreover, in the theory scope, mind internal functioning is considered. Gagné is the most representative theorist of Neo-Behaviorist school and to him learning is a behavior change, followed by changing permanency. Learning can be activated by a large range of stimulation from individuals interaction with external environment. The stimulation is considered the learning process's input, able to produce behavior changes, observable as human performance - the output. Intellectual skill complies with a hierarchical sequence: from simple chains, concepts and rules to problem solving. Simples intellectual skills can be composed of simplest skills, that are their pre-requirements, resulting in a skills frame, called learning hierarchy.

Constructivist school considers that learning process is a (re)construction inside individuals, through external environment interactions. The student is the active agent in the learning process, experimenting, researching, questioning and developing the reasoning. Teacher must play, at same time, the role of the learning facilitator, moderator, promoter and challenger of new experiences and must be able to propose strategies and ways that allow students to search and find answers. Piaget and Bruner are important ones in Constructivism school. An usual criticism to Piagetian Constructivism is referred to learning as individual construction viewpoint. Constructivism seems to be uninterested with cultural and social conditionings. Vygotsky is the most representative theorist of learning as a social construction, done by the history and by the culture.

Socio-Interactionism theory points that thoughts are gradually built on a historical and social environment. Social interactions play fundamental role in cognitive development. Development always happens firstly in social setting, among people, and after in the individual setting, inside himself. The child faces three cognitive development stages, extensible to all learners: real development level - determined by individual capacity of solving independently problems; potential development level - determined by individual capacity of solving problems, under supervision of more capable individual or in cooperation with more capable peers; and zones of proximal development - intermediate development stage, situated among real development level and potential development level. Zones of proximal development can be improved through social interactions, i.e., adult help or peers cooperation can develop intellectual skills.

It is complex to draw educational events strictly based on theoretical foundations, but it much more complex to develop educational software under these foundations. Applying theoretical basis in the development of traditional educational software never was usual, since the development process always was *ad-hoc*. Therefore, there are a new scenario - the diffusing of educational hypermedia applications and, more recently, the increasing hypermedia publishing on the Web. It is requiring both theoretical and methodological supports to all development phases, mainly to earliest ones. Educational software designers need to understand the learning process, to integrate, since the beginning of the development, a consistent view of how and under which circumstances people learn.

Behaviorism and Neo-Behaviorism theories are concerned to facts memorization, through the absorption of small and enchained information portions. Constructivism hypothesis is concerned to learning by doing and by acting and transforming the environment, through intellectual challenges and puzzles. Socio-Interactionism rationale is concerned to peers' collaboration, where the "more capable peer" helps the other peers to overcome current knowledge lacking. Behaviorism, Neo-Behaviorism and Constructivism conceive the learning process as an individual process, while the Socio-Interactionism understands it as a historical, temporal and collective process. Navigating over small pieces of enchained information is typically an educational hypermedia application based on the Behaviorist approach. Guided navigation and navigating for hierarchical paths can be seen as an educational hypermedia application based on the Neo-Behaviorist approach. The impromptu discovery, through the free navigation on the Web, the incidental learning, and the exploratory discovery are typical formats of educational hypermedia built under the Constructivism point-of-view. Navigation based on cooperative work, on intense peers' collaboration and on the assumption of learning is a social and shared process are educational formats adopted by the Socio-Interactionism approach.

Not always educational hypermedia applications can be modeled under determined theoretical foundations. Piaget and Vygotsky approaches can not be modeled according to traditional instructional design techniques. These approaches emphasize opened ways of navigating, that can not be modeled. When we try to model these approaches, we often make them closed, contradicting the theoretical principles. On the other hand, educational hypermedia based on Behaviorism foundations can be easily modeled. Moreover, this approach is outdated, proposing poor and limited instructional events.

3. Design Patterns in Educational Hypermedia Modeling

A pattern is the abstraction from a concrete form that keeps recurring in specific non-arbitrary contexts., the notion of a pattern is geared toward solving problems in design. A pattern is more than just a battle-proven solution to a recurring problem. The problem occurs within a certain context, and in the presence of numerous competing concerns. The proposed solution involves some kind of structure that balances these concerns, or "forces," in the manner most appropriate for the given context. Using the pattern form, the description of the solution tries to capture the essential insight that it embodies, so that others may learn from it, and make use of it in similar situations. The pattern is also given a name, which serves as a conceptual handle, to facilitate discussing the pattern and the jewel of information it represents. So a definition that more closely reflects its use within the patterns' community is: a pattern is a named nugget of instructive information that captures the essential structure and insight of a successful family of proven solutions to a recurring problem that arises within a certain context and system of forces. From this background, we describe a set of patterns related to problems met in educational hypermedia.

We have studied the authoring process of educational hypermedia applications under two learning theories - the Bruner's Constructivism and the Gagné's Neo-Behaviorism. These approaches can be modeled, because both Bruner and Gagné have an instructional theories. To start the building of a patterns system we firstly selected two educational hypermedia categories: the exploratory discovery based on Bruner theory and the guided navigation, based on Gagné assumptions. Second, we identified the main modeling problems related to the two formats. Then, we were able to write down our patterns.

Independently the chosen learning theory, a new hypermedia design problem arose due to the increasing publishing in the Web: the Internet functionality. For each problem, we present a pattern, using design patterns concept. The patterns are composed of a name, a brief description, the problem, the related forces, the proposed solution and the known uses. Our work is a work-in-progress yet, since some patterns have not achieved the necessary formalism. Moreover, we are completing and refining the written patterns, aiming to test and validate them. Other related patterns will be described, in order to compose a preliminary pattern system for educational hypermedia modeling.

At the moment, we wrote six patterns: Avoiding disorientation and Minimizing cognitive overhead, concerning the Exploratory Discovery Pedagogical Approach, Enriching Navigational Paths and Improving browsing, concerning the Guided Navigation Pedagogical Approach, Minimizing answer time and Assuring access to informational links, concerning the Networking Functionality.

Navigation in Exploratory Discovery Pedagogical Approach

Navigation in exploratory discovery pedagogical approach provides student only the educational goals and the navigational spaces. The advantage met in this approach often becomes a serious problem, since student can get lost, feeling disoriented and presenting cognitive overhead. As solution, we propose the patterns "Avoiding disorientation" and "Minimizing cognitive overhead"

AVOIDING DISORIENTATION

Description: This pattern is addressed to avoid user's disorientation in educational hypermedia applications based on free discovery.

Problem: How can we avoid that the user get lost in an educational hyperspace?

Forces - Hypermedia users get lost with poorly structured information landscapes and without appropriate navigational tools. Incidental learning should be maintained, since it is an important and fun way of learning. Navigational space should be maintained, but the student can improve his/her learning environment. Navigational design should allow the use of cognitive strategies related to solve problems and take decisions. Collaboration and communication among peers are important educational issues. Social knowledge construction is a relevant point for the new world social organization

Solution - Incorporate navigational facilities to the hypermedia design to provide the accessing to relevant nodes and informational contexts. Use graphic spatial representation to aid the user's orientation and bookmarks, annotations, navigational maps (local and global) or conceptual spaces of navigation, searching by meaningful keywords to orient the browser. Dispose cooperative virtual spaces and browsing tools. Consider the available platform during the design phase. If the design is for the Web, frames, navigational paths, pathfinders, HTML form for annotations, search engines are practical solution. On stand-alone platform, navigational paths, no ambiguous interface solution and annotation individual notecards are effective solutions.

Known Uses - Museums – Le Louvre and Library – Internet Public Library - http:// www.ipl.org/ref/

Related patterns: Minimizing Cognitive Overhead

MINIMIZING COGNITIVE OVERHEAD

Description: This pattern is addressed to avoid student's cognitive overhead while browsing in information landscapes.

Problem: How can we design an educational hypermedia to avoid that time demands becomes high and the student becomes unmotivated, fells lost and the educational goals fail?

Forces - Besides the challenge of solving proposed problems, the student faces the navigational design when browsing an educational hypermedia. Cognitive overhead happens when the student does not feel how the informational space is organized, its depth and extension. Incidental learning should be maintained, since it is an important way of learning and fun. Exploratory opportunities should be preserved.

Solution - Plan the hypermedia design using facilities in order to provide access to relevant marks. Use pathfinders, search engines or mechanisms, index, embedded menus, bookmarks, annotations, navigational maps. Index, embedded menus and accessing keys resolve partially cognitive overhead problems. Key points must be signed by special marks.

Known Uses - Museums – Le Louvre and Library – Internet Public Library- http://www.ipl.org/ref/

Related patterns: Avoiding Disorientation

Guided Navigation Pedagogical Approach

In guided navigation, instructional contents are offered in little portions, though embedded menus. Entry encyclopedia and text book are the metaphors commonly adopted. Students exceptionally get lost, but their navigational spaces are very restricted, causing lack of motivation. As solution, we propose the patterns "Enriching navigational paths" and "Improving browsing".

ENRICHING NAVIGATIONAL PATHS

Description: This pattern is addressed to enrich navigational paths to improve the learning environment and the student choices.

Problems - How can we guarantee that powerful navigational paths are offered?

Forces - Very restricted information landscapes make the student gathers inappropriate range of knowledge. Guided navigation guaranties that the relevant paths will be browsed

Tours, tracks and pre-defined paths are typical design decision in this approach. It assures user's orientation and can help educational goals achievement. If the educational goals are related to improve skills and to solve very specific tasks, this approach can be useful

Solution - Take in count the possibilities of the student to expand the learning environment by himself, offering additional information. Make sure that an alternative path always return to the main one. Learning environment enrichment can be reached by offering paths with additional information. Additional information paths must be planned and linked to the main path.
Known Uses - Education – Cooperative Distance Learning - (http://venus.rdc.puc-rio.br/kids/kidlink/acd/acd_index.htm)
Related pattern: Improving browsing

IMPROVING BROWSING
Description: This pattern is addressed to improve browsing possibilities in guided navigation approach, in order to enrich the information landscapes.
Problems - How can we avoid poor browsing and restrict learning environment in a guides navigation approach?
Forces - Guided navigation assures user's orientation and often do not cause cognitive overhead. This pedagogical approach that supports this kind of learning often lets the student boring and unmotivated. When the hypermedia planning is based on closed tours, it may result in a poorly browsing, restraining the learning environment Tours, tracks and pre-defined paths assure user's orientation and can help educational goals achievement. If the educational goals must be reached, guided navigation is a good design decision. If the educational goals are related to improve skills and to solve very specific tasks, this approach can be useful. A guided navigation guaranties the accessing to main path related to the problem solving. Time demands to find and retrieve effective information is short.
Solution - Costume the browsing considering learning speed, learning context (levels), individual annotations of documents. so the student can feel responsible to some decisions taken. The designer must take in count the student's possibilities to expand the learning environment by himself, offering them additional information choices. It must offer navigational level portraying a range of choices to students with different knowledge and skills, at distinct moments. It must use a comprehensive set of navigational tools, such as personal notes, reports and databases facilities to individualize the navigation.
Known Uses - Education – Cooperative Distance Learning (http://venus.rdc.puc-rio.br/kids/kidlink/acd/acd_index.htm)
Related pattern: Enriching navigational paths

Networking Functionality

The Internet is growing fast and becoming more and more sophisticated. It brings out serious problems, such as long answer time, links cut and access denied. As solution, we propose the patterns "Minimizing answer time" and Assuring access to informational links

MINIMIZING ANSWER TIME
Description: Due to current networking bandwidth, informational links often present a long answer time. The user becomes boring, unmotivated, frustrated and anxious. It makes the user jump the node and choose another link.
Problem - How can we minimize the long answer time when we access a informational link?
Forces - The answer time delay can be minimized if the users know what is going on with the information retrieval.
Solution - If the link belongs to the application scope (internal link), the designer must analyze the media benefits (video, animation, images) to decide about its importance to the users interaction and learning process. The designers can use smaller images, with low/medium resolution, use small video sequences. If the link is Web-site (external link) the designer must provide information about the time spent for information retrieval. He can also give the user the choice of accessing or not the information. Moreover, he should provide similar information as internal links.

ASSURING ACCESS TO INFORMATIONAL LINKS
Name: Internet functionality
Description: Some Internet functionality can get the user lost and confuse, since he can meet cut informational links, with access denied and with different interfaces layout.

Problem - How can we avoid that the user get lost and confuse facing not linked informational nodes, denied access and different interface layout?
Forces - All users can publish and cut out pages in the Internet, at any time. The page belongs to him, so he can also deny the user's access any time. The Internet is in frequent changing, with the addition or suppression of links. Moreover, its dynamism is a useful feature for gathering new information.
Solution - For each particular situation use one of the solutions below: Link cut - store external links and information into databases in its server. Therefore high storage cost, lost of performance and maybe requires a hard programming step or phase. Access denied - be sure that all external links are available. If the links were not available after implementation, find and present similar links. Interface layout - search sites with simple and clear interface layout and that do not confuse the user or make him tired. Final solution to the Internet functionality related problems will only come with network stability and the definition of clear access rules.

Conclusions and Future Works

Changing on the educational process focus has impacting educational software development. Now, software design must encapsulate hypermedia features, but educational hypermedia applications can assume different pedagogical categories. To support the new scene, learning and methodological guidelines must be available to help designers' work. An accurate authoring process of educational hypermedia applications can result in an appropriate navigation. In this sense, we are proposing a meta-model for helping all phases of the authoring process plus a set of pedagogical guidelines expressed as design patterns. Developers and teachers care for this conceptual information and the pattern system will be reused according to specific need. Our work is a work-in-progress, moreover, we are finishing and refining the written patterns, aiming to test and validate them. Other related patterns will be described, in order to compose a preliminary pattern system for educational hypermedia modeling.

Distance Learning and Working over High Speed Internet

Riitta Rinta-Filppula

CERN

Switzerland

riitta.rinta-filppula@cern.ch

Abstract: Web University (WU) is a project based on the concept of virtual university where distance participants communicate over networks by using applications such as email, World Wide Web (Web), multicast interactive videoconferencing and video-on-demand. The project uses national research networks and European wide high speed Internet connections.

The Web University started as a collaborative pilot project between CERN and Finnish universities and extended to other countries in 1998. This article describes how the WU-pilot has used public domain software for creating interactive, real time distance learning and working environment and video-on-demand services on FUNET (Finnish University and Research Network). The WU-pilot has tested and applied new technologies to the service of distance learning and working as efficiently, user-friendly and economically as possible.

1 Web University (WU) project

1.1 Goals and background

The Web University project (WU) works as a virtual university. It started on transferring the latest results of high-energy physics directly to universities. Physics researchers can update their knowledge by participating in CERN (European Laboratory for Particle Physics) [1] seminars and experiments from their personal workstations over real-time broadband network based on ATM (Asynchronous Transfer Mode) and Internet technology. Teaching is interactive and it is in principle targeting researchers and postgraduate students, but some courses in physics and information technology have been additionally offered to undergraduate students and special groups, such as journalists and general public.

The participating universities have selected lectures and seminars from the WU home page [2] on the World Wide Web (Web). WU has transmitted the lectures by the means of real-time videoconferencing from CERN to participating sites over the European and national broadband research networks. These transmissions have been

---

[1] CERN home page http://www.cern.ch/

[2] WU home page http://wwwcs.cern.ch/, projects, Web University

interactive. In addition, the learning has been independent of place and time because the real-time sessions have been recorded on a server. All the time, WU has tested and used the latest technology.

Distance work has been started with user tests, where the supervisor observes and communicates with test users over the network. The supervisor has been at CERN, in Switzerland, and the test users in Helsinki Institute of Physics, in Finland. These user tests have been part of the development and evaluation work of a Web based document management system (more Eronen 1998).

The WU project started as a collaborative pilot between CERN and Finland in 1995. Since 1997, the activities in the WU project at CERN were planned and conducted in collaboration with Finnish distance learning projects, Finnish Distance Learning in Multimedia Network project (ETÄKAMU, 1996-1999) and Finnish Open Learning Environment (OLE, 1999-2002). Since 1998, the real-time sessions have been transmitted at the same time to Finland, Italy, Holland and Slovak.

In particular, the following Finnish companies are funding the WU project: Technology Development Center (Tekes), Center for Scientific Computing (CSC), Helsinki Institute of Physics (HIP) and HPY/ Finnet Group. CSC is the enterprise of the Ministry of Education and it is operating the Finnish University and Research Network (FUNET). Helsinki Institute of Physics coordinates cooperation between CERN and Finland and does high energy physics research in Finland.

WU is open to all universities and research centers to participate. So far, real-time distance participants have been from the following 11 universities and institutes: in Finland, the University of Helsinki/Helsinki Institute of Physics, Helsinki University of Technology, the University of Jyväskylä, Tampere University of Technology, Pori School of Technology and Economics, the University of Oulu and Oulu Institute of Technology; in Holland, the University of Twente; in Italy, the University of Rome 2 "Tor Vergata" and the High Energy Physics Laboratory of Pisa and in Slovak, Pratislav University of Technology.

1.2 Communication networks

The Web University project started by transmitting CERN lectures to Finnish universities over ISDN but since June 1996 the videoconferencing has been done over IP/ATM, as that was when the European Commission launched its telecommunication programs based on broadband network services.

The Web University project became a customer of JAMES (Joint ATM Experiment on European Services) in 1996 and used a point to point connection with a communication speed 1- 2 Mbps between CERN in Switzerland and Helsinki in Finland. Since 1998, WU has used TEN-34 and TEN-155 and the seminars have also been transmitted to Italy, Holland over TEN and to Slovak over a private network.

The lectures were multicast in each country by the national research network operators. FUNET, the Finnish University and Research Network has multicast lectures to universities in Finland. The communication speed of the FUNET backbone network is 155 Mbps and mainly based on ATM.

1.3 Software

The learning and working environment of WU is based on tools of the MBONE technology. At the beginning of the project, the connection for the real-time videoconferencing was created manually by Rtptrans software and digital recordings were also done manually. Since the autumn 1998, the connection has been created automatically by the Virtual Room Videoconferencing System (VRVS). VRVS is Web based and it is being developed at CERN. Digital recording and playback have also been done by VRVS. The recordings have been copied to the WrtpVod server of FUNET for retransmissions on demand.

1.4 What do you need to participate in WU?

The project discovered that *every country*, that wants to participate in WU, requires:

1. Universities and research centers, which are connected to the European academic and research infrastructure and are willing to join the project. These universities should be interested in using or producing freely available courses as part of an academic distance curriculum. Moreover, these universities and research centers should be

motivated to receive or distribute the latest research results and support local costs.

2. At least one technical person and one educational contact person, who co-ordinate activities in the country. The technical contact person should be involved with a national network provider.

3. A technical contact person and an educational contact person for each institute.

2 Results and conclusions

CERN is a research laboratory where the best specialists of scientific institutes and universities often come to give lectures. WU has made these seminars available for researchers and students in remote universities. Moreover, it has enabled researchers and their students even at small universities to attend the CERN seminars from their own university. They can participate in interactive, real-time seminars from their personal computers or local auditoriums and ask questions from the lecturer either as the audience at CERN or by using email. WU has transmitted more than 100 hours of different kind of lectures and seminars to the universities. If participants are occupied during the real-time session, they can study the subject by using the video-on-demand service of FUNET some hours later when the time is convenient for them.

In this context, WU found out how to make a successful distance learning session by studying distance students' attitudes and by evaluating distance learning (Rinta-Filppula 1998).

These findings proved that, at the beginning, the pedagogical expectations should not be too high, as the students need time to adapt to a new situation and learning environment. In addition, it turned out that it is difficult create an interactive distance learning session because a lecturer and distance students are different every time and to thus, they do not know each other.

It appears that undergraduate students need academic credits as a motivator but postgraduate students, on the contrary, are interested in the latest research results even without getting any. Academic freedom gives students many possibilities to select study courses. Undergraduate students are unlikely to be willing to spend their time looking at a video screen and studying in a foreign language, English, if they do not get any credits.

2.1 How to make face to face studies successful distance learning

Distance learning sessions can be planned for distance learning or they can be a part of face to face learning, where the students participate over networks. This article concentrates on the latter case, where it is very important to provide lecturers with preliminary information about the distance students in order to give them a possibility to adapt their lectures for the distance learners. The feedback collected has shown that the lecturers should more commit themselves to adapt their presentation for distance participants. On the other hand, the lecturers would need support and help how to apply the technology from pedagogical point of view.

Distributed real-time sessions are differently. Distance participants have proved to be especially satisfied if the speaker is well-known (e.g. a Nobel price winner or a Web inventor) and they can communicate real-time with him or her. In addition, they can later integrate the presentation to their teaching or studies because it is available on the network based multimedia service.

Flexible learning should be planed different if the distance learners are allowed to include the sessions to their studies and obtain credits. In this case, learning process should start before the real time session to enable to take full advantage of the possibilities that modern learning theories and technology provide. This can not happen without an agreement and cooperation of a local teaching staff in a distance institute. A network base multimedia service built on video-on-demand service, course discussion channel, knowledge exchange of the best practices of distributed programs etc. is an essential part of distance learning but even more important is to develop and adapt teamwork and active learning methods to new high speed network environment. This can take place for example, as follows:

A lecturer who will give a presentation in a real-time session publishes his abstract and reference material on the Web in advance. In distance universities, a local teaching staff and their students agree on draft plans of distance student teamwork, work methods and evaluation. The drafts will be published on the Web in a course discussion channel. The students study the reference material before the interactive, real-time session gets started. After the session, the plans of the distance groups will be published on the Web and the students will work with their group presentation papers by using teamwork tools, project tools etc. They will then publish their papers on the Web and present them in a real-time virtual seminar, where they also will act as opponents to the other students. This is not only an excellent possibility for students to practice project and teamwork but also planning and giving a presentation in an international conference. In addition, through the student works, the teachers can enrich their teaching methods. After a virtual seminar, the students will publish the second part of their distance work, i.e. the evaluation. It can consist of e.g. a report of their work progress, their individual, as well as group analyses of what they have learnt, their group analysis about learning and work practices and recommendations for getting better learning results. It should be noticed that the students are constantly expected to pay attention to justify their opinions, in order to derive full advantage from the learning process.

The virtual learning described above can take place only in universities (e.g. Finnish universities and the university of Twente in Holland (Collis & Fisser 1998)) where the teachers have applied teleteaching, teamwork tools, project learning and other active learning methods as a part of their curriculum. The pedagogical background of the model lays on the seven properties of meaningful learning (Pohjolainen 1999) that are suitable for lifelong learning – from comprehensive school to university level and to adult learning – independent of time and place. This kind of virtual learning carries out the active learning (Jonassen 1995).

Copyrighting Cyberspace: The Digital Millennium Copyright Act

Abstract

The Internet is the largest computer system. The net or cyberspace provides much useful information as we navigate URL's, browsers and hyperlinks. With advanced technology comes new legal issues to battle. Copyright law is at the forefront of cyberspace debate. Thus, we need to examine and stay abreast of issues so important to all those being affected by this area of law.

In this work I will endeavor to explain the latest legislation regarding copyright in cyberspace. I hope that such information will prove to be a resource as well as a guide to all those interested in traversing these navigable waters.

On October 28, 1998 President Clinton signed a bill providing new game rules for the treatment and respecting of online copyrighted material. The Digital Millennium Copyright Act, (hereinafter referred to as the *DMCA*),[1]
passed both houses of the one hundred and fifth (105[th]) Congress earlier in the month.[2]

The DMCA adds two (2) new chapters to Title 17 as it strengthens international law worldwide and protects domestic technology.
President Clinton was please with the measure.[3]

The one hundred and fifty (150)-page document divides into five (5) titles in *Fig. 1* below:

Fig.1: THE DMCA

Note: Except for Title I (Treaty), each the following are effective upon enactment:

Title I: Implementation of two (2) treaties dealing with digital issues, copyright protection and management systems.

Title II: Limitation of Online infringement liability for ISPs (Internet Service Providers) (reducing legal uncertainties regarding such items as digital networks, strengthening anti-online piracy, outlining copyright owners' notification procedures, defining university liability, and creating a "safe harbor" for ISPs in four (4) situational activities):

(1) Conduits (provision of materials transmission, routing and connections)

(2) System Caching (temporary or intermediate materials storage)

(3) User Storage (materials)

(4) Information Locators (linkage provision)

Note: 1 and 2: transmission must be initiated by a third party.
3 and 4: requires the ISP to be without knowledge or having reason to know of any infringement, to obtain no direct financial benefit and to not change the materials.

Title III: "The Computer Maintenance Competition Assurance Act" (formerly H.R. 72) (creation of an exception for temporary computer program reproduction in maintenance/repair).

Title IV: "Miscellaneous Provisions" (distance education, exemption for libraries/archives, ephemeral (momentary) recordings).

Title V: "The Vessel Hull Design Protection Act" (formerly H.R. 2696) (creation of new protections for boat hull designs, effective for two (2) years only).[4]

Oddly enough Congress handed down the measure around Columbus Day. It would seem Americans were in store for more than celebrating the discovery of the country. Although technically the Senate still must ratify international pacts before governments of the world give credence to the measure, the law does prepare for the ratification and execution of two (2) treaties regarding *WIPO*, The World Intellectual Property Organization. In December 1996 over one hundred and fifty (150) countries agreed on WIPO at a conference on digital information and copyrights in Geneva. The first treaty clears up digital authors' rights. The second pact focuses upon the Internet and sound recordings. Thirty (30) nations must ratify the agreement for it to be effective globally.[5]

Internet service providers, software industry groups, music/movie companies and the like herald the DMCA. Attorney Jonathan Band, a partner in the Washington, D.C. office of San Francisco's Morrison & Forester, L.L.P, practices copyright law. He states:

> The Digital Millennium Copyright Act accomplishes four things... *First*, it implements the World Intellectual Property Organization treaties, thus harmonizing U.S. copyright law with international law. *Second*, the DMCA establishes "safe harbors" for online

service providers who unknowingly transmit copyrighted works. *Third*, the act permits the copying of software during computer maintenance. *Finally*, the DMCA facilitates Internet broadcasting.[6]

However, members of the academic and research communities express mixed feelings about the measure. Some claim the DMCA would hinder concepts of fair use and other acceptable means of validly utilizing copyrighted materials. Most library organizations opposed the measure citing it does not contain many desired provisions. Specifically, according to Professor Bob Oakley, Library Director of the Georgetown University Law Center, H.R. 2281 will be a hindrance to reading, browsing, classroom teaching and applying of fair use standards:

> HR 2281, as drafted, would grant copyright owners a new and unrestricted exclusive right to control access to information in digital works which could negate one of the most basic principles...the ability to gain access information in published or publicly available works...[7]

Many groups voiced support and opposition for the bill.[8] The Digital Future Coalition, a forty-two (42) member organization comprised of non-profit and for-profit entities interested in intellectual property law in the digital era, opines:

> In the final version of the DMCA, Congress recognized the importance of ensuring balance in the treaty implementing legislation. The DMCA safeguards such crucial activities as computer security testing, reverse engineering to achieve interoperability, the protection of personal privacy, parental supervision of minors on the Internet and the preservation of materials by libraries and archives. It also assures the availability of the next generation of consumer electronics and computer products. In addition, it provides a mechanism to assure the continued vitality of the fair use privilege enjoyed by teachers, students, library patrons and all other information users. These provisions represent a dramatic departure from earlier drafts of the legislation....[10]

Another bill, *The Digital Era Copyright Enhancement Act,* H.R. 3048, is still awaiting approval. The measure included an increase for the preservation of author's rights similar to the provisions in the Berne Convention for the Protection of Literary and Artistic Works. In March 1989 the United States joined the Convention that produced a multinational treaty.[11]

H.R. 3048 amends the first sentence of section 107 of The Copyright Act by adding "analog or digital" in applying fair use to all transmissions.[12] In actual comparison, H.R. 3048 includes many safeguards lacking in H.R. 2281. Among them include legal protections with allowances for the creation of incidental copies, fostering of distance learning[13] protecting of consumers against so-called shrink wrap licenses, negating of ephemeral copyright liability (i.e. making copies incidentally in relation to computer operation), preserving of microfiche technologies, exempting library/archive uses (allowing for the making of temporary computer program copies and utilizing a "knowledge" test as the basis for civil liability; note that criminal liability is not available at this level)[14], and, most importantly for many, the preserving of fair use doctrinal principles.[15] Indeed the two bills have been very much compared and contested of late.[16]

H.R. 3048 indeed expands the fair use doctrine toward notions that library, teaching and research purposes fall into acceptable practices in relation to technological advances. Penalties apply against infringers rather than those on the fringe that may wish to legally and ethically utilize materials.[17]

According to the Software Publishers Association, copyright piracy costs over eighteen (18) billion dollars worldwide.[18] Regarding penalties and liabilities, in general, the DMCA's Sections 1203 and 1204 imposes updated standards and gives guidance for works on the Net especially regarding criminality. Plaintiffs recovering successfully for wrongdoing have the choice of illegally obtained profits, statutory damages or injunctive relief. In a year and a half, it will be unlawful to create or sell any technology used to break copyright protection devices. It also will be illegal to commit acts of circumvention as each will carry statutory damages of twenty-five hundred dollars ($2500.00).[19] And, in a limited manner, willful and purposeful defendants could face serious criminal penalties of several hundred thousand for each violation.[20]

The DMCA contains many criminal impositions for conduct unrelated to infringement. For example section 104 provides for violations regarding circumvention of copyright protection systems in section 1201 or integrity of copyright management in 1202. Anyone who violates either section for "purposes of commercial advantage or private financial gain" faces up to five hundred thousand (500,000) dollars or imprisonment of up to five (5) years, or both for the first (1st) offense. The penalty is up to one million (1,000,000) dollars and up to ten (10) years, or both, for subsequent offenses.[21] DMCA sections 1204 a & b. Courts will have the power to award triple damages against repeat offenders. A five (5) year statute of limitations applies here.[22] H.R. 3048, on the other hand, applies civil relief rather than criminal punishment.

And, H.R. 3048 provides that "no person, for the purpose of facilitating or engaging in an act of infringement, shall engage in conduct so as knowingly to remove, deactivate or otherwise circumvent the application or operation of any effective technological measure used by a copyright owner to preclude or limit reproduction of a work or a portion thereof."[23] The DMCA makes it illegal to "manufacture, import, offer to the public, provide or otherwise traffic in any technology, product, service, device, component or part thereof " that may be used to circumvent a technological protection measure.[24] The law affords protection toward encryption research, security testing and related matters. And devices as to safeguard against child pornography on the Internet were given exemption in this respect.

Conclusion

There are several bills such as H.R. 3048 still on Congress's plate. The DMCA is a massive complexity of rules and regulations. If we are to advance in the digital age, we must have a compromise between right and rule. It will be a test of time as to whether or not the Clinton administration's efforts will be a cure or a curse for the new millenium in copyright. The only way to examine the DMCA's validity is by trial and error. Unfortunately we will be cursed with many of each.

Computer-Mediated Learning, Synchronicity and the Metaphysics of Presence

Ray Land, Centre for Teaching, Learning and Assessment, University of Edinburgh, Scotland, ray.land@ed.ac.uk

Siân Bayne, Educational Development Unit, Napier University, Scotland, s.bayne@napier.ac.uk

Abstract: This paper addresses the question of the noticed resistance of many learners, and indeed teachers, to the use of computer-mediated discussion in the support and delivery of learning programmes, and their preference for face-to-face modes of teaching. It applies some of the insights gained from post-structuralist theories of language in order to approach a fuller understanding of this preference, and concludes that a fundamental re-thinking of our understanding of the educational experience, and its cultural context, is necessary if we are fully to engage with the opportunities presented by computer-mediated approaches to learning.

Introduction

This paper originates in attempts to explain, at a practical level, the perceived disinclination of learners to participate in computer-mediated conferencing (CMC) in contrast to traditional face-to-face teaching. This apparent privileging by learners of face-to-face environments in our own experience of managing CMC programmes, in addition to similar learner resistance reported by other providers (Akers 1997; Finkelstein & Dryden 1998; Grint 1989; Von Prümmer 1995) led us to seek theoretical explanations of such preference, the better to be able to deal with related pedagogical considerations. Earlier explanatory models have attempted to account for face-to-face preference through, for example, the idea, derived from social presence theory, of reduced social cues (Gundewara 1994), or of the ephemeral nature of 'orality' (Zuboff 1988). In psychology, more determinist social learning approaches, derived from the psychological Theory of Mind (TOM), suggest that we are hardwired for social interaction, with the mind expecting to find intersubjectivity. Most of these studies, it seems to us, lack explanatory power in relation to CMC and pedagogical implications for the management and practice of learning in CMC environments. This is not surprising, since such perspectives reside within a realist/humanist tradition which by definition, as will be explained below, always cedes precedence to face-to-face approaches to teaching and learning.

There is need for a theorised account of CMC from an alternative perspective. Given that CMC is essentially a *text*-based environment, one in which learning is mediated entirely through the processes of reading and writing, a much more compelling approach may be derived from the insights gained from post-structuralist theories of language, in particular the work of the French philosopher, Jacques Derrida. Our claim is that the privileging of face-to-face learning over CMC derives, from the privileging of speech over writing that Derrida has forcefully identified as the most central hierarchical opposition in the history of Western metaphysics. The privileging of speech, moreover, is associated with the notion of personal *presence*. As Feenberg has noted:

> In our culture the face-to-face encounter is the ideal paradigm of the meeting of minds. Communication seems most complete and successful where the person is physically present 'in' the message. This physical presence is supposed to be the guarantor of authenticity: you can look your interlocutor in the eye and search for tacit signs of truthfulness or falsehood, where context and tone permit a subtler interpretation of the spoken word. (Feenberg 1989)

Such a position appears so commonsensical within traditional western culture that it comes as something of a shock to find Derrida describing speech as another form of 'writing' and denying its status as a more authentic source of 'truth'. This paper will argue that resistance to the loss of face-to-face teaching can be seen as attributable to a generally unexpressed awareness that CMC undermines the position of speech over writing, and in doing so also undermines the entire realist and humanist perspective from which, in Western culture, we construct ideas of truth, presence and subjectivity.

These are indeed large and no doubt provocative claims. Hence priority is assigned below to a careful exposition of the philosophical basis of our argument. The final purpose of the paper, however, is to return to the pedagogical considerations from where the discussion originated, and to describe what in our view are crucial implications for the roles of tutor, moderator and learner in CMC environments, and even for the nature of the institutions in which such programmes operate.

Language and the dispersed nature of meaning

To approach the issue of why CMC participants seem uneasy with the loss of face-to-face teaching it is first necessary to 'problematise' the nature of language. The seeming nature of language as a transparent lens through which we perceive 'reality' rather than as the medium through which realities are constructed is part of a process operating within CMC which we are here concerned to challenge. It is easy to forget that the computer-mediated learning environment is essentially a collection of written texts – a 'written world', to use Feenberg's phrase. Though we often refer to participants in CMC environments as 'speaking', 'chatting', 'talking', having a 'voice' and engaging in 'conversation' and 'discussion', and refer to them collectively as an 'audience' that 'hears', such metaphors are themselves examples of the privileging of speech over writing mentioned earlier.

The full impact of post-structuralist thought, and its relevance to computer-mediated learning, can be approached through the work of the structuralist linguistic theoretician Ferdinand de Saussure. Saussure views language as a system of signs; each sign is composed of a signifier (a word, written or spoken) and a signified (the concept or meaning) (Saussure 1974). The relation between the signifier and the signified is arbitrary. There is no intrinsic or given connection, for example, between the word 'mouse' and the small mammal. If there were, the word for 'mouse' would be the same in every language, and 'mouse' would not also mean 'a small device which controls the cursor on a PC screen'. What is more, the meaning of a sign is not complete in itself – it has meaning only because of its difference from other signs. For example, 'mouse' only means 'mouse' because it is *not* 'house', 'mousse' or 'louse'. Despite the fact that language appears transparent (the connection between the word 'mouse' and the concept of a mouse seems clear and unproblematic to the user of the language) the construction of meaning is actually complex; language becomes a system of differences with no positive terms, meaning can only be a product of social and historical convention.

Further, language does not provide us with a set of terms or labels which we use to name entities which already exist independently in the world. Rather language precedes the existence of these entities, enabling us to make the world intelligible by differentiating between concepts in a way which is particular to our own cultural context. For example, in Welsh the colour 'glas' ('blue') includes elements which in English would be identified as 'green' or 'grey'. There is no objective experience of the colour 'blue' – like language itself, colour terms form a system of differences which seem 'natural' but are in fact enabled or constructed by the language itself (Belsey 1980). The language forms our view of the world, and therefore forms us as conscious, social entities.

Post-structuralist theorists such as Derrida take these ideas further. They highlight what is implicit in Saussure's theory, which is that, if every sign gets its meaning from the fact that it is *not* all other signs, every sign consists only of an infinite web of differences. In other words, because the meaning of a sign consists of what the sign is *not*, meaning is never fully present and complete in the sign – rather it is dispersed among all the other signs in existence. Meaning cannot be nailed down, it is inherently unstable, 'never fully present in any one sign alone, but rather a kind of constant flickering of presence and absence together' (Eagleton 1983).

The implications of these ideas are serious for traditional systems of thought. Language loses its status as a handy tool which enables us to speak about and reflect on 'reality'. To use language at all involves us in a dispersal of meaning throughout the infinity of the system of signs. And since we ourselves *are* in a sense our language (it is the means through which our world and our place within it are constructed), the status of our identities (or selves) as stable and unified is also under question.

Logocentrism and the metaphysics of presence

Derrida, whose brand of post-structuralist philosophy is termed 'deconstruction', sees the history of Western philosophy as being based in 'logocentrism' – the belief in some centre, some ultimate Word ('*logos*'), truth or reality which is not subject to this dispersal, which anchors all thought, language and experience, and provides an ultimate meaning which cannot be questioned. Notions of God, Truth, the Self, Nature and so on can all be seen as having their roots in logocentrism which, for Derrida, is closely bound up with what he calls the 'metaphysics of presence'.

> Presence appears as the things we see; as the immediacy of the ideas and representations we have; as substance, essence and existence; as the temporal present, the now of the moment, as the self-presence of consciousness, of subjectivity, as one's own inner experiences and ideas etc... Presence constitutes the essential truth of reality; hidden from our sight possibly, but present in its entirety to some divine mind. (ibid)

Post-structuralist thought stresses that any such transcendental meaning is fictional, in the sense of being constructed. There is no concept which exists outside systems of thought and language; there is no concept which is not involved in the infinite play of meaning. In order to function socially we do make temporary determinations of meaning but meaning itself is never determinate (Derrida 1978).

Textuality

Ideas about the nature of text itself are radically affected by the ideas of the post-structuralists. Texts are no longer seen as closed, stable entities, holding within them definite meanings which the reader is required to decipher. Rather, they become a temporary arena for the endless play of signifiers – they cannot be tied down to any one meaning, but remain open and pluralistic, subject to multiple interpretation. All texts are woven out of other texts in that every element of them refers to other writings which surround, precede or follow, much as the sign itself is composed of traces of every other sign. This is broadly referred to as 'inter-textuality'.

The relevance of the post-structuralist vision of language to the study of electronic texts such as those found in CMC – and, increasingly, in web-interfaced versions where CMC texts become increasingly hypertextual and linked – becomes clear. Eagleton's account of the play of language from a post-structural perspective is powerfully suggestive of the kind of interplay found in CMC discussion.

> Instead of being a well-defined, clearly demarcated structure containing symmetrical units of signifiers and signifieds, [language] now begins to look much more like a sprawling limitless web where there is a constant interchange and circulation of elements, where none of the elements is absolutely definable and where everything is caught up and traced through by everything else. (Eagleton 1983)

What is more, the traditional hierarchical relationship between texts is undermined. Where traditionally a so-called central or 'primary' text takes a central position, provides a focus for discussion and interpretation in the form of marginal or 'secondary' texts, deconstructionists would claim not only that the central can become marginal (and vice versa) but that the very difference between the two is brought into question. Since both are subject to infinite play of meaning and interpretation, we cannot say where one ends and the other begins. When we apply this insight to the realm of CMC intertextual 'discussion' we can immediately conceive of a questioning of traditional assumptions relating to which 'voice' or text is authoritative and takes precedence over the others. A levelling effect in the relationship between tutor and student can perhaps be seen as one inevitable consequence of the move from the face-to-face interchange to one taking place in a CMC environment.

Speech, synchronicity and presence in CMC

In addition to its essentially textual nature, CMC is characterised in most instances of its use by its other distinctive feature – *asynchronicity*. It is not difficult to see how asynchronicity can become identified in the minds of learners with inauthenticity.

> Traditionally speech is favoured as the concept which best represents the semantic relationship of language to thought in virtue of its own essential and immediate causal proximity both to the thoughts which give it its meaning and to the thinker having those thoughts, expressing these meanings... (Parker 1997)

Speech appears to emanate directly from its 'author'– the presence of the author is self-evidently required for speech. In this regard *presence*, in the sense of physical presence, requires synchronicity. If a logocentric perspective is maintained then *a*synchronous activity undermines such truth at a glance, and the house of cards collapses. And of course *writing* is by definition asynchronous in nature, traditionally seen as being a step removed from the 'author' in a way that speech is not. Hence text-based conferencing comes to be seen as 'inauthentic'.

CMC, of course, is heavily and obviously mediated both through written text and computer technology. Face-to-face, in comparison, *appears* deceptively to approximate to the ideal speech situation. It is of course no such thing and is as mediated, though by no means as self-evidently, through linguistic signs and signifiers that are as independent of the self and *as dependent on a linguistic system and interpretation* as any written text.

Bivalence, realism, and deconstruction

As Culler has pointed out, Derrida's claim is twofold:

> First the moment of speech, or rather the moment of one's own speech, where signifier and signified seem simultaneously given, where inside and outside, material and spiritual seem fused, serves as a point of reference in relation to which all these essential distinctions can be posited. Second, this reference to the moment of one's own speech enables one to treat the resulting distinctions as hierarchical oppositions, in which one term belongs to presence and the logos and the other denotes a fall from presence. To tamper with the privilege of speech would be to threaten the entire edifice. (Culler 1983)

Culler draws attention here to a final key concept in our argument, what he terms 'hierarchical oppositions', derived from Derrida's notion of *bivalence*. In Western thought and reason, Derrida claims, bivalence has consistently served to sustain a central conceptual hierarchy of terms. Western philosophy has historically operated through a network of conceptual hierarchies, dependent upon the function of binary oppositions, in which one pole of the binary opposition is always privileged over the other.

> In a traditional philosophical opposition we have not a peaceful co-existence of facing terms but a violent hierarchy. One of the terms dominates the other...occupies the commanding position. To deconstruct the opposition is above all, at a particular moment, to reverse the hierarchy. (Derrida 1981)

As Culler emphasized, the dominant term is always that which 'belongs to presence and the logos'. Such binary oppositions underpin traditional Western ideologies and value structures such as realism in philosophy, humanism in the arts and positivism in science. Examples of such oppositions would be: mind/body, male/female, white/black, self/other, nature/culture, presence/absence, theory/practice and so on. In each of these cases, the latter term is seen as a deviation from or perversion of the former. As Parker suggests:

> The hierarchical ordering is a symptom of the way in which a text *assumes the normality* of one pole of the opposition and sees the other as simply a negative, a distortion, a perversion or a parasite of the original concept. Texts, consequently cannot be viewed as possessing a structure which is natural, value-neutral, uniform. Instead, the textual structure is an economy in which the currency of a concept is determined by its place among other concepts within a system of value exchange and difference. (Parker 1997)

Implications for teaching and learning using CMC

If we consider the discourse of education in textual terms it is interesting to speculate what might be the binary oppositions that would emerge and what normality would be 'assumed', in Parker's phrase. A tentative conceptual hierarchy might include the following:

- teaching/learning
- tutor/student
- research/teaching
- education/training
- face-to-face/distance-mediated
- synchronicity/asynchronicity
- speech/writing
- author/reader
- cognitive/affective
- individual/collective
- disciplinar(it)y/interdisciplinarity
- singularity/multiplicity
- local/global
- institutional/personal
- rationality/irrationality
- competition/collaboration
- unity/fragmentation

Again, it is reasonable to assume that dominance and presence reside in the former terms. It is not surprising, for example, to find that in quantitative research into face-to-face tutorial group interaction, the amount of teacher talk massively outweighs that of student talk (Foster 1981).

We can only conclude that a dispensation such as that above is not only the product of an existing realist-positivist academic culture but also serves to sustain such a culture. Traditional academic institutions that maintain such hierarchical bivalences as teaching/learning, tutor/student, author/reader will *always* favour face-to-face modes of learning, not only because such a mode privileges the role of teacher over taught and institution over person but because 'realism is situated as having a phonocentric bias which is symptomatic of a deeper commitment: logocentrism or the metaphysics of presence.' (Parker 1997)

George Landow (1997) has commented on the way in which CMC and other new learning technologies pose a challenge to traditions which, as we have attempted to show, have their basis in logocentrism and the metaphysics of presence, through enabling and indeed requiring ways of working which are traditionally resisted in the academic context. Studying in the electronic arena encourages collaborative rather than competitive approaches, the violation of disciplinary boundaries and the re-thinking of the tutor/student relationship.

Just as in the literary domain Roland Barthes famously announced in 1967 the Death of the Author, it may well be that reports of the Death of the Tutor have not yet been sufficiently exaggerated as the new medium replaces this hierarchical role with the more democratic one of moderator/facilitator who acts as co-learner. But the online moderator needs to acknowledge that identities created online may well differ from face-to-face identities, whilst remaining equally valid. Turkle (1995) provides lucid insights into the creativity, energy, irony and playfulness of online identity and behaviour.

The moderator role in CMC assumes critical importance in this respect. As online writing allows for the possibility of much greater freedom and elaboration of identity, the unified self assumed within face-to-face encounters may fragment into many facets or faces in online environments. The loss of one face may permit the emergence of several. As Baltz has pointed out:

> instead of identity having the status of an initial given (with which the communication usually begins), it becomes a stake, a product of the communication. (Baltz 1984:185)

To have a centre is important but, as Derrida has commented in respect of the notion of 'de-centering', the centre is a *function*, not a being. In the same way, online moderation is a function that does not necessarily have to be dominated by one individual, traditionally the tutor.

At a practical level of operation CMC offers an unprecedented opportunity for the encouragement of the active, empowered reader/learner. CMC and related hypertextual technologies resist the grip of logocentrism in a new way, and provide opportunities for learners (and 'tutors') to work explicitly with ideas of plurality and multiplicity that have been historically denied, and which could well be emancipatory in their effects. In order to fully explore these effects we need, however, to change our perspective, understanding and expectations of educational experience and purpose. If we do not, face-to-face modes will always remain dominant – working within the existing realist paradigm will never lead to a questioning of its own (occluded) assumptions.

But the alternative will be challenging, risky and difficult. The effects of post-structuralist thought are unsettling. It does seem to threaten, in Culler's phrase, 'the entire edifice', much in the manner perhaps in which Darwinism threatened the edifice of prevailing Victorian thought and values. And unsettling the fundamental values of our students – and colleagues – is not something to be countenanced lightly, however educationally well intentioned. We do not underestimate he potentially negative aspects of online interaction, nor do we ignore the capacity of virtual environments to be colonised in the interests of managerialist imperatives. Our intention is to lay emphasis on the emancipatory effects of CMC.

The strategy of a deconstructivist approach is to undertake a reversal of hierarchical opposition, not to replace one generalising conceptual hierarchy with another, but to subvert the original logocentric stance by bringing various realities into play. CMC is ideally suited for this purpose. In similar fashion it has been our intention in this paper to provoke debate through challenging the realist perspective by drawing it into play with alternatives. We hope that colleagues will enter into the spirit of plurality we wish to foster by reciprocating the challenge.

Designing Effective Learning Environments for Distance Education: Integrating Technologies to Promote Learner Ownership and Collaborative Problem Solving

Dennis Knapczyk: Special Education, Indiana University, U.S.A., knapczyk@indiana.edu

Haejin Chung: Special Education, Indiana University, U.S.A., hachung@indiana.edu

Abstracts: Rapidly developing technologies do not themselves create more interactive distance education learning environments. Investigations of teaching practices coupled with a review of the literature have led us to establish three major aims to guide in the design of coursework and the selection of distance education technologies. These aims are to promote learner ownership, to foster situated learning, and to encourage collaborative problem solving. This article describes the different types of distance education technologies we use and how these technologies are integrated to meet these aims.

The Collaborative Teacher Education Program (CTEP) at Indiana University was created twelve years ago to address the critical shortage of special education teachers in Indiana (Knapczyk & Rodes 1995; Knapczyk, Rodes, & Brush 1994). The lack of fully certified teachers in many communities is compounded by the difficulty teachers have obtaining university training. By offering coursework via distance education, CTEP allows in-service teachers to complete the entire 36-credit hour requirement for earning special education licenses in their communities.

Over the years, the communication technologies used in CTEP have advanced from speaker phones and the U.S. Postal Service, to computer-based audiographics and fax machines, to multi-point videoconferencing, web conferencing and e-mail. New technologies and increasing capabilities of interactivity are providing new tools for distance education. However, the advancement of technology alone does not automatically guarantee a more interactive and effective learning environment.

Investigations of teaching practices coupled with a review of the literature associated with teacher education have led us to establish three major aims to guide in the design of coursework and practicum activities and the selection of distance education technologies. These aims are to promote learner ownership, to foster situated learning, and to encourage collaborative problem solving. One challenge that has remained constant from the beginning of CTEP is tailoring the capabilities of new technologies to create an effective learning environment that meets these aims. In the next section we describe the different types of distance education technologies we use and discuss how these technologies are integrated to meet our program aims.

Distance Education Technologies

Audiographics

We began the program using audiographics to support in-class communication with students. Audiographics involves two telecommunications links, one that connects computers via modems and a second link that provides an audioconferencing medium through a normal telephone connection. Although audiographics is usually overlooked in the rush to more up-to-date video options, its low cost and broad delivery capabilities make it still viable for programs that emphasize outreach or low instructor-to-student ratios (Knapczyk & Rodes 1995).

One real advantage we found when using audiographic technology is that the limitations of a non-video format forced us to adopt effective teaching strategies that are often overlooked in campus-based courses. Rather than lecturing over the speakerphone, we learned to encourage the trainees at the remote site to lead discussions, explain key point from the text, and take part in small-group activities that relate to the projects they are conducting in their classrooms. To facilitate this process, we had trainees take turns acting as on-site coordinators, and we contacted them in advance to help them prepare to lead the class. We also found it very important to include specific written guidelines for any class activities and text materials that are closely adapted to the needs of the course, as there is little opportunity for the kind of lecture that takes place in campus-based courses to provide background information.

Two-Way Videoconferencing System

Two years ago we began offering coursework using a large-group videoconferencing system that employs high-speed telephone lines to transmit quality video and audio. Both origination and remote sites have large-screen monitors, speakers, and built-in cameras and microphones. In addition, the sites also have computers, document cameras, and videotape units for displaying graphics, hard copies or videos. This system has allowed us to connect two or more remote groups for our class sessions.

Videoconferencing equipment offers the obvious advantage of trainees and instructors being able to see one another and follow visual cues. Seeing the instructors makes students much more comfortable, and it is much easier to explain issues and spot problems. Even so, we have made a deliberate effort not to lose the insights we gained from our experience with audiographics. We still have many student-centered activities and discussions, and we involve trainees as much as possible in running the class, including operating the video equipment. The importance of using text materials that are functional and closely adapted to the course remains the same with videoconferencing system. Although our trainees can now see us, they are just as likely as students using audiographics to become restless if we do not keep them actively involved in class activities.

Web-Based Conferencing System

Web-based conferencing provides a powerful internet tool for creating a more interactive and less isolated experience for distance learners. We have incorporated a web-based conferencing system into CTEP to encourage interactions among students across training sites to help make them feel more a part of a class group. We are using an asynchronous web-based conferencing system, called Alta Vista Forum. All discussion on the conferencing system is directed toward existing course content and practicum projects: rather than using this opportunity to create extra work for learners, we use it to help improve their understanding and application of the work they do through collaborative learning. We created teams of 4-5 students across sites to encourage closer ties between our remote sites. We have also provided a "chat room" and "teachers' lounge" to give students open forums for socializing with one another and for discussing more personalized issues and concerns.

Support Technologies

Simple technologies such as fax machines and e-mail are among the most reliable and flexible tools we have for communicating with distance learners. Both of these technologies give us continuous access to our trainees and provide for rapid asynchronous communication between university instructors and learners.

Integrated Use of Technologies to Meet Program Aims

Fostering Ownership among Learners

A strong sense of ownership is a critical factor for learners in distance education settings. Learners who are not in close physical proximity to their instructors must often work more independently than learners in traditional settings (Kember 1995). In fact many distance educators attest that independence and a strong sense of ownership are essential predictors of success in distance education learners (Riddle 1994; Wagner & McCombs 1995). But distance education must also cater to the needs of students who may not have such a strong natural inclination to ownership and self-sufficiency. Instructors and instructional designers need to make a deliberate effort to promote and encourage ownership among students, especially for those who may be used to teacher-directed instruction where they make few choices for themselves.

To encourage ownership in CTEP, we emphasize new roles of instructors and learners in the beginning of the semester. We use trainees as student coordinators to oversee such instructional aspects of the class sessions as working out grouping arrangements for activities, assisting with the actual course instruction and duplicating and passing out papers. Further, we structure class sessions so learners act as on-site facilitators to lead discussions and present material from the text rather than having the campus-based instructors do these tasks. Since we have more than one remote sites in a live class, we have the on-site coordinators ask the other site to present ideas and examples instead of us directing the activity in order to promote greater communication across groups. A typical class period involves several small-group work and discussion activities, with instructors acting as consultants more than as presenters. We have found that adult learners bring a wealth of professional skill and experience with them to their classes. Distance education can capitalize on these experiences in a manner that facilitates the mechanics of course delivery, enriching the content and teaching interactions of the class sessions and more closely involving teachers in their professional development.

Promoting Situated Learning

A major criticism of many current pedagogies is that they are too abstract, removed as they are from real world experience (Brown, Collins, & Duguid, 1989). An important concern for educators is the degree to which classroom learning transfers to external situations in which the application of knowledge, skills, and attitudes is appropriate (Oliver & Reeves 1996). The field of teacher education has also shared this similar concern. Many teacher education programs have no effective way of ensuring that students learn to apply course concepts to their actual teaching situations (Cole 1992; Dessent, 1987). Students may enroll in a practicum or student teaching experience after their coursework is complete, and may work in another teacher's classroom rather than a setting of their own.

Distance education can be designed to offer students an opportunity to work on authentic tasks in a real-world setting in which students construct knowledge for themselves. This type of instruction is referred to as *situated learning* (Winn 1993), because the process of constructing new knowledge is situated in meaningful, relevant contexts. To promote situated learning in CTEP, we assign practicum projects that serve as a focus of the trainees' learning experiences. We structure the practica and academic coursework as a single unified instructional activity so teachers practice new methods as we cover them in the classes. They learn to integrate these approaches with their existing routines, combining their new skills with the skills they already have to form increasingly complex and unified teaching practices. At each stage of training, teachers learn how to fully integrate theoretical concepts into teaching practices that match their particular job situations.

We further ensure situated learning by visiting the remote sites so we can obtain firsthand information about the circumstances in which the trainees teach. Meeting with students in person at their work sites helps instructors better understand their practicum situation, which in turn, enables instructors to give detailed and situation-specific guidance and feedback to each trainee. By combining e-mail and fax transmissions with site visitations, we are able to bring a high level of supervision not just to their understanding of course concepts, but to their actual application of these concepts in real-life settings.

Encouraging Collaboration among Teachers and Facilitating School Change

Research in teacher education has shown the value of within-school professional team building and collaboration among teachers (Friend & Cook 1993; Koehler & Baxter 1997). Fullan (1991) argued that school improvement is most surely and thoroughly achieved when teachers engage in "frequent, continuous and increasingly concrete and precise talk about teaching practice" (p. 78) with other teachers. Today each special education teacher must operate as part of a team in many aspects of his or her role (Polloway & Patton 1997). However, traditional models of teacher preparation usually do not include strategies for promoting collaborative problem solving with other adults.

Because CTEP is field-based, we attract teachers who work in the same schools or in the same school district. We take advantage of our trainees' shared circumstances by incorporating collaborative team building techniques into the very structure of our coursework. In CTEP collaborative techniques serve both as means to encourage interaction among learners in a live class and as ends to help them collaborate with other adults at their job sites. As stated by Johnson and Johnson (1987) and Slavin (1990), when instructional delivery systems are structured to foster cooperative learning, learners benefit both instructionally and socially.

The technologies we use help us structure a variety of in-class and out-of-class activities in which teachers describe their teaching experiences, brainstorm solutions to real-life problem situations, and help one another apply and adapt the course concepts to their job circumstances. For example, as out-of-class activities we are using web-based conferencing to promote collaborative learning. While in-class groups are formed according to shared interests or circumstances within the same remote site, groups for web activities are formed across multiple sites so teachers can benefit from an even broader and more diverse range of perspectives. To structure these discussions, we require students to participate in three kinds of interaction: posting examples from their projects, discussing course content, and consulting with peer teams to generate a fuller range of ideas for their field-based projects. In each of these formats, the asynchronous environment gives trainees the opportunity to review other teachers' work, evaluate their comments and develop their own understanding of course concepts and procedures.

We have found that eliciting a quality discussion on the web requires careful preparation and being cautious about when to ask learners to post examples of their work. Instructors must decide whether to post models of assignments and ask trainees to give only appropriate examples, or to have all learners post work-in-progress and then attach instructors' comments so learners do not accidentally consult nonexamples. Instructors also need to make sure that discussion topics are content-based and that the outcomes of the activities are reasonably beneficial to all trainees; the topics should not be too abstract, general, or contrived. In addition, the way learners are supposed to reply to each other also must be clearly specified so trainees do not just post short "I-agree-with-you" type comments to fulfill the requirement. Furthermore, instructors should also be careful that learners do not go too much ahead of the course schedule and suggest ideas solely based on their own teaching habits, which might not be consistent with the goals of the course. Finally, like any other learning activity, instructors must monitor and evaluate web activities and provide feedback to the class, if not to each learner.

Conclusion

Rapidly developing technologies do not themselves create more interactive distance education learning environments. One challenge that has remained constant from the beginning of our program is adapting new technologies to match our instructional aims. Distance education has traditionally been more successful with students who exhibit a strong sense of ownership: students who are independent and highly motivated. In CTEP we have attempted to structure course and practicum activities to build this type of ownership in students with all types of learning characteristics. We have also encouraged a level of collaboration in which trainees can take advantage of the wealth of experiences each brings with them into the program. In CTEP collaborative techniques serve both as means to encourage interaction among learners in a live class and as ends to help them become more effective teachers at their job sites.

Abstract: While experts in educational multimedia generally welcome the Web in education, it is important to take into account the views of learners about the role of the Web in teaching and learning, as they are the primary participants in the Web-based educational experience. This paper discusses a Web-based study on learners' views of the Web. The discussion starts with an examination of the emergence of the Web in education and some key features, which represent a shift to a new educational paradigm. However, what Web specialists' value may not be necessarily accepted by learners. Therefore, it is important to examine learners' view in relation to the Web impact. The second part of the paper deals with a study using a Web-based research approach to investigate the attitudes of university students towards the role of the Web in teaching and learning.

Introduction

The emergence of the Web in education has generated a great deal of interest among theorists as well practitioners. For many Web enthusiasts, the Web has challenged the traditional strict curriculum control approach in which learning is at the mercy of teaching. The Web can be used to foster three significant aspects of learning: independent learning, creative learning, and flexible learning. While it is generally accepted that the Web is an important facility for teaching and learning in a modern world, its role in education can be questioned from different fronts. From the critical theory perspective, for instance, the Web-based teaching may easily commit the same ideological 'crime' as other conventional teaching methods: cultural insensitivity, misempowerment, mistreatment of learners as virtual beings.

It is important to take into account the views of learners about the role of the Web in teaching and learning, as they are the primary participants in the Web-based educational experience. This paper discusses a qualitative study, which investigated how learners valued the Web educationally. The paper will start with an examination of the emergence of the Web in education and some key features, which represent a shift of educational paradigm. The follow-up discussion will present a study using a Web-based research approach to investigate the attitudes of students towards the role of the Internet, mainly the Web, in teaching and learning.

The Emergence of Web-based Teaching

The Web has become a world phenomenon. It has permeated many aspects of the modern world, particularly in business and education. The 10th World Conference on Educational Multimedia and Hypermedia held in Freiburg, Germany in June 1998 attracted over 1000 participants from 46 countries, with a total of 485 papers and 130 posters. This is one of many Web-related seminars and conferences around the world in the same year. The cliché 'www dot' has appeared constantly in many TV ads and public announcements. The Web has created its own culture with its own language and its own people with their discourse community. In the educational context, the Web has provided a new platform, which stimulates a new spirit and practice of teaching and learning. In the context of multimedia, as Fisher (1994) points out, the real appeal is in more than the ability to merge video and computer technology in a single application, although that has provided the excitement that drives multimedia research and product development. The hypertext aspect of multimedia provides the underlying informational motive force that stands to revolutionise the presentation of information. Hyperlinks, automatic searches, and the ability to connect pieces of information in a network or web of knowledge offer new capabilities to information developers using multimedia, but the added complexity offers new challenges as well (Fisher 1994).

The Web with a New Educational Paradigm

Roberts (1997) describes a paradigm shift caused by the introduction of the Internet in education. He says:

> In the field of education, it is argued that we are undergoing a 'paradigm shift'; the rejection of one set of values and ideas about education and the adoption of a new set with regards to what constitute effective pedagogy. This paradigm shift is said to be occurring world-wide but faster in some parts than others depending on the availability of resources, existing infrastructure and the stage of development reached.
>
> (Roberts, 1997, p.380)

The emergence of the Web in education can be viewed in three phases. Broadly speaking, a teacher or learner who becomes a member of a Web discourse community tends to go through three stages, which can be described in terms of the relationship between the Web and learning: learning about the Web, learning the Web and learning via the Web.

- *Learning about the Web*: This is the initial stage of getting to know what the Web is all about. A decade ago, the World Wide Web was not in existence. A few years later, the Web metaphorically became a street directory for commuters on the superhighway embedded in a complex network of electronic interaction like a spider web.
- *Learning the Web:* The Web is not a terrifying land where novices are tortured. It can be used and enjoyed by computer experts as well as lay people. Web- oriented devices are produced constantly to ensure user-friendliness. Learning the Web can range from learning complex tasks with the use of Java technology to create powerful 'web-ware' to learning how to navigate on the superhighway simply by 'pointing and clicking'. In other words, the Web can be a great challenge for Web-based software developers as well as a relaxing tool for Internet travellers.
- *Learning via the Web:* This is the most crucial stage of Web orientation. The Web provides a special key to education: Teaching and learning can take place in a virtual reality. The traditional face-to-face teaching in a classroom is no longer the only way of teaching. Learners are no longer confined to their seats in front of a teacher. They do not have to wait for the time when a library is open to search for information.

The Web has become a challenge to traditional face-to-face teaching. Its emergence in educational theory and practice has been marked by the following Web phenomena: Web-based learner, virtual class, and courseware.

Web-based Learners

In the current context of teaching and learning, lecture in its tradition sense does not meet the demand of learners as lecture can only function in a very limited context. Lectures are traditionally the kernel of university education. This traditional form implies that everybody who wants to attend has to be in the lecture room at lecture time. If the target group for the lecture is distributed over a larger area, attending lecture can often be time-consuming or even impossible (Anderl & Vogel 1998). In a narrow traditional approach to teaching, students are normally treated as passive learners. Their minds are treated as empty vessels to be filled with knowledge. Teachers are knowledge transmitters and are therefore the primary resource for learning. Learners are taught how to learn. This notion of learning has been challenged on the grounds that learning is not to receive knowledge but to make sense of knowledge and to promote in a learner an independent mind, which can inform, reflect, and even challenge the conventional knowledge and wisdom. The Web is claimed to be one of the most powerful tools for providing teachers and learners with necessary conditions for independent and interactive learning. It provides an educational discourse in which learners can interact widely with other members of a learning community at the same time learners are in control of their own learning. Their interaction for learning can be immediate, prompt, widely shared and resource-supportive and this may not be possible in a traditional mode of teaching in which teachers and students are heavily constrained by the physical condition of a classroom.

Virtual Class

The concept 'virtual reality' has generated generic concepts such as virtual course, virtual university, virtual conference etc., which have become realities in current academic activities around the world. Since the world has become a global village in which villagers communicate quite conveniently via the Internet, education is no longer confined to a group of local students coming from a community in which a university or school is located. Universities have offered courses for students of diversified geographical and cultural backgrounds. These courses were originally offered in an off-campus mode in which students received course packages via mail such as course materials, textbooks and video tapes and they participated in telephone-based discussions. Aoki, Fasse and Stowe (1998) pointed out that virtual universities are identical to traditional universities in the traditional sense. The key difference is that virtual universities do not require students to commute to campus and to physically attend classes. The rapid development of multimedia and hypermedia has provided universities with information technology which has transformed the traditional off-campus teaching into virtual teaching in which interaction is not only much quicker but there is great improvement of the quantity and quality of course delivery.

Courseware

The concept 'courseware' designates the method of course delivery via the Internet. A virtual class needs courseware, which guides and facilitates students' learning. Aedo, Diaz and Montero (1998) argue that 'a flexible CAL system should provide teachers with mechanisms to adapt the courseware to their own methods as well as their students' needs'. A courseware may include traditional reading materials. However, the fundamental difference is that it liberates learners from the traditional linear mode of learning. Fisher (1994) pointed out that computers have given users a power not widely understood till now; the power to break the enforced linearity of information, if not of time. The computer's ability to search far more quickly than any human can do makes possible an almost seamless presentation of information that can come from sources that are not only diverse, but that are invisible - and ultimately of no concern - to the user. There is no need to organise vast quantities of information in a strictly linear manner. The problem now is learning to think in such a way that this power can be put to use (Fisher 1994). However, there is still a danger that the old transmission model of one-way instructional delivery will be repeated, ignoring the importance of students' interaction and leaving students autonomous and isolated. Teachers can use the Web to place their course materials for students' retrieval, but still the Web may be a primitive media for creating an interactive learning environment (Aoki et al. 1998).

Learners' Evaluative View of the Web

One of the big shifts in educational theory and practice is the focus on learning rather than teaching. This shift has been reflected by the recent emergence of innovative concepts such as learner-centred, independent learning, process-oriented, negotiated-curriculum etc. The great attention given to constructivism in educational multimedia in the past decade has reinforced the premise that learners are the key players, not passive receivers, in the educational process. Teaching methodology, learning environment and teaching resources are critically considered to ensure that the new paradigm is not just 'old wine in new bottle'. However, curriculum innovation cannot meaningfully take place unless learners are allowed to play a part in the innovation process. The obvious step to be taken is to seek the views of learners on teaching and learning as they are 'real experiencers', not virtual beings. Their feelings and thoughts on teaching and learning should be the basis for curriculum innovation. In the context of Web-based education, the logical step is to conduct a study to find out learners' perception of the Web and its role in education.

Web-based Discussion Board

A big advantage of the qualitative over quantitative approach is that learners were encouraged to express as much as possible and as freely as possible their views on the use of the Web in teaching and learning. To achieve this, a number of discussions were conducted using the Web as a free and convenient forum for learners to voice their own opinions. A Web-based discussion board was created with the following features to ensure confidentiality and effectiveness.

- Participants were not required to identify their names and email addresses.
- Pseudonyms were encouraged to use to promote interpersonal communication. For example, addressing the other participants personally as 'Jim', 'Puzzled', ' T&T' etc instead of 'the previous writer', 'the first person in the discussion'.
- Informal discussion was the nature of interaction. Participants were encouraged to write down what came into their heads. They did not have to be concerned about grammar and spelling.

Discussion Format and Data Gathering

The data gathering was conducted as a normal learning activity in a university context.. Undergraduate and postgraduate students were invited to participate via the Discussion Board. Invitations were informally extended to students through their teachers in lecture times, notices on notice boards, and in public places such as canteens and sport events. Education students were particularly targeted as they were familiar with Web-based teaching and they were introduced to a courseware on communication as a component of their course.

There were three discussion topics covering four different aspects relating to the theme ' the Web and its role in education'. Each topic started with a discussion statement, which aimed at stimulating responses from learners. The three discussion statements were:

Topic 1: The role of the Web in education

The Web has been introduced to teaching and learning. Some people are very excited at the prospect that the Web will not be just another added tool to education but also present a significant alternative to the traditional face-to-face teaching and learning; while others are either unenthusiastic or sceptical about its educational significance. What do you think? Please share your views on this issue?

Topic 2: Critical Educational Web

Critical theory stresses the importance of critical examination of the nature of the discourse or the context in which teaching and learning take place. Such critical examination may reveal problems in education such as ideological imposition, misempowerment, imperialism, cultural insensitivity etc. Some people argue that the Internet or the Web can cause such problems. What do you think? Please share.

Topic 3: Learners in courseware development

Web-based teaching in the form of courseware has been introduced to tertiary education. Courseware is often constructed jointly by subject specialists and Web specialists to teach an on-line course on the Web. Some people argue that learners should be involved in the development and evaluation of Web-based courseware while others argue that learners' involvement is not necessary or impractical and we should have good faith in experts. What do you think?

Data Analysis and Results

The use of the discussion board in this study was to identify the meanings and concepts underlying learners' attitudes toward the use of the Web in education. Therefore the data collected from the discussion board were analysed in terms of conceptual issues which could be grouped under three headings: positive aspects, negative aspects and suggestions.

Positive Aspects

- The Web as a resource
- Non-threatening condition
- Choice and independence
- Interactivity with people
- Planning for the Web

Negative Aspects

- No virtual learners
- Ideological bias loaded
- Imperialism/ commercialism
- Unnatural/false pretending

Suggestions

- Experts & learners' contribution to courseware
- Learner as partners

Discussion Based on the Conceptual Issues

One of the advantages of a qualitative approach is that the focus is uncovering the meanings (concern, inspiration, mind-puzzling etc) which could not be captured easily in a quantitative study. These meanings are not necessarily in the imagination of the researcher when the research is planned and carried out. The following conceptual issues reflect strongly the meanings underlying the attitudes of the respondents.

Positive Aspects

Learners viewed the Web as a powerful resource, an inspiring teacher and an innovative device, which gives learners motivation, responsibility and independence in learning. The Web provides a dynamic discourse, which could not be replaced by the traditional face-to-face teaching. Learners can travel virtually in a world of knowledge and interaction. This positive evaluation could be demonstrated in the following selected responses from different learners:

- *The Web is a friendly forum. It is real to me, not artificial at all, no way!*

- *I feel more relaxed to discuss via the Web. It's fun. You don't feel as if someone would laugh at you. You have more time for thinking properly.*

- *On the Internet, I have the choice of selecting which issues to discuss and whom to discuss with. This is very important to me. I could not easily do this in a face-to-face situation. If you don't think this is real interaction, what else then!!!!*

- *We can exchange our views on various issues and aspects of life. We can chat on many things, which are of interest to us. You don't have to 'talk' if you don't feel like it. We talk about travel, cooking, politics, literature, science....If you think this is not learning, what is it then?*

Negative aspects

Some learners were not quite enthusiastic or optimistic about the role of the Web in education while others accepted the contribution of the Web in education but also pointed out some potential problems. Attention was given to the area of 'imperialist Web' and its ideology-loaded mission. This reflected their concern about the whole discourse of education to which the Web is attached.

- In face-to-face discussion, we can interact, I mean 'real' interact together. I enjoyed real group discussion. On the Web, all the personal things are not there any more. Of course, I still can do it on the Web, if I have to...but still it is not real interaction, is it?

- Everything we do, think, act reflect our culture, our attitudes, and cultural and social backgrounds. How could we leave all these behind when we travel on the Internet. Thus, teaching and learning on the Web cannot be immuned from cultural and social interference. We may think that we are neutral. I don't think so.

- When students come from different countries, different cultures, there must be some misunderstanding, misinterpretation, and all these can create mistrust, confusion and perhaps conflict.

- The Internet is a product of a commercial world. It is commercially motivated. The main aim of commerce is to make money. It is interesting to see how education with the use of the Internet can be free from commercial influences and controls? We need to look beyond the surface level to see how imperialism, in a new form, enters other human cultures. I think the Internet reflects the ideology of its masters. Just look at hardware and software! Where do they come from?

Suggestions

Apart from many responses, which reflect some concern as well as admiration for the Web and its role in education, learners also offered some ideas and reservations, which should be taken into consideration by Web instructional designers and teachers. Issues raised in their responses include the importance of partnership in Web-based courseware development, learning-centred approach of Web-based teaching, and learners' feedback.

- Navigation is an important feature and device. Some navigation on the Web are so well thought out that users can expand their learning and curiosity while travelling on the Www due to excellent design. I have come across many Web sites, which are technically very complicated, but educationally they are hopeless

- I don't think that we should allow experts to control our destiny. We should take an active part in it.

-'Learners are partners'? As partners, they must be involved partially or wholly. Of course, not everyone wants to be involved. It must be on a voluntary basis. Forced feedback leads to superficial results.

- I do well in subjects when lecturers give me flexibility, take interest in what I think. My feedback is always sought and valued. With this approach, I can learn so much.

The Web and Face-to-face Teaching

The Web has won the hearts of many university students who are trained to be teachers. It is clear from their messages that they have made use of the Web in the course of their learning at the university. The word 'however' was constantly in their consciousness when they discussed about the role of the Web in teaching and learning. In other words, there was some reservation about the idea that the Web can take over face-to-face teaching as seen in the following two responses from students.

- The first response emphasises the significance of social interaction which the Web could not adequately provide.
  The availability of the Web as a classroom tool is exciting! It is not only a way for students to be able to access up-to-date information, but for teachers as well. The Web is loaded with teaching ideas and lesson plans on almost any topic you can think of and there are of course the 'wonderous' mailing lists we all learned about last year which provide the opportunity for contact with fellow professionals. However, while an undeniably useful tool, the Web for me is not really an 'absolute' alternative for traditional face-to-face teaching. Today's society demands that the mastering of all types of personal interaction be included as part of a school's curriculum. But with the way technology is heading, the scary thing is that tomorrow's society may not...?
- The second response emphasises the access problem facing students and teachers.
  I don't think the Internet will be used to replace teachers, but they will become more important, especially when trying to get up-to-date information. I also think that even though the web has a lot of things to offer teachers and students alike, it also requires a fair bit of time to access and find the relevant information you need. Some teachers don't have that time with all the other requirements they have and this might be another reason why they hesitate to use the Internet in their classrooms.

The following response raised the problems of Web control and Web abuse in the class.

Although the web is an exciting new introduction into classrooms, I also believe that in some cases many students use it for their own entertainment purpose. This is fine if not in school and class time. But some of the material that these kids are getting hold of is just not suitable. The teachers and parents of these children should make sure that they have suitable blocking benefits such as net nanny or similar programs so that these sites are not available to younger children.

Conclusion

The Web has been introduced to education and its role has been subject to critical discussion by educational multimedia experts as clearly indicated by various papers presented at this conference and other similar conferences in the world. It is important for us to share our exciting experiences brought to us by educational multimedia. We may expect that the superhighway will bring more educational innovations to the world. However, the most important thing for us to remember is that the journey on this educational superhighway should include learners as our travelling partners. As one of the learners in this study has inspired us with the following statement: 'Virtual teaching is a fascinating growing area and I think we should support it. Support does not mean to learners are like obedient sheep which know nothing and are at the mercy of their master. They should be consulted if learning takes place meaningfully.'

Abstract: The Web, today, is a firmly established (virtual) reality. A few years after its impressive break through, from limited professional circles to everybody's working and social life, the Web constitutes an additional space for people to communicate, work, trade or spend leisure time. And increasingly, too, a place to learn. We have currently reached a stage at which a mapping of Web-based learning environments (WBLE) is required to answer crucial questions at the content, teaching, learning and communication levels. To relate to these questions we developed a Taxonomy of WBLE's, implemented it for the study of about 500 educational Websites, and elaborated on practical implications of the study's results. The overall picture we have unveiled may sound deceptive, and can be summarized as "one step ahead for the technology, two steps back for the pedagogy". But a more thoughtful consideration of the results suggest directions for the further development of novel Web-based educational models.

The Web, today, is a firmly established (virtual) reality. A few years after its impressive break through, from limited professional circles to everybody's working and social life, the Web constitutes an additional space for people to communicate, work, trade or spend leisure time. And increasingly, too, a place to learn (Berenfeld, 1996).

Within the global network, already an unknown quantity of educational Websites of various kinds has been developed, and their number is daily growing. These Web-based learning environments (WBLE) reflect educators' attempts to wrap together Web technology features (e.g., information manipulation, communication, and creation tools) according to their educational and pedagogical beliefs in pursue of learning goals. The sites differ from each other for instance in terms of the identity of their originators (e.g., teachers, students, development centers, research centers) and their goals and motivations, in regard to subject matter, focus (e.g., communication, information retrieval), pedagogical approach, or learning activities. An obvious result of this variability is the uneven educational value and quality that characterizes the growing aggregate of educational sites.

Given the continuous increase in quantity and diversification in quality, and the high level of expectations in the educational community regarding the educational potential of the Web technology, we have reached a stage at which an appropriate mapping of the WBLE landscape is required. Key questions to be answered in the mapping process are:

- *What characterizes educational Websites at the content, teaching, learning and communication levels?* (Detailed mapping of relevant features)
- *What is the current overall picture of the educational Websites field regarding key teaching and learning issues, vis-a-vis the educators' expectations?* (Overall analysis and evaluation of trends and solutions)
- *What can be concluded from the current state of affairs as a basis for the further development and implementation of educational Websites?* (Practical implications and conclusions)

To answer these questions we developed a mapping or classification scheme, the Taxonomy of WBLE (Nachmias, Mioduser, Oren & Lahav, in press), implemented it for the study of about 500 educational Websites, and elaborated on practical implications of the study's results. In the following sections, we will briefly describe our classification scheme, we will present the study and its findings, and finally we will discuss key issues resulting from the observed picture and suggest directions for further development of WBLE.

Taxonomy of WBLE

For this study we developed a classification scheme or taxonomy of educational Websites aimed to reflect the developers' educational philosophies as well as their actual manifestations, by revealing how different functionalities are configured, the knowledge is structured and represented, and communication features are implemented. Our taxonomy characterizes an educational Website by about 100 variables regarding four main dimensions: basic descriptive information (e.g., site ID, updating, population); pedagogical and educational considerations (e.g., instructional model, interaction, cognitive processes); knowledge attributes (e.g., representational structure, navigation tools); and communication features (e.g., types of telelearning, communication means). For a more detailed presentation of the taxonomy's rationale, background and description refer to Nachmias, Mioduser, Oren & Lahav (in press).

Method

Five evaluators acted as research assistants. All five are students in the graduate program of Communication and Computers in Education in Tel-Aviv University School of Education, have scientific background, and are currently science educators. First, each evaluator was assigned to find about 100 educational Websites meeting all following three criteria: (a) It was deliberately developed for educational purposes; (b) Its topic is clearly defined (in this study the area of science, technology and mathematics teaching was selected); and (c) it is clearly identifiable as a unit as opposed to "mega-sites", links-repositories, or general-access-sites to conglomerates of projects or web pages. In this process 524 sites were initially selected, and at the end 436 Websites were included our final sample. Sample selection took place in March 1998.

Following this stage, each one of the five evaluators received about 90 Websites, randomly selected from our list, to be characterized according to the Taxonomy of WBLE. All the evaluation process was carried during April and May 1998. By June 15th 1998, the database of 436 Websites by all taxonomy variables was completed. In order to assess the validity of the database, a sample of about 25% of the Websites was analyzed once again by a different evaluator.

A detailed presentation of the results is beyond the scope of this paper (see Mioduser, Nachmias, Lahav, & Oren, 1988). In the following we present and discuss a selected sample of findings.

Results and Discussion

The transition of the Web technology from its early rudimental stages to the current "everyone-can-do-it" stage, generated high expectations among educators. These expectations relate to the Web's potential impact on educational processes in three main domains fostering (a) the raise of new pedagogical forms emerging out of unique features of the technology (a "Webagogy"?); (b) the development of improved information-organization, representation, and handling capabilities; and (c) the enhancement of communication processes among students and teachers and support for collaborative learning. Our aim in this study was to assess the extent to which educational Websites, these sites deliberately developed for educational purposes realize the potential and fulfill the expectations.

Pedagogical Characteristics of WBLE's

Current pedagogical approaches support learning processes that include the student active involvement in the construction of knowledge, her interaction with peers and experts, the adaptation of instruction to individual needs, and new ways to assess the students' state of knowledge and learning. Our expectation was that the development process of educational Websites would reflect these approaches. Moreover, given the innovative character of the technology, it could be expected that even new pedagogical forms based on the unique features of the technology would arise.

Notwithstanding, the results indicate that this is not the situation (see Table 1). Only 28.2% of the sites include inquiry-based activities, and more than three-quarters were highly structured placing the control over the learning process mainly on the computer side. Most sites elicit cognitive processes such as retrieving information (52.5%) or rote learning (42%), fewer focus on analysis and inference processes (32.6%) and even less on problem-solving and decision-making (5%). Only a few sites include student-modeling and adaptation mechanisms. In addition, and considering the fact that network technologies appear to be ideal milieu for the implementation of collaborative work, it is highly deceptive to find that only 2.8% of the sites support any form of collaborative learning. These results conclusively show that the pedagogical approaches favored by educators and researchers for the development of valuable learning environments are still far from being implemented in most educational Websites.

The gap is even more evident if we take in account the accomplishments reached within the digital-technology-in-education field in its previous form, namely (non-networked) instructional software. Regarding interaction types, we found that most sites include browsing (76.4%) or simple forms of interaction (42.4%), and few sites offer complex (3%) or even on-line (6.4%) activities. Few sites include any form of feedback, either automatic (16.3%) or human (5.5%). Most sites offer resources and means related to information handling (65%). Only few offer the student online tools (12.8%) or resources external to the site itself such as resources in other sites (31%) or experts (8.7%).

		Yes	No
Instructional configuration	Individualized instruction	407 (93.3%)	29 (6.7%)
	Classroom collaborative learning	54 (12.4%)	382 (87.6%)
	Web collaborative learning	12 (2.8%)	424 (97%)
Instructional model	Directed	330 (75.7%)	106 (24.3%)
	Inquiry-based	123 (28.2%)	313 (71.8%)
Instructional means	Information-base	283 (64.9%)	153 (35.1%)
	Tools	56 (12.8%)	380 (87.2%)
	Structured activity	211 (48.4%)	225 (51.6%)
	Open-ended activity	43 (9.9%)	393 (90.1%)
	Virtual environment	30 (6.9%)	406 (93.1%)
	Student modeling/adaptive mechanism	0 (0%)	427 (97.9%)
Interaction type	Browsing	333 (76.4%)	103 (23.6%)
	Multiple choice question	137 (31.4%)	299 (68.6%)
	Simple activity	185 (42.4%)	251 (57.6%)
	Complex activity	13 (3.0%)	423 (97.0%)
	On-line tool	28 (6.4%)	408 (93.6%)
	Expert consultation	58 (13.3%)	378 (86.7%)
Cognitive process	Information retrieval	229 (52.5%)	207 (47.5)
	Memorizing	183 (42.0%)	253 (58.0%)
	Information analysis and inferencing	142 (32.6%)	294 (67.4%)
	Problem solving and decision making	22 (5.0%)	414 (95.0%)
	Creation and invention	20 (4.6%)	416 (95.4%)
Locus of control	Student controlled	377 (86.5%)	59 (13.5%)
	Software environment controlled	77 (17.7%)	359 (82.3%)
	Mixed initiative	26 (6.0%)	410 (94.0%)
Feedback	Automatic	71 (16.3%)	365 (83.7%)
	Human asynchronous	17 (3.9%)	419 (96.1%)
	Human synchronous	7 (1.6%)	429 (98.4%)
Help functions	Technical help	91 (20.9%)	345 (79.1%)
	Contextualized content-help	152 (34.9%)	284 (65.1%)
	Didactic help	73 (16.7%)	363 (83.3%)
Learning resources	Within Website resources	363 (83.3%)	73 (16.7%)
	Linked WWW resources	135 (31.0%)	301 (69.0%)
	Additional external resources	93 (21.3%)	343 (78.7%)
	External resources only	4 (0.9%)	432 (99.1%)
	Real time data collection	6 (1.4%)	430 (98.6%)
	Ask an expert	38 (8.7%)	398 (91.3%)
	Ask a peer	17 (3.9%)	419 (96.1%)
Evaluation	Standardized tests	29 (6.7%)	407 (93.3%)
	Alternative evaluation	7 (1.6%)	429 (98.4%)

Table 1: Websites analysis for the pedagogical dimension

Pre-Web (digital) educational materials present fascinating examples of the multiple ways educators succeeded in harnessing the new technologies to educational needs and goals (e.g., constructivist environments, intelligent tutoring systems, sophisticated multimedia learning environments). Against this rich background, and looking at pedagogical qualities and resources, the vast majority of educational sites prove to be the unripe fruits of the promising but still immature Web technology.

Information Representation and Handling

In cultural terms, in our digital times the visual-world (e.g., still images, icons, video-clips, animated graphics. movies) has reentered the scene in stronger presence and linguistic status and meaning than in its pre-Gutenberg incarnation. High-level and sophisticated integrated-media is perhaps one of the defining characteristics of state-of-the-art Websites today. But again our results showed that educational Websites march behind (it should be noted that we are not looking after educators' technical –and even pyrotechnical- use of imaging technology, but after their use of visual languages). The vast majority of sites are still heavily based on text (93% of the sites include more than one text field in all its pages). About 58% of the sites include at least one image per page; most sites do not include interactive images (96.1%), animated images (81.9%), or sound (see Table 2).

	Not at all	At list one in the site	50% of pages in the site	One per page	More than one
Text	2 (0.5%)	0 (0%)	3 (0.7%)	24 (5.5%)	407 (93.3%)
Image	63 (14.4%)	64 (14.7%)	55 (12.6%)	117 (26.8%)	137 (31.4%)
Interactive image	419 (96.1%)	9 (2.1%)	1 (0.2%)	1 (0.2%)	5 (1.1%)
Animation	357 (81.9%)	35 (8.0%)	18 (4.1%)	18 (4.1%)	8 (1.8%)
Sound	426 (97.7%)	6 (1.4%)	1 (0.2%)	2 (0.5%)	1 (0.2%)
Real-time updating	431 (98.9%)	0 (0%)	3 (0.7%)	1 (0.2%)	1 (0.2%)

Table 2: Representational means in educational Websites

Regarding structure and organization of knowledge, the Web is the realization of the hypertext (or hypermedia) model. Non-linear structure, complex linkage within and between information units, and appropriate navigation and search tools are defining features of this model. Our results reveal only a shallow presence of these features in the evaluated Websites (Table 3). Only about half of the sites included within-the-site linkage to a reasonable extent (more than one link per page), and about 11% of the sites refer to other sites (external linkage) at the same extent.

	Not at all	At list one in the site	50% of pages in the site	One per page	More than one
Within the site	116 (26.6%)	32 (7.3%)	20 (4.6%)	50 (11.5%)	218 (50.0%)
Links to external sites	253 (58.0%)	68 (15.6%)	37 (8.5%)	32 (7.3%)	46 (10.6%)

LINKS TO:	**Yes (N of sites %)**	**No (N of sites %)**
external databases	74 (17.0%)	362 (83.0%)
external tools	12 (2.8%)	424 (97.2%)
external activities	42 (9.6%)	394 (90.4%)
virtual reality devices	8 (1.8%)	428 (98.2%)
human communication	25 (5.7%)	411 (94.3%)

Table 3: Link structure in educational Websites

Communications

The results of this study show that limited communication resources were used in most Websites (Table 4). The most (and almost sole) resource present in the sites is electronic mail (about 65% of the sites). Other tools such as discussion groups, chat, or any form of distant work (e.g., tele-manipulation, tele-creation) were found only in a few sites. Moreover, features aimed to support working groups or learning communities were not found in any of the evaluated sites. The gap between expectations and actual implementation in the communications domain is even more evident than in the previously discussed domains. The main reason for that is that the technological resources do exist and are being successfully implemented in other areas of people's life (e.g., work, professional training, banking, shopping). In addition, transactions among humans and between humans and information resources are quintessential to education, and it is not hard to conceive endless forms of support that communication technology could offer for these processes. As for today's reality, this support is not yet a function in most educational Websites.

	Yes (N of sites, %)	No (N of sites, %)
Synchronic activities	17 (3.9%)	419 (96.1%)
Communication means		
e-mail	283 (64.9%)	153 (35.1%)
Discussion group without mediator	15 (3.4%)	421 (96.6%)
Discussion group with mediator	10 (2.3%)	426 (97.7%)
Chat	8 (1.8%)	428 (98.2%)
Moo/mud	0 (0%)	436 (100.0%)
Video conference	0 (0%)	436 (100.0%)
Tele-manipulation	1 (0.2%)	435 (99.8%)
Tele-creation	7 (1.6%)	429 (98.4%)

Table 4: Use of communication resources in Websites

Conclusions

One step ahead for the technology, two steps back for the pedagogy. One can depict that way the usual loops affecting the educators' assimilation process of new technologies for the last decades. As experienced educators we hold substantial models regarding the varied facets of our practice (e.g., how to build a lesson plan, to assess a learner's performance or behavior, to develop a learning unit). These models are usually tied to the (technological) resources at hand, and they affect each other mutually. It seems reasonable to assume that when facing the assimilation of a new technology we use these models as input to the process. The result is usually a transition period at which we replicate the known models by means of the new technology. While first assimilating the computer technology developers replicated the programmed instruction paradigm by means of the new technology, initially in the form of electronic worksheets and booklets then evolving in time into sophisticated drill and practice and structured tutoring software (Venezky & Osin, 1991). Our claim is that this study reveals a similar transitional phenomenon regarding the vast majority of educational Websites. Most sites' main component is the information-base, built upon the hypermedia-CD model (even a feature with can be claimed as unique to the Web, as the linkage to external sites, is today included in many hybrid CD-Web products). As for interactivity features based on the implementation of new technological resources (e.g., forms, Java applets, Shockwave), most online activities resemble the automatic-feedback (behaviorist-like) transactions of classic CAI (e.g., multiple-choice, select-correct-part, assemble-correct-configuration).

In light of these results one can adopt the skeptics' perspective and argue that Web technology has little to offer to education. But one can also adopt a more thoughtful perspective, reflecting on the character of this transition stage and generating new possible models and trends based on substantial educational needs.

The authors are part of the community of educators dealing with the problematic involved in the assimilation of Web technology to education (Mioduser & Oren, 1998; Nachmias, Mioduser, Oren & Lahav, in press). Although in this study we have referred to the educational Websites population in quantitative terms, we are aware that a number of fascinating examples of high pedagogical-quality sites do exist in the Web. But our main purpose in this study, rather to focus on the exceptions, was to map and learn what most existing sites and current trends as they are delivered to cyberspace have to offer to educators and learners. Based on this and similar studies, the next steps should focus on the research and development of novel Web-based educational models (Windschite, 1998) and on the implementation of a revised configuration of the technology-assimilation evolutionary loop: two steps ahead for the pedagogy/technology, one step back for reflection and mindful planning of subsequent steps.

Virtual University: Real Challenges

Professor Stephen Brown
Head of Learning Technologies
De Montfort University,
The Gateway
Leicester LE1 9BH
UK
sbrown@dmu.ac.uk

Abstract: Many Higher Education institutions are responding to external pressures by developing an on-line presence. Coincidentally changes in pedagogy are demanding the kinds of functionality offered by on-line learning delivery and support systems. Creation of a virtual university is not a simple transformation from old methods into new media and for traditional universities there is a high degree of risk in developing an off campus, on-line operation. De Montfort University's Electronic Campus is a hybrid approach which aims to re-purpose and integrate existing teaching with new on-line methods as far as possible in order to achieve maximum flexibility of access for existing on-campus students. Given limitations on resource availability, existing resources need to be re-engineered to bring them into line with the chosen venture. This entails obtaining the support of staff at all levels through a conscious programme of culture change, which is described here.

All Change

There is a growing belief that learning is a key to economic success and competitiveness, whether at the level of a company, an individual, or the state. Knowledge is rapidly outdated in a fast changing world, employees need to enhance their attractiveness through periodic self development and employers need to update he skills of their workforce in order to remain competitive (BCC 1998) (IoM 1998). Notwithstanding local labour shortages in the United Kingdom, there is a developing surplus of people combined with a declining number of jobs overall (DfEE 1998a).

The appearance of corporate universities such as Unipart 'U' (http://www.unipart.co.uk/97report/ugc97.htm) and the British Aerospace Virtual University (http://www.bae.co.uk) are manifestations of these concerns and of a growing sense that industry needs are not being adequately met by traditional education and training providers. Recent UK initiatives such as the proposed University for Industry (DfEE 1998b) and Lifelong Learning reflect similar concerns at Government level.

At the same time change is being driven from within as traditional models for mass higher education based on behavioural theories give way to more learner centred and resource based philosophies (Hardy 1997). Learner centred approaches seek to accommodate individual learner needs and acknowledge that learners may have other calls on their time. This leads to more flexible delivery and support strategies which allow learners to shift the time, place and pace of learning. Rigid classroom timetables and enrolment schedules become more relaxed, allowing for multiple delivery of the same curricula at different places at different times. The role of the teacher shifts away from that of expert instructor to learning facilitator. Involvement of the learner in the development of the learning experience necessarily requires the 'teacher expert' to relinquish control and allow others (learners) to contribute (Laurillard 1993). The rapid development of digital, networked multimedia technology such as the Internet, email and computer based and video conferencing assist with this process and at the same time open up opportunities for learners to seek out and utilise learning resources offered by other parties (Bacsich 1998).

Competition, Globalisation and Commoditisation

In the UK, per capita spending on Higher Education students declined by 20 per cent between 1991/2 and 1996/7 (THES 1998), stimulating greater competition between universities for resources. Competition is not just local. UK Higher Education providers are facing increased competition in traditional overseas markets as well, where countries such as the USA and Australia are vigorously recruiting students whom might have otherwise studied in the UK. Many overseas governments are seeking to expand and enhance their local provision instead of sending such large proportions of undergraduates to study abroad, e.g. India, Singapore, Hong Kong, Indonesia, South Africa. From the UK perspective the recent appearance of 'virtual', 'on line' universities such as Western Governors' University (www.wgu.edu) and Colorado University's CU Online (www.cuonline.edu), with their potential to deliver globally, are cause for concern. Commercial on-line organisations such as Phoenix University (www.uophx.edu), or ZD University (www.zdu.com) are further indications of the possible shape of things to come.

Re-inventing the University

All of the above factors are driving Universities to reconsider their roles and methods. What is clear is that new ways have to be found of carrying out at least some of the functions of traditional universities and that overall new ways of doing things will have to cost less than traditional methods. In the absence of significant sums of new money to effect change, the task facing universities today is how best to re-engineer the resources already at their disposal to deliver and support the changes needed.

Many traditional Higher Education institutions are seeking to create some kind of on-line presence. Forbes magazine in the US has published a guide to the 'top 20 Cyber-Us', compiled by Ebeling and Bistayi (1997). Philips and Yager (1998) have published a guide to virtual university study opportunities which profiles 195 accredited universities offering over 1000 distance learning courses. On the face of it, becoming a virtual university appears to be straightforward. Bacsich (1998) has observed that the following methodology is generally accepted:

- Lecturing maps to videoconferencing
- Tutoring maps to computer conferencing
- Books map to CD-ROM and the Internet

However, when one takes a closer look at the reality of virtual university provision to date it is interesting to note how much of it depends on older technologies including books, video, and residential periods on campus as well as videoconferencing (Ebeling and Bistayi (1997), Philips and Yager (1998). There appear to be a number of good reasons why established, traditional Higher Education providers should hold back from large-scale conversion to on-line delivery. These include: the high costs of courseware development; the longer development timescale and relative inflexibility of resource based learning compared with face to face classes; shortages of appropriate ICT infrastructure; staff concerns about the impact of new technologies on their own jobs and on the quality of the student learning experience; and management concerns about the possible consequences of failure if large scale investments do not deliver the required competitive advantage. Also, traditional universities have strengths that are, by definition, missing from cyberspace: physical locations that provide a respite from the everyday demands of home and work; facilities and equipment that are not readily simulated in virtual space; people with whom to socialise, enjoy physical contact, chance encounters, etc.

In seeking to retain the benefits of a traditional university, minimise the risks of a virtual enterprise, while obtaining some of the advantages of on-line delivery, De Montfort University has opted for a hybrid model. The Electronic Campus is an Internet based addition to the face to face delivery and support systems of the university that is intended to enhance flexibility of access to learning *on campus*. In an era of lifelong learning, increasing numbers of individuals are likely to need to access educational opportunities for irregular periods, fitting in with domestic and employment commitments. Even traditional full-time students increasingly have to fit their studies around paid work in order to finance their education. Fixed attendance at lectures, limited opening hours for buildings, communication via notice boards, face to face meetings, seminars and tutorials all create barriers to flexibility of access. Restricting the Electronic Campus to on-campus students may appear at first to be paradoxical. However the rationale for this decision follows logically from the earlier discussion regarding the risks of going virtual. On campus access ensures that the benefits of a traditional style university are retained, with the addition of some of the benefits of on-line access.

The University has a threefold strategy for achieving this goal, involving a combination of in-house development, importation of resources developed elsewhere and collaborative development ventures with other organisations. While the University has aspirations to produce as much of its own material as possible, it is recognised that on our own we are unlikely to be able to achieve a significant shift in favour of telematic methods within a reasonable timescale. More rapid transition can be achieved by leveraging the resources of other organisations, either by importing their materials or through collective, collaborative effort to jointly produce new materials. However, in order to establish a basis for collaboration, potential partners have to have something to share. So in the first instance the emphasis has been on the first two strands of the strategy: in house development and importing.

Progress to date

In the first 22 months over 30 different Electronic Campus development projects have been established, ranging across all Faculties and at all levels including further education, undergraduate, postgraduate and continuing professional development. Some of the projects are complete courses, some are full modules and others are parts of modules. Students started to study the first of these modules during the first semester of 1998 and at the time of writing the total number of students studying on-line is over 1500. In most cases projects have been based on resources already developed in the university and in areas most likely to have maximum impact on students and staff. The learning activities modelled include lectures, seminars, tutorials, practical assignments and cognitive assessments. Materials produced include pdf documents, straight HTML pages, web interfaced databases, including image databanks, and on-line assessment exercises, plus on-line computer conferencing, videoconferencing, FAQs, e-mail and synchronous 'chat'. Projects underway will generate video and audio files as well.

In addition to these in-house projects, the University has been actively embedding into the curriculum learning resources which have been developed at other institutions under the auspices of the UK Teaching and Learning Technology Programme (Scott et al 1998).

In setting up the Electronic Campus initiative, care has been taken to address key issues identified as crucial to success in earlier studies (Brown 1997), in particular:

- Future proofing
- Staff attitudes
- Champions
- Learning support

Future proofing

Standards offer the potential of savings through reduced staff development costs and bulk purchase discounts. They can also reduce the learning curve for inexperienced development teams. Off-set against this is the risk of committing too early to inappropriate tools. The common core of all the Electronic Campus projects is HTML compliant content, enabling material to be accessed from a variety of different platforms via the Internet. HTML was adopted as the standard delivery environment in order to future proof the investment as far as possible. Variations such as Java, XML, DHTML, etc. have been avoided for the time being to ensure that material does not acquire obsolescent legacy status as technologies change in the medium term future.

Staff attitudes

Awareness of the Electronic Campus has been raised through separate meetings with all Deans of Faculties, presentations to senior staff down to the level of Heads of Departments, development of an Electronic Campus web site, publication of articles in the university in-house newsletter (13 so far) and through direct liaison with Faculty members via dedicated central staff with appropriate skills and experience (the Learning Development Managers described below). The Web site (http://dld.mk.dmu.ac.uk/ec/frame/frameset.htm) provides access to news about Electronic Campus developments, virtual university developments elsewhere, relevant professional associations, funding opportunities, tools and learning resources, staff development opportunities and to newsgroups concerned with on-line educational developments.

Within a university context the opportunities for direct financial reward are much more constrained than in industry, however it has been possible to put in place a number of incentives. Pump priming funds have been made available centrally for Faculties to bid against. This money can be used to buy equipment, software, travel, learning resources, staff development and staff time. In practice 78% of the project money allocated to Faculties has been used to buy out staff time to release staff from other duties, particularly teaching. In addition, the University *performance related pay* scheme and the University *promotion* system have been examined to identify ways of explicitly encouraging and supporting the development of teaching excellence. New categories of teacher status have been introduced in anticipation of the accreditation system to be introduced by the Higher Education Funding Council for England Institute for Learning and Teaching.

Care has been taken to ensure that involvement in Electronic Campus activities is as easy as possible. A proforma set of questions guides Faculty staff through the selection criteria applied to proposals for funding. Each Faculty has been allocated a specific, individual, Learning Development Manager, to work with them to:

- Develop appropriate teaching, learning and assessment strategies.
- Develop teaching and learning proposals for internal and external funding.
- Identify and obtain resource based learning materials produced elsewhere.
- Develop and implement learning support strategies and systems.
- Identify and meet staff development needs in relation to implementation of the Electronic Campus.

Learning Development Managers (LDMs) are members of a central curriculum design and production team with educational technology and curriculum development and delivery expertise.

As far as possible, on-line materials have been developed by Faculty staff themselves using simple, readily available tools such as Microsoft Office and Adobe Acrobat. Microsoft Office products were selected as general development tools for their familiarity, ubiquity and simplicity of use, compared with professional authoring tools and programming languages. Given the aim of ensuring that as much of the development as possible could be undertaken by Faculty teaching staff, it was important to avoid creating barriers such as the requirement to learn specialised software packages. Adobe Acrobat was adopted as a means of readily converting large quantities of existing text based documents to HTML readable form. Where more sophisticated products have been required, the LDMs have liased between faculty colleagues and central support teams to provide services using more advanced, professional tools. LDMs provide ongoing assistance with learning materials design and production and a link back to the central production resources (graphic design, courseware authoring, programming, desk top publishing, audio, video and photography, digitising, print, etc.).

Staff development has been identified as another important *enabler*. Electronic Campus staff development is a combination of formal training events and informal problem based learning. For example a programme of formal IT staff training courses has been restructured to provide basic technical authoring skills using Microsoft Office products and more advanced Internet training including HTML authoring, web site development, Internet communications and information search techniques. Project teams are also offered short courses on the use of specific software applications used within the Electronic Campus. Informal development takes place through interaction with the LDM, beginning with the project proposal proforma which encourages teaching staff to consider learning objectives, pre-requisites, relationship with other courses, assessment strategies, teaching methods, learner characteristics and requirements.

Champions

A vital ingredient of change seems to be the presence of enthusiasts in key positions within the organisation with the authority, charisma and skills to both push and facilitate the change process (Brown 1997). The Electronic Campus initiative is led by a Pro Vice Chancellor, supported by a Steering Group, made up of key university senior staff including the Director of Learning Development. Reporting to this group is an Operational Group of managers from key operational areas (Library, Information Services, Educational Technology, Learning and Teaching, Digital Library), charged with identification of implementation issues and solutions in response to steering group policies and strategies. A link between the Operational Group and the Faculties is provided by the LDMs and their Faculty counterparts: Teaching and Learning Co-ordinators. Successful project bids result in the formation of Project Teams within faculties, supported by the Faculty LDM. There is therefore an unbroken chain of champions from the Vice Chancellor down through the organisation to the grass roots of course design and delivery.

Learning support

The quality and availability of support for learners appears to be a vital ingredient for successful independent learning (Laurillard 1993). For this reason emphasis has been given to the development of on-line student support systems using email, computer and videoconferencing. First Class conferencing software is the standard for computer mediated communications within the Electronic Campus. It has been in use within the University for four years, supporting teaching and learning on a number of courses. The University now operates six professional level videoconferencing suites across its main campuses and after some experimentation with different systems has standardised on Picturetel equipment. In addition Microsoft Netmeeting is being trialled on a number of Electronic Campus modules to evaluate its potential for remote class rooms utilising its desk top video and audio conferencing features, combined with application sharing. Web CT is being trialled on two projects to evaluate its effectiveness as a fully integrated on-line course development, delivery and support environment, including conferencing.

What works

While it is too early to make definitive judgements about the effectiveness of the Electronic Campus, it is possible at this stage to comment on the planning implementation process in term of what has worked:

1. Pump priming the innovation to make it easy for Faculty staff to get involved and for resource managers to sanction their involvement. Also to make available additional central resources beneficial to the innovation, e.g. Software site licences for software packages adopted as standards.

2. Maintaining central control over project budgets has enabled close monitoring of expenditure against agreed schedules and deliverables.

3. Faculty based projects and development teams ensures local relevance and ownership and hence commitment and enthusiasm.

4. Establishing identified individuals to work with specific Faculties in an account management type role has developed stronger links between the central support services and Faculties and encouraged a culture of innovation and creativity.

5. Focussing on HTML as the primary medium for delivery and support has helped to simplify the decision making and development process. The choice of medium sets priorities for infrastructure investment, software tools and staff development and defines useful parameters for functionality.

6. Concentrating on unsophisticated, readily available, development tools, such as Microsoft products, ensures that all staff have easy access to them and where necessary, training courses can be made available easily and cheaply.

7. Adoption of a formal process of bidding for identified resource has made the activities of the central teams more visible, accountable and legitimised them to a degree not previously possible.

Conclusions

Re-inventing the university as a hybrid face-to-face/on-line institution is more than just a technical challenge. It requires a culture change which needs to be led from the top, through an unbroken chain of champions down through the organisation, including the resource managers at middle management level. Key factors to pay attention to are staff attitudes, future proofing and student learning support. It also needs to be able to draw on and re-purpose resources already available within the organisation. Because of the large, distributed, nature of De Montfort University it has long had a need to research and exploit the benefits of networking and resource based learning. In the past, small scale, bottom up, experiments in videoconferencing, Computer Mediated Communications, computer marked assignments, video, print, CD ROM and Internet delivered course materials have tended to have only a minor, temporary impact on the organisation because of their inability to succeed in re-engineering sufficient resources to achieve lasting institution-wide change. Other parts of the organisation have tended to resist changes not central to their own goals. At the time of writing (October 1998), the Electronic campus initiative appears to be successful so far in converting these unrelated initiatives into a coherent, management led, university wide programme. During the next twelve months the challenge will be to embed the Electronic Campus activity further into the normal processes of the university.

Abstract: A project is described in which a virtual environment is combined with an intelligent tutoring system for troubleshooting. The virtual environment enables the student to perform troubleshooting activities in a realistic job-situation. The intelligent tutoring system takes care of the learning process, and offers structured guidance and feedback throughout the troubleshooting process. In doing so, a system has been realized that helps to bridge the gap between vocational training which is theoretical and general in nature and the knowledge and skills required in actual job situations. It also helps in raising the attractiveness of training.

1. Introduction

There exists a widely known gap between the contents of vocational training and the knowledge and skills needed in actual job situations. This gap shows itself in a number of ways. The knowledge acquired during vocational training is often rather general and theoretical in nature, leaving the transfer to the real-world practice to practice periods. Students often complain about the fact that they see only a minor relationship between what is trained in schools and what is needed in the actual job context. Employers, on the other hand, have a problem in hiring rightly trained personnell, and have to put in a lot of effort in preparing new employees for their jobs. Another problem, especially with respect to vocational training for the technical subjects, is the mismatch between the number of students in training, and the number of technicians needed in the job market. There is much more demand for technicians than the schools can actually deliver.

Why is it that an insufficient number of students, men and women, choose for technical vocational training, while on the other hand there are plenty of possibilities on the job market afterwards? What can be done in terms of training to raise interest in the technical subjects and to increase the attractiveness of education? One of the answers to this question may be found in establishing a strong relationship between what is trained in schools and what is needed in actual job contexts. Multi-media programs in which a strong link is provided between realistic job situations and the knowledge and skill to be acquired in training environments, could be a strong means to bridge this gap, and thus to enhance the attractiveness of training. The program Attractive Vocational Training , partly sponsored by the dutch government, aims at exactly reaching this goal: establishing a stronger link between training and job contexts, thereby making training more attractive, and thus providing a strong motivator for upcoming students to choose for vocational training.

The Troubleshooter project, partly sponsored by the above mentioned program Attractive Vocational Training, is an example of a multi-media virtual environment, to be used in vocational training, that is able to train students a complex cognitive skill, troubleshooting, in a realistic situation. It combines a virtual job environment with an intelligent tutoring system, that guides the student through the various parts of the problem solving process, and depending on the progress made in learning acts more as a formal coach or as an advisor. The multi-media virtual environment , enables the student to move around freely in a particular simulated building, and act as a realistic troubleshooter in a realistic environment doing realistic jobs, including having conversations with other (simulated) people in this environment, using appropriate documentation, telecommunication facilities, tools etc. This has resulted in an attractive training program in which a realistic job-environment is provided while on the other hand strongly promoting a structured acquisition of troubleshooting skills.

This article will describe the background of the Troubleshooter in some detail. In paragraph two, the method for training of troubleshooting is described. Paragraph three describes features of the virtual environment, while paragraph four will go into some detail about the interactions between the intelligent tutoring system and the virtual environment. Finally, in paragraph five some conclusions are drawn.

2. Training of Troubleshooting: A Structured Approach

Structured Troubleshooting: The Method

The TNO Human Factors Research Institute, on behalf of the Royal Netherlands Navy, has carried out a study into the possibilities of improving the troubleshooting performance of technicians by means of innovating the training practices. The project started with a cognitive task analysis of troubleshooting on board of naval frigates. As part of this analysis we investigated how well technicians were able to solve problems that they were confronted with, coupled with an investigating into the problems at a cognitive level that they have in terms of troubleshooting performance. This analysis showed problems on at least two levels: 1. Beginning technicians lack a systematic approach to troubleshooting, resulting in a lack of goal-directed troubleshooting, and 2. They lack a functional understanding of the installations that they have to maintain (Schraagen & Schaafstal, 1996). These conclusions are remarkably similar to results of Schaafstal (1993), obtained in a rather different domain: troubleshooting in a papermaking installation. These findings have resulted in a number of recommendations for the training of troubleshooting of which the most important ones are:

The training of a structured approach to troubleshooting should be embedded in regular training courses, in such a way that this structured approach becomes a "second nature" of technicians, and is fully integrated in training courses on maintenance of particular installations. For reasons of transfer, it should not be the case that there is a separate course on structured troubleshooting, apart from the 'regular' maintenance courses.

What is meant by this structured approach ? Cognitive task analyses of expert troubleshooters in various domains reveal highly similar strategies in troubleshooting across domains. This strategy consists of four steps: 1. Formulate problem description. 2. Generate causes. 3. Test. 4. Repair and Evaluate.

Ad 1. Formulate problem description

The process of troubleshooting is started when the technician observes abnormal system behaviour or receives a notification of abnormal system behaviour. Besides recognising abnormal behaviour, the technician also needs to identify correct phenomena. This is an important task because determining correct phenomena can limit the number of possible causes. By determining what phenomena are still normal, the technician eliminates certain parts that do not need to be investigated further.

Ad 2. Generate causes

Generating possible causes is a task that can hardly be subdivided further. A distinction can be made between familiar and unfamiliar problems. In case of familiar problems, causes are generated mainly by a process of recognition. A particular combination of normal and abnormal phenomena functions as a cue for the retrieval of a particular cause from memory. For instance, the technician notes that the TeleTypeWriter does not print 'application'. Based on his experience, he knows that this symptom is most often caused by a faulty DCL TTW. A technician who encounters this phenomenon for the first time needs to use reasoning skills and schemata in order to find out whether the phenomenon is caused by the DCL TTW or the TTW itself.

Ad 3. Test

When possible causes have been generated, they need to be tested. The technician needs to choose the right testing method and the right testing equipment. By 'testing equipment' we mean all tools and equipment that can provide clarity to a technician concerning the status of the system. The next task is performing the test. This amounts to the correct setting up and operating of testing means and the correct reading of the outcome of the test. After this, the outcome of the test needs to be interpreted. This implies that the technician needs to formulate an expectation before performing the test and subsequently relates the outcome of the test to this expectation. If a technician expects, on the basis of the proper functioning of the system, a low level (0V) and he measures and observes a high level (5V), then the cause that was tested needs to be accepted, provided all boundary conditions for the proper execution of the test have been fulfilled. If, however, on the basis of the outcome of a test, a possible cause is rejected, the next possible cause needs to be tested. When all possible causes have been rejected, the technician needs to back up to the task of generating causes, since he has probably overlooked something. When the correct cause has been identified, it needs to be evaluated.

Ad 4. Evaluate
If a technician thinks he has identified the correct cause, this cause needs to be eliminated. The goal of troubleshooting is to return the system to its normal state of working, which asks for a thorough check for system functioning.

The knowledge of installations should be taught at a functional level, not at a component level.

A structured approach to troubleshooting should not be trained out of the context of a particular system, but, to enhance transfer, should always be tuned towards a particular system. What are the normal characteristics of a particular system, e.g. an overheadprojector.

The method is supported by the use of a fault isolation form, that is filled in during troubleshooting sessions. This forms keeps the students on track, prevents them from forgetting important results gained sofar, and is therefore an important aid in preventing working memory overload.
The results of this method, more thoroughly described elsewhere (Schaafstal and Schraagen, 1998) show an enormous improvement in performance. Subjects trained in the new method solve twice as many problems as before, and take less time for troubleshooting. Apart from this, there is a significant improvement in the quality of reasoning and the quality of system knowledge

The Pedagogical Approach in The Troubleshooter

The method described above functions as the main guide for troubleshooting in the troubleshooting system. The implemented fault isolation form, which has to be filled in while troubleshooting, is an important tool in determining the progress a student makes in troubleshooting, and explicating the underlying level of knowledge and skill, including bugs and misconceptions. The evaluation strategy follows from an overlay model, in which an ideal and expert solution is compared to the students solution. This does not imply that only one solution is allowed at any point: in fact, if there are more good moves possible at a particular point in the troubleshooting process, they are all allowed.
Students can choose between a strongly guided method or a free method of solving problems. In the guided manner, the student is very strictly evaluated in his use of the fault isolation form and is given appropriate feedback after finishing each stage of the problem solving process. If he makes really bad mistakes, he receives feedback right away. At the end of a case, an overall feedback is given to evaluate the students performance in troubleshooting.

The troubleshooter contains over fifty problems with various variations, and with a varying level of difficulty. A preset selection can be made for particular types of problems (e.g. only problems with the overheadprojector), and for problems with a certain level of difficulty. This ensures that the chances of students getting bored, because they encounter the same problems repeatedly, are low.

Since the training of troubleshooting is embedded in a realistic environment, not only troubleshooting in a strict, technical sense can be trained, but attention can also be given to training and emphasizing the right attitude of student-troubleshooters towards end-users and training them in communicating (e.g. asking the right questions when setting up a problem description).

3. The Virtual Environment in The Troubleshooter

The virtual environment in The Troubleshooter was modelled after a real building, housing an educational institute. It consists of an enormous amount of photographs, which, taken together, make up a realistic environment, containing of classrooms, corridors, elevators, staircases, offices etc. The possible objects for troubleshooting in this building are coffeemakers in various locations, lighting, overheadprojectors in the various classrooms, and a stereo-set. Of all the technical systems, installation documentation is available, which can be taken with you on your way to a particular problem. There are maps available of the layout of the building, test equipment is available, and communication with other people, e.g. end-users complaining about malfunctions is possible through simulated conversation.

4. The Interaction between the Virtual Environment and the Tutoring System

A session with The Troubleshooter (after having completed a sign-up procedure) starts with some notice that there is some system malfunctioning in the building. The task of the chief technician/maintainer (i.e. the student) of the building is to take action and provide adequate solutions and repairs, with the right priority. To accomplish this task, he may ask questions to the complaining person through the phone, write down notices, go to the piece of equipment, open it, take measurements, undertake repairs. While collecting information leading to a problem description, making decisions with respect to the likelihood of certain causes, while collecting measurement information, he fills in his fault isolation form. As soon as the troubleshooting session starts, the behavior of the student is monitored in the background by the tutoring system. Only if the student makes really bad mistakes during troubleshooting (as described above), or after having finished a stage in troubleshooting, he receives an qualitative evaluation of his behavior: what went well, what went wrong, has the student performed sufficiently good to progress to the next phase of the problem. After finishing the problem the student receives an end-evaluation: what went well, and what could be improved in his reasoning throughout the troubleshooting session.

5. Discussion and Conclusions

We believe that the combination of a virtual environment and an intelligent tutoring system is a powerful tool in training a complex cognitive skill such as troubleshooting. It enables training in a realistic job-context, not only concentrating on the technical skills that are needed in a particular domain, but also emphasizing other important skills in job-environments, such as communication skills. In doing so, we believe that multi-media environments are a powerful tool in enhancing the transfer from vocational training to job-related expertise and in increasing the attractiveness of training.

Of particular importance in the project was the approach to troubleshooting that we implemented: it provides a firm grip on the students learning process, and enables intelligent and informative feedback, thus maximizing the possibilities for students to learn.

Abstract: This study reports preliminary findings about critical factors that promote and facilitate collaboration, cooperation and communication between members of design teams who create educational software for classroom use. Factors that discourage or contribute negatively to group interaction and production were also considered. Methods employed included pre- and post-team surveys, peer reviews, participant interviews and journals, and observations. Participants were graduate students in the Instructional Technology program in the College of Education. Although multimedia design teams in commercial settings have been the focus of many articles in business publications, there is little research-based literature about teams composed of educators developing courseware for classroom settings. In order for multimedia design teams to work together effectively, members must possess effective and well-developed skills of collaboration, cooperation and communication. Understanding how these skills may be developed and nurtured plays a critical part in courseware development and may facilitate a more effective model of instruction.

In the business arena, multimedia design teams have been used extensively over the past decade to develop software for commercial purposes. In educational settings, however, most courseware has been developed by individuals who, for the most part, do not have the wide range of skills needed to produce a quality product. By working in multimedia design teams, educators can combine their skills to produce both a worthwhile and well-designed piece of software expressly for their educational setting.

This study reports preliminary findings about critical factors that promote and facilitate collaboration, cooperation and communication between members of design teams who create educational software for classroom use. Factors that discourage or contribute negatively to group interaction and production were also considered. Methods employed included pre- and post-team surveys, peer reviews, participant interviews and journals, and observations. Participants were graduate students in the Instructional Technology program in the College of Education. The students were enrolled in two sections of an instructional technology course, CUIN 7327, the Design and Development of Instructional Packages during spring semesters, 1996 and 1997. In 1998, this course was renamed to more closely match course objectives and divided into two courses which are taken in a fall-spring sequence, CUIN 7327, The Collaborative Design of Multimedia, and CUIN 7357, The Collaborative Development of Multimedia. Data was also gathered from the fall, 1998 section of this two sequence course. The students who enrolled in these classes were from a variety of backgrounds, but most had teaching experience in either K-12 classrooms or in higher education.

This project fits into a larger research focus on educational multimedia courseware development and authoring competencies for educators. Although multimedia design teams in commercial settings have been the focus of many recent articles in business publications, there is little research-based literature about teams composed of educators developing courseware for classroom, not commercial, settings. In order for multimedia design teams to work together effectively, members must possess effective and well-developed skills of collaboration, cooperation and communication. Understanding how these skills may be developed and nurtured plays a critical part in courseware development and may facilitate a more effective model of instruction.

Educational Multimedia

Using the computer to control and deliver a full range of audiovisual media offers educators a way to regain the power and strength of audio, video, animations and interactive simulations, and to build those features into educational materials. These materials actively engage students by giving them the best possible presentation and explanations with whatever media are the most suitable to the task. Interactive multimedia implies multiple forms of communications media, controlled, coordinated and integrated by the computer. The computer allows the individual user to interact with and control the flow of information. Instead of reading the information in a conventional linear way, the user is encouraged to pursue links from one topic to another following a uniquely personal trail through the information. The user becomes an active participant in the flow of the narrative, actively choosing material, and in some cases, modifying the content itself to suit his or her needs and interests.

In the past few years there has been a dramatic growth in the interest and possibilities of using multimedia in educational settings (Ferretti, 1993). However, Wiburg (1995) noted that although there are thousands of articles about multimedia, there is very little research. In addition, Wiburg continued, much of the research that does exist about multimedia has been conducted in other areas and is peripheral to the concerns of most educators.

Effective Use of Technology

There are many viewpoints on the competencies that educators need to effectively use computer technology in their classrooms. Teacher education organizations have proposed that educators should have, "The ability to integrate instructional technology into the classroom to facilitate interdisciplinary teaching and learning, supplement instructional strategies, design instructional materials, and enhance hands-on experiences and problem solving" (National Council for the Association of Teacher Education, 1992) and "demonstrate knowledge of uses of multimedia, hypermedia and telecommunications to support instruction" (International Society for Technology in Education, 1992). D'Ignazio (1993) stated that multimedia has a great potential for educators at all grade levels by bringing even "the driest areas of curriculum to life" and by turning the classroom in "an exciting studio-like area" (p. 490).

Authoring Courseware

Lockard, Abrams, and Many (1997) listed several reasons why teachers may find it advantageous to develop their own software. First, teachers may not find appropriate software. Educational software companies must develop software that meets the needs of many students in order to be cost-effective. Second, budgetary considerations may prevent teachers from purchasing a commercial software package. Third, educational software is not designed with specific students and individual needs in mind. Finally, teachers may have a personal preference for creating their own materials including the natural desire of experienced teachers to produce their own educational materials of all kinds.

Teachers are logical developers of courseware for their classrooms. They have a better knowledge of the content than do commercial software designers, and they bring to the authoring environment their knowledge of good pedagogy and teaching skills. Teachers also have the concrete experience of actually teaching the content. They have learned by experience what strategies work and which ones must be reinforced in multiple ways. Teachers understand the needs of their audience better than anyone else. Many teachers may actually prefer to develop their own materials just as they do with other classroom materials such as handouts and worksheets. Kearsley (1986) suggested that teachers should author their own programs in order to become better software evaluators. He stated that the ability to distinguish a good software program from another is one of the critical skills needed by software designers. He continued by adding that evaluation skills and design skills are mirror images of one another. Finally, teachers are the ultimate users of the software.

As early as 1984, researchers have cited the need of some teachers for producing their own software and have contended that software development is a valid topic for teachers to study at the graduate level (Young, 1984; Monahan, 1987; Overbaugh, 1994). In addition, Turner and Dipinto (1992) stated that hypermedia gave students new insights into writing. Using hypermedia caused students to view information as more than large streams of text, but more as chunks of information that were linked. Turner and Dipinto reported that the study indicated that "the time students invest in learning to use software and hardware not only gives them a powerful new medium of communication but may also give them new insights into organizing and synthesizing information" (p. 198).

Multimedia Design Teams

In spite of these compelling reasons for educators to author courseware for their unique classroom environment, it is not reasonable to expect that educators will be able to produce professional looking courseware taking into consideration both the limitations of time and production capabilities. The range of skills needed to produce a multimedia project include a detailed knowledge of computers, information processing, graphic design, sound and video editing, an authoring language, and instructional design. It is practical, therefore, to view the development of educational courseware much like the development of commercial software utilizing the concept of multimedia design teams with specialists in the various production fields.

A design team usually consists of several individuals with specific talents who contribute in some way to the development of a shared goal. Martin (1995) stated: "A team refers to a small, tightly knit team of people intensely focused on meeting a specified objective that all members of the team are committed to accomplishing together." (p.65)" In a successful and effective design team, each member feels a sense of trust, commitment, and responsibility for other members and a shared vision for team goals and objectives.

Multimedia design teams are, for the most part, organized around a project manager, an instructional designer, a graphic artist, an audio and video producer, a content writer and a programmer. Working with a client, the team develops learning materials that may include some form of computer-assisted software program, a manual or guide and a set of usually print-based teacher materials.

One of the most important factors in a team approach to courseware design is the interaction and communication among team members (Ally, 1985). Team members are required to work cooperatively and must learn to function as a unit. In spite of several different areas of specialization and different levels of interaction with one another, team members must be able to communicate ideas and meanings effectively.

In the business field, design teams may spend several sessions learning to work collaboratively. Unlike the highly structured procedures of cooperative learning, a collaborative learning environment empowers the learners to actively seek knowledge. Teams become more autonomous as they learn to work, interact and nurture each other while working toward the team goal. Bouton and Garth (1983) cited the fact that through a collaborative learning situation, the learners are transformed from spectators to being involved in more complex interactions in an active learning process.

This study investigated some critical factors that enhance collaboration, communication and cooperation among team members developing educational courseware. This research has implications that will impact both students and faculty in the design and development of educational multimedia courseware. Current trends in educational research indicate that the delivery of multimedia materials will increase over the next decade.

Research Design

Objectives

Goals for this study included:

1. determining those behaviors which promote group cooperation and those behaviors which contribute in a negative manner to teamwork and interactions
2. soliciting from participants ways that positive behaviors may be learned and developed
3. examining solutions to problems which occur between members of a team
4. creating guidelines and suggestions for promoting positive team interaction
5. suggesting what role previous team experiences may have on group communication and behavior

Procedures

Procedures included a detailed literature review concerning effective team qualities in multimedia design teams including those used in the business field, pre- and post-team surveys, peer reviews, participant interviews and journals, and observations. Participants included 42 students in two graduate instructional technology courses, CUIN 7327, the Design and Development of Instructional Packages during spring semester, 1996 and 1997, and 18 students in CUIN 7327, The Collaborative Design of Multimedia (renamed and redesigned fall, 1998).

The research plan began with an initial assessment of computer skills, multimedia skills and knowledge of team strategies based on two surveys completed by each group of students the first night of class. The Computer Skills Assessment asked students to rate their skills in such areas as proficiency in specific types of software programs and the ability to use hardware peripherals such as scanners and digital cameras. The Multimedia Skills Assessment asked students to rate their skills in areas such as the use of specific authoring programs such as Macromedia Authorware and Director.

In addition, this survey asked students to rate their multimedia project experience in such areas as designing navigational structures, building a prototype and producing video.

Design Teams

Based on this survey and student interviews, each class was divided into design teams consisting of the following members: a project manager, a graphic designer, a videographer, a programmer and a content writer. During the fall 1996 semester, four teams of five members each worked with four different faculty members to develop a multimedia project according to that client's specifications over the course of the fourteen-week semester. During the fall 1997 semester, four teams worked on different sections of a large project for one client. During the fall, 1998 semester, six teams worked with two different clients to design educational software for an undergraduate history class in the college of Humanities, Fine Arts and Communications and an undergraduate human resources class in the College of Hotel and Restaurant Management. The purpose of this project was to provide students with an introductory, but realistic, experience in developing a piece of software in a team environment for a specific group of users.

Design Process

Students were assigned to different teams based on the skills analysis they completed on the first night of class, the instructor's knowledge of each individual's background, and student preference. For the most part, the graduate students in this class had completed both the introductory instructional design course and overview of multimedia course.

The next few class sessions were spent on discussing team roles and developing competencies that would allow students to complete their part in the projects. Teams also met with their client weekly to discuss and develop preliminary analysis and goals for the project. Students soon realized that working in a team and trying to develop a piece of software for someone else is a lot of work.

Communication began to develop both in class team meetings and through email. One student noted: "I remember all of us being polite to each other at first. However, we had a lot of creative work to accomplish and 'polite' wasn't exactly what I had in mind from this team. But as soon as we got to know each other, our meetings became more open and lively." Another member of the team reflected," I found these discussions, sometimes heated ones, to be thought provoking and interesting. Ideas were put forth, discussed and then tested for consensus. We tossed a lot of ideas back and forth while we were trying to visualize how this product should look and what was needed to make it a reality."

In addition to communication skills, one student noted in his journal, "I've noticed that listening skills are especially important on a project team ... there are times in our groups where people don't stop to listen to each other's ideas and it really slows progress as we discuss (debate) a single item over and over. It's much easier when everyone takes a turn speaking, others listen, the issue is out on the table and a decision is made."Some problems were encountered when quiet students were reluctant to voice their opinions: "I believe other (students) have been frustrated or have kept quiet because of the vocal nature of a few members of the class."

Teams also foundered a bit at first trying to develop ideas and models for their projects. Members soon realized that decisions should be made by the team and not by individuals. It took most of the teams several weeks of meetings both as a team and with the client to develop a plan and direction for the projects. Some team members noted that success was related to early decision making, "We had to 'start from scratch' a few times, but those times were well justified - and were team decisions. It took us about two weeks before we settled on a direction. And we did not make a major change after that point."

Some teams spent several sessions establishing team rules for discussion; this usually facilitated decision making and communication. Although University of Houston graduate students usually work full time and often commute as much as an hour to come to class in the evenings, team members met many meeting requirements by using email.

Many students felt apprehensive about time considerations, working in a team situation and being evaluated by their peers rather than just the instructor, "I fear that the amount of time needed for production will be very demanding. The team process and work is worth the course alone! I'm learning tremendous lessons. It is also a very positive experience with each problem, group interaction, individual interaction building a team spirit. I like this!" A student remarked, "I think everyone is 'nervous' because the expectations of the finished product is high everyone wants to create something really good."

Student Resources

Several different types of resources were available for student learning. These included the textbooks, I Sing the Body Electronic by Fred Moody and Multimedia Making It Work by Tay Vaughn. In addition Web pages for each class were developed and used as means for sharing information and progress on the projects.

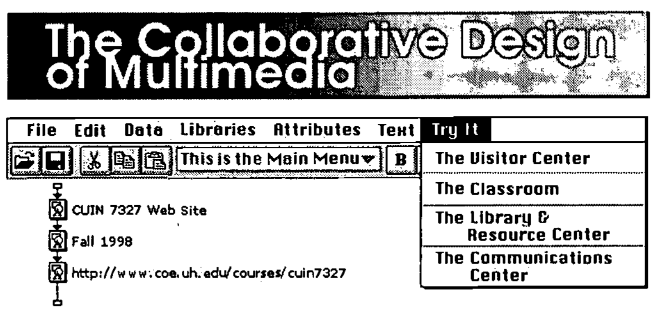

Figure 1.: Web Site for CUIN 7327 for fall, 1998 semester

Several students remarked on the Web pages in their journals noting, "The web pages have some interesting links and the material is organized in a logical and consistent fashion... The pages are a good way to stay connected to the class when at work or at home - important in creating a 'community' because of job or personal schedules."

To access the pages used during fall and spring, 1998: http://www.coe.uh.edu/courses/cuin7327

Hypergroups

In addition to face-to-face communication, Hypergroups, a web-based, hypertextual interface for the automated E-mail distribution lists was used to facilitate discussion among teams and clients. There were several discusison areas created. In addition to a common discussion area for all students, there were private, password protected, areas for individual teams.

Project Presentations

At the end of each semester, team members shared their final projects in a special evening presentation. Although the content and quality of each project differed greatly, the goals of the class were clearly met - students experienced working in an authentic learning situation. Several teams exceeded expectations in functioning as a cohesive unit noting, "We functioned as a team and not a collection of individuals. Our group rose to the highest definition of a team."

Preliminary Findings

In each semester, a mid-semester and final survey on Project Team Attitude was completed by each member anonymously. This survey has been adapted from closely related surveys used in business (Systems One, 1996). In addition, students participated in both mid-semester and final peer reviews. Peer reviews asked students to rate such competencies as "Quality of Assignments," "Responsibility to Team," "Contributions to Team," "Attitude," "Teamwork," and "Overall Team Member" for each member of the team and to also rate themselves. Comments at this time included, "My group is very eager and positive we feel a sense of 'group.' I still think we're showing our best selves."

Direct observation of team meetings and interviews with team members were also conducted by the researcher at critical milestones for courseware development over the course of the semester. In addition, team members were also required to keep journals of their thoughts and feelings during team meetings and other development opportunities.

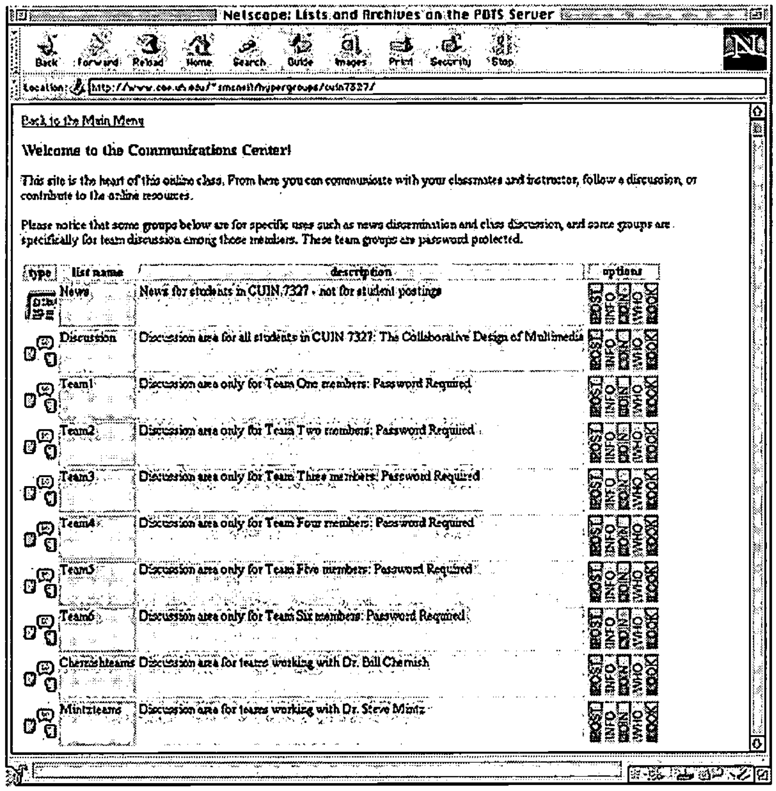

Figure 2: Hypergroups Menu for Project Teams

Midterm Evaluations

Participants used a likert scale to rate their perceptions of their team health and well-being. Using a scale ranging from 1 strongly agree to 5 strongly disagree, participants responded to such statements as: The goals of the team are clearly understood by team members. Team meetings are productive. I feel that I have been an important part of this team so far.

The highest disagreement among all teams was shown on statements such as, "The team is using their meeting time effectively." and " The team is learning to effectively address and resolve problems within the team." The most agreement among all teams occurred on such statements as, "The team is developing effective strategies to meet objectives," and "Team members are making efforts to get jobs completed." The ratings ranged from 2.65 to 1.85. These collective results, not individual ratings, were shared with the participants and strategies for facilitating better interaction and problem solving were addressed in a group discussion. At this stage in the project, there was a steep learning curve and many problems were being worked out, both with the clients and between team members. The overall attitude of the project teams ranged from 4 responses of excellent, 6 responses of very good, 4 good, and 4 fair.

Final Evaluations

Similar evaluations were completed at the end of each semester. As in the midterm evaluations, one of the highest areas of dissatisfaction among all teams continued to be, "The team is learning to effectively address and resolve problems within the team." The most agreement among all teams occurred on such statements as, I feel that I have been an important member of this team so far," "Team members are making efforts to get jobs completed," and "Team members have been generally positive in their outlook regarding the project." The ratings ranged from 2.09 to 1.52.

Peer Reviews

Peer reviews asked students to rate such competencies as "Quality of Assignments," "Responsibility to Team," "Contributions to Team," "Attitude," "Teamwork," and "Overall Team Member" for each member of the team and to also rate themselves. Consistently across all teams, team members rated their other members above average on most categories. Peer reviews in all three semesters of the course have proven very effective in addressing grading issues.

1998 Redesign of the Course

In the fall semester of 1998, the course was redesigned and divided in two parts which students take in sequence. Students had noted on their evaluations that the time was not sufficient to both design and develop the piece of software in one semester. Students now design the software during the fall semester. They develop it using Macromedia's Authorware and perform a simple evalution during the spring semester. This redesign has been very effective from both the students' and teacher's points of view. Because of the additional time, students have had more opportunities to both present and share informally knowledge of the instructional design process and authoring strategies. In addition, one client has been more involved in the process, learning the software and participating in both the design and development process every class. It is also interesting to note that team roles were not assigned during this semesterso that each team could develop the most effective structure for that particular group.

Discussion

Although many components of this research are still being evaluated and researched, it seems from a preliminary investigation that the areas of communication, collaboration and cooperation in a team environment are rich in experiences and nuances. Successful teams, as demonstrated in both project development and peer reviews, were able to work together and resolve problems quickly without any single person assuming a dominant or overpowering role. Teams that experienced some dissatisfaction with the team process typically did not form a cohesive group or work together to solve problems that arose. Although a leadership role is expected of the project manager, successful teams clearly developed a process for equal participation among team members. Further research is needed to explore other influences such as time constraints and different skill levels among members.

Student Achievement in Distance Education Courses

Michael K. Swan
Washington State University

Diane H. Jackman
North Dakota State University

Introduction

As we enter the 21st century and embark on the information age, many institutions and schools are turning to technology to enhance their programs and to expand their horizons. Geography is no longer a barrier for preventing people from accessing information and education (Dixon, 1996). Rapid developments in telecommunication technologies, tightening budgets, and changes in student demographics have stimulated an increasing interest in distance education in all educational settings (Honeyman & Miller, 1993). Through the use of videoconferencing, computers, modems and the Internet, schools are able to deliver courses and degree programs to students in distance locations without requiring them to set foot in a traditional classroom.

Distance education is an emerging technology intended to deliver both resident and remote site instruction and educators who use distance education must provide educational experiences that will equal resident education in terms of quality and quantity. Both resident and distance education are intended to provide students with valid, useful information that promotes learning. According to Swan and Brehmer (1994), distance education refers to "the simultaneous delivery of instruction from a host site or classroom to remote site(s), coupled with real time live audio and real time live video interaction between teacher and student(s) – not correspondence, video, or internet courses." Distance education, according to the United States Department of Agriculture, is a process to create and provide access to learning when the source of information and the learners are separated by time and distance, or both. Rather it is the process of designing educational experiences that best suit the learner whom may not be in a classroom with an instructor at a specific time. Murphy (1997) defined distance education as a premeditated and persistent attempt to promote learning in an environment that includes geographic, temporal, or pedagogical distance.

Swan (1995) noted that advancements in communications technology have dissolved some of the major distinguishable characteristics between distance education and traditional education. According to Swan and Jackman (1996), strategies of teaching at a distance and host site are converging because traditional teaching strategies are being abandoned or modified in favor of a problem-based, resource-based, or activity based approach that de-emphasizes the teacher as the main source of knowledge.

The increasing availability of telecommunications has provided vocational or applied education faculty with unique opportunities to plan and deliver distance education courses and programs. Vocational education students are also enrolling in more distance courses and programs due to availability, time, and place. However, there is a lack of studies that compare student achievement by students receiving instruction via distance technology versus students receiving the same instruction through the traditional resident, host site, classroom setting.

Purpose/Objectives

The purpose of the study was to ascertain if student's achievement differences existed in courses delivered via distance education. Specific research objectives were:

1. Describe student's enrolled, remote site and host site, in distance education courses on selected demographic characteristics
2. Ascertain if differences existed between remote site and host site student's achievement based on grades/scores (GPA) obtained by grade level.
3. Ascertain if differences existed between remote site and host site student's achievement (final grade received) based on individual course success.

Methodology

Definitions

Host site: The school where the instructing teacher is residing or located and where the course originates from during the course sessions. Location where the instructing teacher is physically in the classroom with the students.

Remote site: The receiving classroom where the students are physically in the school setting but the instructing teacher is teaching students via an electronic format. Location where the instructing teacher is not physically in the classroom with the students

Populations

The population of remote site and host site schools was identified from an alphabetical list of secondary schools utilizing distance education technologies supplied by the State Department of Pubic Instruction. The schools were all located within one Midwestern State. Each of the identified schools administration were asked to participate in the study. From the total list of schools using distance education, a total population of schools willing to participate were identified, N = 46 schools. From this revised list of schools, a study sample was selected using appropriate cluster sampling methods outlined by Wiersma (1995).

As each school was selected, all courses/classes being offered via distance education from that school were selected for this study. Each student in the study, n = 623, was enrolled in at least one course being offered via distance education. To retain the confidentiality of the student, administrators or the assigned school representative was asked to assign an identification number to each student. This number was used to report all data concerning that student. The researcher did not know or have knowledge of any student name, only their assigned number.

Instrumentation / Data Collection

The study instrument was completed from student's records by the administration or assigned school representative. The instrument was assessed for content and face validity by graduate students, teacher educators, and state supervisors in vocational education. This procedure was followed because more than one person in a school was responsible for providing the data required by the researcher. Reliability of the instrument was .89 (Cronbach's alpha coefficient). They were asked to report gender, grade level of student, period(s) taking distance education courses, name(s) of specific distance education course(s), location of student (remote or host site), total daily assignment scores, exams and/or quiz scores, and final exam score.

Data Analysis

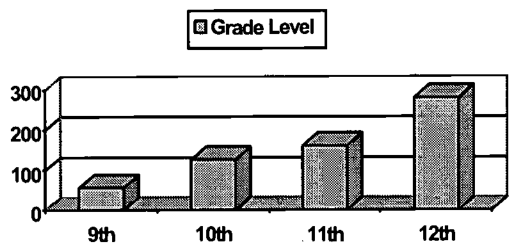
Data were analyzed using the Statistical Package for the Social Sciences (SPSS Version 6.1) for Windows. All tests were run at the .05 alpha level.

Results

Objective 1: Demographic Characteristics

Demographically, students in the study were predominately located at remote sites, 68.1% (424), and 31.9% at host sites (199). In the study, there were 245 male students (39.3%) and 378 female students (60.7%). The study identified ten individual courses being offered via distance education, one course was eliminated from the study because no results were made available to the researcher. Table 1 identifies the total number of students by grade level, 9^{th} = 56 (9%), 10^{th} = 126 (20.2%), 11^{th} = 161 (25.9%), and 12^{th} = 280 (44.9%).

Table 1 Grade Level of all Students



As shown in Table 2, the study group is divided into groups identified by specific course name and by location receiving the course. Frequencies and percentages are used to identify students enrolled in distance education courses all sites in the study.

Table 2 Individual Course Enrollment Frequencies and Percentages

Course Name	All Sites		Host Site		Remote Site	
	N	%	N	%	N	%
Foreign Language	231	37.1	91	39.4	140	60.6
Ag Business Mgt.	77	12.4	3	3.9	74	96.1
Vocational Marketing	21	3.4	14	66.7	7	33.3
Natural Resources	42	6.8	4	9.5	38	90.5
Math - Calculus	119	19.1	63	52.9	56	47.1
Chemistry	70	11.2	9	12.9	61	87.1
Art	14	2.2	5	35.7	9	64.3
Statistics	14	2.2	6	42.9	8	57.1
Animal Science	35	5.6	4	11.4	31	88.6
Total	623	100	199	31.9	424	68.1

Objective 2

One way analysis of variance was used to test if differences in student achievement existed between remote and host site students based on mean GPA. No significant differences were found.

Table 3 identifies the mean Grade Point Average (GPA) of students located at remote sites and at host sites. The grade point averages of students enrolled in distance education courses at both the remote and host sites were very similar.

Table 3 Grade Point Average According to Location Receiving Course

Location	N	GPA	SD
Remote Site	424	3.19	.76
Host Site	199	3.14	.84
Total All Sites	623	3.18	.78

ANOVA was used to test if differences in student achievement existed between grade levels based on mean GPA. There were significant differences among the four groups (9th grade, 10th grade, 11th grade, and 12th grade). The analysis of the data yielded an F value of 2.84 with a p of .037. Ninth grade students earned a GPA significantly higher than 11th grade students and 9th grade students earned a significantly high GPA than did 12th grade students as reported in Table 4.

Table 4 Comparison of students Grade Point Average by grade level and by site

Grade Level / Site	N	GPA	SD	SE
9th Host Site	2	3.35	.92	.65
9th Remote Site	54	3.43	.73	.09
9th Total	56	3.43	.72	.09
GPA / Grade Comparison 9, 10 p= .095, 9, 11 p= .045*, 9, 12 p= .005*				
10th Host Site	70	3.19	.71	.08
10th Remote Site	56	3.25	.58	.07
10th Total	126	3.22	.65	.05
GPA / Grade Comparison 10, 11 p= .712, 10, 12 p= .171				
11th Host Site	71	3.31	.57	.06
11th Remote Site	90	3.08	.79	.08
11th Total	161	3.18	.71	.05
GPA / Grade Comparison 11, 12 p= .297				
12th Host Site	56	2.87	1.16	.15
12th Remote Site	224	3.16	.78	.05
12th Total	280	3.10	.87	.05

Objective 3

One way analysis of variance was used to test if differences existed between remote site students GPA and host site students GPA by individual course. There were no significant differences among the two groups (remote site and host site). The analysis yielded an F value of .51 with a p = .47 as reported in Table 5. There were significant differences between the groups by grade level. The analysis yielded an F value of 12.23 with a p = <.0001. Analysis of data of student achievement (GPA) by remote site or host site by individual course identified no significant differences. The analysis yielded an F value of .77 with a p = .62 as reported in Table 5.

Table 5 Analysis of Variance for Grade Point Average on Site Location and Individual Course

Source	df	SS	MS	F	p
Site	1	.262	.262	.511	.4749
Class	8	50.194	6.274	12.231	<.0001
Site * Class	8	3.186	.398	.776	.6237

When comparing student GPA by course we see differences in individual courses. All courses GPA's were identified as being significantly higher than GPA's in Vocational Marketing. Foreign Languages GPA's were significantly higher then GPA's in Vocational Marketing. Natural Resources GPA's, Chemistry GPA's, and Art GPA's were significantly higher than GPA's in Foreign Languages. Natural Resources GPA's were significantly higher than GPA's in Ag Business Mgt., Math, and Animal Science as reported in Table 6. Significant differences were found when grouping traditional vocational courses, Ag Business Mgt., Vocational Marketing, Natural Resources, and Animal Science, together and comparing to the traditional academic in student achievement as measured by Grade Point Average. Students in traditional academic courses (3.25 GPA) had a higher GPA than did students in vocational courses (2.99 GPA). The analysis yielded an F value of 13.56 with a p = .0003 as reported in Table 7.

Table 6 Individual Course Success (GPA) by Host Site and Remote Site

Course Name	Host Site		Remote Site	
	N	GPA	N	GPA
Foreign Language	91	3.29	140	3.06
Ag Business Mgt.	3	3.23	74	3.09

Conclusions

1. Students enrolled in distance education courses were primarily located at remote sites. Remote site students were provided the opportunity to take these courses because courses were being offered via distance education technology. Without this opportunity, most of these students (424) would not have been able to enroll in these courses
2. Receiving instruction by distance education resulted in no differences in grade point average for all students at either remote site or host site. Students in 9 th grade did have higher grade point averages then did 11 th grade and 12 th students. Twelfth grade students located at host sites had a significantly lower GPA than 12 th grade students located at remote sites. This area needs further analysis to determine exact reason for this occurrence.
3. Individual courses being offered via distance education revealed differences in student achievement. Grouping traditional academic courses and comparing to the vocational courses offerings significant differences were revealed.
4. The results of the study offer promise that distance education courses do provide opportunities for students who would otherwise not be able to take these courses. Additionally student success, GPA, was above average (mean GPA whole group = 3.18) in these courses.

XML – A Solution for Publishing Up-to-date Educational Information on the Internet?

Ruairi O'Donnell, Crawford Revie, Monica Landoni, Colm McCartan

26 Richmond St, Glasgow, G1 1XH, UK
Email: ruairi@dis.strath.ac.uk

The Web was first envisaged as an Information Management tool that helped researcher organise and find interesting documents. However with the popularity of the Internet and the its image as a Publication tool for the masses, we now have a Information Mis-Management Tool. Increasingly people are using it for searching using "Web Portals". Web Surfers are morphing into Web Searchers. XML may help us resurrecting the information chaos into some manageable form. This paper will briefly describe XML and its potential benefits for Educational Delivery.

1 Introduction

The Web is based on technology, which was initially invented for small information spaces with a small number of users. HTTP, URLs and HTML are excellent solutions to a uniform information management system. With the Internet explosion these standards have been stretched to their limits.

The Web has evolved rapidly, so rapidly it seems more like a revolution rather then an evolution. To keep up with these changes the Internet authorities have had a busy time! Each of the original Internet technologies has been extended in numerous ways. HTML has seen the biggest change, initially designed for static text only hypertext pages, now incorporating many different technologies which want to get on the Internet bandwagon.

HTML has obvious limitations that need to be resolved. These limitations include:

- Unpredictable appearance of HTML documents in Web browsers;
- The content of an HTML document is inseparable from the presentation tags;
- Meta information in HTML is restricted to document wide semantic name/value pairs;
- The majority of search engines index only the textual content of HTML pages.

This paper will introduce the main elements of Extensible Markup Language (XML). The paper will outline a case for using XML within Courseware systems.

2 Case Study

The potential of XML to improve the delivery of course material is now illustrated through a short case study. The course under consideration is delivered by the authors to first year undergraduate students at the Business School of the University of Strathclyde, and provides an introduction to Business Computing.

Many of the generic issues relating to courses supported on the WWW are of relevance to this case study, including facilities for off-campus access, student centred learning, standard browser access, etc. However, there are a number of specific issues related to this course that make it particularly suited to web-based support. Firstly, it is a rather large class, by UK standards, with around 700 students. There is a need to give students, particularly in the first year, some sense of contact with teaching staff but it is clearly not feasible to use traditional small group meetings due to the time and labour intensity that this implies. Secondly, the course is delivered by four staff members from two different departments within the Faculty (it is felt that as this class is for all Faculty students this is a useful mechanism and indeed proposals are in place to increase the number of staff involved). In this context it is important that the students have a 'focal point' for the provision of course information. Finally, students entering this class come with a range of knowledge and skills relating to the use of computers within business. There is therefore a need to tailor material in such a way as to ensure that novices are not over-awed and yet. At the same time, to challenge those with some prior knowledge to extend and in particular deepen their understanding of the subject.

The use of web-based material aids in addressing a number of these issues for example, the web site provides a 'virtual' focal point to which the students can be pointed as a source of initial reference. In addition to finding a course overview, copies of the course handbook and timetable details, information can also be found for classes as they take place each week: tutorial material; preparatory reading; useful web links and even weekly student feedback can be checked on the site. When the 'virtual' solution cannot provide adequate support the site points the student to the most appropriate staff member to deal with their query and encourages e-mail contact in the first instance. The flexibility that the WWW provides to allow the four staff members to interact with the students and the course material, as well as with each other, has many advantages however it can also lead to problems.

The fact that no one person has overall editorial control can lead to conflicting information or to inconsistent presentation over a period of time. Thus there is a tension between the benefits, in terms of flexibility and immediacy, which the WWW offers and the requirement from the students point of view to be able to rely on the site as the authoritative source of course information. The need for increased control on the consistency and accuracy of information has been partially addressed by the creation of course 'style sheets' but this rather informal mechanism does not provide a complete solution and the potential of XML to assist in this context is explored below.

As yet, little progress has been made in addressing the widely differing levels of knowledge students have on entry to the course. This is not because the WWW does not provide suitable mechanisms through which diverse sets of material can be delivered but rather reflects the effort involved in editing and maintaining 3-4 parallel and internally consistent sets of material for the varying levels of student expertise. Once again it is the authors' view that the structuring and delivery of dynamically changing material (i.e. based on student expertise level) can be handled much more adequately using an XML-based approach.

3 XML

XML has generated a lot of attention in the technical press recently where it has been widely referred to as the replacement to HTML. The two languages are, of course, related and share a common parent in the Standard General Markup Language (SGML, ISO-8879). SGML is a complex standard in the form of a meta-language that allows us to describe how a document is structured by means of a Document Type Definition (DTD). A DTD specifies which tags a document may have, what they are composed of and how they are related to one another in the structure of the document in terms of sequence, nesting etc. HTML, for instance, is an SGML DTD defining documents for presentation by a web browser that is 'hard-wired' to understand the HTML DTD. Any users of the web over the last few years will have observed how HTML has been continually updated and expanded to increase its flexibility of presentation, its ability to integrate live data and its functionality for supporting interaction. However, these extensions, as well as being proprietary and non-standard, have been unable to tackle HTML's inability to support document extension or inheritance and its inclusion of document styling alongside structure.

Awareness of the limitations of HTML and the desire to avoid the proliferation of proprietary HTML extensions led to the ratification of XML by the World Wide Web Consortium (W3C) in February of 1998. In terms of complexity, XML lies somewhere between SGML and HTML and is aimed at providing most of the richness of the SGML command set while remaining easy to learn, implement and use. It has been described as a dialect of SGML and is itself a meta-language. Thus, XML allows us to specify not only a marked up document but also to specify which DTD it conforms to. For example, in the case of web documents, there is always an implicit association with the HTML DTD while with an XML document it is usually necessary to refer to the associated DTD explicitly in the header of the document.

This last point highlights what is probably the most important departure from HTML - that XML specifies the structure of a document via its accompanying DTD. Since the document author can define this DTD, any customised tags may be defined and used within the document. The XML markup language is robust enough to describe a wide range of abstract structures in the form of a document and an accompanying DTD describing that abstract structure. XML can therefore be used to describe data objects, structured records, and many other types of structured data. The industry has been quick to see the potential of this new standard for exchanging and sharing not only documents as is currently done on the Internet and various intranets, but also to share a huge variety of structured data using established Internet standards such as HTTP as the mediating protocols.

XML appears to offer a potentially industry-wide, customisable format with the robustness and flexibility to model a huge range of document types. It seems safe to suppose that support for XML in the form of toolsets and application suites will be forthcoming from an industry increasingly accustomed to and demanding of interoperability between vendors' products. A long list of "Who's Who" of software companies--including Microsoft, Netscape, Lotus, IBM, and Adobe Systems--have publicly committed to supporting the XML language.[1]

The three most important parts of XML are the Document Type Definition (DTD); the Extensible Style Language (XSL); and the Extensible Link Language (XLL) [Bradly 1998].

DTD - The Document Type Definition specifies the logical structure of a document. It defines the grammar of a document and enables an XML parser to validate a page's use of its tags. The DTD defines the permitted use of each tag and it's associated attributes. The DTD consists of three structures:

- A description of the nesting of hierarchies for document structures (i.e. A Chapter contains Headings and sections, sections contain paragraphs and so on.)
- The sequence in which the structures are permitted (i.e. A Title is before an Abstract and so on)
- Finally the DTD describes if structures are optional and also repeatable. (i.e. A Paragraph must have at least one or more sentences).

XSL - Extensible Style Language is the language used to specify style sheets for XML documents. XSL enables Web browsers to change the presentation of a document. This is similar to the Cascading Style Sheets (CSS) used in HTML 4.0.

XLL - Extensible Link Language supports today's Web links and it also extends links. It will include indirect links, which should resolve dead links and other hyper link problems. XLL is currently under development. XLL will support a number of link mechanisms [WWW3 XLL 98].

4 Internet versioning with HTML

For a corporate Internet to succeed the content needs to be up-to-date. Most companies have data and information stored in vendor specific file formats, such as Microsoft Word, Corel Draw, etc. For these file formats to be stored on the corporate Internet requires exporting to HTML and then FTP or "Published" to a Web server.

HTML is a poor presentation language with little or no structural information. Sadly most HTML file exporting tools remove important semantic information, stored in vendor specific file formats. Vendors are producing new software tools that can export to HTML but these are merely add-on features. For an Internet to succeed vendors must create software that use a Web file format as the primary file format. In time software vendors will become Web centric, until then we have a versioning problem.

IMAGE NOT AVAILABLE

Figure 1.1 illustrates the current situation when an employee saves a Microsoft Word document on a Corporate Internet. This two phased saving & publishing to the Web means that there are always two versions of the document which can lead to versioning control problems. HTML files are secondary file stores, much like a printed document,

[1] For more information on XML have a look at http://www.xml.com/

if the original document is updated then the HTML document must also be changed. For an Internet to succeed then the primary file store, on the Web, must be stored for company access.

5 XML Benefits

We propose storing vendor specific file format in XML. The software vendor can add all the extra "proprietary" information within the file format using XML. Then this XML document can be downloaded and interpreted by any XML compliant Web viewer. Thus we have a vendor neutral viewing facility, allowing users to have thin-clients with few installed programs.

Figure 1.2 shows that vendors can publish the DTD for a document and allow many users to view the information in its full glory. The DTD specifies the complete semantic of the document. In its purest form, XML will allow software vendors to create complex document viewers.

Another advantage of XML is that the appearance of the document can change depending on the media, allowing the document creator to harness all features of each medium. An author must customise a document for a single media and hope that it looks well in different media. Potentially, a single XML based document can take advantage of all the features of a specific printer and all the benefits of a Web browser. Also XML documents can be customised to a number of users, a manager may view an executive summary of a project report while the project team views the complete report.

Research by [Rath 98] has highlighted that XML can assist in the Management of Content, where the document content can be maintained by editorial support systems. Also Metadata can be incorporated into the XML documents so that the documents can be easily indexed and searched. Information stored in a database could also be used by XML documents by enhancing the tag definitions for Database elements such as table names and fields.

Data delivered in XML to a browser can "give Java something to do". This would mean XML could convey data and data types to a browser in a standardised form. In the past migrating data between systems has either been impossible, because proprietary software actually prevented batch upload and download, or it has been a tedious process of reducing complex data formats to flat structures like comma-separated variables. In this process there are ample opportunities for sophistication in the data structure to be lost. XML promises to be the lingua franca for data migration

5.1 Standardised DTDs for XML

For XML to succeed the domain specific DTDs must be globally accepted within a particular domain. There is little point developing numerous DTDs that describe Educational Course Material as we could then have incompatibility issues between the different Educational DTDs. For XML to succeed then there must be some central standards organisation that controls the evolution of one single DTD for a particular Domain such as Educational DTDs. In other Domains XML DTDs are under development, these include:

- Mathematics Markup Language (*MML* used for displaying Math symbols and equations etc)
- Chemistry Markup Language (*CML* to describe molecules and their structure etc)
- Electronic Document Interchange (*XML-EDI*)
- Channel Definition Format (*CDF* used for some 'Push' technologies)
- Synchronised Multimedia Integration Language (*SMIL*)
- XML Metadata Interchange (*XMI* used for exchanging software models)

We propose developing a standard DTD for courseware systems.[2]

5.2 Developing a Courseware DTD using Visual Rhetoric and existing Learning Models

We are currently developing a generic Courseware XML DTD that will allow us to create re-usable Courseware systems. To do this we are using a Graphical User Interface model called Visual Rhetoric to define how course

[2] We are interested in developing a Standard XML DTD that can be widely used. If your Organisations is interested in helping develop this Courseware DTD please contact us.

content should be presented. We are also hoping to improve the quality of the information delivery by using existing learning methods to develop XML DTD tags.

A document can be interpreted as a visible representation of a text according to its semantic contents [Southall 89]. The use of different fonts and typographical styles, as well as the introduction of spacing and pagination rules helps to draw attention to selected parts of the text [Southall 92]. Thus the translation into graphical terms of the text rhetoric which results from both the logical structure of the text and its pragmatic component can be called visual rhetoric [Landoni 97]. The idea is to define those parts that are more important for the comprehension of the meaning of the text.

Visual rhetoric provides the reader with a graphical mark up language that is immediately recognisable on the basis of previous reading activity. Different graphical presentations suggest different readings and affect deeply the interpretation of the contents of the same text. These observations lead one to conclude that visual rhetoric is a crucial aspect for both reading and browsing a document. We will be adopting this approach visual rhetoric when developing the XSL and XLL that will define the presentational aspects of the DTD. It is hoped that visual rhetoric will give us the possibility to control/predict the way student interprets and interacts with the Courseware documents.

One of our main goals is to improve we improve the effectiveness of a Courseware system. A DTD that uses 'semantic elements to exploit knowledge inside the information' can help increase the quality of the data and the service of online information [Rath 98]. At present we are identifying teaching models that encapsulate most learning methods and teaching techniques. We will then create XML tag definitions that correspond to each element of these teaching models. It is a relatively straightforward task to translate each of the teaching elements into DTD tag definitions. However developing a DTD from scratch is time consuming, and requires a great deal of testing [Maler 96].

6 Commercial acceptance of XML

Many software vendors are investigating XML as the future file format for universal viewing, editing and saving. "XML can potentially revolutionize the Web," said Chris Lilley, from the World Wide Web Consortium (W3C). "It's not a magic bullet ... but as a cornerstone of an open network computing environment it's very important." Microsoft's plans a new HTML-XML hybrid file format and both Lotus and Corel plan to support XML in their next releases. It could eventually supply the basis for universal file formats usable by all suites [PC World 98].

Berners-Lee [Montgomery 98] is optimistic about the use of XML markup tags outside the Web. This will overcome the problem of backward incompatibility between document formats. The W3C is talking to Microsoft Corporation about using XML as a cross-platform file format for Word. Berners-Lee suggests that HTML will remain reasonably static at Version 4.0, as XML allow vendor to extend and customise tags for specific purposes.

7 Future Work

At present there are very few software tools that support XML. To us XML properly within a educational environment we need software that can support XML: author a course; publish course material; capture and manage ongoing student/instructor interaction; store course material and allow easy retrieval methods for all types of users; and a user interface/browsers to view interact with the material. To date this XML support is limited however most software vendors have identified XML as a feature which will be added to forthcoming products. So to conclude when it comes to XML: "Watch this (Name)Space!".

Totally Integrated Internet Courses

Richard Dwight Laws
Independent Study
Brigham Young University
United States
dwight_laws@byu.edu

Abstract: The notion of a totally integrated course is ambitious, particularly when that integration goes beyond course delivery to include grading, data entry, testing, feedback, and management of all aspects of the process. Imagine, if you will, a totally integrated Internet course (TIIC) in which a student can find the appropriate course, investigate it, register for it, receive all necessary materials, submit assignments, get grades and feedback, take the final exam, get a course grade, and receive a transcript in the mail without any human intervention (or for that matter without the university even knowing that the student had been there). This paper briefly explains how totally integrated Internet courses are delivered and managed at the Brigham Young University, Continuing Education, Department of Independent Study.

Introduction

Brigham Young University (BYU) is moving boldly into Internet courses. BYU has one of the largest home study programs in the nation, with over 500 courses and 42,000 enrollments. The Department of Independent Study manages these courses and plans to move many of them onto the Internet. Currently, BYU Independent Study offers over 70 totally integrated Internet courses (TIIC). There are problems associated with TIIC: they are not synchronous, and they are not social. However, TIIC have major strengths, which will be the subject of this paper.

Technology has given faculty new tools. However, those tools can quickly become burdensome if not properly used or designed. For example, the most prevalent form of distance courses that faculty have attempted is the use of e-mail for interaction with students in an attempt to be synchronous. However, faculty have been overwhelmed with demands on their time using this method and have, for the most part, been forced to discontinue using the tool for that express purpose. Those who continue to use e-mail have had to restrict enrollment to a manageable few. Michael P. Lambert (1999) says that "the brand of distance education that traditional educators are talking about for the most part is "synchronous" learning. . . . the concept of 'anytime' learning is not yet ascendant."

Another example is that faculty find their time almost consumed when they try to do their own course development using technology. They often do it well and like what they have created, but it just takes too much time to create, manage, update, and trouble-shoot. The problem is of nationwide significance and needs to be addressed in order for technology to fully benefit faculty.

TIIC address the problem of "anywhere, anytime" learning quite well. TIIC accommodate unlimited enrollment. They also reduce faculty burden and at the same time generate large amounts of faculty feedback asynchronously.

The Model

The system that drives BYU Independent Study's TIIC has the following components:

- Web course catalog
- automatic registration and credit card clearance
- delivery of course instruction
- assignment submission
- computer grading of all submissions
- faculty-designed computer feedback for all missed questions
- testing
- grade posting

• personalized Web report card accessibility for students
• and transcript distribution.

Faculty are paid up front for the development of the course and then receive a royalty per enrollment on the back end. They do not test or grade. Faculty involvement and time, after the course has been developed, is virtually zero. Therefore, there is no faculty burden nor enrollment limit.

As assignments come in and are graded, the data is stored for item analysis (ITEMAN). With a sufficient number of the same assignment from multiple students, ITEMAN then analyzes the data and determines which questions are weak. These questions are discarded and the faculty create new ones. By this process the courses and assessment become stronger through use.

When a student comes to BYU Independent Study's Web page (http://coned.byu.edu/is/) they are given the options of exploring all aspects of the TIIC. They can read through the course catalog, which includes all 500 courses. They can find information about diplomas, certificates, and how to succeed, and they can view frequently asked questions. They can learn about other free online services, such as grade checking, exam requests, and questions and interaction with the faculty for special circumstances. Finally, they can explore the listing of college, high school, and personal enrichment courses available to them—both paper and pencil and Internet courses.

When a student picks a course to inspect, they are taken to a screen that gives them additional information about the course, including an audio introduction to the faculty, instructions about navigating the course, course features, frequently asked questions, and course specific how-to-succeed instructions. They are given a sample test to learn how testing works on the Internet. They are shown a table of contents so they can know if the course teaches what they need. Finally, they are given the opportunity to enroll. If the student enrolls using a credit card, a password and a CD-ROM are immediately mailed to them. The CD is used in a seamless presentation of the video and audio part of the TIIC (this will be modified when streaming is sufficiently robust and dependable). The student is then able to open the main part of the course and proceed with the instruction and assignments.

There is also a powerful tool, located on the home page, that allows faculty access to a training segment which teaches them how to write Internet courses. This training guide was developed by professional instructional designers to help faculty move through the standard design steps for instructional delivery at a distance. (Incidentally, some on-campus faculty have discovered this faculty guide tool and are using it as a guide for developing the practicum for their in-class presentation.)

When the student has enrolled in the course and has received their password, they can open the course and begin studying. When they are ready to submit an assignment, they complete the questions and click on the Submit button. They immediately see a report of their grade, followed by a list of all questions they missed. These missed questions are then explained by feedback from the faculty-designed databank. This aspect of TIIC is the most popular element with the students. They love to have immediate, and complete, feedback for their work—something they don't often get even in a classroom. Many students who have enrolled in a TIIC have given the reason for the enrollment as being the feedback statements that they receive. The assignment grade is immediately transferred to the student's data bank and entered in their record. The student doesn't have to wait for answers through the mail and is therefore able to continue on with the next lesson if they choose. Immediate feedback also leads to higher completion rates among distance education students.

After all assignments have been graded and submitted, the student must find a proctor. The TIIC system will either forward the test to the proctor to be administered, or will send the proctor a code word which will open the test on the Internet. In the case of the Internet version, the test is graded online and entered immediately into the student record. The password for the test is then no longer valid. The TIIC system calculates the student's assignment grades, test grades, and overall course grade, and then sends a transcript by mail to the student.

None of the aforementioned steps require faculty input or interaction; therefore, the course does not add to faculty load and can accommodate unlimited enrollment.

Strengths/Weaknesses

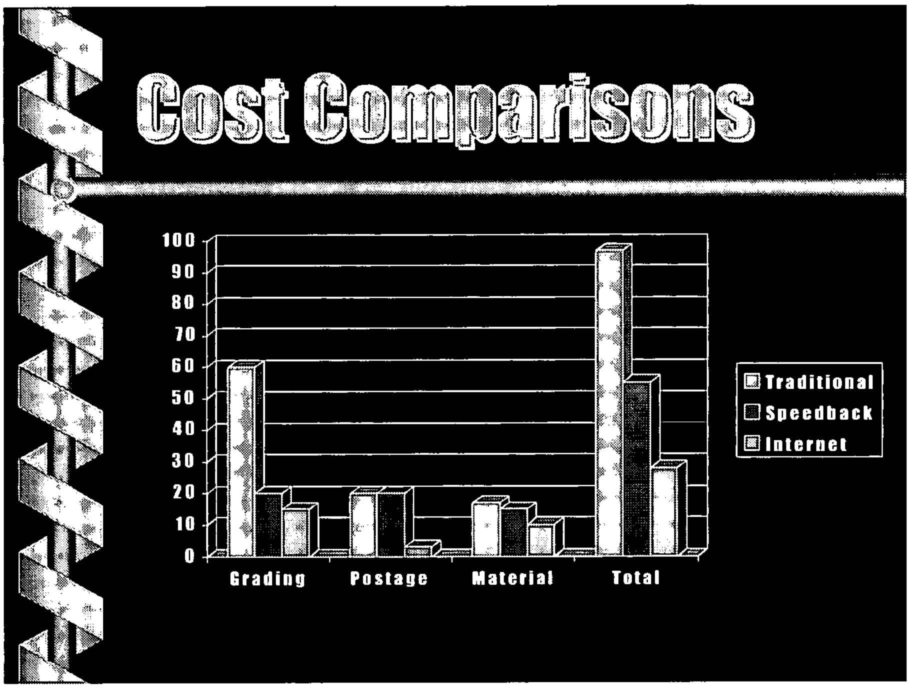
Some features of face-to-face learning (synchronous) are not currently available with technology. The attitude of many faculty is that this weakness makes distance delivery of courses unacceptable. However, face-to-face instruction, however strong it may be, is not necessarily a reality even in the classroom. Consider large classes where individuals never have access to the teacher. Also consider shy or less-aggressive students who seldom get interaction even in small classes. While lack of synchronous interaction may be perceived as a weakness, research has for years shown that distance education is not significantly less effective than on-campus classroom education. Thomas L. Russell compiled 248 research reports, summaries, and papers dating from 1928 to 1996 into a meta-analysis which he called the "No Significant Difference" phenomenon (http://teleeducation.nb.ca/nosignificantdifference/). Michael P. Lambert, executive director of Distance Education and Training Council, in Washington, D.C. (1999) said, "It is clear that distance education is here to stay. . . . Within the next three years, I predict that 3 out of 4 institutions of any significant size will be offering distance education courses." However, Lambert is well aware that "the faculty is the single biggest asset of any university and is at the same time the single biggest stumbling block to the rapid adoption of distance learning techniques on a massive scale." Lambert says that, "some faculties fear distance learning, seeing it as a threat to their jobs, to academic freedom and to sound learning." But Lambert predicts that "over time, most faculty will learn to love distance learning and come to see it as a personally liberating and empowering force, where they will become tutors and facilitators."

The TIIC system was designed to accommodate learning "anywhere, anytime." Its weaknesses are the weaknesses of current technology. Its strengths are the strengths of current technology. Included in those strengths is the ability to fashion excellent, educationally strong feedback statements to continue the learning process when students submit assignments. This feedback occurs for every student, even if there are 1,000 submissions. Such feedback and attention would be impossible for a single faculty member, or even a team of graders.

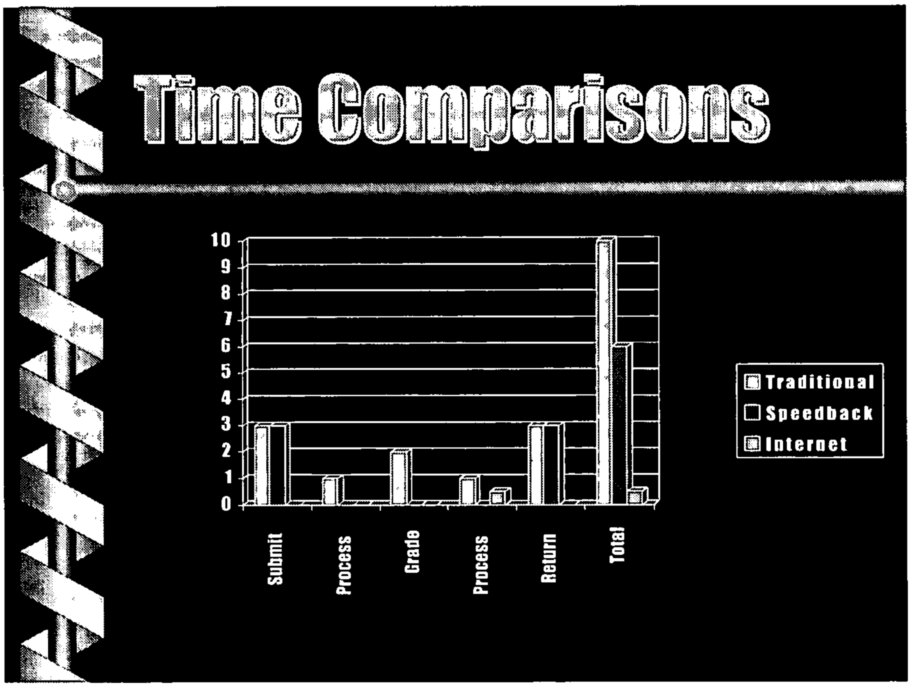
TIIC allows students their own place, their own space, and their own pace. TIIC is not subjective nor bias in its grading. Currently, assignments, quizzes, and tests are well-designed multiple-choice and other objective forms. It is anticipated that essay will soon be added to the system. It is also anticipated that computer adaptive testing (CAT) will soon become a part of the BYU TIIC system.

Management

While TIIC has strong educational and learning features it also has some distribution and management benefits. The system has reduced mail handling by 400,000 pieces per year even as enrollment has increased. Totally integrated Internet courses are easy to update and keep current (unlike printed inventory that must be used before reprinting). TIIC are easily formatted and changed to be attractive and easily navigated. The cost of a TIIC is only slightly more ($3,000 average) than developing traditional home study paper and pencil courses. However, TIIC pay themselves back as much as three times faster. The following graph shows the cost comparisons between three types of courses: traditional paper and pencil, computer-graded and managed paper and pencil (called Speedback), and Internet (TIIC).

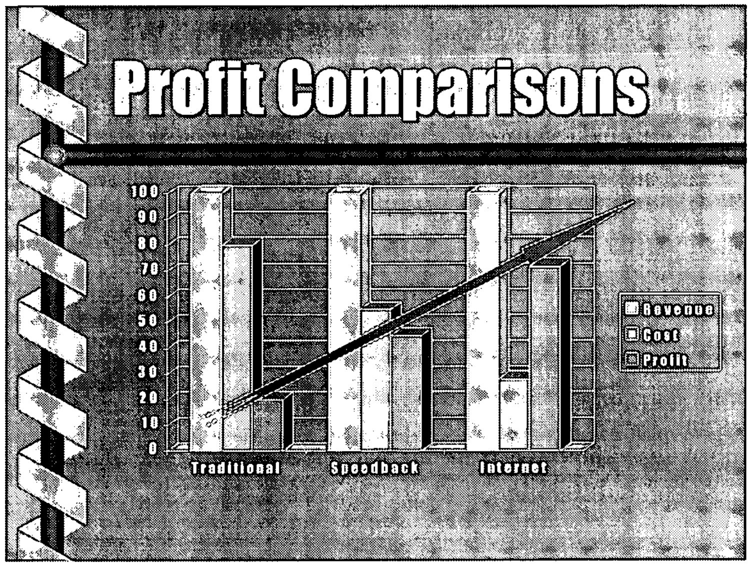


The following graph shows the comparison of time a student must wait to get feedback from an assignment submission or test with traditional, Speedback, and TIIC courses.



BEST COPY AVAILABLE

Finally, the profit comparisons of using the TIIC as compared to traditional or computer-managed courses is presented below. From a management or operational point of view, the difference is absolutely compelling. Because of the potential for education for profit, we see many corporations rushing to the totally integrated Internet courses market.



Conclusions

Distance educational is here to stay. Internet courses are here to stay. Totally integrated Internet courses can provide quality education, handle unlimited enrollments, and be profitable. The TIIC developed at BYU have had strong enrollments and excellent evaluative feedback from students. Although the TIIC has distracters, some of whom are very determined, the model has attributes and features that are very compelling. However, all technology-based instruction, such as TIIC, must maintain quality education as the foundation principal. At BYU, TIIC are built upon a foundation of instructional design principles, not media design principles.

Multimedia Training and Remote Operating Laboratory: New Solutions for Electronic Measurements Courses

Nicoletta Sala
Academy of Architecture of Mendrisio
University of Italian Switzerland
Largo Bernasconi
CH 6850 Mendrisio - Switzerland
nsala @ arch.unisi.ch

Abstract: This paper describes an activity developed at the Department of Electronic (Dipartimento di Elettronica) - Politecnico of Torino in the field of computer based training in electronic instrumentation and measurements, where the author was a supervisor for educational process. Several modules have been developed, using multimedia technologies, to assist the students to acquire the fundamentals of the basic instrumentation. A client-server system has been designed in order to allow the students to operate on a remote laboratory for experimental training. The courseware includes lessons, exercises, and a training on virtual instruments which emulate actual instruments. The students can also carry out several real laboratory experiments without actually being in the laboratory, by using a client-server structure based on the Internet. The students have shown a favourable acceptance and have satisfactorily used the new tools. Demos of both the theoretical and practical part of the courses are available through the Internet.

Introduction

Education in fields such as electronic measurement requires students to gain a reasonable skill in using various kinds of instrumentation (Pisani et al. 1995). Such a skill cannot be achieved by theoretical lessons only, an intensive laboratory activity is also always required. This problem exists both for the first level and for qualifying courses (Sala 1999).

Basic instrumentation teaching is required for first level courses that are followed by a large number of students.

The cost of basic level instruments is often low, but large classrooms means large workbench availability and a massive and qualified assistance that is not easily found.

Qualifying courses are followed by few students so that the assistance problem is reduced, but the instrument cost in such a case is often rather high, thus preventing the possibility of arranging more than a few workbenches.

Some years ago the Department of Electronics, of Politecnico of Torino, was involved in activating traditional degree and diploma courses in several educational structures, throughout the Piedmont region. At that time requirements stemming from a large demand for education on experimental subjects and laboratory training had to be met with limited human and financial resources.

While trying to find a solution, it was realised that most of the time the students spent in the laboratories, especially for first level courses, was devoted to learning the operating functions and the use of the same basic instruments. It was therefore decided to invest time and resources to develop an alternative solution to the laboratory replication by using the new technologies offered by computer based multimedia courseware.

The goal was to allow the students to carry out a pre-training activity outside the laboratory and possibly at home; each student could thus individually adequate the learning rate to his own capabilities. After this pre-training phase, students who enter the laboratory require reduced assistance and less time to complete the training activity.

About six years ago several tutorial modules were developed that were organized like lectures, each being on a particular subject. Each module contains theoretical and functional concepts of a basic electronic instrument and allows for a simulated instrument exercising by providing a series of instrument simulators. By means of the realistic control panel of the virtual instrument the students practice under several operating conditions and situations. The pre-training problem is now becoming more important since the Department is getting involved in an education experiment named "Nettuno", in which the lectures are broadcast on TV or distributed on videocassettes, but students are still required to attend laboratories to achieve practical experience under the guidance of an instructor.

New modules were developed to tackle both the demand of laboratories distributed throughout the territory and requirements of the distance learning courses.

In addition, it was decided to explore the possibility of making a real instrument laboratory available for use at home. This work is devoted to reorganise our traditional educational approach, based on lectures and successive laboratory practice, using multimedia tools which combine two different learning phases:

- theoretical
- practice

in a single tutorial stage self-managed by the student.

Considerations

The actual curriculum of the engineering school include courses where the first practice electronic laboratory came before the first lecturers in which the students learn the theoretical and functional aspects of the instrumentation which deeper knowledge comes in a successive phase respect to the actual student requirements (Brofferio 1998).

It seemed to be necessary to provide the first course students by multimedia tools which allow them to use basic instrumentation in simple physics and first electronic circuit laboratories.

If these tools are organized with different study in depth it is possible to satisfy different needs of different kind of students (undergraduate school level or university education). On the basis of the previous consideration we have designed several didactic modules with the following purposes:

- to expose students to a comprehensive range of electronic instruments and basic measurements techniques;
- to allow students to give practice on the particular instrument whose front panel is simulated on the monitor and the behaviour is emulated by computer.

The learning phase can be managed by students (e.g., as homework) without involving the laboratory structures (Pisani et al. 1995; Sala 1999).

Course description

This multimedia course is structured on a set of lessons (modules) each containing a particular topic or instrument in form of a self – contained multimedia presentation.

Users may reference to selected parts of other lessons through hyperlinks, inserted in the text as hot words, mouse sensitive area and so on.

Differently from the other multimedia applications (e.g., traditional CD-ROM) our case is oriented to defined objectives of knowledge and it is based on a student model with a defined knowledge background, so it was decided to guide the students through a path, based on a structured didactic methodology, to reach the proposed educational goal (Bloom's taxonomy) (Pisani et al. 1995; Sala 1998).

For example a student of a first electric circuits course should be learn the oscilloscope or meter behaviour and should be able to handle them, while the post-graduate student should be interest more deeply to the internal circuitry and use these instruments in more sophisticated applications also involving uncertainty evaluation and so on (Pisani et al. 1995). Each module is divided into subjects (pages) at the same hierarchical level; each level contains a subset of other pages, placed at a lower levels.

Hyperlinks among pages have been studied to give continuity to learning trail (Sala 1999).

During software development, we put a particular care to make "friendly" the user interface (Sala 1997; Sala 1999) by designing:

- icons, with shape and image recall the linking function (e.g., an open door recalls the function to go out from the application);
- text-frame, giving brief information;
- hot words, which open one a few panel of explanations;
- a map, always available in the pages, which performs the "here we are" function and makes easy the navigating from page to page (the navigation inside a hypertext is important) (Calvi 1997);
- visual interface, which involves the choice of colours, background, bottom shape, type of font and so forth (Sala 1998).

Different media are involved e.g.:

- animation techniques, which are an efficient learning tool, when the teaching of a subjects would be difficult by a written description alone (e. g., the electron beam generation and control into a cathode ray tube);
- digitalized television camera images (e. g., to zoom an instrument inside);
- audio supports to stress some topic in a lesson (Figure 1).

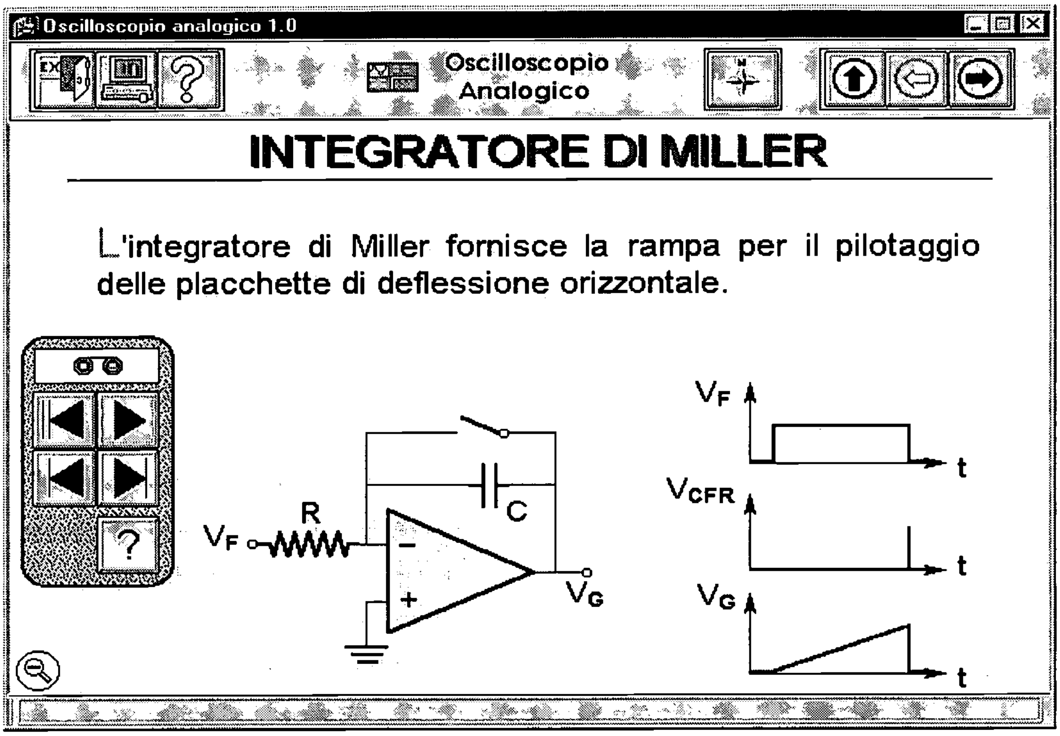

Figure 1 A page dedicated to the analog oscilloscope

Virtual instruments are implemented in the multimedia packages in order to allow simple simulations of the real instruments during the self-training phase. For example when learning the oscilloscope, the student has a virtual instrument panel available, where he can try to select the input signals and can evaluate the effects of the instrument setting on the display (Figure 2).

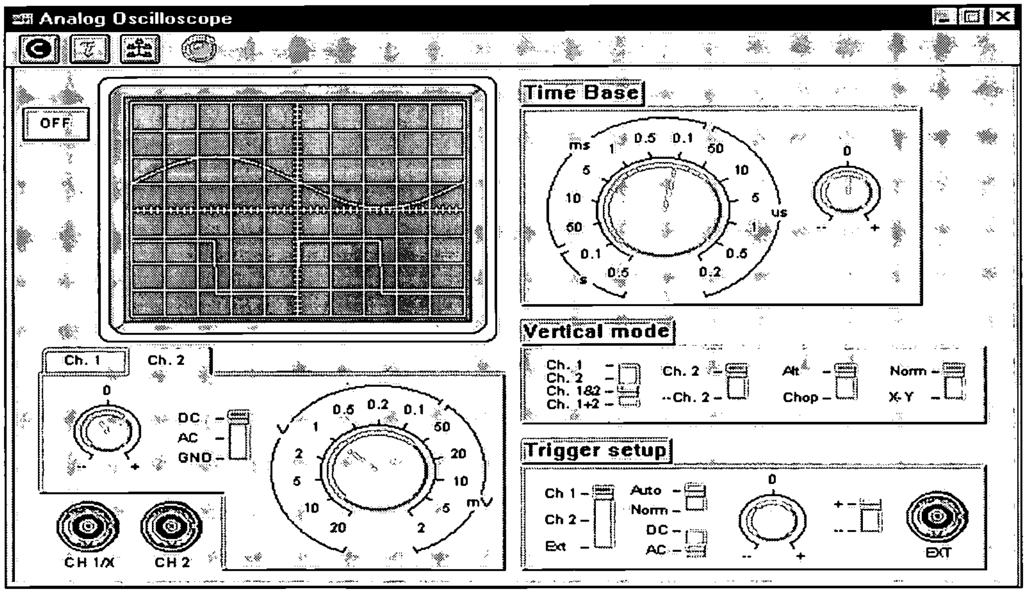

Figure 2 The virtual panel of the analog oscilloscope

Each lecture includes several tests to verify the level of the acquired knowledge on the educational objectives and lesson subjects.
The test results are stored into a database file, which can be processed by an external DBMS (Data Base Management System) program with the possibility to extract statistical indicators on the class by DBMS query.
Examinations include:

- puzzle, where students must rebuild an instrument block diagram (e.g., oscilloscope or electronic instrument) or measurement procedures.
- laboratory quizzes by multiple choices;
- simple projects, which could require few data processing. In all exercises, the data are randomly selected to always generate new projects entry points;

The students can adapt the learning rate to their time availability and cultural background. They can study the theory and then self-verify their knowledge level by solving practical exercises and answering a series of questions. The student only need an inexpensive personal computer with a multimedia extension, that is available in centralized structures of the university or possibly at home.
At present, several modules, concerning the basic laboratory instrumentation have been developed using Toolbook$^{(TM)}$, with the aid of several thesis student.
The subjects are:

- fundamentals of the analog oscilloscope, which includes practical exercises performed on a virtual instrument that emulates the main operating functions;
- fundamentals of the analog and digital voltmeters and their operating theory;
- the IEEE488 standard interface for programmable instrumentation.

Experimental training using hypermedia facilities

The courseware typology explained in the previous section well suits both traditional and innovative courses; however a further step is necessary in order to completely adapt it to the requirements of courses with an intensive experimental activity. Instrument behaviour knowledge is only one of the know-how that are required to carry out a measurement: performing a measurement is not so easy as it requires one to define measurement procedures, to use and correctly connect different instruments, and finally to process the experimental data.
This knowledge stock is traditionally achieved by performing practical activities in different subjects. Unfortunately, such an approach, which requires intensive laboratory attendance, cannot be followed in distance learning courses: a further step is necessary to break the time/distance constraint.
A possible solution could be attained by taking advantage of modern instrumentation, which is equipped with a standard computer interface and is remotely programmable
The idea is to design a laboratory that is simultaneously and remotely accessible to several students, who concurrently share the same instrumentation, but not necessarily the same experiment. The instrumentation and the other hardware resources are accessible in a sort of time sharing process, which is managed by a server and transparent to the user.
The virtual laboratory architecture is composed of two kinds of subsystems: the measurement Server and the measurement clients. In detail:

- The measurement Server is a computer located in the laboratory and directly connected to the programmable instrumentation. The Server program, that runs on the measurement Server accepts measurement requests from several clients, dispatches the commands to the instruments and sends the responses back to the clients.
- The measurement clients are computers running a program that enables the students to manage the experiments via suitable virtual panels and is able to contact the Server and display the measurement results.

Many solutions, based on proprietary or standard protocols, can be designed to obtain the connection between clients and the Server. The standard protocols that are based on the TCP/IP protocol suite using the highest possible protocol layer. Such a choice restricts the connection flexibility, but makes the developed system easily portable to different platforms and greatly simplifies the program development.
The connection among clients and Server is therefore established at the session level by employing the session and transport services which are provided by the computer operating systems: in the Windows environment the session level that is used is the Dynamic Data Exchange (DDE) used with the TCP transport (Figure 3).
In addition, to simplify further the development of the different experiments, an application layer program has been designed to handle the client-server communication. Such a program, which is called Measurement Server Access Facility (MSAF), is composed of a Server and a client part. The Server part, which runs on the

measurement Server, implements the queuing process on the incoming requests and keeps track of the different instrument configurations, that are required by the clients. The client part, which runs on each client, contains procedures to find out the Server, to establish the connection, to post the measurement request and to inform the client program about the expected delay before the measurement is actually performed.
By using the services provided by the MSAF, the experiment designer is only requested to deal with the measurement problem without being bothered by the underlining communication process.
The instruments are connected to the Server via an IEEE488.2 bus while the device under test is managed by a driving device which configures the experiment set-up using a series of switches.

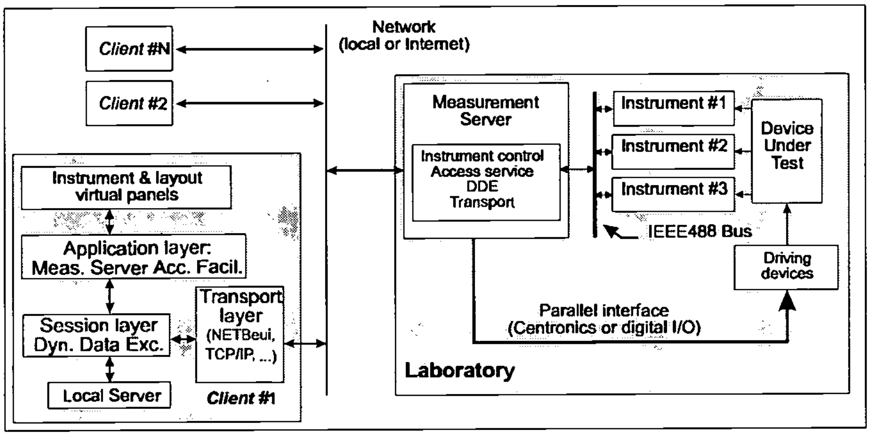

Figure 3 Client Server layout.

The driving device uses a multiplexed address/data scheme that allows a theoretical maximum of 65k switches to be used. The maximum number of concurrent experiments obviously depends on their complexity and layout and on the number of switches that are actually employed.
The experiment-specific part of the Measurement Server is restricted to a parser section which interprets the client requests and dispatches them to the instruments in a proper format. The experiment-specific part of the client is restricted to a virtual panel containing the instrument controls and switch set-up.
The Local Server is a program that runs on the client computer, and which allows a simulated version of the experiment to be carried out in the absence of a network connection between the client computer and the measurement Server. Such a simulation can be used for a "pre-training" on the program to reduce the network traffic.
All the software has been developed in the Visual Basic (TM) environment with the exception of a minor part written in Microsoft C++(TM). The software is released with a set up program that install all the required components in the client computer.
This architecture is capable of servicing about twenty clients within ten seconds which is quite a reasonable waiting time and is suitable for many different experiments. Up to now several experiments regarding both the use of fundamental instruments (oscilloscopes, DMM, ,...) and the basic measurement techniques (for example for measuring resistance, power, ..) have been designed.

Experimental results

About one hundred students (selected courses both in the "Nettuno" project) are involved in the experiment and the first response has been positive. A the moment using these facilities and in conventional degree courses
The testers were got used to the new teaching facility quickly and with great interest. In a short time they have been able to discover minor problems and inconsistencies in the proposed material and suggest valuable remedies. This feedback is quite useful both for teachers and students and allows a continuous quality improvement.
The effectiveness of the learning process of the course cannot yet be stated, since these innovations were only introduced last year, nevertheless the students' marks in the first tests show a positive trend.

Conclusions

Whether it is accepted or not, a fundamental shift is occurring in education as a result of increasing use of computers. Strange (1995) calls the shift as a cultural revolution in teaching and learning. The profound changes in the dissemination of information, the reorganization of information to include multimedia, and the implications of what it is to be a teacher in an era where teaching and learning increasingly means listening and watching as well as reading and writing have not been absorbed. The extent of the changes due to this cultural revolution vary depending on the district, school, and teacher (Rath, Rieck, and Wadsworth 1998).
The use of multimedia solutions in degree level courses has proved to be effective in several different fields. Courseware with important laboratory activities can also be tackled by adding an experimental section to the conventional theoretical approach.
Technical teachers can use these multimedia solutions to train new electronic instrumentation (Sala 1997). Integrating technology into teacher training programs is important because it appears that through the use of technology, teachers change the way they present instruction (Stuhlmann 1998).
Becker (1992) reported that teachers who had more experience with computers were more inclined to integrate the curriculum across subject areas and use computers as a tool for learning (Stuhlmann 1998).
The solution designed by the author for electronic measurement courses is an example of an integrated solution in which the theoretical part is made available through a hypermedia and the laboratory part can be carried out by accessing real instruments through a network connection.
Other modules are in aim to be developed concerning the impedance meters, the spectrum analyser and so on.

Reading and Listening: Issues in the Use of Displayed Text and Recorded Speech in Educational Multimedia

Andy Reilly
Media Development Division
The Open University
United Kingdom
a.a.reilly@open.ac.uk

Note: This paper is based in part on work carried out by the author at Middlesex University, London, U.K.

Abstract: A tempting solution to the problem of too much text on screen is to present some of it via a spoken commentary. Questions then arise as to what is the best balance between displayed and spoken text, what pedagogic implications accompany the use of speech, how does spoken text differ from written text, and whether different types of user prefer information in different media. This study addresses these questions on the basis of tests carried out on an interactive project, and a review of the literature of educational technology. It shows that users express a clear preference for a mix of media, and students complete study tasks more quickly when information is available in sound and text. There is some evidence that preferences for one medium over another can be correlated to educational background and to sex. The potential value of further research in these areas is indicated.

Introduction

Research on the effectiveness of different media within multimedia learning materials has produced no firm evidence on the question of whether speech or text is more effective pedagogically, but users show a clear preference for a combination of text and speech (Alessi, 1991; Barron and Atkins, 1993; Shih and Alessi, 1996). This preference was shared by the volunteers who tested the project prepared as part of this study (Reilly *et al.*, 1997).

There is evidence to show that reading large amounts of continuous text from computer screens is tiresome (Dillon *et al.*, 1988; Gould *et al.*, 1987; Gould and Grischkowsky, 1984), and that tasks linked to reading are performed less efficiently when the text is on screen (O'Hara and Sellen, 1997). Open University students who were required to use a CD-ROM-based library of articles as part of a course in information technology reported a reluctance to read text from screen (Jones *et al.*, 1998). These findings might lead one to suppose that the use of recorded speech to reduce the density of screen text would be welcomed by students, but the evidence from software trials is not clear cut

As interactive media tools become more widely used in teaching there is a need to clarify their value as learning materials, and to determine guidelines for good practice in their design. This study suggests rules of thumb for the appropriate use of recorded speech and displayed text in educational multimedia.

The Renewable Energy Project

In 1998 I was part of a team of four researchers who produced an example of interactive learning material based on an Open University undergraduate course on Renewable Energy (Reilly *et al.*, 1998). Part of the project presented information in a mixture of screen text and audio voiceover. The project was tested in two phases by a total of eighteen subjects.

Educational Techniques and Technologies

The designers of educational multimedia attempt to create products that adopt a student-centred approach to learning. Like the face-to-face tutorial, teaching and learning tools should be adaptive, create a discourse between teacher and learner, encourage reflection, be interactive and enable the student to communicate their conception of what they have learned.

Where these characteristics are present, the teacher, the student and the media of instruction together form a 'conversational framework', which 'serves both to clarify the second-order character of academic learning, and to define its essential components' (Laurillard, 1993, p. 102). This conversational framework allows the student to reflect upon the subject taught, and convey to the teacher his or her understanding. The teacher can adapt the teaching approach in the light of the student's description of their understanding, and the student can amend their conception in the light of the teacher's response. In this way a discourse is established through which the process of learning moves forward.

No artificial presentation can entirely substitute for a one-to-one tutorial dialogue between a teacher and student. But the opportunity to use recorded speech in the context of an interactive presentation can bring something of the quality of real dialogue to a piece of tutorial software.

Our project testing, and the results of research cited in the next section, show that users respond favourably to teaching software that includes recorded speech.

Relative Advantages of Text and Speech

Alessi (1991), writing in the context of the instructional use of interactive video, has proposed a number categories for classifying the relative advantages of text and speech, including: (a) realism, (b) dual modality, (c) learner controllability, and (d) learner characteristics.

Realism

Realism risks overloading students with excessive detail. However, "The use of human voice in the delivery of instruction appears to be a case where increased fidelity does not correspond to increased detail." (Shih and Alessi, 1996: p. 206)

Dual Modality

Do two channels of instruction, textual and auditory, produce a better learning outcome than one channel alone?

Barron and Atkins observe that students with higher verbal skills do not gain significantly from the addition of audio, but that students with lower literacy skills may register better performance with additional audio.

Where both auditory and visual media are used in an instructional product there is some evidence to suggest how they can be synchronised to best effect. Baggett (1984) conducted a series of tests in which students were asked to study the components of an assembly kit. The parts were shown using a videotape sequence, but they were only named in an audio voiceover. Several presentations were made to several different sets of students. Some heard the commentary slightly ahead of the visual information, some saw both video and audio synchronously, and some saw presentations in which the audio lagged behind the video by up to 21 seconds.

The results showed that when the audio preceded the video information much of the audio commentary was forgotten. The best recall was registered by the groups who experienced both audio and video simultaneously or with a 7 second delay. Delays greater than 7 seconds led to success rates 80% worse than the best scores.

Controllability

A weakness of audio instruction is that it is transient. Romiszowski (1988) reports on research carried out at the BBC that showed that only 28% of the content of a five-minute radio programme was retained by the average listener. University graduates took in 48%, while recent school leavers retained only 21%. One of the advantages of text is that it can be rehearsed. Text can also be read at the reader's ideal pace.

For audio instruction to be similarly useable it must be controllable, at least to the extent that users can listen to short sections at a time, and pause and replay them at will. This was borne out by the testing we carried out on our project (Reilly *et al.*, 1997). Our test subjects criticised our first prototype because the audio sequences were too long, and could only be replayed from the beginning. In the second version the sound files were segmented, and each segment could be selected and played separately.

Learner Characteristics

As noted above, variations in literacy skills will have an effect on the suitability of sound or text as the medium of instruction. Other learner characteristics may also play a part in the way in which media are perceived by users. The results of our project testing (Reilly *et al.*, 1997) showed a difference between men and women in the acceptability of spoken commentary.

Our study also suggested that educational background may have an influence on how different media are perceived by users. Of eighteen subjects who worked through our project over the course of two rounds of testing, four were graduates, one was an undergraduate and thirteen were non-graduates. Two of the graduates and the undergraduate expressed a preference for reading over listening to a spoken commentary. All the rest reported that they found the combination of text and commentary helpful. Age variations may also play a part in how different media are accepted and used.

Balancing the Pros and Cons

This analysis suggests that a choice can be made on the basis of the nature of the content, the literacy skills of the target users, and the constraints imposed by the requirements of production and updating. A simple rule of thumb emerges: the more abstract the content and the more literate the users, the more text one would use; the more concrete the content and the less literate the users, the more speech one would use

Design considerations based on these characteristics alone are insufficient. Before this rule of thumb can be used with any confidence it is necessary to examine evidence for its applicability.

Effects on Learning

When Shih and Alessi (1996) offered a group of test subjects a choice of text only, voice only, and a combination of text and voice, 82% showed a strong preference for the combination of text and voice.

Their results are consistent with those of Barron and Atkins (1993) who found no statistical difference in achievement between a text-based tutorial program and a combined audio/text program, although the combined presentation was completed by subjects significantly more quickly.

This observation, that a combination of media leads to a quicker assimilation of information, bears out the results of a number of studies cited by Bagui (1998). Kulik, Bangert and Williams (1983) recorded a substantial cut in study time for a group of secondary school students who followed a computer-based instruction session, compared to another group who were taught the same content in a conventional classroom lesson.

User Preferences

The results of the studies referred to above were more clear cut in showing the preferences of users for types of presentation. When my colleagues and I tested our project (Reilly *et al.* 1997) we found a similar marked preference for combined speech and sound. Our project design included a series of audio/text screen sequences in which a spoken commentary was summarised by bullet points that appeared sequentially on screen. In some sequences the bullet points were verbatim quotes from the commentary. In others they were paraphrases. In all cases the displayed summary appeared on screen slightly ahead of the corresponding commentary. None of the test subjects commented on the difference between the verbatim summaries and the paraphrased ones. This difference either went unnoticed, or was not considered significant.

The sequence of text first, commentary following but overlapping was noticed. Half the subjects suggested that separating the text and speech would be better that having the audio running while the text was being read. "I would prefer the audio sound to come either before or after the bullet points rather than together as I found it distracting." (Quote from test subject (Reilly *et al.*, 1997: p. 3).)

Dual modality in this context was not seen to be helpful. The subjects clearly preferred to experience a single channel of communication.

Most of this group said they would prefer to read the summary before they heard the commentary - although one subject suggested the opposite approach.

Other potential variables that deserve further study include whether personality type, sex or age affect the acceptance of different media types. The test subject who said he would prefer text only commented that he wanted greater control over the pacing of the presentation.

Control was a key element in all the test subjects' responses. The spoken commentary, while generally well received, was perceived to be difficult to select and rehearse. These difficulties are not intrinsic to an audio presentation, but were a consequence of the way in which we designed our use of audio. In our revisions of the project we addressed this issue by dividing the audio files into smaller chunks and allowing them to be individually selected, played, paused and replayed.

The Combination of Text and Speech: the Value of Redundancy

The clear preference expressed by users in all the studies cited for a combination of text and speech suggests the question: 'What merit is there in presenting the same information in two forms?' Donald Norman (1993) lists some advantages for redundant visual information. He describes the case of a business presentation where it is not uncommon for the speaker to use slides that provide no new information, but which essentially repeat what is being said. These slides offer the audience a shared workspace; they afford co-operative work; they represent a permanent memory; they increase available memory; they aid perceptual processing; and they offer an alternative channel of communication for those people who prefer auditory information.

Multimedia presentations extend these advantages. Here time is under the control of the users, not the lecturer. Control is also in the hands of the user if they are able to reselect and replay information. Perceptual processing is afforded not only by the spatial arrangement of ideas on a single screen, but also by the accessibility of other screens. Individual differences can be catered for, not only in offering choices between spoken and displayed text, but also by offering information in other media such as video or animations. The wider the choice of media types, the more a wide range of users will feel accommodated by the presentation.

Greater redundancy provides the opportunity for users to tailor a presentation to their tastes. But the danger of excessive redundancy is that users may feel uncomfortable because they do not have a feel for how much content they should access to gain an adequate understanding. The initial reaction of many students to an Open University CD-ROM that contained a library of reference material was to try to read as much of the content as possible in case they inadvertently missed some important detail (Jones *et al.*, 1998). Only when they had become skilled in carrying out focused searches of the material were they reassured about how much material it was necessary to view.

Successful use of interactive material in which there is a significant degree of redundancy depends upon users acquiring the skills, and the tools, to be selective and to evaluate the relevance of the content they retrieve.

Spoken and Written English

An important aspect of the design of a multimedia product that uses both spoken and displayed text is a recognition of the differences between spoken and written English. The two forms of language are distinct. Written English conforms to rules of style and syntax which do not apply to spoken English. When a speaker uses the style of written English he appears either to be reading or reciting a document, or else he comes across to his listeners as stilted and excessively formal. These characteristics are often interpreted as insincerity (Jay and Jay, 1996).

When a reader reads a text, they can pause over aspects that are not immediately clear. When listening this is more difficult. Although it is possible to provide users with the option to pause an audio sequence, if your user has to pause frequently they will find your product tiresome to use. There are certain key features of well prepared spoken English that help to avoid the need to pause.

Abstract nouns should be avoided. These can cause listeners to struggle with the speaker's meaning.

Spoken English should use short words and sentences, and should avoid abbreviations, lots of numbers, and unfamiliar names (Garrand, 1997). Numbers are particularly difficult to absorb and remember from speech.

The active rather than the passive voice should be used. For example, 'Solar energy provides ten per cent of Greece's winter heating', is better than 'Ten per cent of Greece's winter heating is provided by solar energy.'

Specialist terminology should only be used for specialist audiences, or when its use is specifically explained.

Word and phrase order are important. Whereas the rules of written style suggest that one should avoid placing parenthetical phrases after the main verb, this style is difficult for listeners to follow. Similarly, with a document readers can jump ahead to see how much they still have to read. Headings and paragraphs can provide signposting and orientation. With spoken English it is necessary to build in signposting phrases, such as "Well, that's the basic question, so now we'll take a more detailed look at viable options." (Jay and Jay, 1996: p. 50).

Conclusions

The desire to create a conversational framework or dialogue within which to situate learning has implications for the design of learning tools. Interactivity helps to create this framework, and the use of speech in addition to text adds an element of realism to the media mix.

This dual modality of verbal and textual communication presents advantages in giving learners an aid to processing and remembering information. It offers users choice, and an element of control over the type of learning medium and the pace of study. Combining speech and displayed text is welcomed by users and encourages efficient study.

In examining learning outcomes it will be necessary to classify users by level of literacy, previous educational attainment, age and sex. The evidence from our project testing suggests that the way in which information in different media is received may depend to some extent on these variables. The issue may be complicated by age. Sex also seems to be a factor, with men being less receptive to a spoken commentary than women.

If such differences prove to be significant, the value of media redundancy will become clearer. Redundancy provides the opportunity for users to tailor a presentation to their tastes, and enables a piece of software to cater for a range of users.

Our study also revealed that to be acceptable a spoken commentary must be controllable. It should be available in short discrete parts, each of which can be paused and replayed, and each of which can be selected and played individually (although they may need to run in a particular sequence when first heard).

While media redundancy is welcomed by users, media overlap can be confusing. Users should be given the opportunity to read and listen separately, and not be forced by the design to do both at the same time.

In scripting passages of recorded speech, the scriptwriter must be aware of the difference between spoken and written language. Spoken language follows different rules of syntax from those of written language, and while vocabulary need not differ, the excessive use of specialised vocabulary in speech runs the risk of confusing listeners, even when they are familiar with it.

Further empirical studies and more widespread experience in the use of multimedia in higher education will improve the base of evidence on which future design strategies can be founded. In the meantime, the study described here and the evidence available from the literature suggest that presenting information in complementary media, with careful thought given to the balance, synchronisation, overlap and redundancy of media forms, will assist learners in shaping their own learning strategies and give them greater control over their learning.

Incorporating the Internet in the Classroom

By John F. Bennett Marketing Professor, Stephens College, Columbia, MO. USA

Introduction

Much attention has been devoted in recent years to the development of Internet courses that are targeted to distance learning students. This follows the movement towards the establishment of virtual campuses by many business schools including such prestigious institutions as Duke, which recently graduated its first class in its Global EMBA program, and MIT, which offered its first credit course in accounting over the World Wide Web in fall 1997. While this trend will continue to grow the fact remains that the majority of business courses continue to be offered in a traditional classroom setting. However, while most business courses are being offered in a traditional classroom, they are certainly not being offered in a conventional manner as more business schools have exhorted their faculty to incorporate Internet technologies in their courses. Unfortunately, those faculty desiring or being exhorted to move toward technology-mediated instruction are not always given sufficient guidance on how this should be done. Consequently, many respond by either disdaining technology and holding steadfastly to the status quo or, worse, using a haphazard approach in incorporating technology in their teaching without any real understanding of its pedagogical value. The purpose of this paper is to provide direction to those of want to improve the quality of their on-campus courses by incorporating Internet technology in their teaching.

Rationale for Using Internet Technologies in the Classroom

While there are several Internet technologies that can be used to support instruction, the ones that seem to be generating the greatest interest among educators are email, electronic discussion groups and the World Wide Web. This is hardly surprising when one considers the many benefits these tools offer the classroom teacher. One such benefit is improved communication. Electronic discussion groups, for example, can serve to enhance and extend interactions between students and between students and their instructors (Karayan and Crowe, 1997). Students in a class can share an insight or opinion at any time of day or night rather than having to wait until the next class meeting. It also provides a means of participation for those students who are reluctant to participate in traditional class discussions (Partee, 1996). It is often easier for these students to discuss values and personal concerns in writing than orally, since inadvertent or ambiguous nonverbal signals are not so dominant (Chickering and Ehrmann, 1996). More vocal or impetuous students can also benefit from the increased reflection necessitated by putting thoughts into words for an on-line discussion.

Using email and electronic discussion groups also facilitate such activities as study groups, collaborative learning, group problem solving and discussion of assignments. Students no longer have to worry about finding time on their often busy schedules to have a face to face meeting with their peers. Increasing opportunities for students to work together increases their involvement in learning. As Chickering and Ehrman (1996) note, being able to work collaboratively with one's peers improves thinking and deepens understanding. It also allows students a more real-world experience that contributes to an enhanced educational setting (Hunter, 1990).

Use of these Internet tools can also encourage active learning. Very little learning occurs when students simply listen to a teacher and memorize a set of lecture notes. They must talk about what they are learning, write reflectively about it, relate it to some past experience, and apply it to their daily lives (Chickering and Ehrmann, 1996). In other words, they must become active as opposed to passive learners. If structured into a class in a purposeful, pedagogically-sound manner, listservs can improve learning (Everett and Ahern, 1994). This is supported in one study that found that slightly more that 40% of students indicated that their learning had either increased or increased a lot from using e-mail (Sandell, Stewart, and Stewart, 1996).

Requiring students to communicate via e-mail has been found to improve their ability to write coherently (Kàrayan and Crowe, 1997). In the process of contributing to the on-line discussion, students are using a mode of expression that is a form of writing: composing their ideas at the keyboard, editing their comments, and then "publishing" their comments to the list. The list subscribers then provide feedback, commenting on the quality of the message, objecting to the ideas expressed, asking for clarification, and so on. This public nature of the writing and public exchange of ideas causes students to take their work more seriously. They make a greater effort to ensure that their messages are clearly conveyed and that their claims are adequately substantiated. They also begin to take pride in writing well, especially when others commend them on what they have written. By participating in an public e-mail forum, students learn how to think through ideas, how to anticipate and respond to objections, and how to express themselves with clarity and power all of which improves the quality of the responses to the discussion (Karayan and Crowe, 1997).

Expanding the boundaries of the classroom to include individuals and noted scholars from other parts of the world is made possible through the use of email and electronic discussion groups. This adds an intercultural dimension to a class that might otherwise not be there and expands the diversity of thought being shared in class discussions (Bailey, 1994).

Use of these Internet technologies also makes it easier to appeal to a greater number of learning styles. Visual learners, for example, can access explanatory diagrams or animations to enhance meaning, more active or inquisitive learners can "read around" their subject by means of hypertext links and so on. In addition, the different representations of information (sound, text, video, graphics, etc.) made possible through Web technology, greatly increase the richness and appeal of the learning environment. They present the learner with a much broader coverage of material and more ways to encode and remember that information.. One study conducted by the Center for Innovations in Engineering Education at Vanderbilt University, found that learners using an electronic laboratory simulator on their own time in lieu of physical labs were able to solve problems on physical equipment as fast or faster than those who took physical labs. In addition, the written lab tests were found to be equivalent between the two groups (Campbell, 1998).

Applying Internet Technologies in the Classroom

While the decision about whether or not to use Internet technology in the classroom can be difficult, it is much easier than trying to decide on the specific Internet technologies to use and how they should be applied in the classroom. This is due to the fact that teachers do not all subscribe to the same teaching philosophy or style. Rather, each brings to the classroom his/her own unique teaching style that calls for a specific set of instructional methods and technologies - including Internet technologies - that would not be appropriate for any other teaching style. Therefore, the Internet technologies and applications cited in this paper are meant only to provide the reader with a greater appreciation and understanding of the pedagogical value of the Internet. Whether any of these technologies or their applications would be appropriate for the reader to use would, again, depend on his/her preferred teaching style.

In the remainder of this paper, I will discuss the Internet technologies I currently use in my undergraduate marketing courses, how these technologies are being applied, and the effectiveness of these technologies in enhancing the quality of my courses.

When I became convinced that the Internet had the potential to enhance the quality of my marketing courses and began to incorporate it in my teaching, I was immediately faced with a dilemma: which Internet technologies do I use? There are many different technologies that can be applied in the classroom which is both an advantage and a disadvantage. It is an advantage because it gives the instructor many options to choose from. Everything from email to chat rooms to video conferencing over the Web. However, it is also a disadvantage in that, it makes the task of selecting the most appropriate technologies, especially for someone who has little or no experience using these technologies in the classroom, a most challenging one. To facilitate the task of identifying the most appropriate set of Internet technologies to use in my courses, I applied the following evaluative criteria: 1. does the technology support any of my instructional goals and objectives? , 2. is it technology that I would be comfortable using?, and 3. are there sufficient institutional resources to support the technology? After considering these criteria, I decided to use three Internet technologies in my courses: email, listservs, and the World Wide Web. These were the Internet technologies I was most familiar with and the ones that I believed would best support my instructional goals and objectives. I was also confident that the institution could provide me with the additional resources I would need to utilize these technologies in the classroom.

After identifying the Internet technologies to use in my courses, it was necessary to determine how they should be applied to meet the following instructional objectives: 1. improve communication to, from and among students, 2. facilitate access to course materials, 2. introduce students to the potential of the Internet as an information resource and encourage them to use it as a research tool, 3. increase the interaction between students and marketing practitioners, 4. expand coverage of topical issues in marketing, 5. appeal to a greater variety of learning styles, and 6. facilitate classroom management. The specific strategies used to meet these instructional objectives are detailed in the next section.

Improving Communication

In order to improve communication to, from and among students several strategies were used. During the first week of classes, each student was required to obtain an email account and to subscribe to the class list. This list was used throughout the semester to notify students of scheduling changes, to distribute pertinent news reports from on-line publications, to post a weekly list of learning objectives, and to provide any needed clarification of lecture or reading material. Also, on a weekly basis, the students are required to post to the list responses to questions from assigned readings and to respond to at least two of the postings of their peers. This is meant to augment in-class discussions and provide the students with a communal meeting area where they can share ideas, ask each other questions, seek advice, etc. As noted earlier in this paper, providing students with the opportunity to participate in on-line discussions provides a means of participation for those students who are reluctant to participate in traditional class discussions, promotes active learning and improves students' ability to write coherently.

To encourage students to communicate with each other on-line, a class list with links to students' email addresses was placed on each course's Web site. If a student wanted to send an email message to another student, he/she only had to access the Web page with the class list rather than search for that student's email address. To encourage students to communicate with me on-line, a link to my email address was provided on all on-line documents like the course syllabus, lecture notes, class assignments, and review exams. For those students who wanted to communicate without identifying themselves - most likely to occur when the student has a critical comment to make and fears retribution if anonymity isn't guaranteed - an evaluation form was made available on each course's Web site that could be submitted anonymously.

To Facilitate Access To Course Materials And Introduce Students To The Potential Of The Internet As An Information Resource And Encourage Them To Use It As A Research Tool.

For each course, a Web site was created to facilitate access to all course materials such as the course syllabus, class assignments, review exams, assignment schedule, Powerpoint presentations and lecture notes. To introduce students to the potential of the Internet as an information source and to encourage them to use it as a research tool, links to external resources were provided in many of these Web documents. For example, the lecture notes have links to Web sites containing additional information on topics covered in the notes, the syllabus has links to the on-line publications used in the course such as Business Week, the Wall Street Journal, and Advertising Age, and the class assignments have links to Web sites with information pertinent to the assignments. In addition, a directory of marketing-related Web sites is maintained on each course's Web site as is a directory of Web sites offering guides designed to be helpful to students. These would include guides on writing a research paper, developing a marketing plan, creating an advertising campaign, giving a formal presentation, etc. Also, students are encouraged to seek out Web sites related to the course and post a link to the site on the class list.

To Increase Interaction Between Students And Marketing Practitioners.

In order to help bridge the gap between the classroom and the "real" world, 4 - 6 marketing practitioners with varied types of expertise are invited to participate in on-line discussions with my students. The class submits a list of 5 - 7 questions via email to the marketing practitioner who then posts his/her responses to the class list. The students are then given up to a week to ask the marketing practitioner any follow up questions they may have. The postings of the marketing practitioners are archived and used in future classes.

Expand Coverage Of Topical Issues In Marketing.

To keep the course content focused on topical issues, a summary of marketing news stories from on-line journals, magazines, and newspapers are emailed to the class list on a weekly basis. Students are expected to read these weekly news reports and be prepared to discuss them in class. In addition, on a biweekly basis students are required to participate in an on-line discussion of a current news story related to marketing that has been reported in the Wall Street Journal (which every student is required to read for class). Finally, on each course's Web site, a comprehensive directory of marketing-related Web sites is made available so that students can learn about current events in the different areas of marketing studied in class. To encourage students to use this directory, a summary of the marketing topics discussed at each Web site is provided as is a link to the site. Students who visit these sites and share with the class what they read, can earn extra credit points.

Appeal To A Greater Variety Of Learning Styles

To appeal to the variety of learning styles represented in a typical class, various strategies were used. For visual learners, explanatory diagrams were made available on the course Web site. The diagrams were linked to the topics in the on-line class notes that they were associated with. For inquisitive learners, external links were provided in the on-line class notes and, as noted earlier, a directory of marketing-related Web sites was made available to increase both the range and depth of information available. Finally, the on-line notes were comprehensive (average length was 10 pages) in order to get students, especially auditory learners, to not only pay greater attention to what was being discussed in class but to increase their degree of participation in class discussions.

Facilitate Classroom Management

As noted earlier, all course materials - course syllabus, lecture notes, course assignments, assignment schedule, and review exams - are made available on the course Web site. Besides providing students with greater and immediate access to course materials, this has the added advantage of eliminating the time and expense of making and distributing hard copies. Other time saving measures include the requirement that all homework assignments be submitted electronically so that they can be graded and returned via email, an FAQ section on the course Web site with answers to frequently asked questions about class policies, grading, assignments, etc., and the submission of student progress reports via email.

Student Reactions

Each semester, students in my marketing courses are surveyed to assess their reactions to using the Internet in the classroom. A total of 149 students have been surveyed over a two year time period and asked to comment of the use of electronic discussion group assignments, on-line resources such as lecture notes and review exams, and on-line discussions with marketing practitioners. A summary of the survey results follows.

Electronic Discussion Group Assignments

The students noted several benefits and problems with using electronic discussion group assignments. The most frequently cited problem with using EDG assignments was inconvenient access to computers with Internet connections. Students also indicated that they felt overwhelmed by the number of e-mail messages they were receiving each week. This was particularly true among those students who were on several class lists. Some students noted that there was too little discussion of the pedagogical benefits of electronic discussion groups. Consequently, at the beginning of the semester they failed to understand why in-class discussions were being supplemented with e-mail discussions. It was only after participating in the electronic discussions for a few weeks that the students began to understand their value. Finally, some students lacked experience using e-mail and expressed a fear of this technology. These students noted that their participation in e-mail discussions would have been greater if they had received some remedial assistance with the technology being used.

One benefit mentioned by several of the students was that electronic discussions provided a convenient means of interacting with peers as well as the instructor. They appreciated being able to send and reply to an e-mail message at a time of their choosing. Students also noted that it was easier to collaborate with their peers on group projects. The frustrations caused by trying to arrange convenient meeting times for a group of students to physically meet and work on a project are largely eliminated with electronic discussions groups.

A few of the students commented that they were more comfortable with written rather than oral discourse. They stated that they felt more willing to make provocative assertions during e-mail discussions and to challenge the views of their peers and the instructor. In short, they felt liberated by this new medium.

Some of the students believed that they had a much better understanding of the discussion topics as a result of being required to read and respond to their peers' postings to the list. They appreciated the fact that in electronic discussions they can take more time and reflect longer before responding.

On-Line Resources

Students found the availability of lecture notes, Powerpoint presentations, and review tests on the course Web site to be very beneficial. Many students commented that the on-line notes and Powerpoint presentations allowed them to focus less on note taking and more on participating in class discussions, and improved their comprehension of the lecture/reading material. The placement of links to external resources in the on-line notes was very much appreciated by the students because they made it convenient for them to gather additional information on the concepts being studied.

The on-line review tests were favorably perceived because they provided students an opportunity to conveniently assess their comprehension of the reading/lecture material at any time. The students also indicated that they were encouraged to seek assistance by being provided with several links to the instructor's email address on each on-line review test. Finally, students responded that they found the on-line review tests more helpful than conventional review tests since the questions were linked back to the sections of class notes that they were drawn from. This made it much easier for the students to find detailed explanations for the answers given.

On-Line Guest "Speakers"

The opportunity to engage in on-line discussions with marketing practitioners was favorably perceived by the students. Many of the students indicated that their interest and understanding of the subject matter was greatly enhanced by being able to engage in an on-line discourse with marketers about a wide variety of topics. Students also commented that these on-line discussions gave them a much greater appreciation of the increasingly important role that Internet technologies now assume in the workplace. This was reinforced by many of the guest speakers who often discussed how they utilized the Internet in their jobs. Finally, some of the students thought the on-line guest speakers were much more informative than in-class guest speakers. This is due to the fact that each guest speaker had agreed to hold an on-line discussion with students over a period of several days rather than a single class period as is typically the case when a speaker comes to the classroom.

Conclusions

Based on student feedback and my own observations and experiences over the past two years, I believe the instructional objectives established for the Internet technologies I have incorporated in my courses were largely achieved. For others considering using the Internet technologies in their courses, I offer the following recommendations:

1) Consider only those technologies able to support the teaching and learning strategies being used. Using technology for primarily comestic purposes - perhaps to give one the image of being on the "cutting edge" - will almost certainly lead to a degradation rather than a genuine enhancement of the quality of the course.

2) Determine the availability of the resources and support services needed for the technology being considered. Be especially mindful of the difficulty students may have getting access to computers connected to the Internet. Ideally, all students would have their own computers that would provide access to the Internet. However, it is more realistic to assume that at least a few students will be wholly dependent on the institution's computer resources. Should access to computers on campus be a problem for students, the use of Internet technologies may need to be limited, perhaps significantly, until access improves.

3) Assess whether there are differences in the students' levels of comfort and understanding of the technology being used. If differences are found, provide whatever assistance is needed to eliminate or minimize them. Otherwise, some of the students may become frustrated and simply refuse to use the technology.

4) Consider making computer literacy a prerequisite for the course. Doing so will help eliminate the need for remedial computer training.

5) On a regular basis, measure the extent to which the technologies are meeting their intended objectives and expect to have to make several changes before coming up with the optimal mix of technologies to support your style of teaching.

6) Make sure that students understand the pedagogical benefits of the Internet technologies being used in the course. Doing so can lessen the resistance students may have toward using these technologies.

7) Finally, expect the unexpected. Web links may be rendered invalid, disk drives may crash, pesky viruses may infect your network, etc. However, despite the occasional problems they may cause, Internet technologies have the potential to greatly enhance the quality of the education you provide your students.

The Millennium Satellite Project: A Case Study.

Gill Nicholls
School of Educational Studies
University of Surrey, Guildford Surrey. GU2 5XH
G.Nicholls@surrey.ac.uk

Abstract: This paper will report on the development and implementation of the Millennium Satellite Project (MSP) in five secondary schools in England. It will show how the project was constructed, the roles schools, teachers and pupils had in the development of teaching material and learning experiences. The pilot stage of the research is considered here as a case study. MSP was initially constructed to motivate schools to use the Internet in science teaching, and help promote one particular aspect of the Science National Curriculum in England and Wales; that of Earth and Space. It was intended that pupils would be able to access data from the satellite through a web-site on the Internet. A major objective of the project was to establish the potential of using satellite science within the National Curriculum, and as a means of motivating students towards Science. The project is a collaborative venture between the University of Surrey, Roehampton Institute and MSCL.

Introduction

The use of information and communication technology (ICT) in subject teaching in England and Wales has become a statutory aspect of a teacher's life. Teachers have to have knowledge, understanding and skills in using ICT in subject teaching. Within this remit teachers should encourage pupils to become familiar with ICT and positive users of it, ensure that all pupils have opportunities to use ICT. (adapted from Circular 4/98) This same document talks of ICT being considered as more than just another teaching tool. Its potential for improving the quality and standards of pupils' education is quoted as being significant. (pg.1, Circular 4/98). Against this background the MSP was trialed in schools. The project was not aimed at testing or examining any of the above issues. They serve merely as a way of contextualising the problems that exist in many schools trying to meet the demands of a National Curriculum and ICT programmes. What the project has brought to light is that these problems are real, but that teachers are trying to deal with them.

The purpose of the project was to develop, in conjunction with teachers and schools; suitable teaching material based on satellite technology and communication. The material had to be relevant to the National Curriculum in England and Wales, and allow the topic of "Satellite Science" to be taught in a motivating and innovative way. The lessons were originally designed for Year 9 (age 13/14), pupils, (attainment/assessment levels 6 and 7 within the National Curriculum for Science), but could be adapted to suit Year 7 (age 11/12) and Year 8 (age 12/13) pupils, dependent on the approach chosen by the teacher.

The concept of 'Satellite Science', was introduced to the pilot schools as a series of lessons based on 'Earth' and 'Space'. The first part of the lesson entitled, 'Earth' would be carried out in the classroom as an experiment, while the second part of the lesson entitled, 'Space', was to be used in conjunction with the Internet and satellite data. The aim of this section of the lesson was to allow the pupils to compare data gained from their class experiment "Earth" to the same or similar types of experiment carried out in "Space." The data would be accessed via the Internet, which would have a Web-site designated to the project containing all relevant data from the satellite. The teachers regarded the approach as a particularly motivating one and were keen to participate in the project. The teacher's interest stemmed from their desire to enhance their classroom teaching through this innovative approach to delivering a difficult part of the Science National Curriculum.

The schools that participated in the research project had certain commonalties; these were felt to apply to schools throughout the country. They included the need to meet the requirements of the National Curriculum, had a divers spread of pupils, both in age and ability, had access to computers, the Internet and basic scientific equipment.

The pilot schools

Five schools were selected for the project. These schools were identified through a variety of criteria, namely: motivation and enthusiasm for the project, Internet capacity, science expertise and science teaching facilities. Within these broad criteria a cross-section of schools were chosen from urban and rural environments. Three schools in different London Local Education Authorities and two from East Kent were selected. The schools reflected a wide spectrum of ability and range, as well as diversity of school type. These included a boys Grammar school, a comprehensive school, a community school, a High school, and a 'City' technology school. The school rolls were all greater than 700 pupils.

The pilot teachers

Within each school a science teacher was nominated as co-ordinator of the school-based project. Their collaborative role included assisting with the development of the teaching material, designing experiments and trialing pre-developed lesson plans. In total 6 teachers and approximately 360 pupils took part in the initial stage of the project. Each teacher in their respective schools taught five pre-designed and developed lesson plans. The material was given to pupils ranging in age from 11 to 14 over a period of a month.

Teacher A was working in the boys Grammar school. He was an experienced specialist physics teacher, who used the trial material with year 9 pupils, aiming at the higher levels (6 to 8) within the National Curriculum (NC) assessment levels. He considered the material as a stepping stone for further extension work, by exploring the concepts of 'satellite technology' and its implications in both a qualitative and quantitative manner. Teacher B, an experienced specialist chemist cross-curricular teacher was working in a community school, he used the material with Year 7 groups, extracting relevant aspects of the lessons in a qualitative and conceptual manner. Teacher C, an experienced generalist science teacher, teaching in a High school, followed the suggested lesson plans with a Year 9 group and aimed at reaching the National Curriculum assessment levels 4 to 5. The teacher was also looking to develop the existing lesson material further, with particular interest in developing material that would be of value to investigative science. Teacher D, a young specialist biologist cross-curricular science teacher, working in a comprehensive school with low ability groups, (NC levels 2/3/4), followed the pre-designed lesson plans, but had to create suitable lower level exercises and material to suit the groups. Teacher E a less experienced generalist science teacher, was working in an 11 – 16 comprehensive school with Year 9 (NC levels 4/5) groups, followed the lessons as suggested in the pre-designed teaching pack.

The Trial Period

The project was designed to be in three phases. This paper concentrates on Phase 1 the trial period. This was established to run for a month. The teachers were encouraged to use the pre-designed lessons with their chosen year groups. They were asked to collect work covered by the pupils, keep a log of the lessons they taught, and make notes on any changes or developments made to the pre-designed lessons. The research officer maintained contact throughout the trial period by visiting the schools three times. During this period information was exchanged, difficulties and successes discussed, monitored and recorded.

At each visit to the school the teachers were interviewed, (all of which were taped for future transcription and analysis). During the interviews they were asked to comment on each lesson. Specific importance was given to, the successes and failures of the lesson, the pupils likes and dislikes towards the lesson, problems encountered, both in the classroom and with the equipment, access to Information Technology (IT), and the relevance and suitability of the suggested NC assessment levels. The teachers also completed a questionnaire after each lesson. This was to gain responses to the lessons under specified headings. These included: the practicalities of the lesson plan, teacher reaction to the lesson plan, pupil reaction and the methodology used by the teacher to deliver the particular lesson, and the extent to which differentiation was allowed for.

At the end of the trial period a debriefing meeting was held to discuss the following points:

1. How relevant and useful were the pre-designed lessons in terms of the science National Curriculum?
2. How was teaching and learning affected by the use of IT?
3. What particular problems were encountered when trying to teach using the Internet and specified Web pages?

The pilot project outcomes

The overall project had two distinctive strands, that of curriculum development, and that of satellite communication as a new tool for teaching science. For the purpose of this paper the focus of the discussion is the teachers role in using the lesson plans and developing strategies for using new technologies in the classroom. The teachers themselves played an important role in the development of the lesson plans.

The data collected and initial analysis of the material showed two significant areas for science education within the British context, these included:

- *teaching and learning using ICT in science*: this can be subdivided into three issues;
  - i. problems associated with whole class use of the Internet
  - ii. the implications of satellite data and Web navigation can have on learning;
  - iii. problems associated with differentiated skills and knowledge levels
- *relevance of using the Internet to the Science national curriculum;*

Teaching and learning using ICT in science.

All schools within the project possessed Information Technology (IT) capabilities to some degree, but accessibility varied greatly between the schools. One of the schools had instant and permanent access to the Web directly from their classroom. Three schools needed to justify their need for the use of the Web and bid for regular access. The last school had limited access; there was one computer network for the whole school. This had timetabled time; the teacher had to negotiate use of the network for this project. Despite this diversity of hardware access, all the schools were keen to make use of the IT facilities available to them. All the teachers saw the need to develop their own pedagogical skills in relation to ICT, as well as the possibilities it offered for the development of pupil's use of ICT.

The teachers acknowledged that the concept of satellite science had been a significant motivating factor for the pupils, both interest in science lessons and a will to actively participate within these lessons had been noted. Teacher E commented that " these lessons are much more exciting when you get the information from the Internet instead of giving yet another worksheet. Pulling data from the Web and using the computer to help develop ideas is an excellent way to motivate pupils and enhance their learning." Teacher A, commented that "the pupils all seemed very enthusiastic about getting involved with NASA, the Web and space science". A general comment made by the teachers was how mundane experiments such as hot and cold, could be made more exciting when compared to similar situations in space.

The motivational aspect of using a Web-site devoted to satellite communication is without question, however, the teachers did encounter some fundamental problems related to whole class teaching and learning. The teacher interviews clearly show that the problems encountered fall into three distinct areas, that of classroom management, differentiated learning, and hardware failure/support. The following extract taken from Teacher C and Teacher B's interview highlights some of the key issues raised by the teachers generally when thinking about using 'satellite science' through the Web as a means of teaching and learning.

Researcher: Could you see satellite science drive science lessons forward?
Teacher C: Yes, very much, I got very enthusiastic and thought let's plan this and discovered I didn't have the required equipment to conduct all the experiments in the lesson packs

Researcher: How do you feel teaching with the Web?
Teacher C: I think it would be brilliant, but the only problem would be getting access to it, as the rest of the school wants access too!
Researcher: Could you get access once or twice a week?
Teacher C: If we put our case forward.
Researcher: Do you think using the Web is important to science teaching?
Teacher C: Yes, its such a media topic anyway, kids are into it and anything which gets their enthusiasm for science is valuable.
Teacher B: I've got access to a machine in my room-but the Internet was not functioning. Access to either NASA or the designated Web-site is definitely a motivational factor for kids.

Access, availability and reliability were words continually used by the teachers as reasons for not using the Web. For teachers who could not access the Web from their classrooms, found, what could be termed classroom management issues as key to a successful lesson. The teachers frequently referred to lesson timing and planning, minimising time wasting in taking the pupils to the computer centre or network area, making sure pupils had logged on and had the relevant Web pages. Pupils also required clear instructions on how to effectively navigate the Web-site. With classes of 30+ this was not easy. *Teacher B* was most concerned with this aspect stating that: "I do have worries in a sense access is unlimited, you've only got to click on the wrong icon, you can get anywhere and it is difficult to get back and so lose focus. As I have said before, access, network crashes, lack of up to speed modems can all be demotivating factors for pupils, as well as time wasting for the teacher. It's the management of the practicalities that are worrying."

Pupils in most schools worked in pairs or triads, depending on the availability of machines. *Teacher B* highlighted what all the teachers thought in his comment that, "Two pupils per machine for 8-10 minutes leads to problems of practicality, BUT a few on a machine is better than none. Once on the Web-site pupils were expected to find the data sets required for their specified experiment. Downloading data, saving and using data was for some teachers the most demanding part of the Web-site space element of the lessons. All commented on the different levels of skills and knowledge pupils had regarding both scientific knowledge and ICT skills. *Teacher D* suggested that time allowed for computer use in her school was insufficient for this type of work. She stated that "I've been teaching about satellites and this work consolidates what I've been doing. Fits nicely to the scheme, BUT I've got to finish this unit. We need at least 45 minutes on the computer, this isn't always possible or practical." Pressure of fulfilling the demands of the national curriculum requirements for science take precedence over extended use of the Internet or IT alternatives".

The second point raised by the teachers related to "differentiated learning" based on two variables, one being the pupils ICT capabilities and secondly the pupils understanding of the scientific concepts being explored. On the one hand they thought that the ICT component was a great way to help learners of all abilities, as pupils could work at their own pace. Yet, on the other hand they reported that the differing abilities of the pupils, both scientifically and with respect to ICT, gave the teachers problems in managing the pupils' learning, and directing their own teaching of these sessions. What is interesting about this assertion is that the teachers perceived these two areas as classroom management issues, rather than issues related to pedagogic practice. Although, the teachers were concerned about levels of learning in both science knowledge and ICT skills, their responses were clearly demonstrating a concern that related to managing the learning situation as opposed to how they should or could change their teaching style to accommodate a different tool for learning. In this case the computer and the Internet.

Teacher A was clear about the problems that could occur from a combination of complex scientific concepts, ICT skills and teacher interaction with pupils. He suggested that "what you want is to stimulate the kids with this (*space science)*, and this *will* stimulate them. You will want to be able to perpetuate that stimulation and I can see that with some teachers it could go over their heads. You will get pupils going down to the Internet and finding out information and coming back and saying, 'what about this and that', those teachers who are not switched on to space and satellites would have to manage the situation carefully. Flexibility is the key, but depends on the teacher's approach"

When the teachers were asked about teaching with IT, and to comment on the practicalities of using

ICT skills as a means to improving and extending individual pupil's knowledge base, such as graph work, the following responses were recorded (all comments related to the solar cell experiment, fig 1).

Teacher E: Following this experiment the pupils have to plot a graph, both for the classroom-based experiment and the satellite based experiment. It didn't take them long to do the practical side of the experiment. Most of the practical was taken up with them doing the graph. That took a good 15-20 minutes.

Researcher: Would you have liked to try doing the graphs on the computer?

Teacher E: No, I think that would have confused them. They can do graph drawing on the computer, but it takes an awful lot longer than if they'd done it by hand.

Teacher D: The practical was fine, but I had to sketch out the axes for them (pupils), as that takes a long time. I gave them one of the graphs and they plotted it then joined up the dots. They enjoyed that and are getting more skills, which they need throughout the science curriculum, but this section did take 15-20 minutes.

Researcher: Would you have liked to try doing the graphs on the computer?

Teacher D: No, they would find it too difficult and it would take up much more time, which we do not have.

Teacher C: The kids actually had a go at the practical. It was fine. They enjoyed it so that was good.

Researcher: Plotting the graph, was that a successful exercise?

Teacher C: Yes, but, if you are going to give them the axes, it lowers the attainment level. If you're aiming at a higher level, then they (the pupils) should think about it themselves. The concept is good.

Researcher: Would you have liked to try doing the graphs on the computer?

Teacher C: Well, yes and no. If I had unlimited access yes, it would be good way of differentiating and stretching the able pupils. No for the less able as they would struggle. Time would not allow for it. It is best managed as a whole class activity on the board. This way also allows me to quickly see who can or can't do the graph.

Teacher A: What you can get out of this experiment with Year 9 kids and our more able kids is that they can use the graph to calculate a variety of variables. The very able were looking for patterns of results and so on. Our year 9 are just about into Y= MX+C, into a straight line and inverse relationships and we relate that back to maths.

Researcher: Would you have liked to try doing the graphs on the computer?

Teacher A: That's a difficult one. No not in science lesson time. I would expect that type of exercise in maths lessons. We do expect computer-plotted graphs in science, but the pupils do these in their own time.

Teacher B: I did this with Year 7. My worry was whether we could graph the results. Graphs with year 7 are always useful.

Researcher: Would you have liked to try doing the graphs on the computer?

Teacher B: Not with Year 7, possibly with year 9. My only worry is staff would need to have it all mapped out beforehand, access, network crashes, etc. don't bode well to using science time for such activities.

These comments clearly demonstrate the problems the science teacher faced, in terms of differentiated teaching and learning environments. All the teachers highlighted the issue of "time" for science. The pressure to fulfil the requirements of the National Curriculum is clearly stated. It is also clear that the teachers felt that ICT was a motivating issue in teaching "satellite science", but some of the associated problems, such as drawing graphs, was best taught by the teacher. Direct teacher input was considered a more effective means of facilitating individual learning. It is also interesting to note that the only references to pedagogic practice as related to IT surrounds the issue of time management, and not what the new technology learning tool might offer the teaching environment. This view is not new and has been reported in many academic papers, conferences and books (McAteer, E. 1998, Wegrif,R. 1998, Gilliver, R.S. 1998). What is important to the educational context is that despite there having been great leaps in both hardware and software teachers use of new technologies is constrained and not perceived as part of their pedagogic practice.

Relevance of using the Internet to the Science National Curriculum.

Use of the Internet and science education was considered very important to the pupils developing research skills and meeting the ICT components of the National Curriculum. However, teachers were very clear about the implication of teaching/learning time in science, and the way the Internet use eroded this time. Accessing information had to be a definite part of the science lesson, as with the solar cell, and data being accessed directly form the Web to create graphs of light intensity. As Teacher E commented computer/Internet drove the lesson along.

Researcher: Is 'satellite science' a useful concept?
Teacher E: Don't know!
Researcher: Has it a place in the National Curriculum?
Teacher E: We already have a National Curriculum.
Researcher: Do you like the concept of 'satellite science'?
Teacher D: Yes, but this topic isn't entirely relevant in the National Curriculum. They (pupils) won't be asked about it in their Standard Attainment tests (SATs), but the skills that it brings out, graph skills would be.
Researcher: Do you like the concept of 'satellite science'?
Teacher B: Yes, as a motivating aspect to science.
Researcher: Has it a place in the National Curriculum?
Teacher B: Yes, but it is not that easy. The Curriculum prescribes what we teach and at present, this is not in the Curriculum, but I see it as strength that pupils can access NASH and designated Web-sites. The strength of the Web is the flexibility of movement. A real timetable of constant data, a satellite downloading data would captivate pupil's imagination for this reason it should be included.

Teacher A and C consolidate the above views that the Web aspect of satellite science would be an excellent way for pupils to investigate and download their own information and experimental data. They went on to suggest that 'satellite science' would add a totally different dimension to 'Investigative Science' and Attainment Target 1 of the National Curriculum, at all levels.

Concluding Comments

This paper has reported on the first phase of a multifaceted research project that is looking at the concept of satellite science as a means of motivating students' interest in science. The context has been the National Curriculum for Science in England and the use of ICT. What is important to the report is that despite the will to use new technology as a form of pedagogic practice, teachers feel external pressures constrain their use of these technologies. However, pupils were motivated and did produce innovative and constructive work. The development of the lessons by the teachers showed the need to have teachers at the forefront of curriculum development.

The second phase of the project is extending the number of participant schools and teachers. It is also going to look at other areas of the National Curriculum to see how satellite science can enhance the quality of student learning.

Research Training via the Internet: Developing Web-based Resources for Art and Design Postgraduates

Darren Newbury, Birmingham Institute of Art and Design,
University of Central England, United Kingdom
Email darren.newbury@uce.ac.uk

Abstract: The increasing accessibility of the Internet as a tool for the delivery of educational content and interaction, combined with its importance as a source of information for researchers provided the rationale for the project described in this paper. The paper reports on the development of a web site to support the teaching of research skills to postgraduate students in art and design. The model of development adopted by the project is presented and discussed, with a particular focus on three issues: the revision of existing content for web-based delivery; the development of a web-based form of presentation; and the consideration of how to structure students' use of the resource. In conclusion the paper looks at the piloting and evaluation of the site and areas for future development.

Introduction

Postgraduate education in art and design, in common with many other areas of postgraduate study is undergoing a period of considerable change. Three factors are of particular importance to the resource development project discussed in this paper [1]:

- the increase in the number of postgraduates and postgraduate courses (this has been a general trend affecting most subject areas in higher education)
- the question of what constitutes research in art and design, and what therefore might be considered an appropriate body of research skills
- the significance new developments such as the Internet for teaching, learning, and research

Art and design, like many other areas of postgraduate education, has experienced a considerable increase in the number of students attending taught courses and registering for higher degrees, both in real terms and in proportion to undergraduates. The recent Review of Postgraduate Education in the United Kingdom gives an indication of the extent of this change:

> "In 1979, for example, there were 100,900 postgraduate students in the UK compared with a total student population of 787,000 (13%), whereas in 1994-5, the comparable proportion was 21% (315,400 and 1,538,600 respectively)." (HEFCE 1996)

This general trend towards greater student numbers at postgraduate level has been accompanied by two further developments. Firstly, there has been a lively international debate concerning the nature of research in practical and creative subjects such as art and design [2]. This has in part been driven by the increasing number of students wanting to progress to doctoral work in these areas, but also represents some interesting debates about the nature of knowledge and enquiry in fields of creative and practical endeavour. Although this area of discussion is beyond the scope of this paper, the consequent importance accorded to the teaching and learning

---

[1] The development of the research training web site forms part of a broader project – the Research Training Initiative – initiated in 1995 to develop and publish research training resources for postgraduates in art and design (see Newbury 1996). To date the project has published seven printed research guides (all but one of which are now out of print) and a CD-Rom of case studies of masters projects in jewellery and silversmithing (Newbury 1997). Further information about the project can be found at http://www.biad.uce.ac.uk/research/index.html.

[2] See for example *No Guru, No Method* conference proceedings (Strandman 1998), Gray 1995, UKCGE 1997.

of research skills has been significant for this project. Secondly, the increasing accessibility of the Internet is having a significant impact on the way in which staff in higher education think about teaching and learning [3].

Although electronic resources are often put forward as an efficient solution to the problems raised by increased student numbers without a comparable increase in teaching staff, the majority of work to date has been in relation to undergraduate (often modular) programmes. A brief review of resources currently available suggests that relatively little of the work in this area has been at a postgraduate level [4]. The emphasis on the world wide web and CD-ROMs as virtual storehouses of knowledge and information has tended to favour subjects with large, well structured and relatively stable knowledge bases, rather than practice-based subjects such as art and design where much of the subject knowledge has not been committed to textbooks. Many computer-based learning packages also have a very directive style and are therefore less suited to the more open investigative learning appropriate to postgraduate level study. This is perhaps slightly ironic in that the Internet and the world wide web were originally developed by and for researchers. As Hobbs and Taylor point out:

> "Researchers are still some of the keenest users of the WWW in view of its potential for contact and collaboration, for disseminating research findings, and for facilitating peer review of the outcomes of research." (Hobbs & Taylor 1996)

The development of the research training web site discussed in this paper is a response to this context. An important difference between undergraduate and postgraduate study is that the postgraduate student must learn to find and manage the information that supports his or her own learning. Postgraduate students beginning research for their dissertation or major project are confronted by a complex landscape of information sources. It is interesting that what can be considered a disadvantage of the world wide web for undergraduate students – the lack of any clear narrative which structures the learning process (Laurillard 1995) – has advantages for research students – the direct access it gives to sources, databases, other researchers and even research subjects (Foster 1994). However, it was novice rather than experienced researchers that were the focus of this project. It was therefore important that the material we produced supported students' independent learning and research, as they began to deal with a complex range of sources from which to retrieve information. Our proposal therefore was to take as a starting point material already available on the collection and management of information for research, and to develop from this a web-based interactive environment which would support the learning of a number of key research skills.

A Model of Web Resource Development

New educational technologies have strengthened the trend towards specialisation in the development of teaching and learning. In addition to subject knowledge, two specialised domains of knowledge are emerging. Firstly, knowledge of teaching and learning processes. As Laurillard points out, innovative teaching methods, by which she means those that depart significantly from the narrative or telling mode, "require more pedagogical understanding of the professional teacher" (Laurillard 1995, p.183). Secondly, specialised knowledge in the design (in its broadest sense) of computer-based teaching and learning materials. There is an emerging literature on models of developing electronic resources, which attests to the novel and still problematic nature of this kind of resource development (Borkowski et al. 1996; D'Halluin et al. 1996; Porritt 1997). Porritt, for example, identifies a further degree of specialisation. He outlines four roles - student; tutor; author; designer – and considers the different models of interaction and overlap. These range from the "tutor designer" within which the tutor takes on the additional roles of author and designer, to "open authoring" within which resource development is carried out by teams made up of specialist tutors, authors and designers. Although these specialist areas are separable in theory it is often the case that the discussion of computer-based

[3] When we originally surveyed our higher degree students prior to developing the training resources they indicated that electronic resources were among the least flexible and desirable forms of delivery. Although this situation has changed, many more students now have Internet access, its appropriateness needs to be considered on a case by case basis. On a larger scale the question of the accessibility of web-based course material has been an issue for the Open University where the development of innovative distance learning materials has had to be matched with its policy of accessibility.

[4] There are of course some exceptions to this general observation. See for example Jennings 1997 and Lidstone & Lucas 1998.

learning has become part of a broader debate around innovations in teaching and learning. In some instances computer-based learning developments are seen as a vehicle for introducing changes in teaching practice that are in themselves considered desirable. Underlying this is the view, perhaps not always justified, that there is an inherent compatibility between computers and certain philosophies of education.

This developing context has given rise to a range of approaches to the use of the Internet and multimedia technologies for teaching and learning, from small local developments by enthusiastic teaching staff to large scale centralised funding [5]. The development of this project drew on a number of extant models and had the following five features:

- Specialised content development. The project was a response to developments in the subject area as well as to the introduction of the Internet as a tool for teaching and learning. As a result we had produced a range of new material on research in art and design during the three years of the project. It is also worth noting that the print format we adopted - a series of research guides rather than a sequential programme or single publication - provided a degree of flexibility that proved useful in its conversion to electronic format.

- Central resourcing at a faculty level. A degree of central resourcing meant that the work was not additional burden for already busy teaching staff and therefore enabled the development to get off the ground. However, it was important that the resource retained a subject identity given the relative novelty of research study in art and design (although much of the material had generic applicability). Unlike a number of other universities, which have adopted a university wide approach to research training, our initial audience was specifically art and design students.

- Core team responsible for the resource development. Importantly, however, the main member of staff working on the project was also delivering teaching in research methods on a number of courses. This enabled the resource to be developed in a way that was responsive to student and tutor needs. The use of an intranet/internet based resource offered an opportunity to supplement existing classroom teaching with resources that students could access at times when it was most needed, principally during the period of independent research study.

- Skills development. Although it is possible to consider teaching staff simply as "information owners" (Borkowski et al. 1996), with content handed over to a specialist team for the creation of web pages, this represents only a base level model of development. In this project the member of staff responsible for content development was also responsible for the overall design and navigation of the site. This necessitated learning to use basic web page software. Although the final screen design and authoring was not done this way, the drafting of the pages and site architecture in web format made it possible to think through important issues about how students would use the information. It also highlighted some basic issues such as the need to carefully structure large amounts of text to be accessible on screen.

- Professional design input. The final stage of the project involved working with a professional web design team. Although design in its broadest sense was set largely at an earlier stage, the design of the pages on screen has the potential to either enhance or detract from the overall structure. Given that the project was situated within a faculty of art and design and that it was for use by art and design students, it was considered important that the finished site should be visual attractive, pleasant to use and functional. This stage enabled us to make use of some features of advanced web page authoring which would have otherwise been beyond the skills of the team.

One of the key principles that emerged from the model of development used in this project was the importance of a close integration between the different stages in the process, from content generation to screen design to the placing of material within the curriculum.

---

[5] For example, in the United Kingdom the Teaching and Learning Technology Programme (TLTP) has invested a total of £37 million since 1992 in the development and implementation of technology based learning. Many of the projects has been at an institutional or inter-institutional level.

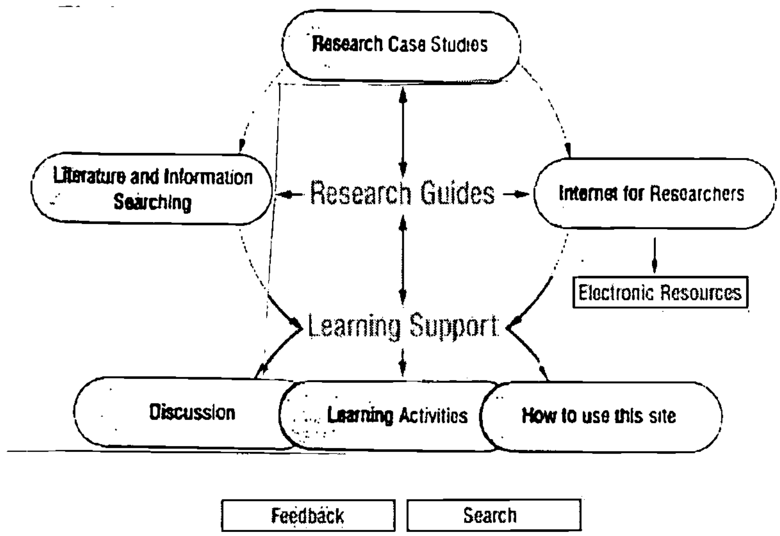

Figure 1: Map of pilot website contents

Contexts for Electronic Learning

One of the dangers of a specialised production model of electronic resource development is the failure to give sufficient consideration to the contexts into which materials are being introduced. The emphasis is placed on the knowledge content at the expense of the processes of teaching and learning. As within any form of teaching there is a need "to change information exchanges into learning activities" (D'Halluin et al. 1996). In order to avoid the pitfall of offering students content without an appropriate learning context or framework, we incorporated two additional features into the web site: a discussion forum; and guided learning activities.

The discussion forum serves three purposes. Firstly, it provides for student interaction both within and across sites (the piloting of the resource is taking place across several universities). It is hoped that this will enable students to share problems and solutions, and disseminate useful information. Secondly, a number of the learning activities invite students to post short written pieces to the forum, for example reviews of particularly good or bad web sites. This is one way of prompting students to think about writing for a semi-public audience. It is envisaged that this may be appropriate as a form of coursework, with the archived messages providing an easy means of assessing students' contributions. Models of practice in this area already exist, though largely at undergraduate level. Thirdly, electronic discussion lists are now an important form of academic research networking (Berge & Collins 1995). It is important therefore that research students are introduced to this form of communication, its benefits and limitations. Although advances in Internet technology mean that video conferencing is becoming increasingly viable, the move towards the "conversational ideal" (Jones 1995) in electronic communication should be subject to scrutiny. The dynamics of asynchronous email communication have some useful advantages for both for research, and for teaching and learning. For example, as something of a hybrid between written and spoken forms of communication, email can offer the opportunity for considered responses without introducing the formality of written essays. It can also reduce some of the inhibitions to participation that exist in face to face encounters (though of course it does introduce new problems of its own).

The learning activities on the site have been designed to facilitate students' use of the content – there are cross links between activities and relevant sections of the electronic research guides – and also to help students to develop strategies for gathering information relevant to their research topic. The site has been constructed to serve a number of different student groups, and at this stage is a supplement to existing teaching rather than a compulsory element. This will obviously have a bearing on students' use of the material and is something we have had to consider carefully. As a result the learning activities try to fit with tasks that students will need to do anyway in order to complete an independent research project. It is important that the activities are optional, as they will not be equally appropriate to all student projects. Also some students' prior knowledge may mean that completion of a particular activity is unlikely to be relevant. For example, for those students already familiar with the use of email discussion lists the activity related to this may be redundant.

These features are intended to provide a learning context that supplements the traditional class or seminar group and guides students' use of electronic sources and the Internet, which despite claims to the contrary can be a sparse and isolating learning environment.

Evaluation: Issues and Methodology

The evaluation of web-based resources is key to the future development of this area of work. The number of new initiatives in web-based learning raise issues both of comparison and also of the sharing of good practice. The evaluation of the web site in its pilot form will consider several aspects:

- Navigation and interface design - the ease with which students were able find their way around and use the materials.
- Interaction – the quality of the interaction in relation to the materials and the suitability of the discussion forum facility for this purpose. The evaluation will also consider what factors may affect the success or failure of this aspect of the site.
- Added value – what the web-based materials contributed to teaching and learning, and the appropriateness of using the web.
- Context – the value and appropriateness of the context in which the materials were introduced and the way in which students' use of the materials was structured (for example through the guided learning activities)

Although it is our intention to monitor the use of the web pages quantitatively, we are principally concerned at this stage with the *quality* of the interaction with the materials within a relatively small user group. The methodological emphasis is therefore on the students' experience of using the materials and tutors' perceptions of the value it added to traditional teaching methods in this area. The evaluation methodology will therefore incorporate the following elements:

- Focus group discussion with small groups of students
- Collation and analysis of discussion forum interaction
- Interviews with tutors
- Expert reviews

Although we intend the material to support students during a relatively long period of independent research study, in order to get some timely feedback we will carry out the piloting over one 15 week semester period. Several small groups of students will be introduced to the resource at the beginning of the semester. They will then have access to the resource throughout the period, with the main evaluation work taking place towards the end. The pilot groups cover both taught masters and research students across a range of art, design and media subjects. This will give some variation in the degree to which students' use of the resource will be guided, and hopefully provide some indicators as to what different students might want from such a resource. In addition a small number of expert reviews will be commissioned in order to subject the material to independent scrutiny, and give some measure of how this work relates to the current 'state of the art'.

Conclusion and Future Directions

The web site is at a pilot stage, and it is difficult to come to any specific conclusions before the process of piloting and evaluation is complete. However, it is worth venturing two general thoughts. Firstly, it seems that to some extent the project is representative of interim work in this area. There is currently a great deal of unevenness in postgraduate students' prior knowledge and experience of the internet. Some will of course be highly proficient and experienced users, others however will have little or no knowledge and experience other than that gleaned from popular representations. However, over time this is likely to change dramatically and resource developers will need to respond to the needs of a more sophisticated group of users. A similar point can be made in relation to staff. The development of web-based materials is new to most academic staff outside of computing and information science. It therefore makes sense to provide additional support in this area. However, in the long term the specialised model of resource production this implies has potential dangers. As I have argued, students and academic subjects are likely to be served better where there is a close integration between subject knowledge and tools for teaching and learning. It seems obvious that a subject tutor needs to understand how the lecture or the seminar works in order to teach. It should be no less obvious that they need to know how their students make sense of electronically based resources. Though as has been noted this does place extra demands, both intellectually and in terms of time, on staff.

Coda

One area not discussed in this paper but important to the philosophy of the project is the use of case study material as resource for teaching and learning. One of the printed research guides was given over to a series of case studies of completed MPhil and PhD projects in art and design. An important area for the future development of this project is the introduction of case study material on to the web site. The use of web-based materials offers an opportunity and a challenge, to develop multimedia forms of the case study approach.

"But Does It Work?" 6 Ways to Evaluate Technology

Rob Foshay, Ph.D.
PLATO® Education
USA
Rfoshay@plato.com

Abstract: This paper outlines six basic evaluation designs. For each, the paper describes the type of technology application for which it is appropriate, and the questions the evaluation design can answer, and summarizes the requirements, data collection and analysis procedures. The six evaluation designs are:

- Mastery-Based Program Effectiveness
- Non-Mastery-Based Program Effectiveness
- Affective Outcomes
- Case Studies / Qualitative Assessments
- Program Comparison
- Cost Comparisons

A more lengthy version of this paper includes details on the requirements for successful evaluation, the procedures for data gathering, and the procedures for data analysis, and guidelines for writing the evaluation report. It is available at http://www.plato.com, or from the author.

Introduction

It is sound educational practice to evaluate the effectiveness of any instructional program, including technology-based implementations. But it's important to use an evaluation design that is appropriate to the way in which you are using the technology, and to your needs for decision-making. When evaluations are inconclusive, it's often the case that an inappropriate evaluation design was used, and the desired result could not have emerged from the evaluation.

To decide what kind of evaluation to do, you must first know who will use the evaluation results and what decisions they need to make. You can then combine and adapt these basic designs to meet your program's needs.

Which Model Do I Want?

Here is a brief summary of the programs to which the six models often apply. For a more complete description, refer to Foshay (1994).

Mastery-Based Program Effectiveness

In programs suitable for this model, the technology provides the primary means of initial instruction, and learners are managed so that learners begin a learning activity only when they are ready for it, and they continue to study the activity until they have fully mastered it. Thus, in contrast to a conventional instructor-led classroom, achievement is fixed but instructional time varies. As an example, mastery-based instruction is typical of GED programs.

Questions

Use this design when you want to find out:

- How well are the learners progressing due to the technology?
- What is the longest, shortest, and average time to mastery?
- What proportion of learners master the skills taught at the required level?

- What proportion of learners do not complete or drop out?

If the technology is the primary instructional mode in a mastery-based program, learning outcomes can be attributed mostly to the technology.

In addition to these questions, people sometimes wish to know about long-term retention of what's learned. Unfortunately, research on long-term retention indicates that it begins as a product of initial level of mastery and the way in which topics are taught, but that by far the biggest single factor influencing long-term retention is whether the learner has an opportunity to use what's been learned. Consequently, there is no simple way to evaluate long-term retention due to any type of instruction.

Non-Mastery-Based Program Effectiveness

In a non-mastery program, instructor-led classes typically are the primary means of initial instruction. It is more for the technology to be used in a complementary or supplementary way. Learners are managed so that instructional time (pacing) is fixed and achievement varies.

Questions

Use this design when you want to find out:

- How well are the learners progressing in the program as a whole?
- What is the longest, shortest, and average time on PLATO?
- What proportion of learners master skills at the required level?
- What proportion of learners do not complete or drop out?

Affective Outcomes

In any evaluation, it's common to be interested in how learners and instructors felt about their use of the system, their confidence and their role in the instructional process.

Research has shown that affective outcomes are largely independent of actual learning. Thus, asking learners how they felt about the value of a course or whether they achieved its objectives is not an adequate substitute for measuring learning using either of the two "program effectiveness" evaluation designs above.

Questions

Use this evaluation design when you want to find out if learners using the technology generally feel...

- good about their experience?
- unembarrassed by wrong answers?
- in control of their learning?
- rushed?
- the system is relevant to their needs?
- the system accommodates their preferred learning style?
- confident of their ability to succeed?
- more goal-oriented?
- motivated to use the system effectively?

And, if instructors using PLATO generally feel...

- good about their experience?
- able to spend more time 1-on-1 with learners?
- in control of the instruction?
- a generally good understanding of what PLATO teaches (and does not)?
- well prepared for the changes?
- adequate time to use the system effectively?
- adequately trained to use the system effectively?
- motivated to use the system effectively?

You can answer these questions at the end of the program, or you can do a "before and after" comparison in which you measure expectations and current attitudes ("before") against actual feelings at the end of the program.

Case Studies/Qualitative Studies
Decision-makers often have difficulty drawing appropriate conclusions from purely numerical evaluation studies. Some decision-makers have an overt distrust for quantitative studies: "figures lie and liars figure." In addition, evaluations which summarize results for an entire group require considerable effort to do, and often aren't available until long after completion of the program. In non-mastery-based classrooms where technology is not the only instructional element, it may not be possible to use a quantitative design to study the effects of the technology. Finally, many people find numerical evaluations too abstract to say what's really important. This is often the case, for example, with collaborative learning programs.

A case study (qualitative) evaluation is an alternative which addresses these criticisms. In general, a qualitative evaluation can:

- Serve as a useful complement to a numerical evaluation, and "put a human face on the numbers."
- Carry more "face validity" than a numerical study, and thus have more impact with some decision-makers.
- Be prepared quickly and at low cost if the number of learners is small.
- Contain "narrow but deep" descriptions of one or more experiences with the program, rather than "wide but shallow" generalizations common of numerical evaluations.

Among the limitations of qualitative studies are:

- Observations are true only of the learners interviewed and may not be generally true.
- Data collection is less objective than numerical studies.
- Including the learner in the study may be an added motivator not available to most learners. This can lead to biased conclusions.
- Data collection and interpretation is costly unless numbers of participants is very small.

A qualitative evaluation can be used instead of or in addition to a more conventional numerical evaluation.

Questions
Use this design when you want to ask:

- What are the needs of the learner?
- What is the motivation and the goals of the learner?
- What is the learner's pattern of technology usage?
- How has the learner integrated the technology with other learning experiences to achieve the class' learning goals?
- In learning from the technology, what facilitators and obstacles were encountered?
- How has the technology usage affected the learner's confidence?
- What have been the learning outcomes for that learner?

Program Comparison

There is over 25 years of research showing that people can learn from computer-based instruction, and that on the whole CBI implementations achieve greater gains in less time than large-group classrooms. However, it is still true that decision makers often want to know if using technology is an improvement over whatever is being done now in their program. Unfortunately, meaningful evaluations of this type require carefully controlled "experimental" designs and are very difficult to do well. There are a number of reasons for this:

- "Whatever is being done now" is often imprecisely defined and varies widely from instructor to instructor, class to class and semester to semester.
- It's common to change more than one thing in a program when technology is introduced, so it's impossible to attribute specific changes to the technology.
- An interpretable "experiment" has requirements which are incompatible with many program structures.

- Everyone's performance improves for a while when they know they're "part of an experiment."

Questions
Use this design when you want to ask:

- What learning gains occur using technology, when compared to our conventional practice?
- What percentage of learners achieve a predetermined mastery level using technology, when compared to our conventional practice?
- What is the longest, shortest and average time to reach mastery level using the technology, when compared to our conventional practice?
- What are the effects of using technology on completion/dropout rate, when compared to our conventional practice?
- Are any of the above comparisons large enough that we can say with confidence that they are not due to chance alone?

Cost Analyses
Program administrators sometimes want to cost-justify use of technology on the basis of reduced (or avoided) costs, increased enrollment income, or increased benefit to the host organization. This kind of cost-effectiveness justification is based on a comparison of the results of conventional and technology-based programs arrayed against the cost of each.

Do not confuse a cost-effectiveness study with a simple cost-cost comparison, in which the costs of the conventional and technology-using programs are compared without reference to the effectiveness of the programs.

Also, do not confuse cost-effectiveness with a cost-benefit study. A cost-benefit evaluation might be done for a new program to see if it is meeting its projected costs and benefits. To do a cost-benefit study, you would use the "Mastery-Based Program Effectiveness" or "Non-Mastery-Based Program Effectiveness" evaluation models, and collect appropriate cost and enrollment income data as well. If your program is justified on the basis of benefits to a host organization or the general community, then you may also be able to gather cost-avoidance data such as reduced follow-on training time, reduced equipment downtime, reduced plant or process startup, and so on. In either case, there is no comparison in a cost-benefit study with an existing program.

To do a cost-effectiveness study, you must use the "Program Comparison" design. Then you must decide if you want to do the cost analysis on the basis of reduced costs or increased enrollments. If you choose to use reduced costs, then add to the evaluation a costing model for each treatment. If you choose to use increased enrollments, then add to the evaluation design a comparison of enrollments (or retention) in each program.

Evaluation Procedures Summary

Often, you'll want to combine the evaluation designs. To help, the tables below include evaluation requirements, data gathering and data analysis procedures for the six evaluation designs.

Requirements

Require-ments	Mastery Prog. Eff.	Non-Mastery Prog. Eff.	Affective Outcomes	Case/ Qualitative	Program Compari-son	Cost Compari-son
Learners match user profile	x	x	x	x	x	x
Unlimited access	x				x	
Individual placement	x				x	

Require-ments	Mastery Prog. Eff.	Non-Mastery Prog. Eff.	Affective Outcomes	Case/ Qualitative	Program Compari-son	Cost Compari-son
Individual routing	x				x	
Work @ own pace	x				x	
"Place out" with module tests	x	x	x	x	x	
Pass module test to go on	x	x	x	x	x	
Offline tests must be aligned	x	x			x	
Offline Learning activities aligned & synchron-ized	x	x			x	
Random assignment					x	
Parallel content					x

Authoring Computer-Based Instruction for Teaching Concepts Using Instructional Event Shells

Yun Ni and Jianping Zhang
Department of Computer Science
Utah State University
Logan, UT 84322-4205 USA
jianping@zhang.cs.usu.edu

Abstract
This paper reports our work towards the development of an authoring system for automating the instructional development of adaptive instruction for teaching concepts. The core of our work is the design of a set of instructional events for concept teaching, *Introduction, Demonstration, Practice, and Test*, and the development of corresponding instructional event shells. An instructional event shell is a piece of program code that executes an instructional event. The focus of this paper is a description of these instructional events and their shells and how these instructional event shells can be used to author computer-based instruction for concept teaching. Issues related content-based and event-based authoring will also be discussed.

Introduction

With the rapid advances of computer network and multimedia technologies, the use of interactive instructional technologies has been experiencing a dramatic increase in recent years. However, development of high quality computer-based courseware is both time consuming and labor intensive. Therefore, only the best funded training programs can afford to be computer-based. Many organizations that are attracted to the concept of computer-based training have to give up when they discover the cost and the time to implement computer-based courseware.

A traditional computer-based courseware development team involves subject matter experts, instructional designers, and programmers. The subject matter expert determines what to teach and provides subject matter knowledge. The instructional designer together with the subject matter expert determines how to teach and designs the instructional treatments for subject matter knowledge to be taught. The programmer generates computer code to implement the instructional treatments for the delivery of the instructional material. The development processes of both instructional design and programming are very long and labor intensive even for some simple training programs.

To reduce the time and cost spent in programming, authoring systems have been developed and used widely. The goal of existing authoring systems is to eliminate programming in the courseware development process and lift the expensive burden from the course developer's shoulders. Solving the programming problem for course developers with authoring systems has greatly influenced the productivity of development of computer-based instruction, and the number of interactive instructional software products has increased geometrically.

However, the current conception of authoring systems has not solved the cost and time problem to a sufficient degree. The quality of many current instructional products still appears to be far below the potential promised by the current computer technology. Even though the expensive programming burden has been lifted from the course developer's shoulders, there remains a equally cost and unnecessarily repetitive instructional design process burden which still rests on the developer (Merrill, 1985).

Merrill and his colleagues (Merrill, Li, & Jones, 1991) introduced the instructional transaction theory that maintains that the basic building block of instruction should be the instructional transaction. This principle applies particularly to the highly interactive medium of computer-based instruction, in which the most powerful vehicle for learning is the pattern of interactions between the student and the computer. Based on the instructional transaction theory, a simple prototype named ID Expert (Merrill & Li, 1989) was developed. ID Expert was intended for use by both novice subject matter experts and experienced instructional designers and provides instructional design and templates for courseware developers. The instructional transaction theory provides a theoretical foundation for the development of authoring systems that automate the instructional design of computer-based instruction (Zhang, et al., 1997). Recently, a few commercial authoring systems such as ToolBook and Authorware included some templates or widgets that speed up the courseware development process.

This paper reports our work towards the development of an authoring system for automating the instructional development of adaptive courseware for teaching concepts. The core of our work is the design of a set of instructional events for concept teaching, *Introduction, Demonstration, Practice, and Test*, (Merrill, et al., 1992) and the development of corresponding instructional event shells. An instructional event shell is a piece of program code that executes an instructional event. The focus of this paper is a description of these instructional events and their shells and how these instructional event shells can be used to author computer-based instruction. The ideas introduced in this paper are being implemented in an authoring system named ConceptAuthor.

Course Structure And Concept Representation

A concept is a set of specific objects, symbols, or events which are grouped together on the basis of shared characteristics and which can be referenced by a name. Authoring a course using ConceptAuthor is to create a course structure and provide content material for all concepts to be taught. The course structure and the content materials of concepts are stored in a database. The course structure is separately stored from the content materials. This section discusses the course structure and concept representation implemented in ConceptAuthor.

Course Structure

A course structure is a tree of course units. The root of the tree is the course and the leaves are instructional events. A course may consist of a set of events and a set of lessons. Instructional events of a course may be a pre-test, a post-test, a course introduction, a course summary, and a comprehensive practice.

A lesson may be composed of a lesson introduction, a lesson summary, a comprehensive practice, a test, and one or more instructional sessions. An instructional session may consist of a set of instructional events and zero or more other instructional sessions. A session may teach one concept or a set of coordinate concepts.

Concept Representation

Each concept in ConceptAuthor is stored as a frame that stores the information about the concept. Information stored in the frame may include the concept name, the concept definition, the concept context, and a list of concept characteristics, lists of discriminans, the concept instances, and the problems. The concept name and definition are required while all others are optional.

The concept name is a string and a concept may have more than one name. Most likely, a concept definition is a paragraph of text, but it could also be some other media such as audio, video, and images. A concept may have several definitions. Especially, when a concept is very complex or disjunctive, the teacher may want to teach the concept in several steps. First, a simple definition is taught, and then this simple definition is gradually expanded until a complete definition is taught. The concept context specifies where, when, and how a concept is used.

A concept characteristic is the property that holds for all examples of the concept. When a concept is fuzzy, a concept characteristic may only hold for all typical examples. A concept characteristic may be a property or a relation. A concept discriminant is a property or a relation that discriminates the concept from its coordinate concepts.

A concept instance is either an example or a counter example of the concept. Some instances are more typical (representative) than other instances. Some instances are easier to understand than other instances. Problems are used for practice or tests. There could be many different types of problems. The types of problem will be discussed in Section 3.

A set of related concepts may form a concept taxonomy. In this taxonomy, a concept may consist of several subordinate concepts. A subordinate concept may be a kind of its superordinate concept or a part of its superordinate concept. Coordinate concepts are a set of concepts in which each member shares the characteristics of the same superordinate concept (Merrill, 1992). The course developer may intentionally group a few concepts for some instructional purpose.

Instructional Events for Teaching Concepts

Concepts may be taught using four instructional events: *Introduction*, *Demonstration*, *Practice*, and *Test* (Merill, et al., 1992). These four instructional events may be used repeatedly. In ConceptAuthor, four corresponding instructional event shells are being implemented to execute these four events.

Introduction Event

An introduction event introduces to a concept to the student by presenting the concept name, the concept definition, and the concept context. In addition, this event also shows the student a representative example of the concept. All materials may be presented using different media such as text (rich text format), pictures, still images, animations, audio, and videos. All materials may be presented in one or more pages. Hyperlinks are allowed.

A set of coordinate concepts could be introduced in sequence or in parallel. If concepts are introduced in sequence, each introduction event only presents materials of one concept. An introduction event presents materials of two or more coordinate concepts if they are introduced in parallel. When coordinate concepts are introduced in parallel, the differences among these concepts may be compared and presented.

For a complex concept or a disjunctive concept, an introduction event may only present a part of the concept definition. Namely, a concept definition may be presented using several introduction events.

Demonstration Event

A demonstration event presents the student a sequence of instances (examples and counter examples of the target concept.) Instances presented should be as divergent as possible. Namely, they should cover all aspects of the target concept (examples of every disjunct and examples showing every characteristic of the target concept.) Easy and simple instances should be presented before difficult ones. Typical instances should be presented before atypical ones. Near miss counter examples could be more useful than other counter examples so they should be presented more often than other counter examples.

Instances may be presented together with the concept definition. Each time an example or a counter example is presented to the student, an explanation of the example or counter example may be available upon the request of the student. At any time, the student may inform the event how well he/she understands a presented instance. Presentation of instances may be adjusted according to the student feedback.

Similarly to an introduction, instances of coordinate concepts may be demonstrated in sequence or in parallel. When demonstrated in sequence, only one instance is demonstrated each time. When demonstrated in parallel, multiple instances of different concepts are demonstrated simultaneously. When instances of different concepts are presented in parallel, differences among the instances of different concepts may be highlighted.

For a complex concept or a disjunctive concept, a demonstration event may only present a subset of instances of a concept. Namely, all concept instances may be presented using several demonstration events.

Parameters of a demonstration event may include difficulty level, example number, counter example number, instance presentation order, explanation mode, and control mode.

Difficulty level is the average difficulty level of all presented instances. Example number is the number of examples to be demonstrated. Counter example number is the number of counter examples to be demonstrated. Instance presentation order is the order in which instances are presented. The possible presentation orders include, from easy ones to difficult ones, from typical ones to atypical ones, random, examples before counter examples, one example and one counter example, simultaneous demonstration of examples and counter examples. Explanation mode determines if an explanation of each instance should be provided or not or upon the request of the student. There are two control modes: learner control and system control. What can be controlled include which instances to be demonstrated, the amount of instances to be demonstrated, the order in which instances are demonstrated. The student may have no control at all, partial control, or total control. If the student has total control, a list of all instances will be provided for the student to choose. Learning guidance is always available for the learner control.

Practice Event

A practice event provides an opportunity for the student to apply what they learned in the introduction and demonstration events. The following is a list of different types of problems.

True/False:

Instance I is an example of concept C.
Instance I is a counter example of concept C.
Properties $P_1, \ldots, P_n$ are characteristics of concept C.
Properties $P_1, \ldots, P_n$ are not characteristics of concept C.
Properties $P_1, \ldots, P_n$ discriminate concept C_1 from concept C_2.
Properties $P_1, \ldots, P_n$ do not discriminate concept C_1 from concept C_2.
Instance I is an example of concept C because of Properties $P_1, \ldots, P_n$.
Instance I is a counter example of concept C because of Properties $P_1, \ldots, P_n$.

Multiple Choice:

Which of the following concepts does instance I belong to?
Which of the following instances is an example of concept C?
Which of the following properties is a characteristic of concept C?
Which of the following properties is not a characteristic of concept C?
Which of the following Properties discriminates concept C_1 from concept C_2.
Which of the following Properties does not discriminate concept C_1 from concept C_2.
Instance I is an example of concept C because of which of the following Properties.
Instance I is a counter example of concept C because of which of the following Properties.

Matching:

Given n instances and n concepts, match one instance to one concept.
Given n properties and n concepts, match one property to one concept. A property matches a concept if the property is a characteristic of the concept.

Fill-In-Blank:

Given an instance, name the concept to which it belongs.
Given a concept, name one or more characteristics of the concept.

Problems may be automatically generated by the system or provided by the course developer. After a question is answered, the system may ask the student to provide an explanation for his/her answer. This may be just another question in one of the formats specified above. Hints for each problem may be available. Some examples of hints are concept definition with important characteristics highlighted, a similar problem with its answer, demonstration of a similar instance, and hints given by the course developer. After an answer is given, feedback will be provided. If the answer is correct, some reinforcement message may be given. If the answer is not correct, feedback may include the correct answer, the explanation of the correct answer, why the answer given by the student is not correct, and reference materials relevant to the problem.

Problems given to the student should be as divergent as possible. They should cover all aspects of the target concept. There should be some easy and simple problems as well as difficult ones. Easy and simple problems should be given before difficult ones. The practice event is adaptive and the amount of problems to be given and which problems to be given, and the difficulty level of the problems are dynamically adjusted based on the student performance.

Parameters of a practice event may include: difficulty level, amount of problems, problem type, hint, feedback, and control mode.

Difficulty level is the average difficulty level of all problems. Amount of problems is the number of problems to be presented. Problem type is the percentage of problems to be presented for each question type. Hint is if hints should be available or which hint should be available. Feedback is if feedback should be provided or how much should be provided. There are two control modes: learner control and system control. What can be controlled include the amount of practice problems and the types of problems. The student may have no control at all, may have partial control, or may have total control. If the student has total control, he/she determines if he/she needs more practice and the type and the area of the problems he/she wants to solve. Learning guidance should always be available for learner control. An exploration event could be developed using the demonstration event shell with learner control.

Test Event

The purpose of a test event is self-assessment and its result may be used for adaptive instruction. A test event is similar to a practice event, but hints and feedback are not provided and it is always system controlled. A test event grades every problem and provides a summary of the test result for the student. The types of the problems in a test event are the same as those described in section 3.3. The test may be adaptive.

Parameters of a test event may include difficulty level, amount of problems, and adaptation. Difficulty level is the average difficulty level of all problems. Amount of problems is the number of problems to be included in the test. Adaptation determines if the test is adaptive or not.

Authoring A Course Using Instructional Event Shells

Authoring a course using ConceptAuthor consists of the following three phases.

- Content knowledge acquisition
- Course structure construction
- Instructional event configuration

Content knowledge acquisition is to build concept taxonomies and enter the concept name, the concept definition, the concept context, and a list of concept characteristics, lists of discriminans, the concept instances, and the problems for each concept in the taxonomies. Course structure construction is to create the tree structure of a course and define all course units including instructional events. Instructional event configuration is to associate instructional event with the content knowledge (concepts) to be taught and set values of all parameters of an instructional event. ConceptAuthor includes a set of tools to assist the course developer in all these three authoring phases. Part of the course structure construction phase and the instructional event configuration phase could be automated. In this section, we will not discuss the authoring processes of these three phases and how these tools work. Instead, we will concentrate on the discussions of how instructional event shells can be used to formulate different concept teaching strategies (Merrill, et al., 1992). Many different concept teaching strategies may be created using the four instructional events. We will only discuss a few of them.

A typical and conservative strategy is the sequential strategy that teaches one concept after another. The instructional sequence for teaching one concept is *introduction*, *demonstration*, *practice*, and *test* (Merrill, et al., 1992). Coordinate concepts should not be taught one-by-one and should be taught simultaneously so that similarities and differences of these coordinate concepts may be compared. One strategy for teaching coordinate concepts is the sequential-simultaneous strategy that introduces and demonstrates all coordinate concepts one-by-one and practice and test on all coordinate concepts simultaneously.

An alternative strategy for teaching coordinate concepts is the simultaneous strategy in which all coordinate concepts are introduced, demonstrated, practiced , and tested simultaneously.

The last strategy discussed in this section is the discovery strategy that is very different from previous introduced strategies. The discovery strategy facilitates learning by discovery. It guides the student to discover the definition of the target concept by presenting a sequence of examples and counter examples of the concept. The order in which these examples and counter examples are presented should be well designed. After one or more examples and counter examples are presented, a few problems may be asked to check how well the student learned by discovery. And then, more examples and counter examples may be demonstrated again, and a few more problems are asked. This discovery process repeats until the student discovers the concept definition or the student quits this process. After this discovery process, the concept definition is presented followed by a test. Similarly, the discovery strategy can be sequential and simultaneous. The discovery strategy discussed above is sequential.

Conclusion

In this paper, we reported the work we conducted in development of a concept teaching authoring system, ConceptAuthor. This work is a part of a larger project. One of the objectives of development of ConceptAuthor is to explore the methods for developing authoring systems to support content-based authoring. The second objective of this work is to investigate methods for automating instructional design of adaptive instruction using instructional event shells. ConceptAuthor is being implemented on Windows 95 in Visual C++ and Access.

Abstract: The deficiency of the auditory sense in the hearing impaired raises the question as to what extent this deficiency affects their cognitive development and intellectual abilities. In studies that have been carried out over the years, many theories have been presented on the cognitive development and performance of hearing impaired. The purpose of this study was to discover whether the practice of rotating three-dimensional objects with Virtual Reality will have an effect on the flexible thinking in hearing impaired children. The study was carried out with 60 children, of which 44 were hearing impaired. The hearing impaired children were distributed into two groups: the experimental group and the control group. The experimental group played virtual 3-D "Tetris" individually, for 15 minutes, once a week over a period of three months. The control group played 2-D "Tetris" over the same period of time. In addition, 16 children with normal hearing took part in the study as a second control group in order to establish whether hearing impaired children really are at a disadvantage in terms of their flexible thinking. The experimental group and the hearing impaired control group were evaluated by the Torrance sub-test "Circles" (1966), before and after the experiment. The results clearly indicate that practicing 3D spatial rotations with VR significantly improved the flexible thinking in the experimental group as opposed to the hearing impaired control group, who did not improve significantly. Also, before the experiment, it was discovered that the hearing impaired children attained lowers scores in flexible thinking than the children with normal hearing. After the experiment, however, the results of the experimental group improved to the extent that there was no noticeable difference between them and the control group of children with normal hearing.

Introduction

The concept of "creativity" is regarded and defined in different ways by different researchers. The definitions differ from each other according to the difference in their approaches to creativity. In general, one can divide the definitions into three categories (Nevo, 1997):

1. The definitions which emphasize the creative process.
2. The definitions which deal with the creative person and his/her personality. These definitions focus on inter-personal differences such as the characteristics of the creative person and how s/he differs from the "regular" person.
3. The definitions which deal with the product. They emphasize the realization of the potential of the main idea and the extent to which the final product differs from that which already exists.

The approach of Guilford (1967, 1970) and Nevo (1997) has been of great influence. They refer to factors in activating and factors of character, but their main contribution is in the detailed analysis of the elements found in the process of creative thinking. According to their approach, creative thinking is a complex and diversified phenomenon and it involves a number of capabilities which are almost independent of each other. Guilford distinguishes between a) convergent thinking b) divergent thinking.

Convergent thinking points to the production of information emphasizing one single probable and best result. On the other hand, divergent thinking flows in many different directions and is connected to thinking functions in which there is not just one correct solution. This way of thinking is also known as creative thinking. Guilford identified four factors related to the ability to think creatively:

* Fluency—the ability to think of a number of possible solutions to a given need.
* Flexibility—the ability to change approaches and points of view, and not stick to only one approach.
* Originality—the ability to arrive at new and unconventional solutions.
* Elaboration—the ability to develop and improve basic ideas.

Torrance (1980) points out that most young children are creative, but that this ability wanes as they mature. Schools teach with conventional methods, which focus on precision, speed and the provision of correct answers. There exist specific teaching programs which attempt to develop creative skills using various activities such as: brainstorming, creative drama, activities related to creative art, unconventional uses of daily objects, etc.

This study focused on the child's ability to think flexibly (the second aspect of creativity described by Guilford (1967, 1970) above). Sternberg & Powell (1983) define flexible thinking as the ability to look at things from different angles. They point out that during adolescence the ability of the child to think flexibly is more prominent. This flexibility is expressed in two opposite directions. On the one hand, children exhibit better ability to think consistently and adhere to methods which proved effective in solving problems. On the other hand, when necessary, they are capable of changing their work methods and exchanging them for more successful methods. Flexible thinking is one of the most important characteristics of intelligent behavior.

Guilford (1967, 1970) claims that flexible thinking is the ability to create a flow of ideas while changing direction or correcting information. In his opinion, there are two types of flexibility a) spontaneous flexibility—spontaneous change in the thinking process and the transition to another, and b) adaptive flexibility—the ability to adapt to changing instructions. The component of flexibility appears to Guilford to be related to the ability to generalize and abstract.

Researchers studied the ability of hearing impaired children to think flexibly both verbally and in terms of shapes. This study relates solely to non-verbal ability.

Laughton (1988) compared the traditional approach of teaching art to teaching programs geared to developing creative ability. He studied 28 hearing impaired children between the ages of 8-10, who took part in one of the two programs for twelve weeks. The children were tested in the Torrance formal test before and after the intervention. It was found that there was a significant improvement in flexibility and originality among the children who studied according to the new program. Laughton (1988) summarizes and claims that by means of the appropriate teaching strategy it is possible to develop creative aptitudes with hearing impaired children and to help them to become less concrete and rigid in their thinking.

Saraev & Koslov (1993) examined 100 deaf children and 164 hearing children between the ages of 7–12. One of their findings shows lesser ability in creative imagination among the deaf, and rigidity in their way of thinking.

King & Quigley (1985) also claim that hearing children surpass hearing impaired children in creative ability.

The teaching of art usually receives lower priority than academic subjects in the teaching programs for the hearing impaired. Researchers have found that focusing more on strategies for creative thinking will have a favorable effect on:

a) abstract thinking,
b) imagination,
c) the attention paid to various details of patterns whose basis is visual but which can basically serve as linguistic behavior,
d) potential emphasis on the creation of vocational opportunities,
e) more efficient functioning in situations requiring the solving of problems, etc, (Laughton, 1988).

Bunch (1987) also claims that teachers tend to concentrate on the areas in which the hearing impaired experience the most difficulty—the language, communication and reading. Studies show that the hearing impaired lack the aptitudes required for artistic development. Bunch claims this is not due to lack of potential, but rather the lack of opportunities to develop the potential required for these aptitudes. In his opinion, if these pupils are given the opportunity to develop their potential and the teachers are provided with methods of encouraging creative thinking, hearing impaired children will progress and reach the level of hearing children. He perceives music, dance, drama and visual art as creative tools which can be used to develop language and cognitive skills such as: problem solving, abstract thinking, clarity of thought, developing imagination, etc. Upon examination of various teaching programs, Bunch found three basic goals for the teaching of art to hearing impaired children: strengthening visual awareness; developing pre-artistic abilities; developing imagination.

In recent years, one can notice an active approach of intervention in the cognition of the deaf, in an effort to improve their intellectual functioning. At the root of this trend is the belief that deaf students possess the same range of intellectual potential as hearing pupils. They can reach this potential if their environment, their instruction and the tools employed are appropriate and encourage learning. In addition, the researchers leading this approach point out the great importance of intervention programs for the improvement of the cognitive achievements of the hearing impaired (Gruler & Richard, 1990; Huberty & Koller, 1984; Martin, 1991).

Many other researchers note the close link between creativity and imagination. The ability to imagine and transform images is important in many areas, including creativity (Kaufman, 1985; Kosslyn, 1980; Shepard & Metzler, 1971). Singer (1966) found in his study, that children with developed imaginations were more creative than children with poor imaginative ability. That is to say, the ability to imagine different scenes and animals, the ability to deal with a wide range of changes and imagined transformations and the ability to be flexible in thought—all indicate a tendency toward creativity.

Studies have thus proven that hearing impaired children tend to be more concrete and rigid in their thought processes. They usually choose one familiar means of solving problems and use it to deal with most of the problems that they encounter. The purpose of this study was to prove that it is possible to improve the flexibility of thinking in hearing impaired children with the help of a cutting edge technology—Virtual Reality (VR).

Pantelidis (1995) defines VR as an interactive multimedia environment, based on the computer, in which the user is assimilated into, and becomes an active participant in the virtual world. This technology can present information in a three dimensional format in real time so that the user becomes an active participant in the environment which communicates interactively without the use of words. VR makes it possible to convert the abstract thinking into more concrete by providing a perspective on processes which is not possible in the real world (Darrow, 1995; Durlach & Mavor, 1995; Osberg, 1995; Pantelidis, 1995).

Virtual Reality is a new thinking tool which can be used without language, and it might become an appropriate work tool for hearing impaired children.

Subjects

A pilot study was carried out, in order to validate the Virtual Reality game as a research tool. The pilot study included 10 hearing impaired children, who achieved an average score of 4.2 out of a possible 100 points.

The study examined 44 hearing impaired children between the ages of 8-11 (average age 9.3) who had middling to severe hearing loss, with an average hearing loss of 88.62 dB. They had no additional problems. The children studied in integrated classes in the only two schools under Ministry of Education supervision in the central/ Tel Aviv school district. In these schools hearing impaired children study in small separate classes, but take part in general school activities and are integrated into some of the classes together with hearing children.

In addition, we chose 16 hearing children in order to establish whether hearing impaired children do achieve poorer results than hearing children, in their ability to think flexibly. The ages of the hearing children ranged from 8-10 years old (average age 8.8). The sample included a total of 60 children according to the following divisions:

* 21 hearing impaired children served as the experimental group.
* 23 hearing impaired children served as the control group.
* 16 hearing children served as an additional control group.

Procedure

Each subject in the experimental group played, on his own, a 3D Tetris game, once a week, for 15 minutes, over a period of three months. The hearing impaired control group played, during the same time period, a 2D Tetris game. The control group of the hearing children did not experience any intervention at all.

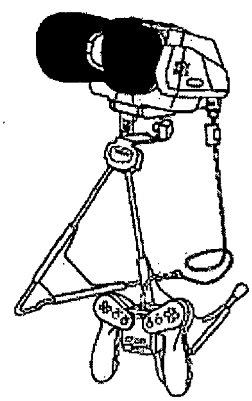
The experimental group and the hearing impaired control group were tested before and after the intervention in the sub-test "Circles" – Torrance (1966). This test was used in order to study whether practice in the rotation of three dimensional objects, which requires the ability to view objects from different angles, will have an influence on the flexibility of thinking in the subjects. The test includes verbal and non-verbal tasks. We used the non-verbal tasks owing to the verbal insufficiency of the subjects. This test has been carried out many times over the years and has received the high score of 90 in reliability (Torrance, 1966).

The instructions for the test were given orally, accompanied by the use of sign language, in order to ensure that all the children understood them fully. The hearing children were tested only once.

Virtual Boy – Nintendo

The game used in this study is an interactive VR game, with a distinctive system which can create a dramatic three-dimensional world. The software included three games (Tetris, Puzzle, Center-Fill), in all of which the objective was to carry out certain demands via control over three dimensional blocks: the subject had to fill a three dimensional block with various shapes made up of smaller blocks. The subject had to put the dropping blocks in the right place, and accordingly, accumulate points. In order to accumulate more points, the user must act accurately and rapidly. This three dimensional VR game presents to the user many ways of solving the problem. Because of the variety and quantity of possibilities, it is usually not possible to remember exactly how the problem was previously solved, and the user solves the problem placed before him differently each time he plays the game. Thus he learns that there are many and varied solutions.

Figure 1: Virtual Boy- Nintendo 1995



Results

The research suggested that a clear difference would be found between the experimental group of hearing impaired children and the control group of hearing children in their ability to think flexibly before practicing spatial rotation, by means of the VR game. After the practice, in contrast, the ability to think flexibly improved in the experimental group to such an extent that no clear difference was found between this group and the control group of hearing children. That is to say, the scores of the hearing impaired children in the experimental group were similar to those of the hearing children in this test. In order to verify this, we conducted a one-way analysis of variance.

Table 1 presents the averages in the measurement of flexibility of thinking in the three research groups–the experimental group of hearing impaired, the control group of hearing impaired and the control group of hearing children, and the analysis of the variations among the groups.

Table number 1: Results of the one-way variance test for the calculation of averages, standard deviation and variance analysis of flexible thinking by research groups (experimental, control hearing impaired and control hearing) and by time.

Time		HI experimental	HI control	Hearing control*	Model P,F	Group P

Before	Average	7.05	5.91	23.00	F(2,57)=177.92 P<0.001	P(1,2)=n.s. P(1,3)<0.001 P(2,3)<0.001
	Standard Deviation.	2.85	3.50	2.37		
	Sample Size	21	23	16		
After	Average	18.10	5.96	23.00	F(2,57)=102.04 P<0.001	P(1,2)<0.001 P(1,3)<0.001 P(2,3)<0.001
	Standard Deviation.	5.76	3.47	2.37		
	Sample Size	21	23	16		

- HI= Hearing Impaired.

* Comment: the control group of hearing children took the tests once only; that is to say, the data in the table was copied from "before" to "after".

Figure 2 presents the average scores in flexible thinking of the three research groups – experimental, control hearing impaired and control hearing, before intervention.

Figure 2: Averages of flexible thinking according to research groups before intervention

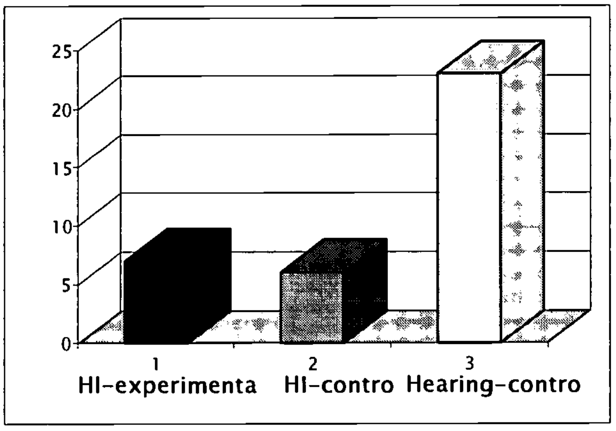


Figure # 3 shows the averages in flexible thinking measured after the intervention.

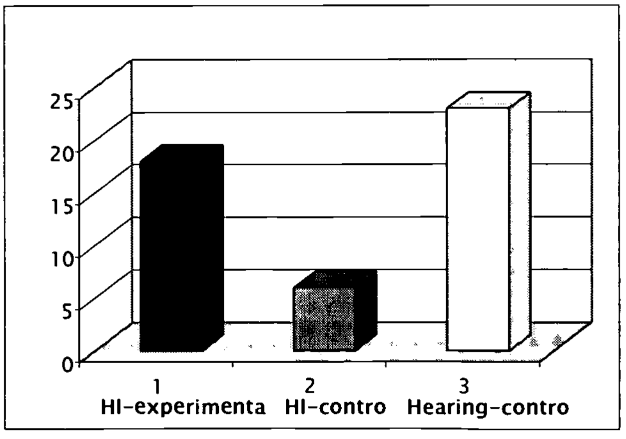
Figure number 3: Averages in flexible thinking according to research groups after the intervention.



A look at Table 1 and Figures 2 and 3 indicate that prior to the practice there was a considerable gap in flexibility of thinking between the research group of hearing impaired children (both the experimental group and the control group) and the control group of hearing children. The difference favored the hearing children. No considerable difference was found between both research groups of hearing impaired children (experimental and control groups). In contrast, after the practice, a clear difference was found between the experimental hearing impaired group and the hearing impaired control group in their ability to think flexibly, favoring the experimental group. No clear difference was found between the experimental group and the control group of hearing children; that is to say, the children in the experimental group improved their achievements significantly and reached the level of the hearing children in this index.

Discussion

One of the goals in the education of hearing impaired in Israel and throughout the world is the emphasis on the importance of nurturing thinking in these children. Studies have found that the functioning of the hearing impaired improved after appropriate learning, training and practice (Gruler & Richard, 1990; Martin, 1991). In addition, the existing programs of intervention do not exploit the vast possibilities of modem technology, especially the modem, attractive technology - VR. This study is unique due to the use it makes of the virtual game, which trains in spatial rotation as a means of improving flexibility of thinking in hearing impaired children. To the best of our knowledge, this is the first experiment of its type to exploit the advantages of VR technology, and of this game specifically, as a means of intervention for nurturing the cognitive skills of the hearing impaired population.

This study found a clear difference in the ability to think flexibly between hearing impaired children and hearing children before practicing, to the advantage of the hearing children. This finding is reinforced in previous studies which found that hearing impaired children possess lesser ability in creative imagination and have a tendency to rigidity in their thinking (Saraev & Koslov, 1993). After practice, the children in the experimental group improved in their ability to think flexibly with the help of the 3D VR game, and no marked difference was found between them and the control group of hearing children. In contrast, the control group of hearing impaired children continued to score poorly and the gap between them and the hearing children did not narrow. In other words, the hearing impaired children who played with the VR game reached the level of the hearing children. This finding parallels that of Bunch (1987) who claimed that if hearing impaired children are afforded opportunities to develop their potential and the teachers are provided with methods of encouraging creative thinking – hearing impaired children will progress and will reach the level of hearing children.

The results indicate a clear advantage of 3 dimensional VR (received by the experimental group) over the conventional 2 dimensional intervention (received by the hearing impaired control group). It is reasonable to assume that these findings were obtained due to the differences between the two types of practice. The children in both groups played, during the same period of time, rotation games via Tetris, with only one difference between the two groups – 3D VR versus a 2D game.

A logical explanation of these findings is found in the nature of VR technology and in earlier studies. This technology creates a "pre-symbolic" form of communication, and its users can communicate with imaginary worlds without the use of words. Thus, a world is created charged with sights, voices and sensations which surpass syntax and language (Passig, 1996). The hearing impaired children who used this technology were able to realize their hidden potential without linguistic or auditory limitations. VR technology does not limit the player in either the manner in which information is presented or in his movements, and the user is able to immerse himself in the learning environment (Pantelidis, 1995). In this virtual manner, the hearing impaired users completely immersed themselves in the game. They felt as though they themselves were moving the blocks, searching for the right ones and rotating them. In other words, the abstract became less vague and more concrete. Various studies in the field of VR also found that this immersion serves to broaden the interface with the senses and also improves the ability to understand abstract concepts by converting them to more concrete ones (Darrow, 1995; Osberg, 1995). Another unique quality of the technology is that VR causes the user to be especially active. The increased liveliness and level of interactivity causes the user to become a part of the virtual world. This tool is able to present information in three dimensions and in real time. This permits the user to be an active participant in the environment and not merely a passive observer (Bricken & Byme, 1992; Heim, 1992; Osberg, 1995; Powers & Darrow, 1994). Hearing impaired children require more active involvement in the learning process than hearing children (Marzam, 1998).

Another fitting explanation of these findings is the fact that this technological tool is fun and motivates the user. Studies have shown that children who use VR enjoy it and wish to continue to learn more by using it (Bricken & Byme, 1992; Talkmitt, 1996). It would appear that the high level of motivation of the children studied led to their continued participation in the intervention program and their success in it.

Summary

This study proved that a significant improvement in flexible thinking took place in hearing impaired children due to the use of a 3D virtual reality game. Beyond this contribution, important in itself, the biggest contribution is the advancement of this field to the point where hearing impaired children reached the level of hearing children. In the light of the findings of this study, and its low cost, we recommend that schools in which hearing impaired children study, purchase this hardware and software.

ISTOPOLIS – A network based hypermedia educational system

C. M. Papaterpos, G. D. Styliaras, G. K. Tsolis, T. S. Papatheodorou
High Performance Computing Lab,
University of Patras, Rion 26500, GREECE
{cmp, gds, gkt, tsp}@hpclab.ceid.upatras.gr

Abstract: Web based technologies and efficient techniques on the LAN and the desktop, can be combined for the development of a single modular and scalable educational system, capable of adopting to and functioning in different learning environments: stand-alone use, use in a LAN enhanced classroom and distance learning on the Web. Such a system is presented in this paper. The design of the system addresses well-defined educational and pedagogical goals and attempts to facilitate different computer cognition levels. The current implementation demonstrates the use of the system with educational material designed especially for teaching Ancient Greek History to 7th grade students.

1 Introduction

ISTOPOLIS is a hypermedia based educational system initially designed for courses in history, culture and related fields. Emphasis has been placed on deployment of the system in the classroom. The design of ISTOPOLIS attempts to address fundamental educational issues and goals, including transformation of available information into knowledge, practicing basic skills and dealing with low and / or highly variable computer cognition level on the part of the students.

The system provides its users (educators, students and content providers) with a broad set of services over media-rich educational material, in a highly configurable manner. The material used may cover many different knowledge areas. Educational material is presented to the end user in the form of hypermedia documents. Each document covers a small subsection of the target knowledge area and constitutes an information item. The collection of information items offered to the user follows a concrete data organization scheme. Efficient access to the document base is facilitated through different views of this organization scheme. Each view is implemented as a highly interactive access tool, which not only helps the user locate documents, but also places the documents within specific contexts, leading to a better comprehension of the material. These views include a thematic categorization, geographical and chronological navigation systems, and a simple to use search facility. It follows that the content of the system consists of a set of independent and multiply structured information items that users can access. Additional content may be accessed from related web sites.

Access to the information items as well as to these tools may be provided to the end-users either through a standard web browser, or through a specialized client. The client, apart from access to the content, enables all users to compose projects (small sets of hypermedia documents in the form of an essay) by reusing parts of the content. Additionally, it enables teachers to create their own views of the content (in the form of guided tours) and teachers and students alike to playback these tours. Finally, the system provides teachers with a tool for creating and grading tests. Each test can incorporate different types of questions and can be completed and submitted on-line by the students. Access to the system is controlled through a server-based mechanism that authenticates users and assigns them their respective workspace.

Many of the services built in the client and the server are by now well established services and are very popular for accessing Web content. Innovation of this system lies in the way that these services interrelate and integrate into a single system, with a unified front-end for the end-user. Porting to other languages is straightforward and an English version of the system is now under development.

2 Pedagogical and educational issues and how they are addressed

There is a great number of pedagogical and educational issues regarding multimedia educational software. In this section we place emphasis on some essential requirements, particularly in the context of "human sciences" and junior high school students. We also discuss ways in which ISTOPOLIS addresses these issues (Papatheodorou, 1998).

2.1 Transforming Information into Knowledge

An important goal in developing an educational application is transforming information into knowledge. According to (Rohrs, 1984), students should be allowed to express "their creativity, one of the most essential goals in education", while the goal is not to "turn students into small libraries but to allow them to take active part in the process of knowledge" (Bruner, 1975). It is also well established that notions are not conquered by students through definitions, but through experience and "trial and error" techniques (Vygotsky, 1962).

Addressing this goal is based on the use of a set of information retrieval tools (Access Tools) that do not only enable the user to locate information (such as in a search system), but, at the same time, place the information within complementary contexts (time, place and subject). The Access Tools are coupled with a facility for the students to reuse located information, combine it with their own narration and personal views and transform it into small essays.

2.2 Practicing basic skills

Some of the most important skills that students should practice are briefly discussed below, together with the ways that ISTOPOLIS attempts to accentuate them. Most of these skills are of particular significance in the case of humanities and especially history (Curtis (1994) and Culpin (1994)). Successful practicing depends both on system qualities and on the way the software itself is used within and outside the classroom, during and after normal teaching hours.

Working alone and within a group. It is essential that students learn to "work as a team" in order to be "able to adapt in a continuously changing world" (Rohrs, 1984). ISTOPOLIS allows students to work in groups by letting teachers assign a unified workspace to students belonging to the same working group. In this workspace, projects may be collectively developed. A student may also use the system individually, either in classroom or at home, since the system can also operate in standalone mode. Moreover, students or groups may exchange pages or bookmarks on pages via email.

Identifying reliable information and distinguishing between facts and opinions, evaluating sources and selecting related information from a variety of sources. ISTOPOLIS enables students to develop projects, using information available locally and on the Web. This way, it offers access to a great variety of sources, which deviates from the common single textbook approach. Material provided with the application is developed and tested by experts and can be a-priori considered reliable. The fact that this information follows a common presentation template makes it visually different from work produced by other students as well as from other material gathered through the Web.

Understanding of terms. Terms that the students are anticipated to be unfamiliar with are visually marked on the screen. Explanation of a term is given as a popup activated by placing the mouse pointer over the term. Elaboration of more significant terms is provided in related pages within the educational material.

Locating and recalling information. ISTOPOLIS places the content within specific time and place contexts and provides clear thematic categorizations, thus offering considerable assistance in locating and recalling interrelated information. Recalling information is accomplished through the same tools students use to locate the material.

Describing, narrating, interpreting, comparing, drawing conclusions from information contained in texts and expressing opinion. Through authoring a project, students are given the chance to combine various tasks, such as composing and serializing facts presented within the educational material, narrating or describing situations and facts and expressing their own views. Comparison of information pieces found in the material is made easier by the fact that these pieces may be very easily inserted into the student's project.

2.3 Computer cognition issues

Some important issues involve the computer cognition level of the targeted users. One issue is the low level of familiarity with computers for the majority of students, especially in low-income cases and rural areas.

Thus, an important requirement is that the system is easily useable by inexperienced users as well. In addition, it should help users to acquire and practice standard computer operation skills through a widely used environment and user interface. A second issue is the large difference in computer cognition levels among students in the same class. The problem is more evident in urban environments where, among inexperienced students, there are a few with strong computer experience. The system should attempt to provide "equal opportunity" for all.

One approach that ISTOPOLIS uses to deal with these issues is to offer different modes of operation, corresponding to different levels of computer experience. The simplest way for a student to use the system is through the *guided tour* operation mode (sequential navigation through a series of "pages" selected by the teacher from the educational material available). In a higher mode, the system provides the option for the student to customize his/her own exploration of the educational material. This is accomplished through hyperlinks embedded in the content and deploying the *Access Tools* described in the next section. In this mode, the student is required to take actions that are normally met in common Web browsing activities. In a third mode, the student may reuse portions of the educational material and compose his / her own hypermedia documents. This process involves basic word processing skills and use of drag' n' drop operations. The teacher may decide on the use of any combination of these modes, according to the level of the classroom.

Another way in which ISTOPOLIS attempts to deal with these issues is through a simple-to-use, consistent user interface. Browsing and authoring are implemented by integrating a common Web browser and a word processor. Thus, the user of the system is assisted by and assists training in such basic tools. Access to content and services is provided through a unified workspace, implemented by a specialized client designed as a single-document interface (SDI) application. The user is not required to wander through windows or switch between different applications and confusion between application oriented and content oriented operations is largely eliminated.

An additional issue strongly related to the user's experience is the use of navigation tools. In hypermedia-based systems, the need for navigation-aiding tools complementary to following embedded hyperlinks is practically self-evident (Christodoulou, 1998). Several tools that are based on navigation structures have been proposed (Schwabe 1995). Initial findings indicate that inexperienced users under-utilize navigational tools based on high levels of abstraction e.g. concept-maps (Zeiliger, 1997). Tools based on structures and models with which students are not familiar (e.g. graphs) would increase the cognition overhead required to exploit these tools. Instead, ISTOPOLIS provides access to multiply structured information through simple navigation tools (e.g. maps), consistent with the students' experience.

2.4 Other issues

Teacher related issues. ISTOPOLIS supports teachers in various stages of the educational process, such as presentations and student evaluation. The teacher is provided with the ability to instruct students to browse through the content or follow a guided tour. ISTOPOLIS enables the teacher to make additional content available to the students through the system, by authoring and publishing his/her own projects. Evaluation of students' performance is assisted through online inspection of student projects, facilitation of test development and online test grading.

On-line / off-line operation. A user may autonomously use the system from home with or without an Internet connection (stand-alone or on-line operation).

Updating the content. In the current implementation, updates of the content and of basic customization of the Access Tools are supported. This includes re-indexing of content for the search system, changes on objects that appear on maps, addition of thematic categories, etc.

3 Functional specification of the system

Users of ISTOPOLIS may be classified into end-users (teachers and students) and content providers. The system may be deployed in the classroom LAN, over a wide area connection with a remote server, or as a stand-alone application. ISTOPOLIS offers two fundamental services and a complementary one for end-users, which constitute the end-user segment of the system: locating educational material; reuse of material for creating projects; and creating and conducting tests. A back-end subsystem, ("preparation segment"), allows the content provider to enter the data and customize the functions that enable end-users to locate material.

The system is based on educational material presented to the user in the form of hypermedia documents, each document being an autonomous information item. Apart from the content provided with the system, the user may access HTML pages from the Web.

The easiest way for students to access information is through a guided tour created by the teacher. In this mode of operation and by using a small set of buttons, the student can sequentially navigate through a series of content pages arranged by the teacher. The teacher can locate the information to include in the guided tour by using the Access Tools described below and can create the guided tour through the use of a pertinent tool incorporated in his/her workspace. The user can leave the guided tour and browse the content through embedded hyperlinks and the use of Access Tools and return to the flow of the tour by clicking a button.

Access Tools presently include four basic tools available to the end user and are briefly outlined as follows. All information items are associated with keywords and are loosely classified according to three basic classification criteria: time, place and subject. Data directly related to the content (such as title, text, images and keywords) as well as fine and coarse-grained classification data follow a single, simple and concrete data organization scheme. This makes it possible to present three different views of the content as main branches of a subject catalogue. The subject catalogue is implemented as an Interactive Thematic Catalogue (ITC) system described in (Styliaras, 1998). For the chronological and geographical classifications, both a coarse-grained (based on eras and greater areas) and a fine-grained (based on years and specific map coordinates) characterization of content is given. Fine-grained classifications are used to support access to the chronological and geographical views through visual tools: a timeline and a map-based navigation tool. All three tools, subject catalogue, timeline and map-based tool, support searching or filtering. Map-based navigation provides filtering based on time and subject related criteria. Finally, keywords correlated with the educational material are used within a search tool that apart from searches on sets of keywords allows for full text searches on the material.

The specific chronological, thematic and geographic context of each information item is exposed to the user as a hyperlink to the corresponding category. Exposing the context of each information item in a typical fashion helps the user recall the information at a later stage (e.g. when authoring a project). Using a hyperlink to the corresponding categories (and tools) enables the user to locate relevant information within specific context.

Customization of the classifications and data entry of the actual educational material is achieved by the "content provider" through a back-end subsystem (preparation segment). Data entry for the system is carried out at the same time for all four tools. Update of a single piece of information automatically updates the behavior of the Access Tools. It should be stated that the content provider need not be confined in the three classifications chosen for the current implementation of the system. In order to facilitate use in different knowledge domains, creation of various classifications is possible for the content provider through the back-end environment.

Reuse of the educational material is achieved within the *specialized client* through storing material and incorporating it into a *project*. The user can store text excerpts, images, bookmarks and hyperlinks. Storing a part of information is implemented through a simple process, which consists of selecting the information item, dragging it and dropping it onto the client's inventory area. Bookmarks are stored in the same way, by selecting and picking up a control next to the page's title. All items in the inventory area are represented by icons. Users may store bookmarks or material not just from the content provided with the system, but also from any HTML page on the Web, exploiting thus a variety of sources.

A project is organized in pages, which are represented by icons in a page-index area. To insert a piece of text or an image, the user selects a page in editing mode (preview of pages is also supported), drag the icon of the text or image and drop it onto the page. Users may create hyperlinks by selecting the source of the link on the page being edited (text or image) drag a link or a bookmark from the inventory or a page of their own from the page index and drop it on a "link creation target area". When editing a page, users can write their own text, modify the text they have included and, of course, write their own text. To keep use of the system simple, a small set of editing functions is provided: it includes character and paragraph formatting and application of predefined styles that help the user translate contextual information (such as project or page heading) into visual (different but concise visual formatting).

A brief overview of the overall architecture and system building blocks is presented in Figure 1. Content and access tools, guided tours (creation and playback), project authoring and publishing and completion of tests are available to the user through a specialized client that, among others, incorporates functionality of a web browser and an HTML Editor. Separate (for the current implementation) tools facilitate creation of tests and support the content preparation and Access Tools customization process. Content and access tools may also be available to the user through a conventional Web browser. In the current implementation, some of these functions are offered only for Microsoft's Internet Explorer.

Within the client, services offered are grouped into operating modes, with varying levels of difficulty, so that the teacher may fine-tune system deployment. *Free navigation* offers use of the Access Tools, bookmarking and tests. *Guided tours* offer all Free navigation services, plus a guided tour creation tool for the teacher and a guided tour playback tool for the students. *Project authoring* offers all free navigation services, plus all operations needed for authoring projects.

The system generally follows the client-server paradigm. The content resides on the server side. The data organization scheme for the content is supported by an RDBMS, over which the Preparation Segment of the system has been built. The biggest part of functions (including the Access Tools) is also implemented on the server side. In order to offer additional services to the teacher (creation of guided tours and tests) the system requires that the user be authenticated. This process authenticates registered users of the application, as either teachers or students (implying different functionality of the client) and as members of specific working groups in the case of students. The process assigns a working area in which users store their work. The relative location of the client and server part of the system determines whether the system is used 1) over a LAN, 2) over a remote connection (on-line), or 3) as a stand-alone application (off-line). Special care has been taken so that the system may be easily reconfigured and used in other languages: most of the reconfiguration needed may be carried out through simple changes on resource files.

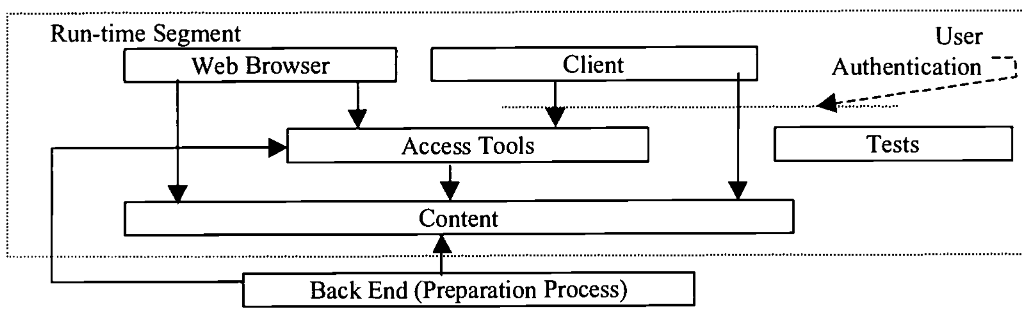

Figure 1: Architecture of ISTOPOLIS.

4 Current implementation details and evaluation results

All building blocks, demonstrated in Figure 1, have been implemented and integrated into the system, which is fully operational. The current implementation has focussed mainly on the system's operation in class. The available content is presently targeting 7th grade students and covers about 450 information items from Ancient Greek History (specifically the Palaeolithic period to 1125 B.C.). For implementing Web browsing and project-page editing functionalities, Microsoft's Internet Explorer and Word 97 have been integrated within the system. Architectural and implementation details may be found in (Papaterpos, 1999). Figure 2 displays how the client looks like in project-creation mode, while a user is locating information through the map-based navigation tool. A list of the projects' pages appears in the left of the screen. The inventory, where chunks of text, links and images are collected, appears in the bottom.

Currently, the system is undergoing a systematic on-site evaluation in a set of Greek High schools. It is expected that the on-site evaluation will be concluded early next year and detailed evaluation statistics will be available at that time. Preliminary in-house testing with students and teachers seems to validate achievement of most of the requirements set. Students relatively unfamiliar with computers easily adjusted to the gradually increasing levels of difficulty provided.

From the testing phase, some possible enhancements have emerged. For example, users would like to have more material from different sources. Furthermore, the backend should be made available to teachers in order to have the ability to add more material (found either on-line or from conventional sources). In this way, there will be no need for an expert content provider to insert the data into the system. Concerning the guided tours, an extra "presentation" view is needed, which will be more suitable for displaying the guided tour within the classroom. What's more, teachers should be given the capability to annotate pages included in the guided tour. Regarding the subject catalogue, more elaborate filtering could be applied to its categories. As it is expected that groups of students will use the system, a better collaboration scheme is needed for students working within the group, so that it won't be necessary for all students in the group to work simultaneously.

Abstract: This paper describes an interactive multimedia learning environment for learning how to diagnose fetal abnormalities. The pedagogical approach adopted in the design of the learning environment is that of goal-based scenarios. The paper sets out the theoretical underpinnings of this approach and illustrates the learning environment by means of a typical system walk-through. It highlights some distinctive features of the system as well as pedagogical strengths of the learning environment. A critique of the learning environment is offered with respect to the criteria laid down for the design of goal-based scenarios.

Introduction

There is considerable evidence today indicating that the knowledge and skills of experts are highly situated and case-based (Kolodner & Jona 1991). This is especially so in the medical domain where expertise is often characterized as being data driven and is attained through exposure to a wide range of cases over long years of practice.

It is now also commonly accepted, especially in medical education, that students learn more effectively by directly participating in interactive case-based learning scenarios rather than by passive reading and observation (see, for example, Barrows 1985). Learning by doing has the advantage of providing for deeper engagement in the learning process and superior retention and transfer of knowledge. Thus, one would expect medical students to learn more effectively when given the opportunity to acquire clinical diagnosis and problem solving skills using the 'learning by doing' approach in a context-rich learning environment. In addition, experientially-grounded learning provides a concrete basis for subsequent reflection on a student's diagnosis and problem solving actions. Attempts to rethink and redesign learning experiences, especially technology-based learning experiences, occur as part of a broader and more fundamental shift in orientation within education (e.g. Schank 1993/1994) and also as part of a shift toward constructivist approaches to supporting learning (see, for example, Savery & Duffy 1995).

The training of medical general practitioners and medical students in the management of fetal abnormalities has always been a difficult matter in practice. This difficulty stems from the fact that:

a. fetal abnormalities in ultrasound scans of pregnant women are the exception rather than the rule
b. the repertoire of abnormalities that a student has the opportunity to experience firsthand is extremely limited
c. access to ultrasound scanning machines and training time on such machines for students is hard to come by because of general resource scarcity

To overcome the above difficulties, we have embarked on the development of a multimedia goal-based scenario for learning how to diagnose and manage fetal abnormalities.

Theoretical Background

A goal-based scenario is a case-based approach to learning. The approach requires instructors to design situated and authentic problem solving activities and domain contents. Within the goal-based learning environment, students are set specific problem solving goals. In pursuit of these goals, they perform tasks that help facilitate the acquisition of the target skills. In so doing, they also learn the underlying concepts upon which the target skills are based.

The goal-based scenario approach to the design of learning environments requires the designer to define a mission, a mission focus, a cover story, and appropriate scenario operations (Schank, Fano, Bell, & Jona 1993/1994). Briefly, the *mission* refers to the primary goal that the student pursues within the goal-based scenario. The *mission focus* refers to the overall organization of the student's activities within the goal-based scenario. Mission foci may be of different orientations, including design, discovery, exploration, and control. The *cover story* refers to the premise, designed by the instructor, under which the mission will be pursued. *Scenario operations* refer to the specific activities that the student performs in pursuit of a mission.

There are seven specific criteria that instructional designers need to consider when designing a goal-based scenario. These are:

a. thematic coherence: ensuring that the process of achieving the goal is thematically consistent with the goal itself
b. realism and richness: ensuring that the learning environment amply encompasses authentic tasks in context-rich settings
c. control and empowerment: ensuring that students are able to take control and feel responsible for the completion of the set task
d. challenge consistency: ensuring that the learning environment presents a consistent degree of challenge and difficulty over the entire process of achieving the goal
e. responsiveness: ensuring that time-critical elements of the environment occur in realistic simulated time, and providing prompt feedback
f. pedagogical goal support: ensuring that the learning scenario is compatible with and amply supports the acquisition of the target skills
g. pedagogical goal resources: ensuring that materials and tools needed to achieve the goal are available within the learning environment

In practice, the extent to which one finds it easy or difficult to achieve each of the above design criteria depends very much on the subject domain in which one is working.

Project Overview

Our research project has two main parts. The first part focuses on helping students learn how to diagnose fetal abnormalities. The second part focuses on training students on how to manage and counsel patients when abnormalities are discovered.

The first part of the project makes extensive use of ultrasonography. Ultrasound images of the unborn fetus are displayed to the user, typically a trainee gynecologist, on request. These images can either be digitized videos of ultrasound investigations or they can be still image "cuts" (i.e. cross-sections) of the unborn fetus at different body locations and orientations. Given the domain of diagnostic ultrasonography, we have made extensive use of multimedia and created a context- and media-rich learning environment where students are given control over what they wish to view or do at any point in time. When the user has reviewed the ultrasound images and the patient's case history to his satisfaction, he is requested to decide whether the unborn fetus suffers from any abnormality, and, if so, identify the type of abnormality.

Once the user has entered a diagnosis, the system makes an internal check to verify the correctness or otherwise of the submitted diagnosis. If the submitted diagnosis is incorrect, the system commences a sequence of interaction with the user. This sequence is designed to help him identify the cause of his mistake.

In the current state of the project's development, the rules that distinguish different abnormalities related to the Central Nervous System have been defined. These rules are stored in a database that the system refers to when trying to ascertain the correctness or otherwise of a student's response. At the same time, a media bank of images and video clips has been created for use as presentation stimuli. Much effort has been expended in designing and prototyping the interface of the system, with a special view toward task support and learning support.

The second section of the project focuses on the management and counseling of patients when a fetal abnormality has been correctly diagnosed. Work on this section has yet to commence.

System Description

The system presents users with the ability to perform "virtual" ultrasound investigations of women who are 24-weeks pregnant. This is a critical stage of pregnancy when abnormalities become identifiable. The goal-based scenario contains many different cases. Some cases have single abnormalities while others contain multiple, but mutually consistent, abnormalities. The system also includes normal cases; i.e.. cases with no abnormality. When a user first logs into the system, he is presented with the system splash screen. On dismissing the splash screen, the user is asked to log in and to enter his password. He can then choose:

a. to be presented with a randomly selected case from his set of unsolved cases
b. to be presented with a specific case based on the patient's medical history
c. to be presented with a particular anatomical system to investigate

The case selected by the user is then presented in the *Diagnosis* screen.

One of the pedagogical goal resources provided by the learning environment is the facility to compare the ultrasound scan presented by the system with a "normal" scan; i.e.. a scan of a fetus with no abnormalities. By clicking on the middle button on the bottom-right pane, a separate window showing a "normal" scan is displayed (Fig. 1).

The provision of this comparison facility is pedagogically driven. The comparison is very useful in helping users to disambiguate between critical features on the scan of a normal versus an abnormal fetus. Because part of the diagnostic skill being trained here is perceptual in nature, the provision of the contrasted images enhances a user's ability to identify and distinguish the contrasting conditions of a feature being examined. In addition to the normal scan facility, the system also provides the user with access to relevant medical terms and definitions and a list of diagnosis names.

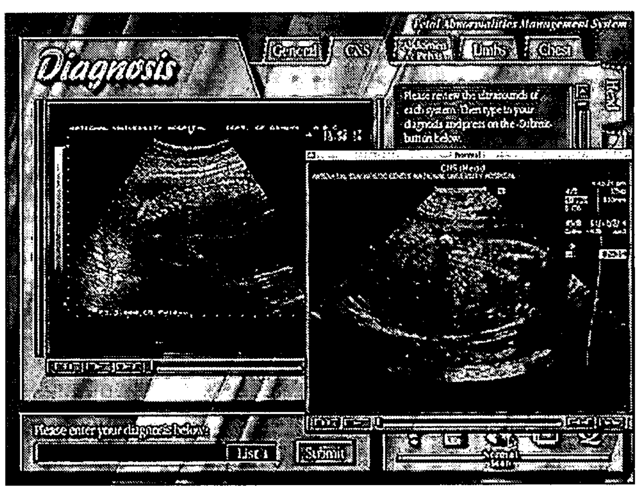

Figure 1: The Diagnosis screen with a “normal” scan comparison

As shown above, the user is able to explore all anatomical regions of the fetus by selecting the appropriate tab along the top of the window. These regions include the Central Nervous System, the Abdomen and Pelvis, the Limbs, and the Chest. Note also that certain regions are further divided into sub-regions: for example, the Central Nervous System is further divided into the Head and the Spine, as reflected in the sub-tabs on the right hand side. After the user has explored the images and scans of his choosing to his satisfaction, he enters his diagnosis in the dialog box shown in the bottom-left of the window. The system allows the user to either type in the diagnosis or make a selection from a pop-up list. We have provided alternative input methods so as to avoid, at least, initially, users experiencing difficulties over the correct spelling of the diagnoses. Once the diagnosis is made, the user clicks on the "Submit" button.

Suppose that the user enters a correct diagnosis: hydrocephalus. The system will then respond as shown in the following screen (Fig. 2).

Figure 2: System response to a correct diagnosis

As a separate pedagogical goal resource, the learning environment provides the user with an option to perform a systematic walk-through of critical features in the Central Nervous System that distinguish between a fetus with hydrocephalus and a normal fetus. Walking through the list of features helps students to imbibe an expert's diagnostic model and reinforces the user's understanding of the critical disambiguating features of the abnormality in question. The walk-through is depicted below (Fig. 3). As the user steps through the list of comparison features, he is requested to address each of the questions posed (e.g. "Is the bony calvarium present?") in the context of comparative images of a normal fetus and a fetus with hydrocephalus. The provision of these images grounds the user's knowledge in the perceptual aspect of the diagnostic skill being nurtured. As the questions are systematically addressed and answered, the Features table is filled out.

Suppose, however, that the user submits an incorrect diagnosis: acrania (i.e. the cranium of the fetus is missing). The system will begin to interact with the user to draw his attention to the particular features of the expert's schema that effectively disambiguate between acrania and hydrocephalus, the correct diagnosis. The system–user interaction is driven by an underlying table that has been defined for all features of interest across the different anatomical subsystems. In the present state of system implementation, the user is advised to work his way through the walk-through and to answer the question posed for each of the salient features that comprise the expert's schema. The next figure (Fig. 4) shows the user addressing the feature related to the presence or absence of the mid-line echo in acrania versus hydrocephalus in the ultrasound image.

To further enhance the salient dimension of the perceptual element that the system is attempting to direct the user's attention to, the user also has the option to turn on a highlighting feature that shows him the portion of the image to which he should be directing his attention.

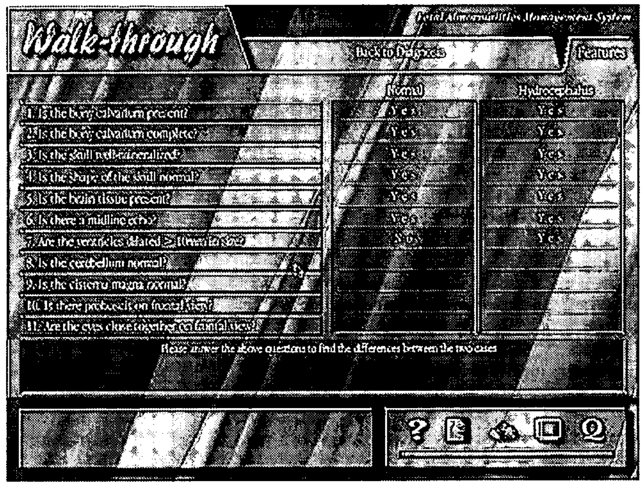

Figure 3: Walk-through for diagnosis of the Central Nervous System

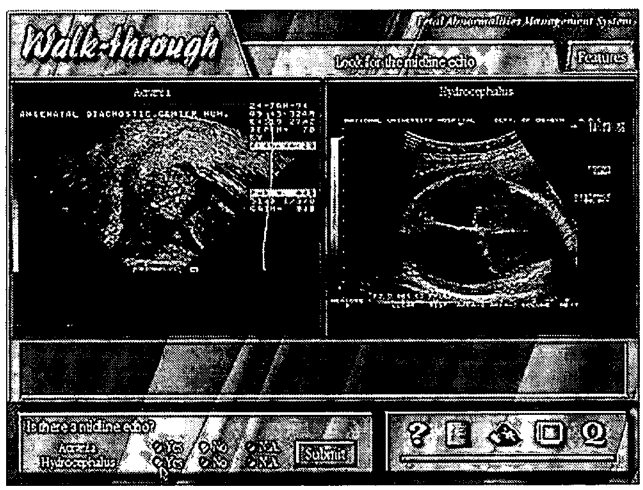

Figure 4: Contrast between the incorrect and correct diagnoses

It should be noted that when considering the above comparison, the user still retains the option of overlaying the image of a normal scan on the two images already displayed, as a further point of reference for making perceptual comparisons. As shown above, the user addresses the question "Is there a mid-line echo?" for both the incorrect diagnosis (acrania) and the correct diagnosis (hydrocephalus) and submits his answer to the system for verification. The radio button style of interface presents the user with a finite set of possible combinations that he can select. Hence, it is not ideal. When user modeling is incorporated, the system will reason interactively with the user on the disambiguating features that he appears not to have grasped or discerned. Notwithstanding, the above systematic walk-through is still a useful component of the system; it will be presented to the user when the system determines that the user's understanding is so weak that it would be more productive to place him in a training-oriented mode of learning.

Assuming that the user makes a correct diagnosis or is led to the correct diagnosis by the system, he then will have the option to proceed to the next section of the learning environment that addresses the management and consultancy of the patient mother or to return to the beginning of the system and select a new case to investigate.

Discussion

The system that has been described above is work in progress. The interface is constantly being revised and refined as we endeavor to provide the system with a stronger case-based orientation. We are also working on developing the system's user model. The main difficulty here is that our medical domain consultants do not, as yet, possess an explicit idea of how they themselves handle user modeling when coaching students in the performance of ultrasound scanning and the diagnosis of fetal abnormalities. In light of this, we intend to perform several empirical investigations of instructor–student interaction to flesh out the relevant attributes that should be tracked by the system and to get a better sense of students' learning processes.

We have reviewed our system with respect to the goal-based scenario design criteria set out at the beginning of this paper. We are satisfied that the system adequately achieves the criteria of thematic coherence, control and empowerment, challenge consistency, and pedagogical goal support. As for realism and richness, we are of the opinion that there is a large degree of realism as the simulated task that a user is confronted with is highly authentic. However, there is some degree of compromise with respect to richness that arises from the ultrasound domain. As a contrast, the domain of upper gastro-intestinal bleeding affords far richer possibilities in terms of the simulation that the system could be made to support. Such a domain supports incorporating the dimension of time criticality in making a diagnosis; this is an element that the ultrasound domain inherently does not support. We have certain reservations with respect to the responsiveness of the system, but we expect this to improve when the user modeling component of the system is in place. Finally, with respect to pedagogical goal resources, we are currently working on supplementing the current system with additional supporting tools and information so that students should not only be able to make the correct diagnosis of a fetal abnormality but also be able to fully understand the cause–effect relations underlying the abnormalities they discover. In this way, system users or trainee gynecologists will be better placed to assess the management and consultancy options open to them when they proceed to the second part of the goal-based learning environment.

Conclusion

In this paper, we have described a multimedia learning environment for learning how to diagnose fetal abnormalities. The system was designed based on principles derived from goal-based scenarios. It consists of two parts: the diagnosis part and the patient management and consultancy part, assuming that an abnormality has been diagnosed. To date, we have worked only on the first part of the project. Most of the media-based element of the project is in place. This work has not been easy to complete and the amount of time and effort needed to sift through and identify suitable video footage and image clips are enormous. We have gone to considerable trouble to ensure that we capture the best quality images that amply show the critical perceptual features of interest. We are proceeding to direct our attention to the user modeling aspect of the work so that the system will be capable of handling more direct and dynamic interaction with the user. The walk-through illustrated in the paper will only be executed when the user demonstrates very poor competence and is moved into a training-orinted mode of learning.

While the goal-based scenario that we are creating is related to the domain of ultrasonography, the system can be readily customized for use with any other image-based technologies in medicine; eg. MRI and CT-scans. As the system was developed using Macromedia Director, we also aim to have a PC–Macintosh cross-platform product when the research project is eventually completed.

Abstract: Both representing cases as fixed scripts as well as the development of initial expert systems as a basis for computer based tutoring systems is particularly difficult and time intensive in a multi-institutional development project. On the other hand, structured systematic knowledge and a common terminology is necessary for automatic generation of information and quiz pages as well as automatic feedback. Therefore we provide an architecture that relates tutoring cases to general concept representation systems containing common terminologies, and facilitates an incremental acquisition of systematic knowledge.

Introduction

When analyzing the problem solving methods of medics, experts combine the application of specialized domain knowledge with a case-based approach to find the right diagnosis and therapy (Patel et al. 1995). Therefore, the education of students of medicine should include both the imparting of systematic knowledge together with case-oriented learning. This applies also to computer based training systems.

Tutoring systems range from a hard coded representation of cases (Mayo Clinic 1996) to applications based on expert systems, where cases form an instantiation of pre-coded systematic knowledge (Schewe et al. 1996). In the former, the author has to develop fixed scripts of the tutoring process and gets no knowledge-based support for authoring and tutoring. The latter support the author by automatic generation of quiz and information pages and make an automatic feedback in the tutoring process possible.

If clinical institutions of different domains have to work on such an expert system component, an initial complete development is difficult and time expensive. On the other hand, an incremental "case by case" coding by different authors requires a common terminology and a framework identifying and relating the central, medical concepts. We developed an architecture that contains terminological groups from different concept representation systems. It allows the construction of systematic knowledge by linking items of these groups together when authors build tutoring cases. As a result of this process we obtain a medical knowledge base that comprises all knowledge acquired case by case. Elements of this knowledge base are integrated with the authoring and tutoring system into a learning environment. The basic parts of both systems are complemented by components that make use of the knowledge base to support authoring and tutoring processes (Fig. 1).

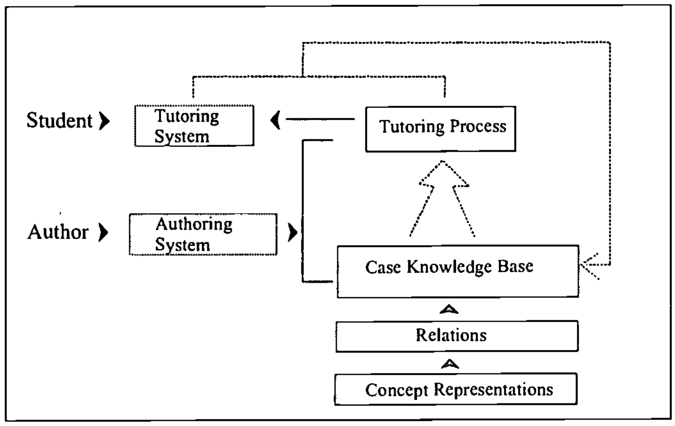

Figure 1: Architecture of the learning environment.

Identification of Central Concepts

The concepts a medic usually uses to describe a medical case can be divided into the following topics: anatomy, phenomena which are located at a specific anatomy (examples for the term 'phenomenon' are 'inflammation', 'pain'...), methods the medic uses to look for or to validate certain phenomena (examinations, technical examination, anamnesis) , diagnoses, and therapies. In our architecture, we reflect the medics' perspective by representing the according terminological groups in different hierarchies and sets:

- the hierarchy of anatomic structures and body systems,
- the set of phenomena,
- the hierarchy of what we call methods, which comprises different (technical and non-technical) examinations and the anamnesis,
- the hierarchy of diagnoses and
- the hierarchy of therapies.

Contrary to the elements in the concept hierarchies, phenomena are structured objects consisting of a phenomenon name and a set of properties. For example, some of the properties the phenomenon 'pain' could have, are 'intensity', 'duration' or 'quality'. In medical technical terminology, there exists a large range of systems for concept representation: classifications, nomenclatures or coding schemes. By separating the different hierarchies mentioned above, we are able to make use of existing terminology systems like special axes or parts of classifications, nomenclatures or special coding schemes. As an example, we utilize the "anatomy" axis of MeSH (Medical Subject Headings) (WHO 1992) and the ICD (Systematic Nomenclature of Medicine) (NLM 1999) diagnosis hierarchy.

Relating the Concepts

The information inherent in medical tutoring cases is mainly represented by links between concepts, which are given as hierarchy items and phenomenon instances. For example, we establish links that relate phenomena at a certain anatomic structure to examination methods they are based upon, and to diagnoses and therapies they imply (Fig. 2). Concrete cases constitute instances of this network.

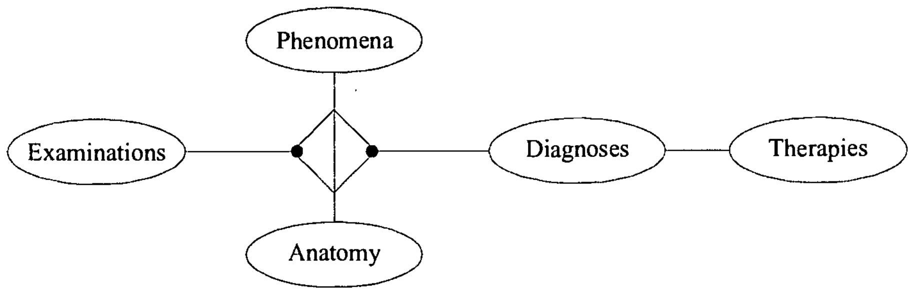

Figure 2: Integration of phenomena into concept graphs.

As an example, a tutoring case may describe a patient with anginose complaints. Because of this, the medic may order an electrocardiogram examination, which reveals a ST-segment depression. Taking other observed facts into consideration, the student's diagnosis should be myocardial infarction. One necessary therapy for this disease is intensive care. When the author describes this case, several links are established. The phenomenon 'ST-segment depression' is connected with the anatomic structure 'heart'. Their combination is linked both to the associated examination 'electrocardiogram' and the diagnosis 'myocardial infarction'. Finally the diagnosis 'myocardial infarction' is linked to the therapy 'intensive care'.

By following explicit links we obtain further implicit ones. For example, a relation between 'electrocardiogram' and 'myocardial infarction' results from their connections to the given anatomy and phenomenon combination.

Supporting the Authoring Process

We can use the hierarchies of anatomy, examination methods, diagnoses and therapies to support the author in formulating elements of tutoring cases. In (Fig. 3) an example of a tree-control is shown that offers a part of the MeSH anatomy structure for defining the location of a phenomenon. This can be done by selecting the appropriate concepts from the tree, which are inserted into the structured representation of the phenomenon on the right hand side of the depicted window.

When building a case for tutoring, the author describes a number of phenomena observed at the patient. Furthermore he is able to relate phenomena at a certain location to one or more differential diagnoses. Offering to him links from already constructed tutoring cases that provide differential diagnoses for the observed phenomena can support this process. Structured medical case knowledge is also useful for building quiz pages by integrating the set or a subset of those differential diagnoses plus some other irrelevant ones into the pages. The aim of these quiz pages is that the student specifies correct differential diagnoses at different stages of the patient information gathering process. The final diagnosis is put together with other differential diagnoses, for which not sufficient evidence exists, to build a quiz page to find the final diagnosis, as it is shown in (Fig. 4).

Furthermore, questions about any direct or indirect links within our architecture can be used to build quiz pages that are aimed at teaching the student the underlying concepts and their interrelations. For example, general questions like "what examinations can be performed on the specified anatomies" can be derived from the linkage of phenomena with examinations and anatomic structures.

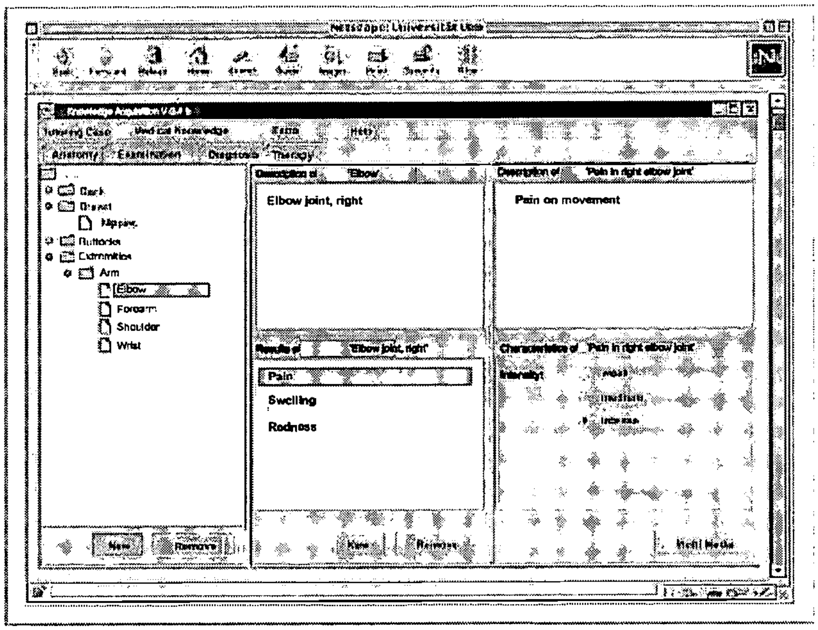

Figure 3: MeSH anatomy structure as a tree-control element.

The author can employ links for building information pages that teach the student the according associations of medical knowledge. Former experiences with tutoring software (Scheuerer et al. 1998) showed that relations we have made explicit in our architecture are an important subject matter in medical teaching. Information pages using text, pictures, animations or sounds illustrate both medical concepts and links between those concepts. Using concepts or concept combinations as indexes into databases of multimedia objects supports the author in creating those pages.

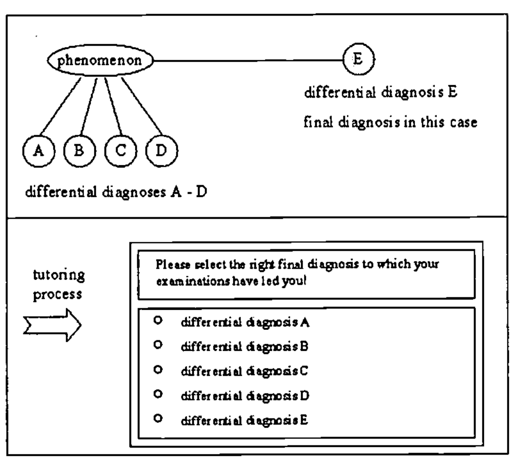

Figure 4: Sample quiz page derived from differential diagnoses and the final diagnosis for a phenomenon.

Supporting the Tutoring Process

The links mentioned above not only support the authoring processes but also the automatic generation of navigation aids, online information windows, and feedback in the tutoring process.

Menus based on hierarchies of examination procedures can be used to provide students in the tutoring process with possible choices for information gathering actions. The author is able to decide if the entire hierarchy or sub-hierarchies are shown to the student. It is also possible to focus examination methods on anatomic structures by using acquired links between them. In that case, a menu primarily showing an anatomic structure can be constructed. Every sub-menu has an additional menu item that pops up the according examination methods. This enables the student to select only those examinations that can be applied at specified anatomies. For example, links from the anatomy 'thyroid' to examinations like 'thyroid function test', 'radioisotope scanning', and 'sonography' could have been established in the case authoring process. Accordingly, this meaningful collection can be shown to the student as a selection of examination methods at the 'thyroid'.

Knowledge formalized within our architecture can be used for an automatic feedback generation in the tutoring process. We allow the quantitative or qualitative assessment of links between phenomenon-anatomy combinations and diagnoses, as it is done for example in the D3 expert system shell (Reinhardt 1997) by a number of positive and negative scores. By using this knowledge, comments and corrections that refer to a diagnosis chosen by the student can be automatically produced. To do this, the system searches for phenomena given in a tutoring case that plead for or rule out the diagnoses the student has chosen, according to the positive and negative links mentioned above. The student may be helped by this function at every stage of the tutoring process, because the described feedback methods take into account, what the student already knows about the patient. This approach can also be applied at links between diagnoses and therapies. Additionally, if not sufficient information about the patient was gathered by examination methods to confirm or exclude a diagnosis, the links mentioned above can be used to give hints to the necessary methods, or just to state that relevant information is still missing.

Conclusion

The presented architecture allows an integration of different concept representation systems for the building of tutoring cases. Additionally, we establish links between these concepts to formalize systematic knowledge within medical cases. This supports the use of a common terminology for cooperating authors and helps to avoid redundant case information. Furthermore, authoring and tutoring processes are supported by mechanisms for generating quiz and information pages and by automatic feedback based on the acquired systematic knowledge.

The presented work constitutes a first step in the project "Docs'n' Drugs – Die virtuelle Poliklinik". In this project, a tutoring system will be developed that shall represent a virtual clinic. Multiple clinical institutions, the University of Ulm, the University of Applied Science Ulm, and industrial partners are involved in this enterprise.

Abstract: This paper describes the design, development, delivery and evaluation of a Web-Based Instruction (WBI) course which has been designed to support a large number of students (approximately 700 per term). The paper describes the course philosophy, purpose and design, but concentrates on the issues that must be addressed when designing WBI courses for large groups of students.

Background

The Faculty of Education at the University of Alberta requires that all students complete a course in "computer applications." Historically, students could meet this requirement by taking either: a) a traditional face-to-face (F2F) lecture/laboratory course offered by the Department of Computing Science which could best be described as an "Introduction to Programming" course, or b) a traditional (F2F) lecture/laboratory course offered by the Faculty of Education which consisted of a 3-hour "demonstration" lecture followed by a 3-hour "workbook" laboratory each week.

In the 1997-98 academic year the computing course requirement for education students was decreased from 3 credits to 1.5 credits, causing an examination and reduction of the content of the course. After strong arguments, this decision was reversed for the 1998-1999 academic year. We decided that rather than simply re-instituting the course used prior to September 1997, we should completely redesign a 3-credit course for delivery in September 1999.

Faculty of the Instructional Technology program at the University of Alberta have been developing WBI courses for a number of years (e.g., Montgomerie & Harapnuik, 1997; Davies, 1998; Davies and Carbonaro, 1998). Because of our commitment to the precepts of active learning, and after examining the costs of delivering WBI (Harapnuik, Montgomerie & Torgerson, 1998), we decided to design the course to be delivered through Web-Based Instruction (WBI). The resulting course, *EDPY202: Instructional Applications of Technology* (http://www.quasar.ualberta.ca/edpy202) is publicly available on the Web.

Philosophy of the Course

Tell me and I will forget.
Show me and I will remember.
Involve me and I will understand.
(Variously Attributed)

The philosophy of this course centers on the theoretical perspective that learning is a process of constructing knowledge as opposed to a process of recording knowledge (Harel & Papert, 1991). From this perspective students are required to be "active participants" in their own learning. To support this perspective, students need to be placed in an environment whereby they have the opportunity to take ownership of their own learning. We have attempted to create such an environment in two ways. First we have designed the course to be self-paced with varying degrees of individualization. This approach allows students a higher level of flexibility with respect to course time commitments and the level of skills and knowledge they wish to acheive. Course materials can be studied individually, in collaboration with peers, or in collaboration with a more knowledgeable assistant. Second, we have focused learning activities on software tools used for problem-solving —"Mindtools" (Jonassen, 1996). This emphasizes students learning "with" the computer as opposed to "from" the computer. In other words, computer-based tools and learning environments (e.g. databases, spreadsheets, semantic networks, computer conferencing, hypermedia construction, or microworld environments) can serve as cognitive tools or extensions of the mind. With the use of such "Mindtools," learners can enter an intellectual partnership with the computer in order to access and interpret information, and organize personal knowledge. A recent article (Connell, 1997) concludes that "IA" (Intelligence Amplification) is preferred over "AI" (Artificial Intelligence). As Connell (1997) states: "In AI, ... models of an individual's cognitive processes ... serve as templates to construct intelligent systems capable of teacher replacement ... In IA, the roles of the machine and user are reversed. Instead of having a system in which the user responds to the machine, you have a system where the user uses a set of provided software construction tools to actively construct more powerful, personally meaningful representations of problem spaces" (p. 27).

Traditional educational paradigms must be shifted somewhat in order to successfully incorporate technology in this way. For technological tools to become student-centered "Mindtools" requires a readiness for change. For example, school schedules, the physical setup of classes, and assessment of both students and teachers may require modification to accommodate these new tools (Barron & Orwig, 1995).

We have made many such adjustments in this course. First, we have attempted to provide students with a lot of scheduling flexibility. We impose no requirement for lecture or lab attendance. The on-campus computer lab facility is available to students during a total of ten to twelve three-hour periods during the week (including some evening times) as well as two additional four-hour periods on the weekend. Subject to space limitations, students are free to use the lab and obtain in-person help from a teaching assistant during any of these time periods. Students also have virtually continuous access to instructor assistance (or peer collaboration) via Computer-Mediated Communication (CMC), in the form of email or web-based conferencing. Most students who prefer to work largely at a distance make extensive use of CMC. We do however, impose traditional assignment and course completion deadlines. This university is currently not prepared to allow undergraduates varying periods of elapsed times in which to finish courses.

Second, we have also changed our assessment methods as compared to many traditional courses. In this course, 60% of a student's grade is based on a portfolio of term work. This portfolio is a series of five modules which students must submit electronically. Each module consists of a computer file (or group of files) which demonstrate the students understanding of the various course topics. The content of their submissions is largely a matter of student choice and creativity, although in most cases, students must indicate how their project relates to the provincial education curriculum. The remaining 40% of a student's grade is based on a practical exam which they must write in-person in the on-campus computer lab facility. This lab exam is really a mini-portfolio of small projects using the same tools the students have learned during the course. The purpose of this exam is to obtain an objective assessment of the computer literacy level of each individual student, in comparison with peers. Students in this course receive final grades on the same traditional 9-point scale as most courses at this university.

Purpose of the Course

The purpose of teaching education students to use computers is so that they will be prepared to integrate the use of technology into the curriculum. This introductory course aims to provide undergraduate education students with the basic skills they will need to apply information technology in Kindergarten - Grade 12 schools. Although this course is primarily a software tools literacy course, it does provide the students with some exposure to curriculum integration. Thus, we hope that these soon-to-be teachers will be in a position to assist their students in using the information technology tools which are commonplace in modern society.

At the same time we were designing this course, the Government of Alberta published *Information and Communication Technology, Kindergarten to Grade 12: An Interim Program of Studies* (Alberta Education, 1998) which will form the basis for the provincial program of studies to be released in June 2000. This document is constructed in terms of "learner outcomes" and the philosophy is stated as:

> This technology curriculum is intended to provide a broad perspective on the nature of technology and its impact on society. Students will be encouraged to grapple with the complexities, as well as the advantages and disadvantages, of technologies in our lives and workplaces. It is not intended to be taught as a stand-alone course but rather to be infused within existing courses. Technology is best learned within the context of applications. Activities, projects, and problems that replicate real-life situations are effective resources for learning technology. (Alberta Education, 1998).

The objectives for EDPY202 are directly related to the Alberta Education document and students are required to complete either an introductory or an advanced module in each of five topic areas:

1. Internet Tools (Email, Web-based conferencing, Internet searching, FTP, Telnet, Simple WWW page creation),
2. Digital Media Processing (clip art, drawing, painting, scanning, digital photography, digital audio/video),
3. Multimedia/hypermedia Presentations: (PowerPoint or HyperStudio),
4. Spreadsheets (e.g. Excel), and
5. Databases (e.g. FileMaker Pro, Access).

Course Design

This course has been designed to be self-paced and modularized with a focus on independent study. Three optional lectures are given:

1. an introductory lecture covering the philosophy and operation of the course,
2. an introductory hands-on workshop concerning basic computer operation and terminology, and
3. a lecture the week before the final exam (lab practical) which explains what will be covered and the exam procedures.

All of this material is also available on the course Web page.

An introductory and an advanced module for each of the five topic areas have been prepared. Students must complete one module from each of the five areas. All modules follow the same structure with each module having sections on:

1. Just the Facts (a short overview of what needs to be done)
2. Purpose
3. Prerequisites

4. Objectives
5. Alberta Learner Outcomes (explanation and direct links to the sections in the "learner outcomes" document which are particularly addressed in this module),
6. Assignments, and
7. Resources.

A 3-hour/week laboratory period is assigned for each student, but students are encouraged to work at home rather than in the laboratory if they have the ability, equipment and software. This has two major results: firstly, many students appreciate the opportunity to take the course wherever and whenever they wish, and secondly, the teaching assistants in the lab can concentrate on helping those students who really need help. For example, students who are very novice computer users find it very difficult to work actively and independently, especially in the early stages of the course.

Issues for Courses with Large Enrollments

Most WBI courses are designed for delivery to a relatively small class of students. Our own courses (Montgomerie & Harapnuik, 1997; Davies, 1998; Davies and Carbonaro, 1998) have been delivered to classes as large as 80. The expected enrollment for EDPY202 is approximately 700 students per term. Given this, a number of issues dealing with efficiency of both instruction and administration needed to be considered.

Instructional Issues

The course home page was designed to give access to a list of navigation headings in the three categories of Course Information, Modules, and Tutorials. Figure 1 shows the drop down menus for the navigation categories.

Tutorials were developed for many of the specific topics in the course, but it was felt that it would be a waste of time to develop new, extensive tutorials on the Macintosh and Windows operating systems and on commercial productivity tools such as Microsoft Word, Microsoft Excel, Microsoft Access and FileMaker Pro. Our website has a extensive set of links to existing web-based tutorials. Some of these were developed at our university, while others are links to various external Internet sources. We also reviewed a number of commercial tutorials and chose the *MacAcademy / Windows Academy* series of CD-ROM-based instructional programs (http://www.macacademy.com/). We feel that these programs come extremely close to the kind of instruction that would occur in a small group demonstration with the additional ability for the student to stop the instruction, move to a different place in the instruction, and to search for a specific topic. We purchased a number of sets of these CD-ROMs and placed them on 48-hour reserve in the library. We have Macintosh computers in our laboratory, and we negotiated a license with *MacAcademy / Windows Academy* which allows us to put images of the Macintosh instructional CD-ROMs on a Macintosh G3 Server and to allow up to forty concurrent accesses. This has turned out to be an extremely good solution. Students can access the instruction whenever they want and can proceed at their own pace. The programs they are learning about are available on the same workstation, so students can move between the instruction and the application giving them the ability to pause the instruction to try what they just learned on the real application. While we have not yet permitted it (due to licensing issues), these instructional programs can be accessed over the Internet, and, with a relatively high-speed modem, they work extremely well.

Administrative Issues

When one is working with a class of 20 students, a number of administrative tasks are handled without thought. It is necessary to automate these tasks wherever possible when one is planning for a class of 700 students.

Computing Infrastructure

The delivery of a WBI course to large numbers of students, requires you to be cognizant of various computing infrastructure issues. The Web Server must be capable of handling a high number of concurrent hits and the local and wide area networks must be prepared for a large volume of traffic. Our course website (run on a Sun Unix system) is fairly busy; at the time of this writing we are experiencing thousands of hits per week with no problems. The Windows NT server which handles our web-based conferencing system (WebBoard) is extremely busy with several courses sharing this server. We have had to increase the memory in this server substantially to be able to handle the demand.

Identification of Students

An automated procedure was written to merge data from a number of different central university administrative files into a single record which contains the data necessary for the course, including: Name, Student ID number, Computer Identification (assigned to each student when they enroll at the University of Alberta), Course Section Identifier, and Laboratory Section Identifier.

Student Server Storage Space

Students need to have a place where they can store projects they are working on. We assign each student space on a central server which they can access either over AppleShare or via the File Transfer Protocol (FTP). An automated process creates the Server Identification (Login ID) for each student which is the same as their University Computer Identification. An obvious scaling issue that arises in this area is how much disk space one can afford to allocate to students, particularly in a course such as ours in which students are expected to create rather large multimedia files. We provide students with a very modest 20 MB of space on our course server (in addition to the 5 MB they receive on the university's general server). However, when multiplied by several hundred students, it amounts to several gigabytes of hard drive storage that we must budget for and arrange with the university's network administration. We insist that students compress (e.g. Stuffit or Zip) assignment files to help conserve disk space. However, most students do eventually exhaust their 20 MB, so we suggest that they archive older assignments on other media such as a 100MB ZIP disk.

Web-Based Conference System

We feel that it is important that students can communicate with each other, with the laboratory assistants and with the instructors. We use WebBoard (O'Reilly Software, 1999), a computer conferencing system, to provide for this communication. An automated process creates the WebBoard Identification for each student that is the same as their University Computer Identification.

There are various scaling issues that arise when utilizing such a conferencing system for a large group of students. One must be prepared for a large volume of messages. We have found it very useful to break up the conferencing system into more manageable sub-conferences, particularly in the case (such as in one of our course modules) where student conferencing messages are an assignment requirement. Students should not be required to wade through hundreds of messages at a time. In our course, we have also set up conference sub-topics for help questions related to specific software tools.

Another problem is that some students do not naturally know how to provide enough details when asking a question on a web-based conferencing system. They ask a question as if they are talking to someone looking over their shoulder. Instructors have to reply asking for more information - multiply this by large numbers of students and you add to the volume of messages. This is particularly a problem at the beginning of the course, but as the students get used to this mode of communication they learn to describe their situation more accurately the first time.

Another consideration is that adequate, paid instructor / teaching assistant time must be allocated to monitoring and answering conference messages relatively quickly, including evenings and weekends. This last consideration is also an important factor in dealing with student email messages in a large course. Although general questions are raised on the WebBoard, student concerns of a more personal nature are handled via private email. In a large course such as ours, the volume of messages can obviously become very high.

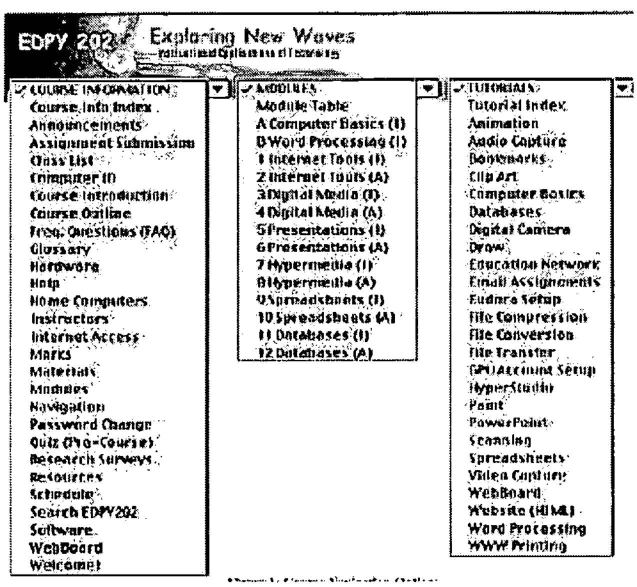

Figure 1: Course Navigation Options

Common Password

Students in our course access four individual computer systems (i.e. the WebBoard, the Marks Database, the Course File

Server, and the University's general purpose server), each of which has its own logon ID and Password. During our registration procedure we force all the IDs for a user to be the same as that already set for access to the general university server. We also set the password for the three systems under our control to have the same password. On the Web page (and in the first laboratory period), we demonstrate how to set the general university password to be the same as the other three. Finally, we provide a single Web page that allows student to change all of their passwords at once. Students very quickly forget that they are using a number of different computers with different ID/password configurations when all their IDs and Passwords are the same.

Our university is installing a common file system: *Andrew File System* (Transarc, 1998); and common authentication service: *Kerberos* (Neuman & Ts'o, 1994). Many other post-secondary education institutions and businesses are installing similar systems. At this time our Faculty has not integrated with AFS and Kerberos. In some ways this is unfortunate - it would have been nice not to have to "reinvent the wheel", but having to build our own systems did give us a little more control.

Submission of Assignments

Students need to be able to submit their assignments for marking. When server storage space is set up for the student, a "submit" directory is set up within that space. Students are told to place their assignments in that directory (either through AppleShare or FTP) when it is ready to be marked. We require that the assignments for each module be placed in a single compressed archive. At the time the assignment is due, an automated procedure scans the "submit" directories in the student files, makes a copy of any new archives which are in the students' "submit" directories, reassigns ownership of these copied archives and places them in a folder for the Markers to access. This procedure also sends an automated, time stamped e-mail message to each student telling them which (if any) files were copied and which were not copied. The message also states specifically why a file was not copied (e.g., an earlier copy of the file existed, the file was not in an archive (i.e., it was not in .sit or .zip format)).

Marking Assignments/Exams

A marks database was built using a Web enhanced ACCESS database. This is a modification of the system reported in Montgomerie, Harapnuik & Palmer (1997). Markers and staff view the database as if it is a spreadsheet and can enter and change marks and comments for each assignment via a web browser. We provide students with a web-based query which allows them to see only their own marks and comments. We have also developed several customized database queries that help to ensure the correctness and completeness of our marking, for example, by pointing out students who have not received a grade for a particular module. In smaller courses this is usually done manually with little effort, but in a large course, ensuring that all marks have been entered is a serious concern. The course administrator also has the ability to automatically compute the final course 9-point grade for all students by specifying raw-score cutoffs. This is a huge time saver, as manual entry of each student's final grade would take several hours. The database also has a report capability that produces the "official" mark sheets in the form that the Office of the Registrar requires. It is hoped that when the University's new student record system is completed, electronic transfer of marks to the Registrar system will be allowed.

Student Evaluation of the Course

The first administration of the course was during September – December, 1998. Two hundred and forty students enrolled in 12 lab sections were asked to rate their technology anxiety and personal thoughts about using computers. These students were observed working in the lab. Some of these students were also interviewed.

Students enrolled in the Faculty of Education are required to take either this course or a course offered by the Department of Computing Science; therefore, student motivation could affect the ratings. Students did not know the identity of the teaching assistants at the time of registration, hence they could not select their laboratory section based on teaching assistant reputation. Both Elementary and Secondary Education students were enrolled in the course. Students can attend any lab section which had space available. Each lab section has at least two teaching assistants with the ratio is one TA for each 15 students.

Overall students had a positive perception of technology, the use of computers and the course. Students liked the idea of working on their own pace. Students felt comfortable knowing that they could always find a TA in any lab section and were glad that extra Saturday and Sunday lab sections were offered. Students found the course interesting and 69% of the students interviewed believed that they would use this knowledge in classroom. Although students reported a high the level of anxiety in the beginning of the course, the same students reported that this anxiety dropped considerably after one month in the course.

Students working at home reported that they were very pleased with the course and the support they received from the course instructor and teaching assistants. They stressed that they can work fast since all the material they need is on the Internet and it is relevant to the curriculum. They also point out that this kind of course saves their time because they did not need to be at the university.

However there is always some room for improvement. Novice computer users scored high in the anxiety scale survey. Most of the novice students reported that the material was very challenging and there was not enough time to study the material on the Internet and do the assignments. They also reported that the teaching assistants did not spend enough time with them. This situation was also observed in some lab sections.

The course had some communications problems. Some of the students reported not being able to contact the instructor or the TA using the e-mail or the WebBoard. The WebBoard was also underutilized. A large number of students stated that they used the WebBoard only to do the required assignment and they never looked at it again until the end of the course. Other students reported that they did not get good answers to questions which were e-mailed to the TA. On the other hand, it was observed that some students can not state their questions or comments clearly when they are writing the e-mail messages. Some students reported that they were unable to get any assignment marks back until the end of the course and others reported that assignments were apparently not marked.

The course has a great number of teaching assistants and it was observed that different TAs gave different interpretations of requirements. It was observed that there were not enough TAs in some lab sections to provide good service to the students. In some situations it was observed that students had to wait more than fifteen minutes for help. Some students also wanted to see the course instructors in the lab sections.

These criticisms are being addressed in the current implementation of the course.

Conclusion

This paper has discussed the philosophy, purpose and design of *EDPY202: Instructional Applications of Technology* and provided some of the student feedback. The course is offered primarily through Web-Based Instruction. While there have been some "birthing pains," and we expect even more "growing pains," we are very pleased with the results so far.

Quipunet: A "Virtual", Educational Organization;

Martha Davies, President
Quipunet
1888 Yukon Harbor Dr.
Port Orchard, WA 98366
mdavies@telebyte.net

Abstract: Quipunet, a "virtual", educational organization, with the use of Internet's simplest tools has been acquiring valuable experiences since the latter part of 1995. We have presented virtual seminars in cooperation with UN-IDNDR (United Nations- International Decade for Natural Disasters Reduction); have established communication networks with rural areas in Peru, allowing us to help the victims of disasters ; have used same networks to build "bridges" to embrace needy schools; and have sponsored virtual, Writing Contests among the schools of Peru, involving students, teachers, schools and city officials.

Introduction

From the beginning of time when man ventured into uncharted territories, with no one to guide him, with no rules to follow, he had to improvise, try out, make mistakes, and try again; in short, he had to *Learn by Doing*.

The Internet was to us that uncharted territory, a new frontier that offered untold wealth of information and knowledge; the place where Quipunet could be created. http://www.quipu.net

Quipunet is a grassroots, "virtual", non-profit organization, legally incorporated in the State of Washington since November of 1995. Quipunet is made up of Peruvian volunteers living all over the world, who have formed a cybernetic link to help our country of birth.

We come from all walks of life, architects, engineers, professors, students, diplomats, business people, and housewives. We reside in different parts of the world, some of us, computer literate, and some, unfamiliar with the Internet. We are, truly, a virtual village.

The name, Quipunet, was taken from the *Quechua* word *Quipus*. The *Quipus* were used by the Incas as a means of maintaining a statistical inventory of their Empire. Long, braided strands of colored yarn each strand had a number of varied knots. Using a coded system where each color, each knot, each strand represented something, the Incas were able to tally and record their resources. Our pages, filled with information, are, our electronic *Quipus*.

We like to think that we are creating a new future utilizing modern technology -and - ancient, Inca customs.

Who we are

What we have learned during our three and a half short years of our existence merits the telling. We have been pioneering the Internet with no one funding us.
We never dreamt that our small group, with scant means, could help so many, from so far. It is the Internet that has given us these new tools, to learn and use; it is the Internet that has been our "frontier" where everyday we find more rich lodes to mine. Where the potential to really make a difference is open to anyone no matter where he or she lives. All anyone needs is the most basic knowledge of one of the most useful tools of the Internet; the electronic mail.

Along with e-mail comes the use of mailing lists. These are something like network conversation clubs, or special interest groups. San Francisco State University had such a list for Peruvians, where we discussed affairs of our country, exchanged recipes, told stories, and had serious debates. It was during one of these debates that the idea to help at a distance was put forth, and it caught the imagination of us all! This idea turned into a project, the project into an organization. A dream was born! It was very emotional seeing the messages "count me in!", "count me in!". What started with only a handful, soon grew to seventy, then eighty, ninety volunteers. It was time to organize our ideas formally, thus, a committee of six persons was formed: Alberto Delgado in Japan, Herbert Luna in Brazil, Fernando Hermoza in Peru, Ricardo Corzo in Virginia, USA, Felipe Polo Wood in North Carolina, USA, and Martha Davies in Washington, USA. Six persons who hardly knew each other, with the task to organize this volunteer group!

The First Learning Experience:

The first few days we all had excuses; the national holidays, vacations, weekends, etc. Nobody wanted to be the "first". I think we were all asking ourselves: "now, what?" Up to this day, none of us can recall how we started, but once we did there was no stopping us. After 186 e-mail messages, and 6 complete corrections, we finished the "draft" of our By-laws, Action Plan, Time Schedule, and even the subscription form! All done in three and a half weeks! It was an experience we'll never forget! The experienced "old hands" in the Internet, as well as the neophytes, were in awe at seeing the documents taking shape line by line, day by day. We all had learned how to use a virtual table!

The Second Learning Experience:

The "draft" was presented to the rest of the members and Quipunet's second learning experience was put into motion. Another committee was formed - it was their turn to learn. They used pre-registration and voting "tables" to make it easier to handle and to avoid a sea of e-mail. Even with all this careful planning we received complains of too much mail. But the results were worth all the trouble. The election was a totally transparent event!

And so, Quipunet was born, in November of 1995, with the following mission:

"To Channel resources, materials, and knowledge available all over the world to the places most in need in South America, with emphasis on Peru".

The Third Learning Experience:

Our first official incursion on this new, exciting field called Internet, was planned by our Vice-president, Alberto Delgado, who at that time was living in Japan. He convinced several of his colleagues at work and from the University of Kobe to contribute information gathered after the terrible earthquake in Kobe.

In January of 1996. We presented: *"Kobe-Japan: the Earthquake of 1995 and its Lessons"* - We had 167 attendees from 16 countries. We were delighted to learn that some attendees were from rural areas. The presenters were top-notch people from Japan whose experiences were still fresh in their minds.

The Fourth Learning Experience:

Somebody from the UN-IDNDR. (United Nations- International Decade for Natural Disasters Reduction) took notice of this seminar and asked us to collaborate with them on their first virtual seminar: *"Solutions for Cities at Risk"*. It was scheduled for September-October 1996. http://www.quipu.net:1996
That event attracted 458 attendees from 58 countries. Our pages registered over 8,000 "hits". We learned about the Master plan of Istanbul for earthquake hazards; we learned of the vast potential of the Internet to link individuals and institutions around the world; we learned about building codes, and about urban protection strategies.

On September -to- October, 1997 in cooperation with UN-IDNDR we presented: *"Floods and Droughts: Issues of the 21st Century"*. http://www.quipu.net:1997
This seminar was a smashing hit! Presented in two languages, Spanish and English, both on our pages and on two lists. This one had close to 700 attendees from 60 countries and our pages registered over 9,000 hits. This seminar was also the first one I was involved from the beginning and let me tell you how impressed I was.

Picture this: From Geneva, the word goes to Alberto Delgado, our vice-president who by then lived in Ecuador. Let's have the seminar. Alberto gets his "team" ready. Three Webmasters: one in Australia, one in Peru and one in USA. The workplace: San Francisco State University, where our server resides, and where we had two more team members. Manager for the Spanish list was in Taiwan; and manager for the English list, Alberto, in Ecuador. Two volunteers in Peru took care of the publicity in Spanish. That year we had eleven translators, five in Peru, four in the States, one in Spain and one in Taiwan.
We took care of only the technical part. UN-IDNDR took care of the presenters, who that time were from Australia, Burkina Faso, Argentina, Spain, USA, Cambodia and many other countries. Quite an undertaking...and what a good example of sharing problems and solutions... globally! We learned about the community response to the Red River flooding in Manitoba, Canada; the risks of flooding in Australia; the risks and prevention in Valencia, Spain... we learned this and more. It was an excellent seminar with valuable, first hand information.

Last year's seminar: *"Prevention Begins with Information.* http://www.quipu.net:1998 involved the media as a very important partner to build a culture of prevention. Information prior to disasters is crucial to the saving of lives and property. The media has to help educate the public but it is up to the scientists to relay clear and understandable messages. We had several representatives of the International media and also representatives of different organizations around the world.

These seminars have helped developed nations as well as developing nations. We have shared wisdom and valued experiences on equal footing. Rich technology and ingenuity based on necessity, make good partners.
As for our personal learning. Early on we realized that we had to keep the seminars relatively simple in order to reach the rural areas where the cost of connectivity is so high. By presenting the seminars in the WWW -page format, without the frills that takes so long to load; and also by using lists, we were able to reach people that have only e-mail.

The Fifth Learning Experience:

The next lessons were painful to learn, because it was through tragedy that we were made aware of the Importance of telecommunication -and- the power of networking during disasters.

The visit from "El Niño"

On February, 1998 El Niño, the current that had always been welcomed as the giver of bounty to my country, that year was the destroyer of life, property, and hope, bringing along heavy rains in places where never rained, washing away whole towns that were ill prepared to resist the flooding.

When Edwin San Roman, one of our volunteers who lives in Lima, Peru, heard of the devastation caused by flooding in Ica, a city 3 hrs away from Lima, he took off with an industrial bread making machine in the back of his pick-up. With the help of the Catholic Church, he installed the machine in an empty school.
He sent a message to our list asking for help. I forwarded his message and urged our members: "Let's help Edwin, to help Ica". As the pledges arrived I would post the amount and the running total to our mailing list. Edwin, in Lima, reading the totals, would in turn, use his credit to buy flour and yeast. His messages kept us abreast of what was happening. He made each of us participants. Perhaps not in body, but in spirit. We were there--- helping make 30,000 rolls of bread a day to feed the homeless, hungry people. We held the fort--- until the big organizations took over. According to the bishop of Ica, it was the best organized team effort! And all this was possible- thanks to e-mail and the mailing lists!

The next story is one with a lesson we are taking to heart.

Another volunteer, Raul Nakasone, resident of the USA, spends his vacations in Guadalupe, a small town in Peru. Last vacation he persuaded Hugo Cortez, President of the Board of Directors of the "Public Aid Office" of Guadalupe, to invest in a computer for the town. It would be a "window to the world" he told them. And so it was. When the computer was installed only three people knew how to use it. Before Raul left he taught a few more.
Back in Olympia, WA, Raul kept in contact with his town via e-mail. And he gave them instructions on how to be prepared for the rains that were supposed to arrive. Of course nobody was prepared for the magnitude of the disaster that was to hit them. The heavy rains caused mudslides that destroyed the roads. The town was isolated....but not abandoned. Raul wrote, "Be sure to boil all the water to prevent cholera". The people followed his advice and bought two wood-stoves and kept them going day and night. But two stoves weren't enough for the whole town. So Raul asked Quipunet for help and since we had been collecting funds, we had $1,000 to send to Guadalupe. Raul's instruction-at-a-distance went like this: "Sra. Juanita- (she is the president of the association of mothers in Guadalupe), be sure to buy a notebook and keep track of all the money, who is getting what. Have everybody sign. You and your committee can decide what your most important needs are." One computer in that town and only a handful of people that knew how to use it! But it was enough to help them!

The Sixth Learning Experience:

One of our most successful projects this one was born at one of the lists of interest called SEDERUL (Servicio de Desarrollo Rural). We had wanted to promote an interchange of ideas and experiences in three important fields. Education, Agriculture and Rural Tourism. Combining these three, the Work Group in charge of this project decided to have a writing contest for high school students from public schools in Peru. The theme they choose was "The Natural Resources of my Land."
Invitations were sent to 130 schools, and to involve the whole community prizes were offered for the student, the teacher, the school and the community.
First prize was a computer for the school, and $100 US for the student and another $100 for the teacher, prizes went all the way down to $10.
This project, like all the other projects we have worked at, was planned and executed at-a distance. With small groups at each end taking care of the details like diplomas, prizes, etc.
It was an outstanding success and one we are going to repeat again this year!

Other projects we are working on:

Embrace a School:

We have created nine work groups in the USA, which through benefits such as dinners, dances, and musicals are helping needy rural schools. Our aim is to provide these schools with one computer each. We believe that computers and several donated educative programs, makes a better, long-term, cost-efficient investment that will last for a number of years. We want to provide instruction and education -at-a-distance not only to the kids but also to the teachers, opening a window to the world. Educational materials are almost non-existent in many of the rural schools.
The reports from an inspection trip on November 1998 were very encouraging. All the projects were working as planned; the results better than expected. The following are the best examples:
1- Embracing the Little Farmers, in Cusco, Peru. We are working with an organization formed by young business owners, giving of their time and whose aim is to teach native kids the best ways to farm their small lots of land. Whatever the kids can produce, and if of good quality, it is bought at market prices by the business owners. This is the best, well-planned, full-cycle, program we have seen.
2- A Training Center for Street Kids. These are kids that only two years ago were stealing in the streets. With our help, they are being trained to make shoes. The self-esteem, and pride while showing their product, was beautiful to see.
3- The Women Carpenters. A whole town had to be resettled after the flooding caused by El Niño that left them homeless. Our volunteers who visited their camp, after seeing the women making benches from apple crates,

decided to pay for the training and material to enable them to help themselves. After 3 months of training, the women delivered benches, tables, and bookshelves for the school. They also *learned by doing!*

My Friend: The Book:

We collect used text books and when we have enough boxes, we send them to different universities.

What have we learned?

That this era of information and knowledge will drastically change our world as we know it.

That we, the people from developing countries, have to use more imagination and creativity, in lieu of money we don't have. But it can be done.

That we must use simple tools to reach the people that only has simple technology.

That the communication networking is the most important component for the dissemination of information.

That the Internet is open to all the world to be mined with sophisticated technology, or with rudimentary tools.

That we all have valuable information to exchange. Traditional knowledge, in exchange for up-to-date information.

That there is room for us all in this new frontier. We all are needed to fill out the different jobs being created.

And most important of all, that we have a unique chance to really stop the devastation of the world by channeling education and information so people can better understand and take care of their quality of life, preserve their environment, and their own culture.

Abstract: The study outlined in this paper was part of a larger study that examined the use of interactive multimedia in motivating and engaging adult learners. This paper describes the use of the multimedia microworld to explore and promote the use of self-regulated learning, and in particular examines the degree to which higher order thinking was achieved and concludes by suggesting ways in which these learner effects could be achieved to a higher degree.

Introduction

As computers become more and more integrated into higher education activities, it is imperative that learning programs be designed to exploit the flexibility that resource-based, self-paced learning can provide. In order to use the computer as a primary learning tool, the very nature of learning with technology has to be rethought. Interactive Multimedia has, to date, failed to fulfil its early promise of making a significant difference to the way in which learners learn (Russell, 1997). One of the reasons for this may be that multimedia programs are designed for a single focal point teaching through a linear sequential process, with students confined to a narrow learning experience. However, with a well constructed multimedia program, the experience of the student changes to one of cooperative, contextual learning where students are left to explore the learning environment in their own time, at their own pace and in any order of their choosing. This form of learning has the potential to increase the motivation and engagement of the students (Stoney & Oliver, 1997).

This paper will explore the notion that students who learn in an applied setting, such as a microworld, will experience cognitive engagement and motivation through the relevance of the material to the students' real world or macroworld.

Cognitive Engagement

Cognitive engagement is observable when the learners are giving sustained, engaged attention to a task requiring mental effort; and authentic, useful learning is produced by extended engagement in optimally complex cognitive activities (Corno & Mandinach, 1983). Cognitive engagement and motivation are inextricably linked together through mental representations, monitoring, and evaluation of responses and strategic thinking. The amount of cognitive effort expended is an appropriate index of motivation as it relies on the learner focusing on mastering the learning task and maintaining a high sense of personal efficacy (Shunk, 1989).

The highest form of cognitive engagement is self-regulated learning (Corno & Mandinach, 1983), where learners plan and manage their own learning and have a high degree of personal control and autonomy. This is critical to beginning and ongoing motivation through specific cognitive activities, and assumes that the students' prior learning will act in concert with the instruction to determine the types of cognitive engagement they exhibit, such as attention to specific information, analysis and synthesis of information, visualisation and ability to filter out relevant from irrelevant information. Effective cognitive engagement involves selectivity, task-specific planning, drawing on previous experience and transferring new knowledge to the world outside the classroom. The use of interactive multimedia can foster and develop cognitive engagement through its ability to attract and hold students' attention and focus. The very attributes that provide the potential to develop cognitive engagement, however, are also those that hold strong prospects for limiting and impeding learning. Research into programs and applications which encourage self-regulation and learner control frequently reports problems associated with learners' inabilities to successfully monitor and manage their learning, and to remain engaged and focussed on the learning tasks. Solutions that seek to enforce control or direction over learners, help to encourage the focus but are able to stifle the freedom associated with the forms of cognitive processing and engagement associated with higher order learning.

This paper describes a study in which a multimedia program—developed for use in a university course in the business field—was implemented in controlled settings that enabled an exploration of the higher order learning processes of learners. The program, *Principles of Financial Investment*, was designed and developed to support and encourage independent and self-regulated learning. Deliberate aspects of the design included elements to motivate and engage adult learners and past papers have explored and described:

- the instructional design principles guiding program development (Stoney & Oliver, 1998);
- learner response to the various design elements, (Stoney & Oliver, 1998); and
- the forms of motivation and engagement among adult learners supported by the learning environment (Stoney & Oliver, 1998).

Principles of Finance

The IMM program that was planned to replace a conventional course in business finance, was carefully designed to incorporate not only the learning sequences needed to bring about the cognitive outcomes but also to include a strong affective component. The microworld consists of an office building called "Investment House". Upon entering the building students are asked to register at the reception desk allowing the program to be personalised.

There are four main working/operating areas; the stock exchange, a stock broker, the Institute of Sound Investment and the student's office. The nature of the interactions was also considered to maximise engagement and motivation, so a passive click and read type program was avoided. The interaction style supported the narrative intention, enhancing the participant's relationship with the product (Stoney & Oliver, 1997).

The Study

The multimedia program was incorporated into the course of study for students studying Finance. Eight of the students were divided into dyads for the purpose of this study and used the program in a collaborative fashion. The students worked in a self-regulated fashion to complete the learning activities supported by the program in controlled settings that enabled the researchers to observe their activities and to record their communication and interactions. These students participated in an in-depth study and their discourse was transcribed and analysed to determine the forms and scope of cognitive engagement and to enable exploration of the higher order learning that occurred.

Findings

The resultant conversations revealed several levels of cognitive engagement and activity among the dyads. To further explore and analyse the instances of cognitive engagement, an array of learning activities were categorised and identified in the dyad activities. In the following discussion, we have separated the analysis and discussion of the forms of talk and cognitive activity into sections that describe lower and higher order thinking and learning.

Lower Order Activity

Lower order activity can be identified as any operational tasks requiring more than mechanistic activities, needing almost no cognitive engagement, problem solving or decision making (Stoney & Oliver, 1998). The students' lower order activities were divided into three main sections—lower order talk, information seeking, procedural, and browsing. Table 1 provides an overview of the categories by which the lower order talk and thinking was identified (after Herrington, 1997):

Table 1. Summary chart of classification of talk by pairs

Category	Sub-Category	Definition	Summary of student talk	Example of type
Procedural	Equipment	Any discussion regarding the hardware.	These comments related to the computer crashing.	M: Oh, the computer's stuck. We'll have to start again.
	Software	Any discussion regarding the operation of the program or problems with the software.	There were very few comments of this nature, but one pair could see the desktop behind the program which caused one of them some difficulties.	K: Do you find it a bit disconcerting with all this behind it? B: It is a bit, yeah K: You're trying to read it and there's all the little bits.
	Task	Any discussion regarding the requirements of the tasks.	This type of talk related to the ways in which the students decided to move through the program and the order of their tasks.	J: What do you reckon? Do you think we have to go back to the Institute?
Browsing		Any exchange where the students were talking about looking to see what was available.	There were very few incidences of this type of talk. The collaborating students did very little browsing.	S: Let's have a quick look round first. M: Good idea, see what's here.
Lower Order		Any exchange which was of a routine nature, such as agreeing, commenting without applying thought or judgement.	Talk in this category included many routine comments about the task.	G: Tell you what this program really brings some concepts back.
Information Seeking		Any exchange where the students were actively seeking information, but were not making judgements about it.	Comments in this category were made when students decided to look for information provided to help them make the investment decisions. There were comparatively few comments in this area as most of the pairs worked out their own information.	M: Let's check what the economic forecasts have to say about all this.

Off task activities are those that occur when the students lose engagement with the program. The off task activities noted in the study in question, were caused by students being tired or listening to what other students were doing. The technology also caused some distraction from the program when it crashed or failed to operate as expected. Table 2 shows the percentage of time each pair spent in the lower order activities as defined above.

Table 2. Percentage of time spent in lower activities by each pair

Pair No	Procedural, equipment, s/ware, task	Browsing	Lower order talk	Information seeking	Total time in Lower order activities
1	10	1	18	3	32
2	22	1	16	9	48
3	15	3	25	7	50
4	10	4	25	13	52

It was noted from the in-depth study that generally the students spent very little time browsing, instead preferring to talk their way through the program and the problems. There was quite a high percentage of procedural talk, probably due to the fact that the program was a test version and had some minor glitches. The percentage of time spent in information seeking was generally low, with the exception of pair 4, who spent more than 10% of their time in this activity. The incidence of lower order talk was much higher than expected, and this could be attributed to the fact that the program was fairly complex and therefore students spent time reading aloud to each other, discussing routine factors such as where to go next and making comments that did not apply thought or judgement. Although there were many instances where the lower order talk was intermingled with the higher order talk, generally most of the students spent the initial part of their time discussing procedures and actively seeking information before moving on to higher order thinking.

The initial high percentage of lower order talk by students using the program was expected, as the students explored and experimented with the structure of the program, and this dropped away towards the middle and end of the time as students became more familiar with the structure and content of the program. Although the amount of time spent in lower order activities varied between the dyad groups, they spent fairly similar amounts of time browsing. The main differences between the groups were information seeking (ranging from 3% to 13%), procedural issues (ranging from 10% to 22%), and lower order talk (ranging from 16% to 25%). The types of issues which contributed to the lower order activities were problems with the system; for example when one of the students was distracted by the desktop showing behind the program, or when the system crashed. Some of the students also found that they needed to be directed to the paper-based instructions, although they still tended to want to talk through their navigational problems than read a manual. Much of the lower order activity involved student talk which was of a routine nature, where students were agreeing, reading aloud, and commenting without judging. A much smaller percentage of the lower order activities involved information seeking where students were actively looking for information and discussing it without judging it. Although much of the lower order talk was necessary in terms of the students working out how the program worked and commenting on incidents occurring in the program, some of the occurrences could have been eliminated by ensuring that the program was more stable, and by including more problems for the students to solve.

Higher order thinking

An important facet of developing higher order thinking skills is the ability to reflect on the learning experience and incorporate new knowledge with the pre-existing knowledge. Although the importance of reflection is well documented (eg Laurillard, 1995; Merriam, 1993), it is rarely supported as it is internalised by the student often without the instructor being aware of the process (Laurillard, 1995). Teacher oriented classes provide the least amount of time for reflection, but self-paced, resource-based instruction, such as multimedia, is capable of promoting the links between conceptual and experiential learning. This can be achieved by building in a variety of scenarios that offer alternatives to students, giving them choices from which to change their understanding of a concept whilst being able to relate it to their own world.

Traditional teaching often employs a lock-step approach to the acquisition of skills, with lower order skills being taught first. There is a belief that lower order skills are prerequisites to higher order skills and that mastery of lower order skills automatically leads to higher order skills. In fact, lower order and higher order skills can be taught concomitantly, with students mastering both levels as they apply their learning, rather than learning the skills, practicing and then applying them. This prevents skills being learned in isolation and students then having to relearn their application to real world tasks. The students are active in the learning process, applying problem-solving in context which in turn aids in the acquisition of skills, giving the students a reason to learn and helping them how to learn. In the study described in this paper, higher order thinking was classified into five main categories: planning/strategy; uncertainty; predicting/imposing meaning; multiple perspectives; and coaching (Herrington, 1997). Table 3. gives a breakdown of the classification of the categories.

Table 3. Summary chart of classification of higher order talk by pairs

Category	Definition	Example of student talk
Planning/ Strategy	Decision making (Lewis & Smith, 1993), considering strategies and planning events.	"Yeah, well I reckon that Castle Mining is overvalued so why don't we check out what the broker has to say about that, and then maybe look at the quarterly reports to see if there's some sort of a trend?" (Steve talk).
Uncertainty	Any statement expressing uncertainty. Any question clarifying a point (Ennis, 1993).	"One point one, where's the 12 come from, percent, where's the 16% come from? Don't know?" (Mark talk)
Predicting/ Imposing	Making a prediction, deciding what to believe, solving non-routine problems (Lewis & Smith, 1993), making	"Net present value is the current value or adjusted value on the discounted cash flow rates, huh" (Gary talk)

meaning	judgements (Ennis, 1993). Exploration of the problem, using inference, induction and deduction (Garrison, 1992).	
Multiple perspectives	Establishing different perspectives (Duchastel, 1990). Grounding in the real world (Garrison, 1992).	"I know, isn't that interesting, Northern Queensland, Western Australia, Cuba. I didn't know Cuba produced gold. I don't know what to do with the market at the moment 'cos you wouldn't buy gold at the moment" (Kelly talk).
Coaching	Accessing hints help in the form of support, advice, and explanations. Students teaching each other the material.	"Yes D is probably whatever the figure that they say starting 6 years from now but its only 5periods working here but it must be in the backtrack of the 5 periods.."(Brad talk).

Incidences of higher order thinking

Although three of the pairs spent half their time or more, in higher order thinking, it was felt that more student time should have been spent in higher order thinking. Part of the reason for the lower than expected number of incidences could have been the fact that the program was very procedurally oriented and therefore there was a high incidence of lower order talk. Analysis of the time spent in each facet of higher order thinking highlights the fact that students did not allocate as much of their talk time to grounding their new knowledge with existing knowledge as had been expected. One pair also spent very little time in planning and strategic thinking, and another pair did not coach each other as much as the other three pairs.

Table 4. Percentage of time spent by pairs in Higher Order talk

Pair Number	Planning /Strategy	Uncertainty	Predicting/ Imposing Meaning	Multiple Perspectives	Coaching	Total time spent in HOT
1	12	8	36	8	4	68
2	12	4	26	5	5	52
3	19	8	21	1	1	50
4	4	15	21	2	6	48

Although the learners were crafting solutions to problems, leading to higher order talk, building more problems into the program would increase the levels of planning and strategic thinking.

The students' talk gradually took on more higher order aspects as students became absorbed by the content and began planning their investment strategies. The degrees of higher order talk varied between the four dyads, as did the incidents that triggered it. These triggering events varied from relating real world events to the program's events, relating new information back to old learning acquired in other units, judging new information and projecting outcomes of decisions. The incidence of coaching also occurred to various degrees, although only one pair utilised it in a very limited way.

The dyads tended to have fairly different examples of higher order talk, with Pair 4 doing very little planning/strategic thinking (2%) and Pair 3 doing 19%. On the other hand, Pair 4 spent quite a lot of time (15%) clarifying statements and 21% of their time predicting and imposing meaning. Pair 1 spent the longest percentage of time on prediction (36%) and also the longest percentage of time on establishing different perspectives (8%). Pair 4 spent the most time accessing the on-line support and help (6%) which is perhaps reflected in their monetary results and also some of their comments about their lack of comfort with the program theory. A comparison of the time spent and totals profits accumulated with the degree of lower and higher order talk show a clear correlation. Pair 1 who had the highest percentage of higher order activities made the most profit, and this correlation holds true for the other three dyads. It also holds true for the time spent in the program with the exception of Pair 2 who spent longer in the program than Pair 1 but made less money.

Table 5. Comparison of lower and higher order activities with time spent and total profits made

Pair Number	Lower Order Activities (%)	Higher Order Activities (%)	Time spent in program (minutes)	Total profit ($)
1	32	68	103	39,345
2	48	52	112	35,239
3	50	50	101	23,500
4	52	48	92	22,080

Summary and Conclusions

It is clear from this study that the use of well designed interactive microworlds leads to learner cognitive engagement which in turn promotes greater degrees of concentration for longer periods of time. Further, if well designed, a program will drive learners towards greater levels of higher order thinking which in turn will assist in the ready attainment of implicit goals set by the program itself and explicit goals personally set by the learners. The use of the game and its motivating and engaging factors created an environment that resulted in high levels of higher order thinking, through triggering events. The program provided information and data from various perspectives and sources and facilitated a real connection between that information and information and learning already possessed by learners. The program's materials encouraged and indeed required, learners to judge and assess the credibility of potentially conflicting information, and to develop strategies to resolve those conflicts, to clarify issues, to solve problems, to experiment, to think strategically and critically, to sift information, to predict and impose meaning and to make judgements and decisions in spite of apparent contradictions.

The materials within the program were written to be understandable, interesting and relevant, not isolated from reality, and attempted to link theory to practice by requiring the application of content. In other words, the program attempted to focus on the functional context of acquired knowledge through the integration of skills in an authentic and realistic manner and setting. In an attempt to minimise the level of lower order thinking, which requires by definition, little sustained mental effort, the program was designed in such a way as to reduce the level of operational mechanistic tasks and allowed easy flow, exploration and ready access to information. In order to further reduce the levels of lower order thinking, an increase in problem solving could be encouraged by providing an increased opportunity for reflection, providing cognitive scaffolds to move learners more quickly to levels of higher order thinking, and by creating cognitive dissonance in both teaching materials and strategies.

Abstract

WWWIC, the NDSU WorldWide Web Instructional Committee, is engaged in developing a range of Virtual Environments for Education. These projects span a range of disciplines, from Earth Science to Anthropology, and from Business to Biology. However, all of these projects share a strategy, a set of assumptions, an approach to assessment, and an emerging tool set, which allows each to leverage from the insights and advances of the others.

Introduction

The NDSU World Wide Web Instructional Committee (WWWIC) is currently engaged in several virtual/visual development projects: three are NSF-supported, the Geology Explorer (Saini-Eidukat, Schwert, and Slator, 1998; Slator et al., 1998; Slator, Schwert, Saini-Eidukat, 1999; Schwert, Slator, Saini-Eidukat, 1999), the Virtual Cell (McClean, 1998; White, McClean and Slator, 1999) the Visual Computer Program and the ProgrammingLand MOO (Hill and Slator, 1998 Slator and Hill, 1999). These have shared and individual goals. Shared goals include the mission to teach Science structure and process: the Scientific Method, scientific problem solving, deduction, hypothesis formation and testing, and experimental design. The individual goals are to teach the content of individual scientific disciplines: Geoscience, Cell Biology, Computer Science.

In addition, WWWIC is applying what has been learned in Science education to new domains: history, microeconomics, and anthropology. Further, WWWIC has active research projects in two highly related areas: subjective student assessment and tools for building virtual educational environments.

The WWWIC program for designing and developing educational media implements a coherent strategy for all of its efforts. This strategy is to deploy teaching systems that share critical assumptions and technologies in order to leverage from each other's efforts. In particular, systems are designed to employ consistent elements across disciplines and, as a consequence, foster the potential for intersecting development plans and common tools for that development.

Geology Explorer

Geology Explorer is a virtual world where learners assume the role of a geologist on an expedition to explore the geology of a mythical planet. Learners participate in field-oriented expedition planning, sample collection, and "hands on" scientific problem solving. The Geology Explorer world is simulated on an Object Oriented Multiuser Domain, the Xerox PARC LambdaMOO (Curtis 1992). A text-based version of Geology Explorer was tested in an introductory geology class during the Summer 1998. Results of that test were used to prepare for a larger test in the same geology class during Fall 1998. A graphical user interface to the Geology Explorer is in the process of design.

To play the game, students are transported to the planet's surface and acquire a standard set of field instruments. Students are issued an "electronic log book" to record their findings and, most importantly, are assigned a sequence of exploratory goals. These goals are intended to motivate the students to view their surroundings with a critical eye, as a geologist would. Goals are assigned from a principled set, in order to leverage the role-based elements of the game. The students make their field observations, conduct small experiments, take note of the environment, and generally act like geologists as they work towards their goal of, say, locating a kimberlite deposit. A scoring system has been developed, so students can compete with each other and with themselves.

The Geology Explorer prototype can be visited at
http://www.cs.ndsu.nodak.edu/~slator/html/PLANET/

Virtual Cell

The Virtual Cell (VCell) is an interactive, 3-dimensional visualization of a bio-environment. VCell has been prototyped using the Virtual Reality Modeling Language (VRML), and is to be available via the Internet. To the student, the Virtual Cell looks like an enormous navigable space populated with 3D organelles. In this environment, experimental goals in the form of question-based assignments promote deductive reasoning and problem-solving in an authentic visualized context.

The initial point of entry for the Virtual Cell is a VRML-based laboratory. Here the learner encounters a scientific mentor and receives a specific assignment. In this laboratory, the student performs simple experiments and learns the basic physical and chemical features of the cell and its components. More notably, our laboratory procedures are crafted such that they necessitate a voyage into the Virtual Cell where experimental Science meets virtual reality. As the project progresses, students will revisit the laboratory to receive more assignments. Periodically, the student will bring cellular samples back to the virtual lab for experimentation.

The implementation of the Virtual Cell depends on coordinating three technologies: 1) VRML visualization, 2) Java client and simulation software, and 3) a text-based MOO server. Students use a standard WWW browser to launch a Java applet. The applet provides a connection to an object-oriented, multi-user domain where cellular processes are simulated and multi-user viewpoints are synchronized. The Java applet also controls the agent-based implementation of organic constituents, and launches an interface to the VRML representation of the Virtual Cell, allowing the student to explore and experiment within the 3D representation.

The Virtual Cell prototype can be visited at

Visual Computer Program and ProgrammingLand Museum

The goal of the Visual Program project is to provide an environment in which students can study and learn programming techniques. We provide tools to support active learning using visualizations of AI programs. These visualizations include animation, fly-through models and more interactive information models. The ProgrammingLand Museum implements an Exploratorium-style museum metaphor to create a hyper-course in computer programming principles aimed at structuring the curriculum as a tour through a virtual museum. Student visitors are invited to participate in a self-paced exploration of the exhibit space where they are introduced to the concepts of computer programming, are given demonstrations of these concepts in action, and are encouraged to manipulate the interactive exhibits as a way of experiencing the principles being taught.

ProgrammingLand is being developed on the Valley City State University (VCSU) campus as a Virtual Lecture adjunct to introductory programming language classes. Students peruse the exhibits of the museum, reading explanatory text that is displayed when they enter a room. A topic may be covered in one or more connected rooms. In addition to the displayed text there are a number of interactive demonstration objects in the museum that clarify or demonstrate the concepts. One such object is a code machine. It contains a short portion of programming language code and can perform any of the following functions: display the code; display the code with a line by line explanation of the purpose or syntax of each line; or display an execution of the code on a line by line basis. The goal of ProgrammingLand is to facilitate programming language courses, either locally or at a distance. At the beginning of this course the MOO had four wings, each incomplete. One of these was an introduction to using a MOO, each of the other three dealt with the one of the following programming languages: C++, Java and BASIC.

Blackwood

WWWIC is in the process of designing a virtual environment to simulate a 19th Century Western town. We will populate this town with intelligent software agents to simulate an economic environment representative of the times. This spatially oriented virtual environment, will borrow freely from historical records and digital images from archives at the NDSU Institute for Regional Studies.

The educational "game" will be one where players join the simulation and accept a retailer's role in the virtual environment. Rather than everyone vying for a portion of the same economic market, roles will be variable and specific. For example, in this simulation players will be purveyors of dry goods, food stuffs, blacksmithing services, mortuary services, saloons and gambling establishments, banks, barber shops, apothecaries, messenger services, news stands, gunsmiths, implement dealers and so forth. Therefore, players will only directly compete against other players with similar roles, or with software agents in the same profession, but not be in instant competition with every other player (Slator and Chaput, 1986).

In addition, the environment will support period-authentic atmosphere in the form of entertainments. For example, the circus might come to town, the weekly train will arrive from the east, a cattle drive will appear on the scene, preachers and circuit judges and medicine shows will pass through, and the occasional crime will be reported.

Virtual Polynesia

WWWIC is in the process of designing an immersive, synthetic environment where students, in the role of anthropologist or trader, step ashore on an island in western Polynesia, in the south Pacific, near the turn of the 19th century. That island, and the culture encountered, is modeled after the Samoan islands at a time a time when Samoan culture was still unaltered by Western goods and ideas. The environment will focus on a small valley and surrounding territory which represent a microcosm of Samoan society. The anthropologist is able to observe and explore the traditional society as it had developed to that time. He/she is also able to witness the contact of cultures as the trader enters the picture. While the environment will be fictitious, it will be based on careful attention to actual Samoan materials and cultural traditions.

Virtual Polynesia is another experiment in creating virtual worlds where more than one role is available to students. In this scenario, he most obvious roles are trader and anthropologist. The trader will visit the culture looking to exchange western goods for items in Samoan culture that would have value in the west. The anthropologist will look to the discovery of cultural artifacts that in some way illuminate our understanding of Samoan society.

The WWWIC Research Strategy

The WWWIC projects are designed to capitalize on the affordances provided by virtual environments. For example, to

- control virtual time and collapse virtual distance,
- create shared spaces that are physical or practical impossibilities,
- support shared experiences for participants in different physical locations,
- implement shared agents and artifacts according to specific pedagogical goals,
- support multi-user collaborations and competitive play.

Specifically, the WWWIC projects each design with the following over-arching principles.

Role-based: Simulated environments enable learners to assume roles in particular contexts and have meaningful, authentic experiences. In the popular culture, this approach is captured in the John Houseman adage, "learning not the law, but learning to think like a lawyer". More formally, WWWIC promotes a learning strategy based on ancient apprenticeship where, in modern terms, the student progresses by "modeling the expertise" of the master. Role-based learning is learning-by-doing, but not the mere goal oriented "doing" of a task. Rather, it is learning-by-doing within the structure of playing a role in context. Instead of simply teaching goal-based behavior and tactical task-oriented skills and methods, the role-based approach communicates a general, strategic, manner of practice (McLuhan, 1964).

Goal-oriented: Goals are important, but within the context of roles. It is through goals that obstacles leading to problem solving are encountered. It is within the local goal framework that techniques and methods are learned and rehearsed. Practice and repetition in problem-solving is how apprentices learn the master's craft. Goals provide problems to solve.

Learn by Doing: When experiences are structured and arranged such that playing a role in the environment illustrates the important concepts and procedures of the simulated domain, students are able to "learn by doing" (Dewey, 1900). Experiences are the best teachers.

Spatially oriented: WWWIC simulations are spatially-oriented to leverage off the natural human propensity to towards physically plausible context. In this way, simulations promote the "willing suspension of disbelief" which in turn reinforces the role-based elements of the environments.

Immersive: The combination of role-based scenarios and spatially oriented simulations is conducive to an immersive atmosphere. The concept of immersion has long been shown valuable in foreign language learning (where, it is anecdotally understood, the key moment arrives when the learner succeeds in reaching the point where they are "thinking in X", where X is French, German, Farsi, or whatever). Immersion, then, is elemental to the concept of role- based learning where it is the strategic thinking of the master the apprentice eventually learns to model

Exploratory: Exploratory simulation means enabling students to pursue their own interests. This approach, usually referred to as User-centered design, promotes a pedagogical environment where learners are self-directed and given the freedom to structure, construct, and internalize their own experience (Duffy, Lowyck, and Jonassen, 1983; Duffy and Jonassen, 1992).

Game-like: The value of play in learning can hardly be over-stressed. Students quickly tire of rigid tutorial systems designed to teach at any cost and at some predetermined pace (Schank, 1991). However, since simulations can be adaptive and responsive, playing a role in a simulation can be fun. Players will throw themselves terrier-like into an environment if it feels like a game. Insofar as possible, educational software should be engaging, entertaining, attractive, interactive, and flexible: in short, game-like (Slator and Chaput, 1986).

Highly Interactive: One major challenge for science educators is to develop educational tools and methods that deliver the principles but also teach important content material in a meaningful way. At the same time, the need for computer- based education and distance learning systems has become increasingly obvious, while the value of "active" versus "passive" learning has become increasingly clear (Reid, 1994).

Multi-user/player: One challenge is to craft role-based, goal-oriented environments that promote collaboration as well as the more easily conceived competition. The answer lies in designing systems where student/players have multiple roles to choose from, and to carefully construct the simulation so that these roles are inherently complementary. WWWIC educational systems are uniformly multi-user, and hosted on the MOO architecture.

Software Agents: Software agents are implemented to exhibit authentic behavior(s) of the following types:

- **atmosphere agents:** an agent that simply lends to the local color. For example, in an urban simulation there might be a street magician, a street vendor, a beat cop, a street sweeper, and so forth; in a museum simulation there might be visitors wandering the exhibits or vendors selling popcorn; on a planet perhaps animals roaming the desert.
- **infrastructure agents:** an agent who contributes in some way to the gameplay: in an urban simulation perhaps a banker, an employee, an advertising consultant, and so forth; in a museum, one might expect a guide; on a planet, another kind of guide.
- **tutoring agents:** an agent that monitors player moves, and visits players to give them advice in the form of expert stories and cases, or in some other way assists players in learning to play. These will represent expertise or past experiences of other players.

Unintrusive Tutoring: A key feature of educational media is the ability to tutor students. In WWWIC environments, tutoring is done through unintrusive but proactive software agents. Agents monitor student actions and "visit" a student when the need arises. Tutors give advice, but they do not mandate or insist on student actions, nor do they block or prevent student actions.

Intelligent Software Tutoring Agents: we implement three different approaches to intelligent tutoring, based on the knowledge available to the tutoring agent.

1. **Deductive Tutors** provide assistance to players in the course of their deductive reasoning within the scientific problem solving required for the accomplishment of their goals. **Example:** intelligent tutoring agents in the NDSU Geology Explorer, which work from knowledge of the rocks and minerals, and knowledge of the "experiments" needed to confirm or deny the identity of a rock or mineral. Three opportunities for deductive tutoring present themselves:
    1. an **equipment tutor** detects when a student has failed to acquire equipment necessary to achieving their goals
    2. an **exploration tutor** detects when a student has overlooked a goal in their travels
    3. a **science tutor** detects when a student makes a wrong identification and why (i.e. what evidence they are lacking); or when a student makes a correct identification, but with insufficient evidence (i.e. a lucky guess)
2. **Case-based Tutors** provide assistance to players by presenting them with examples of relevant experience. This is accomplished by
    - creating a library of prototypical cases of success and failure,
    - treating the student's experience as though it were a case
    - matching the student's case with the library and retrieving the most similar, relevant case for remediation
3. **Rule Based Tutors** provide assistance by
    - encoding a set of rules about the domain

• monitoring student action looking for one of these rules to be "broken"
• "visiting" the student to present an expert dialog, or a tutorial.

Shared Courseware Tools: Creating virtual/visual worlds is an intensive process in terms of pedagogical design, knowledge engineering, and software development. Having gained experience in the hand-crafting of these systems, WWWIC is now in the process of designing and developing an integrated library of software tools to substantially streamline the development of future worlds. These tools primarily support simulation and agent building, and are of the following types:

• **Virtual Abstraction Tool:** Jia (1998) implements a first version of a graphical tool for building abstraction hierarchies in LambdaMOO. This tool enables the creation, deletion, renaming, and recategorizing of objects. Tools of this sort enable content experts to visualize the structure of the knowledgebase and assist with creating the taxonomic structures for representing conceptual knowledge.

• **Virtual Entity Tool:** We are implementing a tool to employ an entity template system with a form-filling interface to enable creation of multiple instances of a category. For example, we will define a template for minerals that specifies the properties indigenous to minerals, and ranges of values associated with each property. Then, a content specialist will create new minerals, quartz, tourmaline, talc, etc., with a graphical form-filling interface where values such as color, texture, and hardness can be quickly and easily selected from menus. This tool is general in that any category of entity (animal, mineral, or vegetable) can be constructed with it.

• **Spatial Environment Tool:** We are implementing a spatial environment tool (i.e. a virtual map building tool) to allow environment designers to graphically create and manipulate spaces in a virtual world. By using a map-like interface, content specialists will decide on the specification of locations, such as geological formations and placement of these in relation to each other.

• **Integrated Virtual World Building Tool:** We are implementing a master tool that coordinates and manages the process of building virtual worlds. This tool supports the implementation of virtual worlds from the ground up, by giving access to the construction tools, and a "surface" view of the world as it develops. For example, content specialists building, say, virtual space for paleontology, will use the **Virtual Abstraction Tool** to create the hierarchy of concepts related to fossils. Then the **Virtual Entity Tool** will be used to create an inventory of fossils in different categories. Meanwhile, the **Spatial Environment Tool** will be used to create canyons and mountains where the fossils will reside. The integrated tools set, which we are calling GUMI Suite (Graphical User-friendly MOO Interface) will support the developer's exploration of the virtual world as they develop it. At the same time, the integrated tool will support the **Deductive Tutoring Agent Tool** (described next), since they operate on the same objects.

• **Deductive Tutoring Agent Tool:** We are implementing a tool to
1. provide a menu of virtual testing equipment and the range of values each produces -- from this a subject matter expert can choose the appropriate instrument-value pairs;
2. provide a menu of substances in the same category, to serve as a template; and
3. check other substances to insure a unique set of plausibly sufficient criteria for each.

These three functions will insure that tutoring is supported on all identification tasks and will have the further benefit of checking for consistency of artifacts in the synthetic world. This tool will be integrated into GUMI-Suite, described above.

The ultimate aim in developing software tools is to support the construction of synthetic environments and move development into the hands of content specialists, teachers, and curriculum developers, rather than computer programmers.

Subjective Assessment: Developing methods for the assessment of student learning are a central element of this research (Slator et al., 1998). Briefly, the assessment goal is to determine the benefit to students derived from their "learn by doing" experiences.

Our assessment strategy rejects the notion of standardized multiple choice tests as an adequate instrument in this pedagogical context. While there are, indeed, facts and concepts acquired in the course of exploration, which are neatly packageable and testable with objective instruments, the effect on student learning in that arena will not be significant, nor would we expect it to be.

Therefore, our assessment protocol is a subjective one that seeks to measure how student thinking has improved. To do this, players are given a pre-game narrative-based survey where they are told short problem solving stories and asked to record their impressions and any questions that occur to them. These surveys are analyzed for the presence of what could be considered "important" domain or problem-solving concepts or procedures.

Abstract
A mixed media approach to distance education was developed which combined 1) traditional classroom lectures with Interactive Video Network (IVN) multicasting, 2) WWW-based assignments, notes, and course materials, 3) WWW-based quizzes, 4) assignments turned in, and results returned, using E-mail, and, most notably, 5) a virtual environment modeled on the Museum metaphor, where students explored singly and in groups, developed virtual machines that became part of the Museum's "collection", and interacted with instructors who kept "virtual" office hours. The course was attended by students from two campuses 70 miles apart, and delivered by two instructors, one from a third campus, 60 miles in the other direction.

Introduction

Methods for managing distance education continue to evolve. Interactive Video Networks (IVN) are one method for delivering lecture and other programming to remote locations. The Worldwide Web provides the ability to compose attractive text and image presentations, and has become an increasingly vibrant medium with animation and even video. It is more and more common to find course materials online in the form of syllabi, lecture notes, and reference materials. Recently, more active elements have appeared in the form of online quizzes and simple demonstrations. These two approaches supplement the time-honored methods of distance education: correspondence courses and broadcast media. Most recently, research into the development of virtual environments for education have started to have a limited but highly promising impact.

Approach

There are many challenges, both in terms of developing new approaches to content and curriculum, and in delivering that content to remote learners. This paper describes a curricular experience that combined virtual lecture with virtual laboratory to produce a virtual course. In particular, we combined a Virtual Lecture, using the Interactive Video Network (IVN), with a Virtual Laboratory and Museum of Computer Science, the ProgrammingLand MOO (Hill and Slator, 1998), to deliver both lecture-based and hands on instruction to students in remote locations. In doing so we pursued a particular theoretical approach to this new pedagogy - an approach that stresses the importance of virtual environments, authentic experiences, and active learning. We developed a relatively standard IVN course, but then augmented it with networked, multi-player, simulation-based, interactive multi-media - an educational environment that is both immersive and highly interactive (Reid, 1994).

The ProgrammingLand Museum implements an Exploratorium-style museum metaphor to create a hyper-course in computer programming principles aimed at structuring the curriculum as a tour through a virtual museum. Student visitors are invited to participate in a self-paced exploration of the exhibit space where they are introduced to the concepts of computer programming, are given demonstrations of these concepts in action, and are encouraged to manipulate the interactive exhibits as a way of experiencing the principles being taught (Duffy, Lowyck, Jonassen, 1983; Duffy and Jonassen, 1992).

Locality and Temporality

Virtual classrooms and virtual laboratories will help solve many of the problems facing the modern university: distance learning will become a reality, learner diversity will be accommodated (both in terms of learning styles and life styles), and in many cases the curriculum will become more active, more role-based, more self-paced, and more "learn by doing" than "learn by listening" (Schank, 1994).

It is not hard to imagine a day when the curriculum is taught in both real and virtual laboratories - or to foresee a time when students will take virtual field trips in order to prepare for the real thing. One can also imagine a curriculum that combines physical classrooms with virtual ones: where some lecture material is delivered same time and same place, and other material, employing "time shifting" and "place shifting," is not (see Figure 1).

Time/Place Shifting	Same Time	Different Time
Same Place	**Classroom Lectures** **Pros:** personal, sometimes interactive, **Cons:** inflexible schedule, social pressures, mostly passive learner experience, strictly local audience	**Virtual Environments** **Pros:** self-paced, immersive, potential for active learner experience, programmable **Cons:** high development costs
Different Place	**Live Broadcast (e.g. IVN)** **Pros:** personal, sometimes interactive, recordable for later review, potential for wide (broadcast) audience **Cons:** similar to lecture: inflexible schedule, social pressures, mostly passive learner experience	**Recorded or Broadcast Programming** **Pros:** self-paced (rewindable) **Cons:** non-interactive, passive learner experience

Figure 1: Time and Place Shifting

Recursion

From the first day, and throughout the course (COMP 372: Comparative Programming Languages, a required upper division course), we attempted to stress recursion as a theme. This served two purposes. First, recursion is one of the most difficult concepts in computer science. It is an elegant and abstruse mathematical construct that often baffles undergraduate students. Unlike most other computing concepts, recursion is difficult to teach because of the relatively few common sense day-to-day activities that depend on it, making it difficult to draw useful analogies. And unlike previous generations of computer science curricula, it is common in these enlightened times to introduce recursion as early and as often as possible, in an attempt to reinforce the concept until it becomes familiar and workable.

One of the most productive moments for covering recursion in the curriculum is during a course on programming languages. In this context program execution is viewed from the viewpoint of the runtime environment where all programs are managed in terms of memory allocations and activation records on a runtime stack. From this point of view, recursion is not a matter of infinitely embedded abstractions, but a more concrete matter of pushing and popping activation records from a stack. The stack is a powerful metaphor in computer science, and provides an excellent image for understanding recursion, but understanding stacks requires understanding more fundamental computing concepts, and so stacks are not immediately introduced to beginning students. Ironically, with recursion so early in the curriculum, it is now possible for students to be introduced to recursion before they learn about stacks.

Second, in the interest of approaching recursion from an unusual angle, and in order to motivate the programming assignments in the course, we decided to assign projects that called for building virtual machines that illustrated programming language concepts, as a method of teaching these concepts to others. In other words, the students were asked to learn about concepts in order to build artifacts that would be used to teach those concepts. The virtual course, as we styled it (because of the IVN, WWW, and MOO mix), was about studying programming languages in order to recursively implement museum exhibits in order to teach about programming languages.

Course Components

NDSU COMP372: Comparative Programming Languages, was offered in the Summer of 1998 during the 4-week session, and was comprised of the following elements.

IVN, The North Dakota Interactive Video Network

The North Dakota Interactive Video Network (ND IVN) is a two-way interactive telecommunications system located at many sites throughout the state. Any combination of two to fourteen sites may be connected together for a single event and several events may occur at the same time. Over 25 specially equipped telecommunications classrooms and conference rooms link the 11 North Dakota State University System campuses, the state capitol, 5 tribal colleges in ND, and 25 high schools in the state. In addition, ND IVN has the ability to connect to sites world-wide. ND IVN participants can hear all sites at all times but see only one other site. The Network automatically switches the video to the site that is currently speaking. For the automatic switching to occur, a sound must last about two seconds.

An IVN room is designed to as closely resemble a traditional classroom as practical. Each room had approximately 25 seats. There are two television monitors, one displays the current image and the other the image being transmitted from this location. Each student has a microphone on their table. When a student speaks, then the image from that location is broadcast to the other locations. Thus a reasonable conversation can be carried out; however, the originating site can not tell if their image is being transmitted or not. An instructor can also transmit computer images or the display of a paper that then functions like a blackboard. In this particular course, there were four such sites: two on the NDSU campus, one on the UND campus and one on the VCSU campus.

WWW Syllabus and Assignments

All pertinent documents, such as the syllabus and assignments, were posted on web pages. In most classes this is a courtesy to students. In this course it was a requirement since none of the locations were within 50 miles of each other.

WWW Exams

The WWW test system was developed at NDSU for multiple choice tests on the web. It is similar to many other such test-giving systems. A student may log in by registering their name and obtaining an ID. They may then take a test during a particular window of time, which was usually from Friday after class to Monday before class. On completion of the test they were immediately given their resulting score. An instructor could gain access to enter a test, modify a test or obtain class scores. Any common web browser could be used.

E-mail

In such a situation e-mail becomes a critical communication form, since distance keeps face to face conversations at a minimum. E-mail was used for a variety of situations in this course. Assignments that were not MOO based were handed in through e-mail, with the program and other documentation as an attachment. The time stamp of the e-mail determined whether the item is on-time or late. MOO assignments were handed in by e-mail that announced its completion and specified the object numbers of the finished products. Many of the office visit situations were also handled with e-mail, sometimes more easily than a real visit; questions could be answered and programs could be examined. For example, it is often easier to attach an example program to an e-mail than it is to put it in the students hands in a visit, moreover it is much easier for them to run it later. The time delays of this approach leave something to be desired, but this is remedied by virtual office hours as discussed below.

The importance of E-mail made it crucial that both authors processed all e-mail several times a day. The course had a very short time duration, just four weeks. It was imperative for students to receive quick response to e-mail; and three exchanges with a single student in a single day was not uncommon.

The ProgrammingLand Musuem

ProgrammingLand is a MOO (Curtis, 1992) being developed on the VCSU campus as a Virtual Lecture adjunct to introductory programming language classes. The paradigm employed is that of a museum where students examine exhibits, reading the explanatory text displayed on the walls of each room. In addition to the displayed text there are a number of interactive demonstration objects in the museum that clarify or demonstrate the concepts. One such object is a code machine which contains a short segment of programming language code and can display the code; display with line by line explanations; or display a line by line execution of the code. ProgrammingLand augments programming language courses, either locally or at a distance. At the beginning of this course there were four wings under construction. One of these was an introduction to using a MOO, each of the other three dealt with the one of C++, Java or BASIC.

This approach to a MOO has much in common with many web oriented approaches, with some differences as well. A room in a MOO corresponds to a single web page. The MOO is exclusively text-based while a web page can augment the text with various multimedia objects. However, every room of a MOO is also a chat room and users of the MOO are aware of the presence of others in the room or in the MOO, unlike web pages. The MOO keeps more and better server side records of the students and their actions. The MOO server code actually has a web interface, but using it loses many of the interactive advantages of the MOO.

Three assignments in COMP372 were completely MOO based. The first was a trivial exercise in MOO navigation. They were to find an object, which was called the totem pole. When they found it, that fact was marked on their MOO user ID. The purpose of this was so that the students could explore the MOO and see how it was arranged and how exhibits conveyed the desired content. In the second assignment each student was given a LISP function. Students had to build an instructional suite of rooms about their particular function. They were to reinforce their learning by teaching others in the context of the MOO. The third MOO assignment was to create an interactive machine that demonstrated their particular LISP function. This gave them some unique insights into their function, but also the object oriented script of the MOO. The machine in question took one of several function calls and results and verified that the function did indeed produce the stated output.

Since every room of a MOO is a chat room, the students interact with each other and the instructors in the MOO. This suggested the concept of virtual office hours. Each instructor would guarantee that they would be in the MOO at a particular time. Any student with a question or problem could then go and have a real time conversation with the instructor. If that conversation involved a MOO project, then it was a simple matter to visit the room and give what ever help was needed. This approach is not quite as personal as a face to face meeting and it does tend to test the typing skills of the student, but is a solution to the distance problem.

Textbook

The textbook was Concepts of Programming Languages (3rd Edition) by **Robert W. Sebesta**. Published by Addison Wesley, 1996, ISBN 0-8053-7133-8.

Course Details

This course was a typical Junior level Programming Languages courses for Computer Science majors and minors. The first author had taught the course in previous terms, using a MOO. However, a number of wrinkles were requested by the administration. There was some demand for the course on another campus of the NDUS system, so it was requested that the course be taught over the Interactive Video Network (IVN). The course was to be taught in a four-week session, but the number of contact hours available on IVN was three hours short of what was needed for a three hour course. These constraints provoked us to use a strategy not previously used by either of us. The content materials would come from lectures delivered by IVN and the student's offline reading of the textbook. Tests would be delivered through a World Wide Web test system developed at NDSU. All assignments and related material, such as the syllabus, would be available on a WWW page. Conventional programming assignments were done on a separate minicomputer using a LISP interpreter and handed in via email. The recursive learn-by-teaching approach was used, by having students generate lessons inside the MOO.

The course was completed over the course of four weeks (actually, 18 class meetings), and was composed of the elements just listed. Lectures were multicast daily by the first author from an instrumented IVN classroom on the NDSU campus. There were several students in that IVN room, several more in an IVN classroom across campus, and a handful in another IVN classroom on a campus 70 miles to the north. In addition, the second author participated from another IVN location 60 miles to the west. There were 50 students altogether. This technology, described above, is relatively solid and caused few problems (there were, however, occasional audio anomalies, where sudden bursts of static or other noise would be emitted, and there were times when the voice-activated nature of the two-way audio communication was awkward, as sometimes disembodied voices would emanate over the transmission but the accompanying video would never arrive).

The course syllabus was posted at a website online, and reading assignments (both from the text and from online sources), and homework assignments were posted on that site too. In addition, the details of the homework assignments, as well as information on how to negotiate the pitfalls of electronically submitting homework.

Although hosting the course on the Interactive Video Network, and posting the syllabus on the WorldWide Web were steps in the virtual direction, the technologies of the Internet were employed in even more interesting ways than that. In particular, exams were held outside of class and administered over the

Web. Tools for creating these online quizzes were provided by the NDSU Multimedia Center, but they were experimental and proved problematic. Uploading quizzes was painfully time consuming and fault-intolerant. Some students complained about not being able to re-take a quiz if they lost their connection, and there were a few anomalies in grade reporting that had to be corrected by hand. However, the technological difficulties with online quizzes were not extreme.

The pedagogical difficulties with online quizzes were a little more profound, because of the offline, self-paced nature of the Web. In this class, tests were posted on Friday and students were given until Monday evening to complete them. This unstructured, unproctored protocol meant students could take quizzes at their leisure with their textbooks open on their lap. As a consequence of all these factors, quizzes were painful to implement and were relatively weak indicators of student progress. Hence, quiz grades were quite high on average.

There was no attempt made to conceal that this approach was as new to the authors as to the students. It was perceived that they responded well and entered into the adventure. This did require flexibility when various technical problems occurred. In the end, the students rated the class highly (see below).

Local Context

The NDSU World Wide Web Instructional Committee (WWWIC) is currently engaged in several virtual/visual development projects: three NSF-supported, The Geology Explorer (Slator et al., 1998; Saini-Eidukat, Schwert and Slator 1999; Slator, Schwert, Saini-Eidukat, 1999; Schwert, Slator, Saini-Eidukat, 1999), The Virtual Cell (White, McClean, Slator, 1999), and The Visual Computer Program, as well as others. These have shared and individual goals. Shared goals include the mission to teach Science structure and process: the Scientific Method, scientific problem solving, deduction, hypothesis formation and testing, and experimental design. The individual goals are to teach the content of individual scientific disciplines: Geoscience, Cell Biology, and Computer Science.

These projects are designed to capitalize on the affordances provided by virtual environments. For example, to

- control virtual time and collapse virtual distance,
- create shared spaces that are physical or practical impossibilities,
- support shared experiences for participants in different physical locations,
- implement shared agents and artifacts according to specific pedagogical goals,
- support multi-user collaborations and competitive play.

Summary

The combination of IVN, WWW, and MOO proved to be quite effective and stronger than any of these alone. The use of the MOO greatly enhanced the effectiveness of the course by reducing the perceived separation of student and instructor. Student evaluations of the course were quite high, with 92% of the students responding rating the quality of the course as either above or much above average. Similarly, 88% of the students believed their understanding of the course content was either good or very good.

Future Plans

We intend to conduct a more thorough study of this approach when the course is offered again in the first summer session of 1999. This study will include a survey given at the beginning of the class and follow up survey at the end that attempts to capture student perceptions of this form of distance learning.

Abstract: The Virtual University is an Internet-based learning environment that includes all aspects of a university, developed at the University of Hagen. The project is experimenting with and evaluating different forms of teaching and learning. A new form of teaching is the virtual seminar. Our experiences show that the virtual seminar is leading towards a major quality improvement. in open and distance education. Learning activities are changing, the alternation of receptive and active-expressive activities is possible. The seminar develops into a new and constant cooperation and communication process.

1. Introduction

As life-long learning is getting more and more essential in professional life, learning via Intra-and Internet will more and more succeed, mainly with the increase of open and distant learning [MITT98a]. The benefits of distance education, time- and location independence and the advantages of the Internet (fast information, easy communication and co-operation possibilities) are combined in the project virtual university. A prototype with about 4.000 students is running since 1996 at the University of Hagen
The Virtual University [BM96] of the University Hagen is a virtual university system that integrates all functions of a university into a complete, homogeneous, extensible and cost-effective system with an easy to use and intuitive user-interface. The main menu of the Virtual University [Fig. 1] offers the functions:

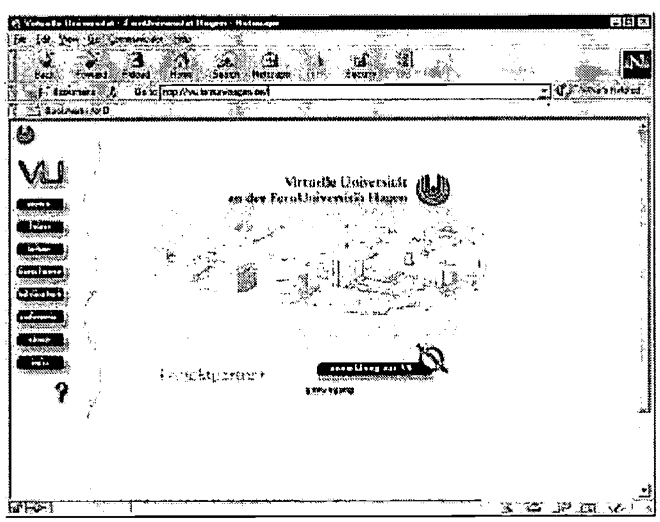

Fig. 1: Home page of the Virtual University, http://vu.fernuni-hagen.de

education - for participation in courses, seminars, practical training and exercises; news - a campus wide blackboard containing all sorts of up-to-date information relevant to the users of the Virtual University; office - the component including administrative functions; research - offering access to all research-related activities in the university; cafeteria - a forum for social contacts between students; library - offering access to both traditional and digital libraries; information - a menu containing general information about the university; and shop - offering all material that can be purchased from the university.
This paper aims to describe the different phases of traditional and virtual seminars in open and distance teaching at the University Hagen in correlation with the use of different communication tools, objectives, and learning activities. The major breakthrough is attributed to the multitude of communication and cooperation facilities given in the Virtual University. The differences and the results of these differences are described in part 3 of the paper, the fourth part gives some insights our experience with virtual seminars. In the summary and prospects (part 5) recommendations for doing successful virtual seminars are given.

2. Conventional Seminars and Virtual Seminars

The seminar is traditionally an important teaching method in higher education, also at the University of Hagen, which is specialized in open and distance education. The main objective of the seminar as teaching form is to maintain and acquire scientific work prospective and to present and discuss the results of this work. So far, these objectives of a seminar were only partly fulfilled by the conventional seminar, because a continuos communication-, cooperation- and learning process is hardly possible.
The virtual seminar is much more like a seminar in presence education. Moreover the communication-, cooperation- and learning process is much more structured and more disciplined than in presence education.
The following part describes the different phases of conventional and virtual seminars at the University of Hagen out of a student's perspective.

2.1 Traditional seminar at a distance university

The conventional way to take part in a seminar is the following:
Students get their topics by mail, work out their contribution, travel to the university and present their contribution in the presence phase (two days). There are only three seminar phases (introduction, elaboration and presence phase), with nearly no cooperation or alternation of different learning activities. This way causes different problems:

- students have rarely contact to tutors, students are working alone mostly
- little communication between the students
- discussing questions and problems is time-consuming
- students can not participate in the selection of topics
- groupwork is nearly impossible
- nearly no cooperation / arrangement between students to deal with overlaps concerning their topics
- there is less alternation in the students' learning activities
- students have to travel
- the presence phase is completely taken up with presentations, there is little time for discussions

2.2 Traditional seminar at a campus university:

The traditional seminar at a campus university seems to be a more communicative and cooperative way to reach a seminar's objectives. But in it's structure the traditional seminar typically is hardly better than the distance seminar. Normally, students do not know each other, are working on alone their contribution with little communication with other students or the tutor. The discussion process is short at best and not very deep, the students usually are unaware of the written contribution of each other.
The lively, interesting, well-structured seminar with only good presentations and very active, cooperating and communicating participants is a rare exceptional case, even though the students are less isolated than in traditional distance teaching seminars.

2.3 Virtual seminar at a distance university:

The virtual seminar is one of various teaching activities at the Virtual University. The Internet services used for such a seminar are email, ftp, news, chat, audio- and video conferencing [BERK97]. Services were individually combined for different seminar phases. There are also mixed forms between virtual and conventional seminars, e. g. only certain seminar phases are assisted by Internet-based tools. In the following only pure virtual seminars are considered.

The average number of participants is about 15 students preparing lectures (either individually or in co-operation with other participants), supported by Internet communication services. Furthermore there are about 40-70 students taking part as so called "passive" participants. These passive participants are having the possibility to take part in the seminar's communication process but are not producing lectures.

Since the beginning of the Virtual University project about six pure virtual seminars have taken place in our computer science department. The way to execute such a virtual seminar is as follows:

Seminar phase		**Communication tools**	**Objective**	**Learning activities**	**Co-operation**	**Time**
Enrolment		Mail, Email (Mailinglist)	Interesting the students for a special topic	None	None	Two months before the term starts
Orientation		WWW, News, Email,	Decision for a specific theme to elaborate during the seminar with student's participation	Receptive and active, expressive	Discussion about the topics with the tutor and other students	four weeks before the term starts
Introduction		News, WWW	Presentation of the participants and the tutor, first introduction in the seminar's theme	Active-expressive and receptive	With the tutor and students	At the beginning of the term
Preparation of Groups		News, Email, telephone	Building of seminar work groups, which will work out one topic together.	Active-expressive	With the tutor and other students	At the beginning of the term
Elaboration	Recherché	News, Email,	Knowledge acquisition about a special topic of a certain theme	Active-expressive	With the tutor and other students	
	Structuring	News, www, Email	Structuring the information, presentation in the newsgroup or www Finding out overlaps to other topics	Active-expressive	Discussion about the structure with the tutor and other students	Six weeks after the term started (average number)
	Correction	Email, news	Correction and revision of the reviewed structure	Active-expressive	With the tutor and other students	Two weeks after Structuring
	Writing	Mail	Final version of the written contribution	Active	With the tutor and other students	Four to six weeks (average number)
	Finish	WWW, news, Chat, Audio- and/or Videoconferencing	Publishing the contribution in the web, discussion	Active	With the tutor and other students	Gradual, two months before the term is ending until
Presence		Personally, or www	Presentation and discussion of lectures	Active-expressive, receptive	With tutor and other students	End of the seminar

Table 1: Seminar phases of a virtual seminar

To summarize the advantages of virtual seminars:

- students have rather good contact to tutors and other students
- continuous communication between the students, throughout all seminar phases
- discussing questions and problems is time- and cost-effective
- students can easily participate in the selection of topics
- building of learning and working groups is possible
- it is possible to find out overlap concerning the student's topics and to provide hyperlinks to each others contribution
- students do not have to travel at all
- in the case the presence phase is taking place, the time could be used for discussions. Furthermore, the time needed to getting to know each other is less than in
- conventional courses

3. Differences

As shown, the main differences are in the use of communication tools and in the learning activities. The virtual seminar is much more structured than a conventional seminar, particularly in the elaboration phase, which is one of the most important phases.
Our experience show, that a well-structured teaching process and a continuing guided learning process, supported by alternating learning activities, are the best guarantee for a major quality improvement. The experiences of virtual seminars could also be used to rise quality of traditional seminars at a presence university.

A short comparative overview:

3.1 Seminar Phases

In contrast to conventional seminars, the virtual seminar is enriched by the phases Introduction and Preparation of Groups. The introduction phase has the objective
to introduce the participants and the tutor to each other, mostly in the seminar's newsgroup, sometimes in the WWW by the help of HTML-Pages.
New is also the preparation of groups. In conventional seminars the group building process was nearly impossible.
Normally, the presence phase is shortened from two days to one, which reduces the costs of overnight stays for the students, but it is also possible to do the whole presentation and discussion phase online in the Web, e. g. by the use of text-chat, audio- and videoconferencing.

3.2 Communication

The conventional seminar uses traditional communication tools, like mail, telephone, fax, etc.. The communication tools in a virtual seminar are Internet based. These communication tools enable the very active communication, co-operation and discussing process. For the first time synchronous communication with several students and tutor is possible in a cost-effective way.

3.3 Objectives

Some new objectives are given in the virtual seminar: The introduction of participants and tutor, the participation of students in defining seminar topics. Furthermore, finding out overlaps with other topics, publishing and discussing the contribution in the web.
For the first time the classical objectives of the seminar as teaching method, to learn to work scientifically, to present and to discuss the results, are given in distance education.

3.4 Learning activities

It is evident that the alternation of receptive, active and expressive learning activities is much better given in the virtual seminar form. Nearly each seminar phase contains all learning activities, in contrast to the conventional seminar form, which comprises only two phases with all above mentioned learning activities.

3.5 Co-operation

Co-operation is hardly possible in the conventional seminar, but one of the most important advantages of virtual seminars, even if the cooperation process is guided by the tutor.

3.6 Time

The term time in virtual seminars is structured in greater detail, especially in the elaboration phase. Giving feedback to the students is fast and easily possible, for the students the possibility to give feedback to each other is really new. The visualization of the working process in the elaboration phase is an important step to break through the student's isolation. Over-all the virtual seminar is a time-effective teaching method.

4. Some Experiences

Since the Virtual University started (in winter term 1996/1997) about six completely virtual seminars have taken place.

The experiences made with virtual seminars in the project Virtual University are throughout positive. A user's survey of participants of the virtual university in spring 1998 showed, that the intensity of the contacts virtual seminars is much better than in conventional seminars, also the building of work and learning groups.

Furthermore, most of the students were of the opinion that the discussion quality is higher than in conventional seminars. The majority of the students scored the offer of online-seminars with "very useful" [MITT98b].

Another aspect is the dropout rate, always a problem in open and distance teaching. The drop out rate in the virtual seminars was significant less than in conventional seminars.

Robin Mason [MASO94] describes related results in the context of synchronous communication.

5. Summary and Prospects

The virtual seminar allows a well-structured teaching process with alternating receptive and active-expressive learning activities which promote the student's learning success.

In contrast to conventional seminars a continuing learning process is now possible, the discussions, taking place in the Internet are much more structured and disciplined than in the conventional seminars presence phase.

Internet based communication tools enable the very active communication, co-operation and discussing processes. The forming of groups and learning together are new and highly valuable activities for the distance students.

By working out the seminar contributions in HTML it is for the first time possible to have seminar contributions as a homogenous hypertext, to avoid overlapping of topics and learn from each others contribution.

The successive publishing of the contributions enables the student to discuss continuously about certain topics, in contrast to discuss all contributions at one time. Furthermore, the student is able to concentrate on the main thesis of his/her presentation, because of the most others know his/her work. In addition, the students are able to learn from each others work.

Criteria to give a successful virtual seminar

Moderation process
Critical for the success of a virtual seminar is the moderation process. It is necessary to look regularly in the seminar newsgroup, to read daily emails, to bundle frequently asked questions and to answer quickly to the students' questions. In the beginning of the seminar many messages will arrive, but then their number will decline, because the students prefer to communicate with each other, using the newsgroup and other communication tools.

Structuring and Support
As in conventional seminars it is helpful for the students, if the seminar themes are clearly structured and support is given for the literature research and outline of the contribution (even if the contribution should have the HTML-format).

Discussion process
The system with active and passive participants is useful to reach the "critical mass" of students to have a rich discussion process.

Communication and cooperation
The cooperation process should be guided by the tutors and the tutors should have a look at the students communication styles and topics.

Access control
In the Virtual University the newsgroups have an access control (like the Virtual University itself) to protect the students communication process.

Abstract: A Technology Development Centre of Finland (Tekes) funded ProTest project has been researching and developing methods and systems intended for improving the testing performed within embedded systems product development. The Raahe Institute of Computer Engineering being one of the project participants constructed and demonstrated the embedded system laboratory environment, which can be used as part of everyday engineering education activities. In this paper, the remotely accessible laboratory environment, which improves the possibilities and flexibility of engineering education in the field of embedded system design and development, is presented. In addition to this, the demonstration of the environment with engineering students, and the corresponding results, will be described and analysed.

Introduction

The ever-increasing need of the electronics industry for engineering professionals, and the extensive growth of markets in the field, require new and more efficient methods for training engineers. In order to keep up with the rapid development pace, educational and training institutes must drastically change and modify their existing laboratory systems, which are often much too expensive for being truly cost-effective. The high-cost equipment needed for modern applications require efficient usage and a high utilisation percentage in order to guarantee manageable operation costs. Even in the most optimistic situations, the expenses will probably still be too high for smaller training institutes [Paaso and Manninen 97].

Keeping the aforementioned aspects in mind, the Technology Development Centre of Finland (Tekes) funded ProTest project has been researching and developing methods and systems intended primarily for improvements in product development testing. The Raahe Institute of Computer Engineering (RATOL), being one of the project participants (together with Nokia, Elektrobit, and TH Engineering), concentrated on the embedded system test environment, which could be used as part of the everyday engineering education activities. With close co-operation between RATOL and the Raahe Laboratory of Oulu University, the experiences from the IDEALS project (EU Telematics Applications programme) could be utilised in a more hardware-oriented environment [Manninen and Paaso 98, Ideals 95].

Remote access or tele-operating systems provide new possibilities for cost-effective usage. Tele-operating systems enable location-independent control, as well as monitoring and result analysing of the laboratory work and system. The students or trainees may, thus, access and operate a fully equipped high-tech laboratory, regardless of their current place of learning, which could be a computer class room, work place, or even the trainee's home. This would mean less travelling and a more flexible usage schedule for the students. In addition, the remote access systems provide smaller institutes the possibility of using external laboratory facilities rented from other organisations. With this kind of arrangement, the high-end equipment would have a higher utilisation percentage, which in turn would reduce the operational costs even for the institutes that have acquired the systems [Wunnava and Hoo 96, Referowski et al 97].

The current lack of human resources in the field forces the institutes to search for solutions that would require the least possible amount of personnel. Modern laboratory facilities, e.g. micro-controller development tools and emulators, are very complex and usually require constant monitoring by Laboratory Engineers. The laboratory facility centralisation model (Figure 1) will enable integrated support and services, while the remote access systems will provide support-on-demand even for the remotest locations.

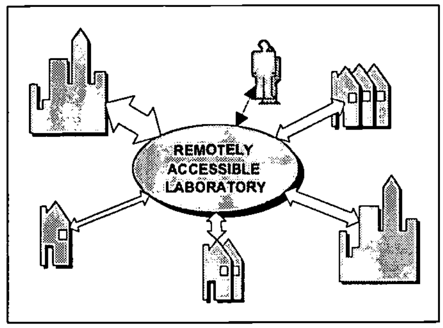

Figure 1. Laboratory Facility Centralisation Model

In this paper, the laboratory environment, which improves the possibilities and flexibility of engineering education in the field of embedded system design and development, is presented. In addition to this, the demonstration of the environment, and the corresponding results, will be described and analysed.

Laboratory Environment

The design and development of the remotely accessible laboratory is based on two factors: automation and tele-operation. Automation enhances the laboratory work process by providing learners with a set of tools and procedures they can use in order to avoid long and tedious routine work. The tele-operation system acts as the remote hands and eyes of the learners, who might be physically located hundreds of kilometres away from the actual laboratory environment.

Both automation and tele-operation have been studied within various research projects around the world. Automated testing is only a partial solution when designing the remotely accessible laboratory. The practical work conducted with a high level of automation, and usually as batch-jobs, prevents the learner from getting a real hands-on experience on the subject [Knight and DeWeerth 96]. However, the technical demands of versatile high-tech tele-operation systems may exceed the budget and expertise of most educational institutes. Even if the system itself could be achievable, the networks and applicable bandwidth will probably create problems when attempting to transfer high-quality and immersive tele-presence environments to end-users. The optimal solution would be, first, to combine some of the features from both of the factors (automation and tele-operation), and then to construct supportive solutions to enhance the quality and usability. For example, virtual tele-operation with the help of a 3D model of the remote system is one approach to the problem [Rastogi et al. 96].

The laboratory environment constructed in the Raahe Institute of Computer Engineering includes a complete and remotely accessible development and testing system, which is automated with the aid of scripting language. The modular system is built mostly from standard components so that it is easily modifiable based on the needs of various laboratory projects. Figure 2 illustrates the layout and infrastructure of the remotely accessible laboratory environment. The testing facility included in the environment is developed with educational requirements in mind, in order to guarantee the easiness of concrete usage within the areas of training and learning. Furthermore, the system is integrated in a way that it can be easily moved to another location.

The testing laboratory environment consists of the system constructed specifically for verification and demonstration. The central components of the system are the unit under test, robot, video camera, and the measurement and data transfer equipment connected to the control computer. In this case, the unit under test consists of a Lauterbach emulator, an Intel196 micro-controller, and a Bytronics card attached to the controller.

The remotely accessible laboratory environment is connected to the outer world through two Ethernet cables and one power cord. The transmission and access to the system is managed through the controlling computer, with the aid of remote access software.

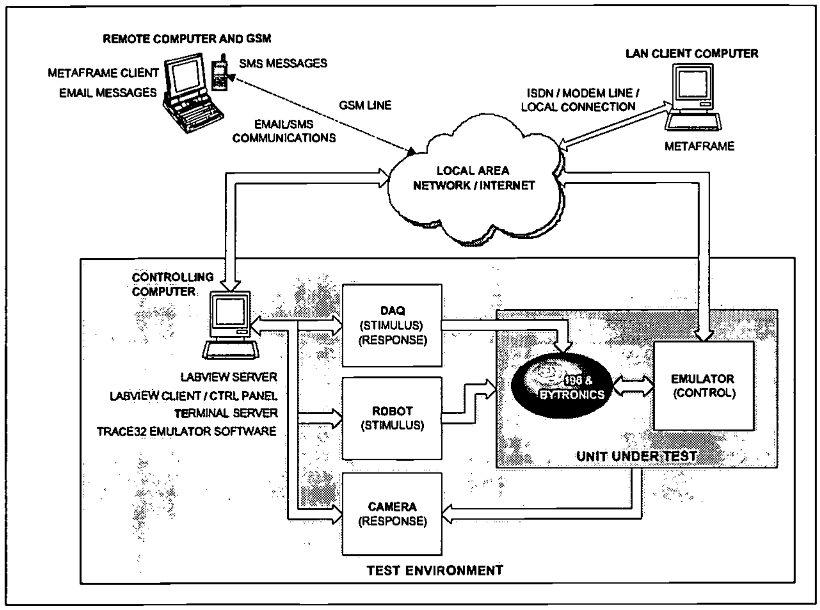

Figure 2. Remotely Accessible Testing Laboratory

The control computer contains all the software needed to operate the system locally and remotely. The Windows NT Server 4.0 (Terminal Server Edition) acts as a platform for the LabView software, which in turn manages the robot, camera, Input/Output devices, and the emulator control. The remote access is accomplished by operating the control computer from an external PC containing either Terminal Server Client or Windows MetaFrame software. Figure 3 represents the desktop view of an external PC, which is remotely accessing the control computer, and thus, all the resources manageable through that computer. The main user interface consists of main LabView test engine control, manual robot control, and the video camera view from the laboratory environment.

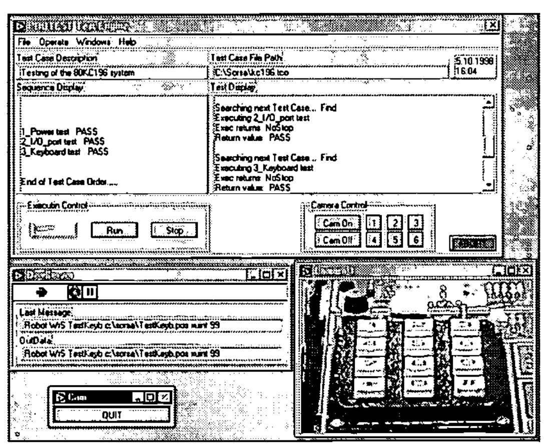

Figure 3. The Desktop view from the remote control and monitoring terminal.

Verification Demonstration of the Environment

In addition to the evaluation with end-users, a wide variety of heuristic evaluations from experts in the field were used to identify the possible flaws of the system. These evaluations were combined with the system demonstration used to verify the features and functionality of the system. Within the verification demonstration of the remotely accessible laboratory environment, the possibilities to use and control the environment through tele-operation have been widely presented and tested. These possibilities include, for example, alarms in exceptional situations, tele-operation as a recovery procedure (through low bandwidth communication network using a GSM cellular phone, modem and laptop PC), using the robot for mechanical stimulus and as a remote hand (power on, keyboard input, etc.).

The tests and procedures included in the verification demonstration are divided into four scenarios, which are intended to model real usage cases. Each demonstration scenario presents a different aspect of using and accessing the laboratory environment. The various aspects include bandwidth-restricted usage, high level of automation, and high level of manual operations. The underlying engine with the accompanying software and hardware is the same throughout the demonstration scenarios.

Scenario 1 - High level of automation: Illustration of a situation in which the user of the environment is actually operating the system from outside the laboratory premises. With this kind of arrangement, the end-user can, for example, work at the same time while running automated testing sequences. The basic principle in this scenario is the high level of automation within the laboratory environment, and the possibility to control and monitor the system outside the laboratory. Within the demonstration, the connectivity and the usability of the system through the local area network were tested and evaluated.

Scenario 2 - Tele-operation: The emphasis of scenario 2 is on remote operations and on the control of the laboratory environment with the aid of various supporting devices. The scenario is an illustration of a situation in which it is impossible to use the highly automated procedures, and thus, it is compulsory for the end-user to have enhanced manual control of the system. The remote-controlled robot and camera act as the hands and eyes of the user. Figure 4a illustrates the basic structure of the system within scenario 2. The demonstration includes normal batch operations, which are halted by random exception occurring from the unit under test or from the environment itself (e.g. a power off situation).

Scenario 3 - Mobile: Demonstrates the most advanced remote usage situation using wireless data transfer and place-independent control and monitoring possibilities of the laboratory environment. The case illustrated in scenario 3 includes responding to the stimulus created by an exception, obtaining information from the status of the system, and executing operations to recover the procedure from outside the laboratory. The interface between the end-user and laboratory environment consists of a GSM mobile phone, a laptop computer, and GSM connection. Figure 4b illustrates Scenario 3. The demonstration includes responding to an SMS message transmitted by the laboratory environment and the laptop-based monitoring and controlling of the system.

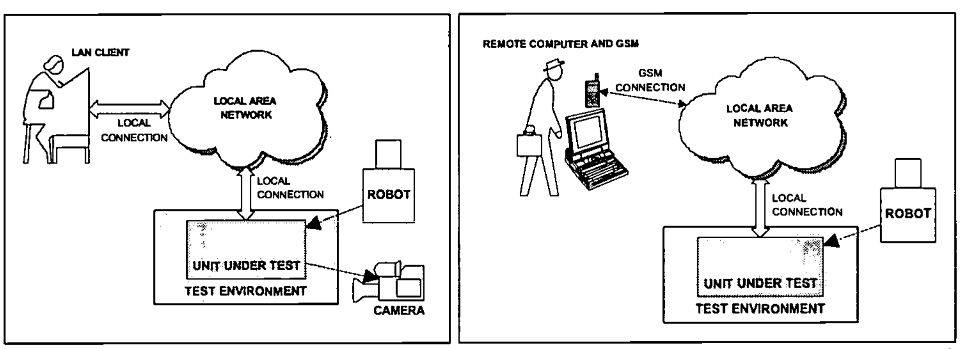

Figure 4. (a) Remote control and monitoring with the aid of a camera and robot. (b) Remote access through wireless communication network (GSM).

Scenario 4 - Tele-teaching through remote expert services: Illustration of a situation in which it is important for the users working in the laboratory environment to get assistance or advice. In order to save on travel expenses, the system presented in scenario 2 may be enhanced with audio and/or video communication equipment, and thus, provide the remote expert with an adequate feeling of being on site. A large proportion of the system features will thus be accessible for the expert who, with the aid of the communication system, will be able to interact with the system as well as with the users working within the laboratory. Figure 5 illustrates the demonstration of scenario 4.

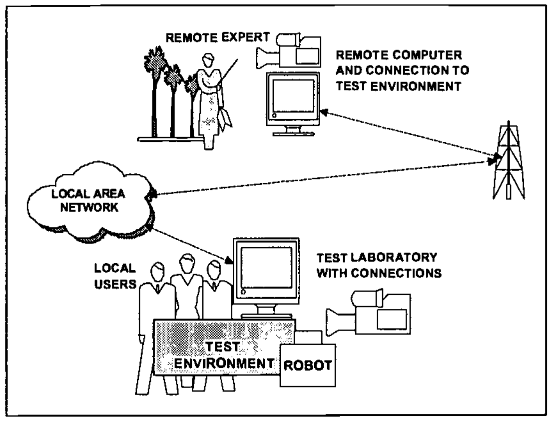

Figure 5. Tele-teaching through remote access and video conferencing.

Experiences with Engineering Students

The aforementioned integrated and remotely accessible laboratory environment has been demonstrated and tested using real end-users in the Raahe Institute of Computer Engineering between January 1999 and March 1999. The demonstration included a total of eleven B.Sc. students (with various levels of previous experience) who completed the assigned laboratory work as part of their compulsory studies. The assignment (30 to 60 minutes in duration) included programming, testing, problem solving, and analysing of the micro controller (Intel 196 with Lauterbach emulator). The objectives of the task were set in a way that students were forced to exploit all features of the system in order to achieve satisfactory results.

The evaluation consisted of scenarios 1 and 2, with scenario 4 downscaled to meet the available resources (the videoconferencing was changed to a mobile phone connection). The students completed their assignments by working in a remote access laboratory with no possibility for "on site" operations. The actions of the students were monitored in their work place as well as within the laboratory. Furthermore, a set of questionnaires was used to collect feedback from the users. Figure 6 outlines the demonstration arrangements.

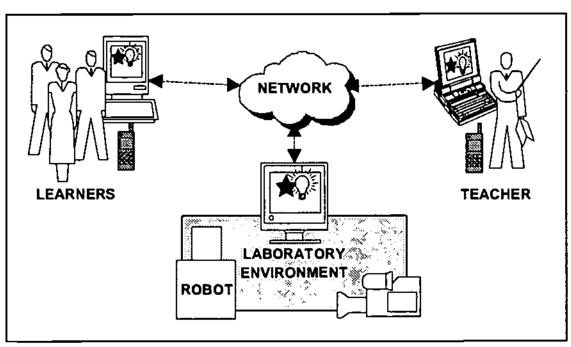

Figure 6. Demonstration and evaluation environment of the remotely accessible laboratory.

The questionnaires were used to gather information about the expectations, experiences, and opinions of the end-users. The questions were divided into the following categories: user background (previous experience), functionality (system performance), and comparison (with the traditional laboratory work).

The analysis of the questionnaires indicates positive feedback from the users. From scale 1 to 5 in a total of 26 system evaluation questions, the lowest average score was 3.1, while 80 per cent of the questions had an average above 3.6. The top 20 per cent of the questions had averages from 4.5 to 4.9. From the averages and from the distribution of the scores within individual questions, the following observations can be made:

- The system, with its current implementation, does not prepare the students for practical work as well as was required (average 3.1), although it may be argued whether the result is actually worse or better than with the traditional laboratory arrangements. Of course, the lack of all the physical elements of the normal laboratory might move the student away from the real world usage.
- The completion of the given assignment was, in the students' opinion, as feasible to accomplish as with the traditional environment (average 4.0). It was even stated that the connection to the teachers was easier to maintain with the arrangement described above (average 4.5).
- Although limited in terms of implementation and usability, the system is far better when compared with the traditional situation with the resulting need to travel to the laboratory facility (average 4.3).
- The students themselves believe in the system and were motivated to exploit its potential also in the future (average 4.7).

Conclusions

The great demand for engineering professionals requires new methods for increasing the output of graduates from universities and polytechnics. One proposed solution to the problem is the integrated and remotely accessible laboratory environment, which enables more efficient learning and practical working, even in sparsely populated areas.

The laboratory environment constructed in the Raahe Institute of Computer Engineering has shown that it is possible to create remotely accessible laboratories with current standard techniques and components. Furthermore, the verification and demonstration of the environment result in a large number of possibilities corresponding to the requirements of the practical learning and training.

The remotely accessible laboratory can be constructed, to a certain extent, with readymade and standard components. However, a large-scale development and testing environment requires more software and hardware components, which in turn results in problems within the system integration. Even in a small-scale realisation, the major problems encountered were caused by the integration of various software components and hardware incompatibilities. All of the problems can be solved with additional work and further development, so the solution presented is realistic even for smaller educational institutes.

The verification indicates that the end-user of a remotely accessible laboratory environment does not necessarily need high-tech futuristic technology, but merely safer, but applicable, lower-end tools and methods. For example, video conferencing with high quality real-time images would seem to be less favoured than the robust and somewhat inferior connection and interfaces enabling the operating in a remote environment.

The remotely accessible laboratory environment provides more flexibility for everyday engineering training, with time and place independent access possibilities. Furthermore, the fact that the environment is usable anywhere from the network enables cost-effective centralisation procedures and, thus, provides an opportunity for smaller organisations to exploit the features of a modern and high-tech development and testing laboratory.

Producing CBT Courseware for Software Engineering Education Cost-Effectively – The IDEALS Methodology and System

Jouko Paaso, Raahe Laboratory of University of Oulu, Finland, jpaaso@tietoteku.ratol.fi
Tony Manninen, Raahe Laboratory of University of Oulu, Finland, tmannine@ratol.fi

Abstract: In the education of embedded software engineers there is a need for increasing the graduate output. A substantial amount of re-training and on-the-job training is needed; thus, there should be plenty of flexibility in the teaching arrangements. CBT utilising telematic facilities is the most relevant form of technology in Northern-Finland and the Oulu area, where distances are long, but the telecommunication infrastructure is well-developed. The IDEALS modular training system (MTS) and methodology, for co-operative learning and authoring utilising CBT courseware, are presented in this paper. Concrete results show the cost-efficiency of the methodology and system in the CBT courseware production.

1. Background

The IDEALS project of the EU Telematics Applications programme was co-ordinated by Fraunhofer-IGD in Darmstadt, Germany. There were thirteen partners from Germany, Greece, Portugal, Holland and Finland in the project, which ended on 30 June 1998. The Raahe Laboratory of the University of Oulu, RATOL, was one of the six local training centres (LTC) in the project learning network, and had, as its main task, to co-operatively create and demonstrate the use of the Computer Based Teaching (CBT) courseware (CW) on the topic "Fundamentals of Computer Graphics" for students in Institutes of Higher Education [Paaso 98, IDEALS 95].

In the Raahe Laboratory of the University of Oulu, the ultimate goal for the CBT research, which was based on the IDEALS methodology and system, was the following: *A CBT-based methodology developed for embedded software engineering education will enable:*

1. *to develop, by utilising the telematic multimedia, the desired and pedagogically functional learning model, which is based on the 'learning-by-doing' -philosophy and on individual student profiles, and which originates from the capabilities of graduates required by industry*
2. *to achieve, as a replacement or alternative to the traditional teacher-centric education model, significant flexibility and efficiency improvements in the delivery of teaching*
3. *to bring a significant cost-effectiveness improvement to the production of CBT courseware by means of CW reuse.*

Essential criteria for the developed learning model in the embedded software engineering education were the support for learning, regardless of time and place, individual learner profiles, learning by doing, industrial type teamwork and collaboration (i.e. concurrent engineering and activation to interaction between students), interactivity between the computer and the student, continuous testing of the knowledge level as an essential part of the learning process [Manninen and Paaso 98a]. In the co-operative telematic authoring part, the essential success criteria for the methodology were the reduction of the CBT production effort and the easy maintenance of the CBT courseware. These criteria were validated by applying the developed methodology to a representative course, the *Graphical User-interface Programming* course, in the embedded software area [IDEALS 96].

2. IDEALS Learning and Authoring Scenarios

The basic architecture of the IDEALS Modular Training System (MTS) is presented in Figure 1.

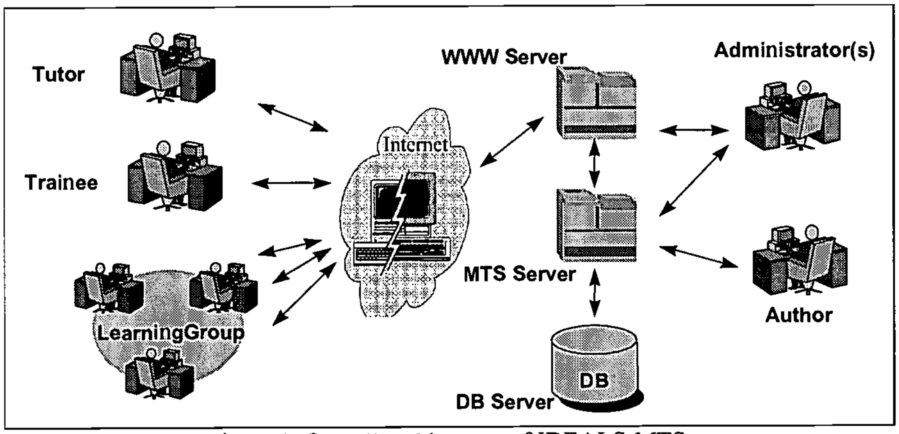

Figure 1. Overall architecture of IDEALS-MTS.

In the IDEALS learning scenario, the following major learning sites supported can be identified:

- remote trainees (individual access to the local training centre, LTC)
- trainees at training service provider (TSP)
- trainees at LTC.

LTCs and TSPs are almost identical in hardware and software. The only difference between them is that LTCs provide management functionality for distributed courseware and administration functionality for users. Each LTC is the owner of a distinct subset of the distributed CW domain. It may also provide copies of CW owned by other LTCs. TSPs provide only copies of CW from LTCs; their purpose is the provision of computing power and CW in close proximity to the trainee's working place. Each LTC and TSP provides a CW domain server and an MTS server. All LTCs are interconnected. Over these trans-European interconnections the LTCs share their CW databases, and, therefore, can be seen as one virtual LTC, giving access to the whole CW domain. Learning can start immediately from the WWW-browser. After login, the trainee can start a new course, resume a saved course, issue a training-on-demand request, or select a learning group. After working on *presentation, exploration* and *test* units, the course status is saved and the learner profile updated. Interactive learning can be added to any type of course usage at any time, either as expert consultation, or by joining a learning group [Paaso *et al.* 97].

An additional important scenario in the IDEALS context is the co-operative authoring of the courseware and final courses. In this scenario, authors located in different LTCs are preparing, discussing, and finalising the common CW domain, using different telecommunication capabilities, such as audio and video conferencing. In order to create a common look and feel for the common CW, IDEALS *style guides* are in use; however, creation of these guides first presumes "base" CW production. Courseware catalogues consisting of the CW module profiling information are available, thus enabling the multiple use of CW.

3. Courseware Characterisation

The target group for the implemented CW on the topic *Graphical User-interface Programming*, was, primarily, students in universities and technical colleges (institutes of higher education, IHE), and also personnel in small and medium sized enterprises (SME). A more detailed target group includes persons who already are able to do programming, e.g. in C++; so, in the course there is no training for programming basics. The course material contents handle Windows-C programming, as a subset of the user-interface programming area. An emphasis area in the course are functional parts, which activate students to learn by themselves (learning-by-doing), and not only follow the course passively. Animations, interactive examples, exercises and versatile hypertext linking support the theory part and make it more illustrative.

Each section of the CW consists of presentation, exploration and test parts, whose total duration and division follow the guidelines agreed upon in the IDEALS consortium, i.e. for presentation 30 per cent exploration 50 per cent and testing 20 per cent:

- In the presentation part, there are typically text-picture-combination presentation pages with hot words (by clicking them sub-windows, which provide users with some specific detail, are opened).
- In the exploration part, the 'Step-by-step' learning principle is applied. The overall learning process of programming is divided into the following four steps:
  1. Assignment Viewing: At the beginning of a new programming subject to be learned, learners are introduced to the final goal, i.e. what they should be able to do after this, in order to obtain an in-depth and clear overview of the assignment.
  2. Virtual Compilations: The *virtual compiler* simulates the features of the real compiler, although in a much restricted scale. This provides the learner with the opportunity to explore, modify and test some ready-made software components without causing the system to crash, i.e. in Windows programming to change the windows attributes, etc.
  3. Real Compilations: When learners have achieved sufficient experience in the virtual environment, they are ready for trying out the same procedures in the *real compiler* environment.
  4. Test/Final Project: A major feature enabled by telematic CBT is the integration of teaching, development tools and teamwork into one learning environment. In RATOL's CW this means distant independent collaboration between group members in designing and developing software using concurrent engineering.
- In the testing phase, the following types of test forms are used at present: *True-False, Matching Items, Fill-In, Single Choice from Multiple Items* and *Multiple Choice from Multiple Items* tests. In the representative sample of Figure 2 from RATOL's CW, three of these test types can be found [Manninen and Paaso 98b].

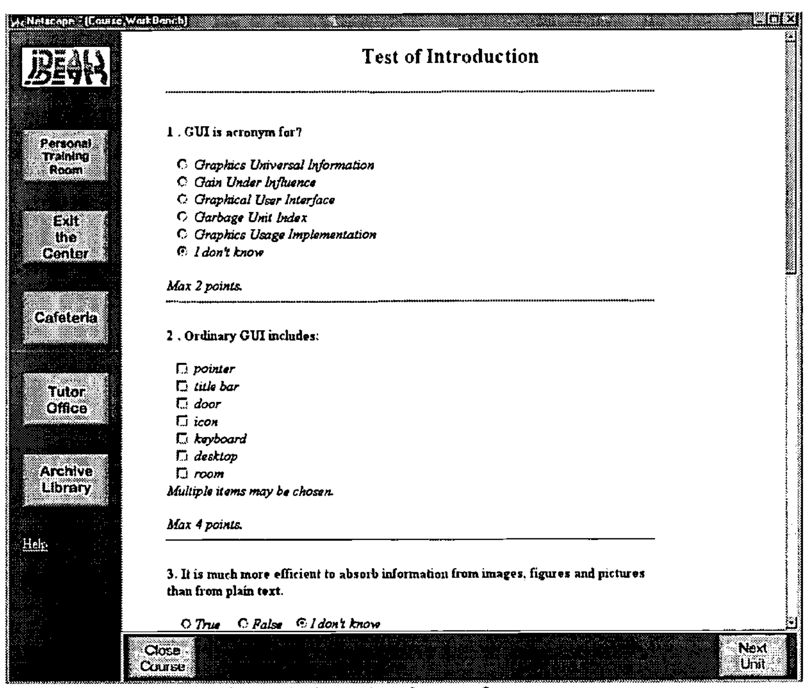

Figure 2. Sample of a test form.

4. Reuse and Multiple Use of Courseware

The multiple use of CW means the use of the same CW entities by many users. The reuse of CW means the use of CW production patterns (so-called templates) by many CW producers for the production of different CW entities. Basic building blocks, BBBs, hold a central role for the multiple use of CW (especially between different LTCs), and for the understanding of extensional and itemisation modularity of CW, and of the procedure of designing courses, as can be seen in Figure 3 (the linkage mechanisms between the modules of the CW shown) (IDEALS 1996). The basic building blocks are the components utilised from the common CW database by a teacher, in order to configure the curriculum of a course and to specify the course flow through it. A basic building block is a composition of one course node, several learning function units and their learning material objects. Their purpose is to represent a certain piece of knowledge in a CBT-based format.

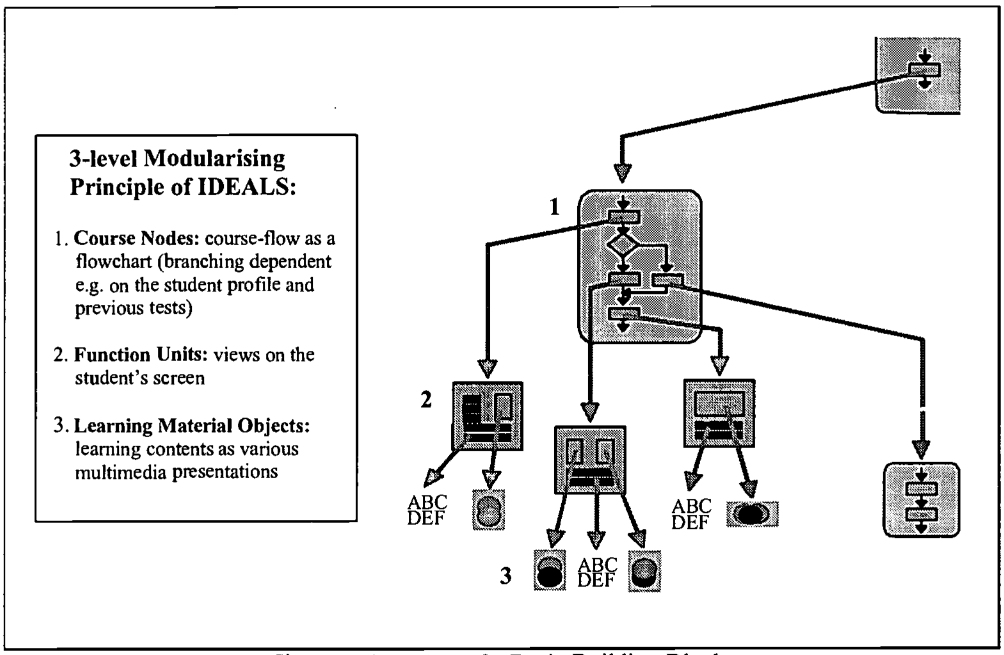

Figure 3. Structure of a Basic Building Block.

The 3-level modularising principle of the CW, with self-descriptions, virtual references and user profiling, are the strong points of the IDEALS methodology. They enable the customisable and individual course flows. Basic building blocks and templates in the common CW database, listed as catalogues, are the basis for multiple use and reuse of courseware.

5. Considerations of Authoring Efforts

The official evaluation of the IDEALS project was performed during spring 1998, and involved the evaluation of both authoring and learning phases in the IDEALS demonstration infrastructure. Based on the results relating to the authoring phase, interesting figures may be presented. In Figure 4, comparisons of the production efforts of the various versions of RATOL's CW are presented (all three phases related to the same CW, i.e. to the various incremental development phases of *Graphical User-Interface Programming, GUIPRO*), including also the case where multiple use of 40 per cent of the CW is utilised. In RATOL's 16-hour GUIPRO course, the multiple use, thus, means producing 9.5 hours of own CW and importing 6.5 hours of CW from other two IDEALS IHE pilot partners.

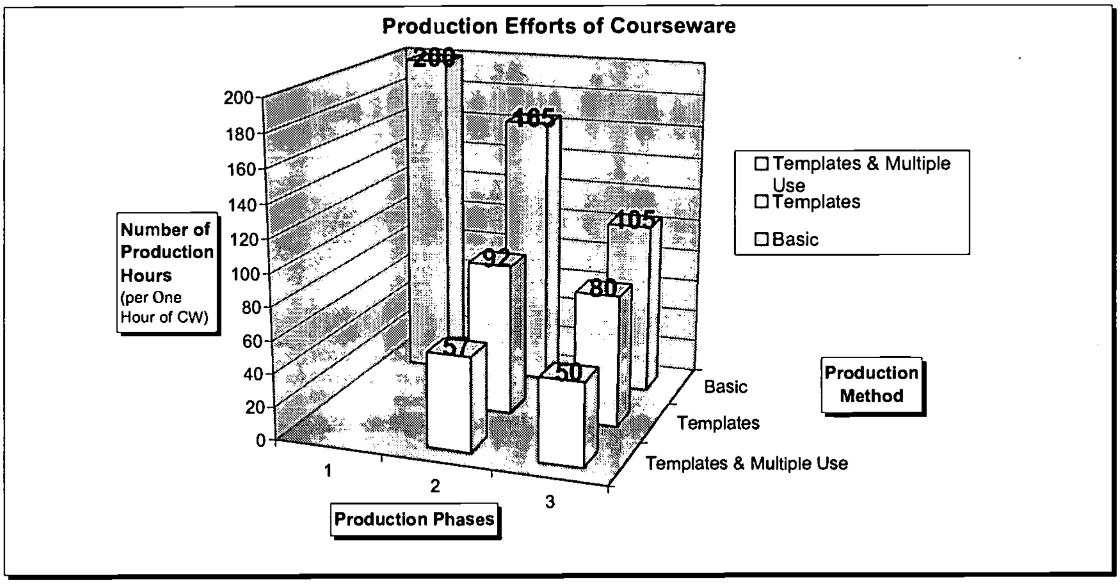

Figure 4. Production effort ratios of RATOL's CW versions.

Some conclusions relating to Figure 4 contents can be drawn:

- Utilising of templates and multiple use clearly reduces production effort. Larger multiple use percentages would, obviously, bring more, nearly linear, reduction in production efforts.
- There is a distinct learning curve in the CW production that can be seen as the development continues. The templates also improve along with the production. Both have a clear positive effect on the CW production efforts.
- The production effort ratio, even with multiple use (i.e. 40 per cent in RATOL's case) is still relatively high, i.e. 50 hours of production for one learning hour. However, it seems, based on RATOL's experiences, that, with high-quality interactive CBT CW, the required CW hours for individual learning could drop to nearly half of the required contact teaching hours for the same learning contents in traditional teaching. This would indicate that the real production effort ratio, for the same learning result, could, thus, be evaluated with this type of interactive CW to be without multiple use at about 45:1, and even better than 30:1 with multiple use of 40 per cent. However, to verify this conclusion, more extensive evaluations with larger amounts of CW and students are required. Naturally, for the first course runs, the proportional production costs are high, but after that the CBT course can be very cost-effectively repeated for large student groups [Paaso 98].

6. Situation and Learning Results

RATOL has been running the IDEALS-MTS based CBT course, *Graphical User Interface Programming,* since the beginning of November 1997. The course is targeted at B.Sc. (Eng.) and M.Sc. (Eng.) students (Engineer and Diploma Engineer students correspondingly) in the field of computer engineering. The course can also be accessed by visiting users also through the internet (Netscape, version 3.0 or later):

- Address: *http://ltc.ratol.fi*
- User-id: *guest*
- Password: *guest.*

From the first two course runs (Nov. – Dec. 1997 and March – April 1998, when also some Nokia test users were involved), there are 18 students who have completed the whole course so far (exam and the teamwork project work); this is about half of those who signed up to the course. It is to be noted that the course is optional in the course curriculum of the students. The average duration of studies among these students was approximately three weeks, resulting in an average of three hours of study per week per student. The learners were relatively motivated to study on their own during the first course run. There were no major activation procedures on the part of the lecturer or the tutors. In the second course run, the overall activity of the learners, and knowledge about their progress, could be increased by means of milestones and rewarding procedures, i.e. some didactic tests were included; they have a slight effect on the student's mark received from the course.

When considering the students who successfully passed the course, the learning results are positive, especially after considering the fact that they have been able to implement the programming project and pass the test. Even more interesting is to know what is the teaching and tutoring effort during the course runs. It is estimated that 10 hours of the highly interactive and repeatable GUIPRO courseware corresponds to about 30 contact teaching lessons (each 45 minutes, in total 22.5 hours). The start-up lesson and tutoring are estimated to require approximately seven hours in total per course run; this means a saving of approximately 15 hours in the teaching effort for this learning result.

The IDEALS methodology applied to embedded software engineering education functions extremely well, and, in fact, the methodology would seem to be excellent. However, the technical status of the IDEALS-MTS leaves plenty of development areas. At present, the instability and the deficiencies in the co-operative authoring support, in particular, are the most challenging technical problems. The technology available almost certainly will change and develop. The next version of IDEALS-MTS will also be an improved version.

7. Conclusions

The greatest value of IDEALS, for the future, is the learning network producing CW in the same modular ('standardised') way, and this is the optimum time to expand the network for new CW authors and courses. By means of co-operative authoring, remarkable cost-effectiveness improvements in the costly CBT production can be achieved. CBT course utilisation may be at least a partial solution to the huge need of increasing the graduate output in the software engineering area. Also, for the students, it can bring an increased amount of flexibility and financial savings, e.g. by decreasing unnecessary travelling, in the learning arrangements. For those who are fully employed during their studies, it might even be the only possibility.

Abstract: The activities of our institute cover various fields in the development process of integrated circuits including digital, analogue design and test.
For these separate fields we developed an interactive learning system. It is based on the capabilities of the hypertext markup language (HTML) and uses the HTTP internet protocol for distributing its contents. The aim was, to improve the quality of the student's education by offering interactive pages, that allows on the one hand access to a knowledge base and on the other hand the training on special dynamic examples. The usage of this system necessitated amplification so additional tools were developed.
The original VHDL (Very high speed integrated circuit Hardware Description Language) tutorial (www.vhdl-online.de) presented an 11 lesson course with an implemented online help system and a VHDL glossary. The additional features are a multiuser editor for moderated teleworking in distributed networks with graphical enhancements and a hardware interface for programming a field programmable gate array (FPGA) with a synthesized VHDL module to start an online test. For our students in the first and second year of electrical engineering, we developed tools for learning nodal analysis and displaying the numerical results as a Bode-plot and the symbolical results as a transfer function.

Motivation

At the moment students use our VHDL Online system to get information about the hardware description language VHDL and the design flow for developing digital circuits. It is an important task of our institute to show students the different possibilities of designing integrated circuits. The digital design methodology is only one

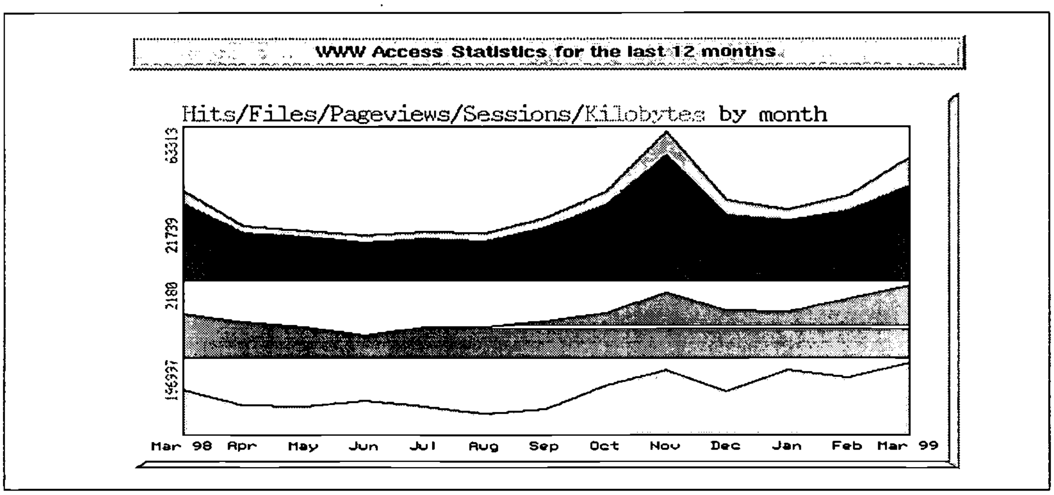

figure 1: VHDL Online Server Statistics

part of this field and in the future the need of mixed signal designs (analogue and digital) will grow. An integrated learning platform for the different fields of circuit design is a good starting basis for the students. The continuous usage of the existing learning environment confirms our strategy in teaching and is highly accepted by the students. Fig. 1 shows the statistics of our VHDL Online web server. For this reason we decided to expand the VHDL Online system with additional submodules and analogue components. The learning system is divided into several submodules.

The VHDL-Online Platform

- VHDL Tutorial: It is structured like a lecture. In one frame the students see the slides used in the normal lec-

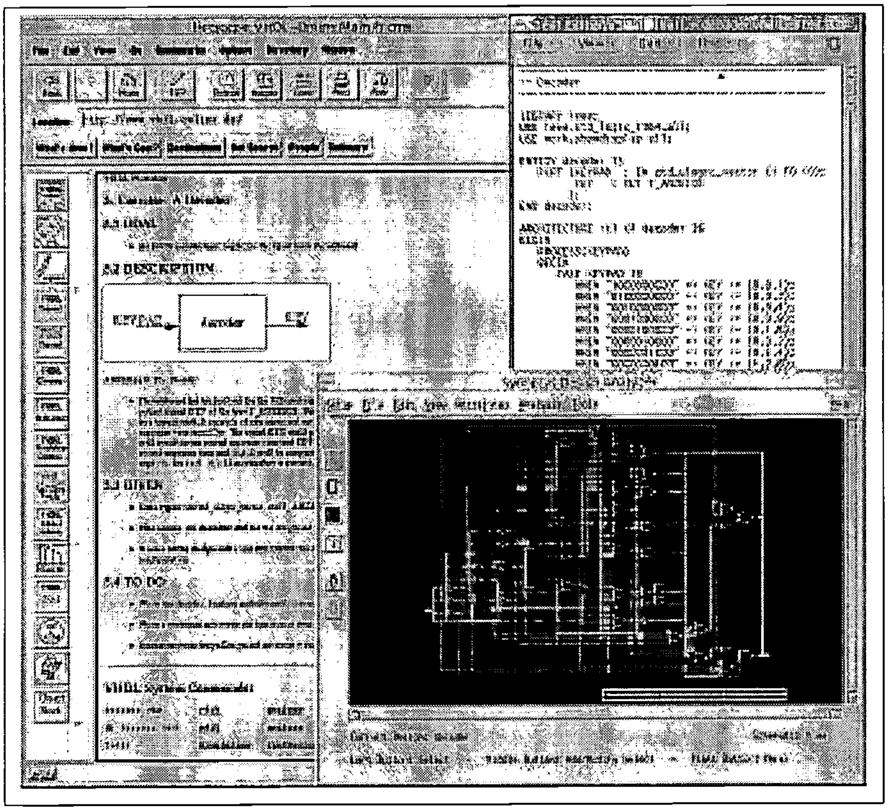

figure 2: VHDL Online Workshop

ture with the major difference that under the frame the slide will be illustrated as plain text. The contents of the text is the same as the tutor tells the students. At the end of a chapter the user can answer multiple choice questions related to the contents. If the answer is wrong, links will appear in the window, where the user gets support to the special topic.
- VHDL Reference: If a designer has got a VHDL problem (e. g. syntax of a procedure) he wants to get the information very fast instead of searching for the answer in a lot of slides. So we implemented a search function in this module.
- VHDL Workshop: In the next step the students apply their new knowledge to a practical training. They design a camera control system using VHDL. During the separate exercises it is possible to get information about a special keyword from our VHDL Reference. The students can use the search function of this module. The aim of this workshop is writing VHDL Code, simulating and synthesizing it with professional design software (Synopsys) from any internet account of the world if the user got the permission from our institute. At the end of this training it is possible to generate a netlist of the circuit. But until now the designer has not been able to transfer the circuit to real hardware. We needed an additional hard- and software module to program a FPGA. The students can verify their lesson results on real hardware. These new features are described later in this

paper.

- VHDL Chat: The first intention for this module was the support of students working outside our office. If a problem occurs they can chat with other users to exchange their experience. But we received negative feedback from the users because it is hard to describe a problem online to other persons who are not able to see the source code. The reason for this problem is the strategy of the IRC (internet relay chat). It is only possible to send one line to the other chat members. Another point is that not every user works at the same time and join the chat group to answer questions. So we decided to develop a multiuser editor where other people (e. g. the tutor) can look at a source code and make comments to special lines. This editor is described later in the paper.

Fig. 2 shows a collection of the tutorial. In the next chapter the functionality and the structure of the new integrated applications are described.

Additional Applications for VHDL Online

Modified Nodal Analysis Environment

Electrical engineering students have to analyze circuits consisting of resistors, capacitors, inductors etc. and qualify the voltage or the electric current of a network. To do this they calculate the transfer function using modified nodal analysis. For a small circuit it is easy to manage with paper and pencil. But it is also important to show the students in a short amount of time how the circuit behaves if the parameters of an electronic component are changed. It is not necessary for the students to recalculate the same circuit. For this reason our institute developed a learning system containing (Fig. 3) the following subcomponents:

The first point is a knowledge database which contains background information about the topic of analyzing

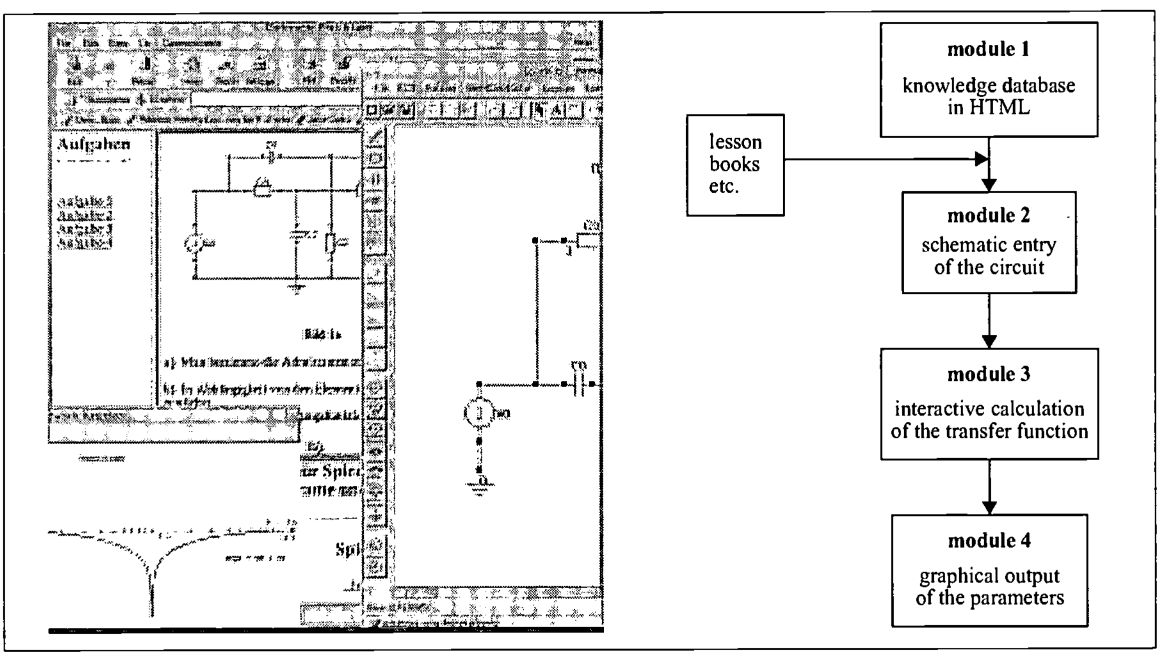

figure 3: Modified Nodal Analysis

electrical circuits. This hypertext based module uses links to get detailed information for students with little experience. In our case the modified nodal analysis will be described. Because of the modular programming structure of the whole system it is possible to exchange this current method with another one. After learning the basics of the modified nodal analysis the student solves exercises to apply this method to an example. This circuit can be drawn in the second module. It is a schematic entry tool where the user can place the electronic components (power supply, measurement instruments, resitstors etc.), assign parameters and connect the modules. This program has got all edit features of a professional graphic tool (copy, paste, rotate, move, zoom in, zoom out etc.). The tool also automatically checks whether the designed schematic is correct and shows the error location in case of a fault. All components and parameters of a spice netlist are supported by the tool. After the input of the whole circuit either the netlist can be exported to another professional simulation tool (HSPICE) or the next system module will be activated to calculate the transfer function. The program shows the elements of the matrix in an any desired way and the student must place them to the fitting position in the matrix. Thus the user does not solve the exercises just by clicking buttons but rather must he comprehend the things he learned in the lessons. To analyze the circuit it is important to get additional information like magnitude or phase of the transfer function. These graphs are generated by the fourth program module and represented in a diagram. Some additional buttons alleviate the operating of the program.

The Multiuser VHDL Editor for Moderated Teleworking

To improve the communication among the students a multiuser editor for moderated teleworking in distributed networks was implemented. The editor allows a user to invite other users to an open document. Several user authorizations can be set by the owner of the document to restrict access. These authorizations are reading, writing, drawing and copying. If there is a project with a common database, all users must have read access to the database, but only the owner of the database has write access. The common database can be a specification or a document

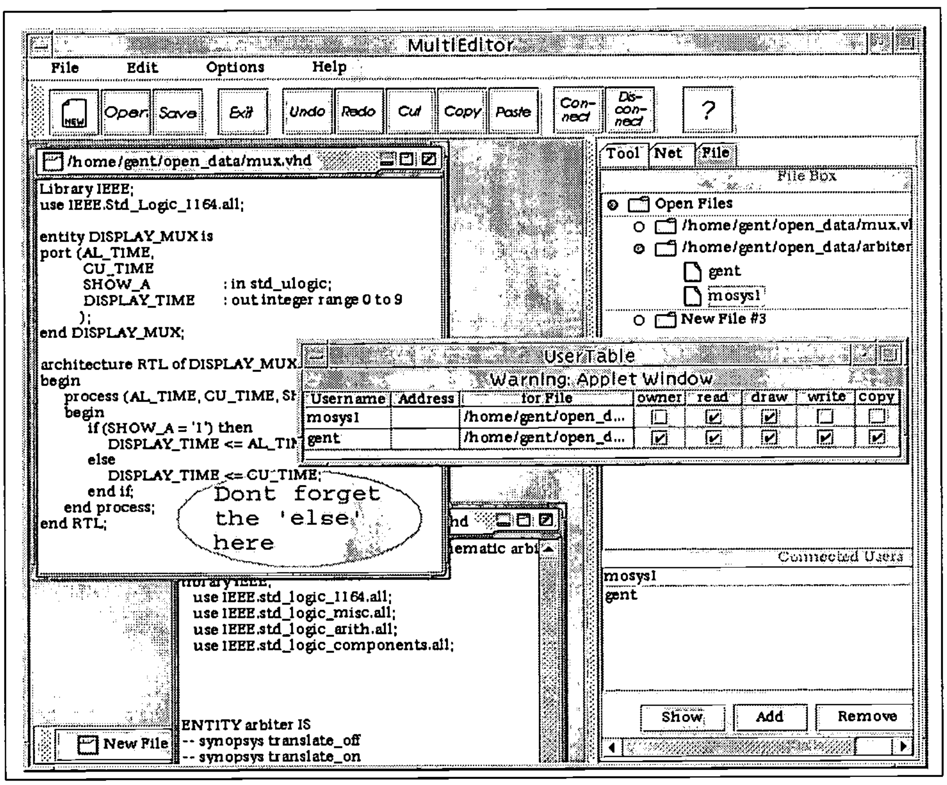

figure 4: Multi User Editor for Moderated Teleworking

that contains global variables or inter module connections. For group work or for interface descriptions only the group members and the concerned interface groups may have access to the core documents, but with different authorizations. The tutor or superuser can see all documents. So group work can be established over a network. Every user, who starts the editor will be connected to a server that is running at our institute providing information about work in progress and retrieving all the documents allowed to participate. Once connected to the server, all documents will be acknowledged, but only those documents with invited co-users are broadcasted to the mentioned users. An easy to use graphical interface was implemented to support this feature. Every user can have different rights on different documents. The document source remains on the computer of the documents owner, even if it is a distributed document. Simultaneous work of more than one user on one document is possible, a scheduling mechanism was implemented. User identification is done by getting a user name and a machine name or an internet address. A further benefit of the editor is an intuitive handling of the editor functions. The editor behaves like a normal text editor, so the user needs no time for practicing. Freely movable text or graphic can be put anywhere in the main text flow and can be anchored there. This is useful for commentating issues in the main text or for building exercises with gap text. Rudimentary graphic functions are also implemented, so readability of the text improves by laying out colored structures. Those additional features have no effect on the structural appearance of the main text flow, therefore the main text can either be saved separately or can be used directly for compiling, syntesizing, etc. Fig. 4 shows an editor screenshot of a VHDL document with some comment text (of course no one is forced to use these colors or comments).

Due to platform independence and best compatibility the editor was developed as a java application running on all platforms supporting java version 1.1. The concept of the editor allows easy updates and adaption to new requirements. It is planned to write a java applet version for using the editor within a HTML document.

The FPGA Programming Environment

Until now, VHDL Online provides a tutorial for VHDL that starts with simple VHDL examples and ends up in the synthesis of a complete design. Our idea now is to extend the tutorial so that students can test their own designs on a real hardware (Fig. 5). To extend our internet services, there are some additional requirements to the hardware. Most important, the new hardware should be available within a very short time. We started a new project to examine the use of medium size, SRAM based FPGAs as hardware resource for the designs from our tutorial. First, we changed the designflow to add some more steps that are required for FPGAs. This especially is the mapping from the result of the synthesis process to the programfile for the FPGA.

The total design flow now has the following steps:

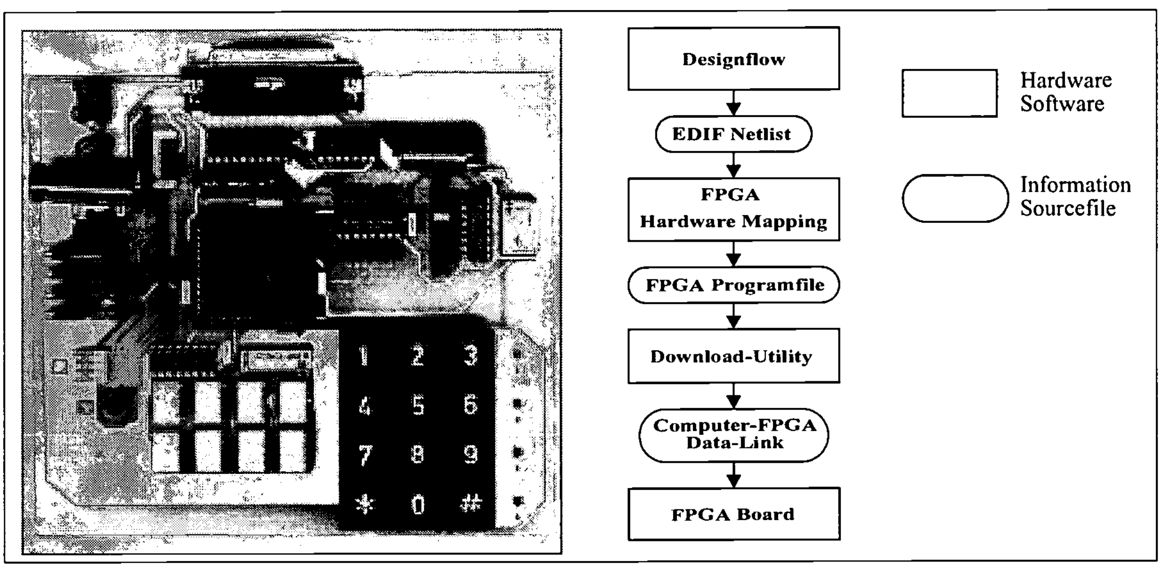

figure 5: FPGA Designflow

1. Synthesis of the VHDL sources to a complete design.
2. Design Optimization with respect to the target hardware. This means that a special synthesis library from the FPGA vendor has been used for the compilation of the design.
3. Export the design as a netlist (EDIF).
4. A special software from the FPGA vendor allows the mapping of the EDIF netlist from step 3 to the target hardware. This will generate a sourcefile that allows the programing of the FPGA (FPGA programfile).
5. Download the FPGA Programfile to the hardware.
6. Provide a suitable user interface though the internet, that enables the user to interact with the hardware.

Until now an experimental board with one small FPGA has been developed. Using this board the complete designflow has been verified. The synthesis step has been modified to generate the required EDIF netlist. We also wrote a small utility for the download of the generated FPGA Programfile. After some additional changes to our design and our hardware we successfully implemented our design on the FPGA hardware. As a result we proved that it is generally possible to provide tests with the real hardware to the internet community. Now our activities concentrate on the development of suitable hard- and software for the access from the internet to our FPGA. We decided to build a java application on the user side. This seems to be the most flexible and portable way to provide a handy interface to control the FPGA hardware.

The complete extension for our VHDL Online tutorial is divided into the following parts

1. A medium size FPGA is used as reprogrammable hardware for our designs.
2. A small digital test circuit has been build around the FPGA. This digital test circuit allows to stimulate and probe all the pins at the FPGA.
3. A small 8 Bit micro controller is responsible for the communication with the HTML server and all the other low level programming of the digital circuit and the FPGA.
4. A special server software handles the communication between the internet and the micro controller on our FPGA board.
5. The java applet on the user's internet browser can now communicate with the server software

Conclusion

To improve the learning performance of our students, we developed some enhancements to the VHDL Online tutorial. In this paper we presented tools for analogous electrical design and verification by modified nodal analysis that are fully usable via the internet. With these tools students learn about simple networks containing sources, controlled sources and passive electrical elements. The other aim was to improve the communication between the students or between student and tutor by using the multiuser editor. So learn groups or designers over the network are possible. The third application is real hardware. Students learn the difficulties of programming an existing real hardware (the FPGA) instead of simulating the behavior of their programs on the computer. This approach enables the students to find some clues for splitting their programs into FPGA fitting parts. With this VHDL tutorial the student can understand the whole VHDL design process from the specification to existing hardware. In the future we want to expand the developed learning environment to build up a system where students get information about developing integrated circuits (digital/analogue, layout, verification etc.).

Abstract: We present a model and system for the cost-value evaluation of teleteaching systems. Basically, the model considers the total costs of a teleteaching systems and, additionally, different levels of benefits. The benefits are classified as either objective, e.g., transmitted audio and video quality, or subjective, e.g., personal feelings. Two cost-value ratios are computed by, first, combining the total costs and the objective benefits and, second, by combining this result with the subjective benefits value. The smaller the cost-value ratio the better is the system. The model is implemented by a number of EXCEL®-worksheets.

1 Introduction

The advanced developments of communication systems, e.g., high-speed networks with guaranteed quality-of-service as in ATM (Asynchronous Transfer Mode) networks (Händel & Huber 91; de Prycker 95), and audio- and video technology, e.g., video compression schemes such as JPEG (Joint Photographic Expert Group) (ISO 92), have yielded very powerful digital and multimedia-oriented information and communication technologies (ICT) (Fluckiger 95; Steinmetz & Nahrstedt 95). These new technologies are influencing most areas of our daily life including education (Dutta-Roy 98). In distance education, these technologies open the door to very efficient education systems (see, e.g., the publications at ED-MEDIA). A matter of fact, however, is that these systems are not for free.

In this paper we discuss a model and system for the cost-value evaluation of teleteaching systems. We define teleteaching as synchronous and interactive distance education: *synchronous* means that teachers and students meet at the same time but not necessarily at the same place. *Interactive* means that all participants can freely interact to post questions or give comments. In our context, teleteaching takes place between geographically distributed classrooms. As a consequence audio, video and data streams have to be transmitted between classrooms. In support of this, classrooms are equipped with devices such as cameras, microphones, beamers, PCs, coder-decoder devices and communication devices, for recording, transmitting and displaying multimedia data. The devices mentioned have to be purchased, installed, maintained, operated etc. Altogether, the costs of a teleteaching system are serious.

Our work on a model and system for the cost-value evaluation of teleteaching systems was motivated by the fact that since 2 ½ years we run the teleteaching system *Telepoly* (Walter & Hänni 98), but its accurate costs were unknown. We developed a system for the calculation of the overall costs for teleteaching systems. The costs can be determined in total, per lecturing hour and per participating student. Furthermore, different teleteaching systems can be compared and ranked in terms of their respective cost-value ratios. Basically, for comparing and ranking systems the model considers costs per hour and, in addition, different levels of benefits. The benefits are classified as either objective, e.g., audio and video quality, or subjective, e.g., personal feelings.

The system consists of a number of EXCEL®-worksheets. The worksheets are given as forms to be filled in. The calculation of different teleteaching systems is possible even for different usage scenarios (in terms of number of classrooms, hours of use etc.).

The paper is structured as follows: In Section 2 we give a brief description of a typical teleteaching scenario. The different types of costs to be considered are discussed in Section 3. Section 4 introduces our system for the evaluation of teleteaching systems. First, we explain the use of the system to evaluate a single system. Second, we show with a real life example how different systems can be compared. In Section 5, we conclude with a summary and an outlook.

2 Teleteaching Scenario

As stated in the introduction, teleteaching is understood as an interactive and synchronous distance education scenario. More specifically, we consider a scenario where teleteaching is done between classrooms only. Teachers and students are located in two or more classrooms. The classroom where the teacher is located is referred to as the *local classroom* all other classrooms are *remote*. Classrooms may be at universities but may also be at private organizations and business companies (Fig. 1).

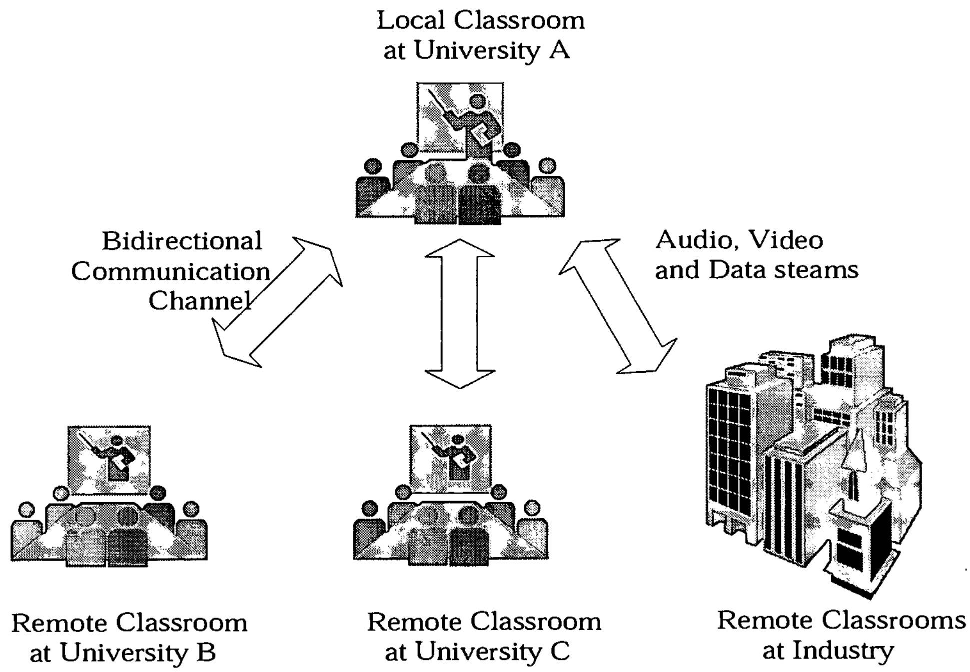

Figure 1: Multipoint Teleteaching Scenario

For the described teleteaching scenario, the following multimedia streams are exchanged between classrooms:

- An audio and a video stream of the teacher which is permanently transmitted to all connected sites.
- An audio and a video of the students in the local classroom. Note that the audio of teacher and students are mixed into one audio stream which is sent to all remote sites.
- A video stream of a visualizer (or document camera) which can be used by the teacher in order to present material which is not available electronically, such as concrete objects, statistics from a present-day journal etc.
- A data stream is transmitted from the local classroom to remote classrooms. This data stream is for teaching aids that are electronically available. A screen or application sharing software is used for making the teaching aids visible at all sites.
- From remote sites, an audio and a video stream are transmitted to all other sites.

We require that at least one audio and one video stream and, additionally, a data stream for teaching aids can be exchanged between classrooms. Alternatively, more than one video stream can be sent which, however, depends on the capabilities of the system used.

3 Types of Costs

In a first step, we made a distinction between types of costs that are independent of the chosen teleteaching system, e.g., training of teachers, preparation of electronic teaching aids, general infrastructure in classrooms, and types of costs directly related to teleteaching. The latter are covered by our model and are discussed below. We have adapted an approach developed in (Gartner 98) (for the total costs of ownership of a PC).

Equipment:

- Audio: microphones for teacher and students, speaker boxes, audio mixer.
- Video: cameras for teacher and students, automatic tracking system for teacher camera, visualizer, LCD-beamers for displaying video (e.g., remote classrooms) and computer data (e.g., teaching aids).
- Communication infrastructure: coder-decoder (CODEC) devices for converting analog signals to digital ones and coding for transmission over a communications network, communication equipment such as switches, network interfaces for switches.
- Hardware and software: PC or workstation for presentation of electronic teaching aids, multimedia equipment for PCs or workstations, network interface cards for PCs or workstations, application or screen sharing software for the presentation of teachings aids locally and remotely, presentation software for the preparation of electronic teaching aids.

Manpower:

- Operator: maintenance of the teleteaching system, preparation of teleteaching sessions, installation and deinstallation of the teleteaching system.
- Teleteaching assistance: support for teachers and learners while a teleteaching session is running.

Operation:

- Communication interface: basic charge or connection fee for access to a communications network.
- Communication links: time and/or volume based transmission costs.

The costs for equipment and manpower have to be calculated for every classroom. This also applies to the costs for communication interfaces. The costs for communication links depend on the number of sites interconnected, the number of connections that are used and the kind of multipoint communication support provided by the network. If, for instance, all multimedia streams are sent from one site to all other sites separately, then one has to set-up one connection per site. If multipoint connections are supported by the network, then duplication and redirection of media streams is done in the network itself which saves communication costs.

It turned out that the investments in audio and video equipment are the driving cost factors. They vary and depend on whether consumer or high-end professional audio and video equipment is used (some figures are given in Section 4.3). These costs are independent of the underlying communication network being used. If a turnkey teleteaching system is purchased the overall costs are fixed.

4 Cost-Value Evaluation System

The system is implemented by a number of Excel®-worksheets. Each worksheet contains mandatory input cells. All the necessary computations described below are programmed into the worksheets which is hidden from the user. The approach and the environment chosen provide the flexibility that the system is adaptable and extensible.

4.1 Total Costs, Objective and Subjective Benefits

In a first worksheet the costs of a teleteaching system according to the types of costs presented in the previous section are collected. From this worksheet the total costs of a system are computed. Furthermore, various other reference figures are calculated such as costs per hour of operation and costs per student. We use the costs per hour figure in our cost-value evaluation. This worksheet has to be filled in for every teleteaching system.

In a second worksheet a value for the *objective benefits* (of a teleteaching system) is computed. Essentially, we identified a number of criteria (referred to as Service Quality in Fig. 2) which allow us to determine the overall performance and quality of a teleteaching system. The criteria include audio and video quality, number of audio and video streams that can be transmitted simultaneously, administrative and operational overhead to set-up and run a teleteaching session etc. These criteria are put into a check list. For each item in the list, a number of options are pre-defined. An option gives a possible instance of the criterion. Every option has a value defined (1 - 5). The value reflects the option's importance, i.e., counts for the benefit that can be gained if this option is supported.

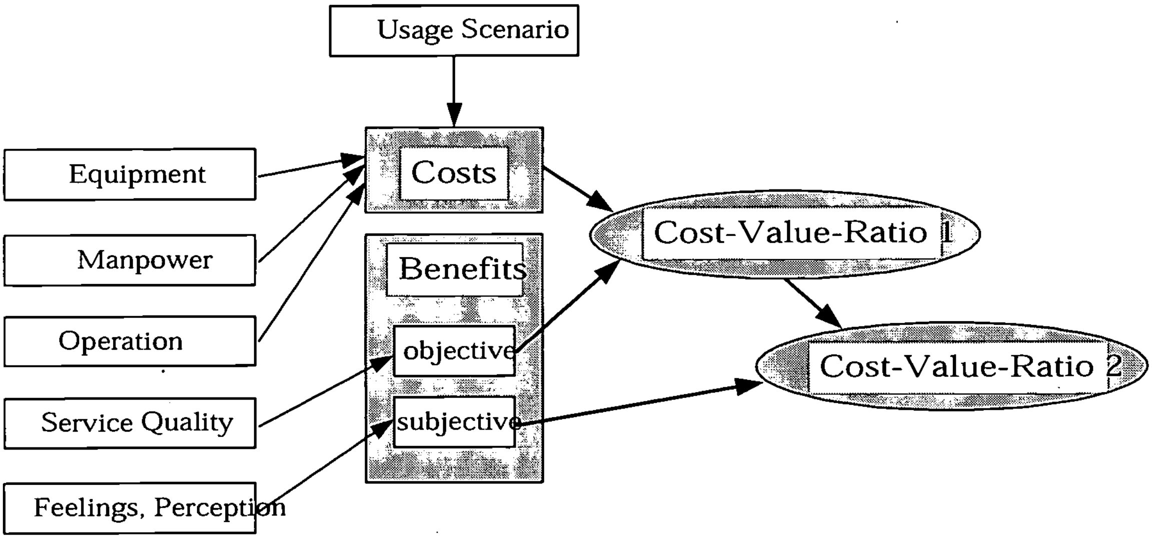

Figure 2: Cost-Value-Ratio Evaluation Process

With each item a second value, called weight, is given (in the range of 1 - 5). The weight represents the importance of the item with respect to all others. The item's value, i.e., the value of the option chosen, is multiplied with the item's weight giving a *relative weight* for this item which defines the relative importance of the item as seen by the user. If the checklist has been completed, a single value, called *objective benefits*, is computed by dividing the sum of all relative weights by the sum of all weights. This worksheet has to be filled in once and will remain fixed for all systems to be evaluated.

Similarly, a third worksheet counts for subjective preferences of users (termed Feelings and Perception in Fig. 2), i.e., how they have perceived a teleteaching session using a specific system. The form of the worksheet and how it is processed is the same as described before. At the end of the procedure, a single value, called *subjective benefits*, is computed. The evaluation of this worksheet changes for different systems.

4.2 Evaluation Process

The evaluation process is done in three steps (Fig. 2). In a first step, all worksheets have to be completed. In addition to the cost summary, a user has to provide figures on the expected usage of the teleteaching system: number of remote classrooms, number of lectures per week, duration of each lecture. From this information the costs per hour are computed. For an application with real world data for two different teleteaching systems refer to Tab. 1.

In the second step, the costs per hour and the value computed from the worksheet for the objective benefits are condensed into a single *cost-value ratio 1*. This is done as follows: The costs per hour value is divided by the objective benefits value. The lower the cost-value ratio the better is the system.

If the computed cost-value ratio 1 is almost the same for the teleteaching systems evaluated, then the better system can be determined by applying the subjective benefits value to the cost-value ratio 1, thus giving the *cost-value ratio 2*.

4.3 Application of the System

As an application of the cost-value evaluation system we compared our ATM-based teleteaching system Telepoly and an ISDN-based (Integrated Services Digital Network) teleteaching system. Telepoly supports the transmission of up to three bidirectional high-quality video and audio streams. We use three video and one audio stream for which we make an ATM-reservation of 38 MBit/s. This means almost 12 MBit/s for the transmission of a Motion JPEG compressed video stream and 2 MBit/s for a CD-quality stereo audio stream. Data transmission for teaching aides uses the Internet and is not included in the following cost calculation.

For the ISDN-based videoconferencing system we assume that three basic rate interfaces are used which gives a total transmission bandwidth of 384 KBit/s. The system supports the bidirectional transmission of one video and one audio stream and, additionally, the transmission of electronic teaching aids.

The cost-value evaluation of the systems is based on the assumption that specific audio and video equipment is purchased. The costs for audio and video equipment are assumed to be the same for both systems. Tab. 1 summarizes the cost evaluation for the systems in Swiss Francs (1 sFr = 0.62 Euro or 1 sFr = 0.74 US$ at time of writing) on the basis of an amortization period for the equipment of three years, 40 students in one remote classroom, six hours of operation per day which gives a total of 840 hours per year (assuming 28 weeks of lectures per year).

The cost evaluation of the systems shows that the ISDN system has an advantage over the Telepoly system. However, the actual transmissions costs in MBit/s are less for ATM (sFr. 37.63) than ISDN (sFr. 90.00) although the reserved bandwidth is much (100 times) higher and three video streams are transmitted simultaneously. Note that transmission of one video stream slightly reduces the transmission costs only.

The second and third step in the cost-value evaluation of the teleteaching systems consists in applying the objective and subjective benefits to determine the cost-value ratios 1 and 2, respectively (Tab. 2).

The ISDN system has a better cost-value ratio 1. Taking into account the subjective benefits then the ATM system performs slightly better. This is because the audio and video quality of the system outperforms the quality that can be achieved with an ISDN system. Note also that Telepoly supports transmission of up to three video and audio streams and supports multipoint sessions which has not been further considered in the above discussion.

5 Conclusions

We have presented a model and system for the cost-value evaluation of teleteaching systems. The model was designed with two main objectives in mind. First, the model should be useful in order to determine the costs of a teleteaching system. For this we defined a comprehensive list of types of costs. Second, the model should be used also for comparing and ranking teleteaching systems. This is done by computing two cost-value ratios. For this, objective and subjective benefits of teleteaching systems are ascertained by having check lists to be filled in. If this has been done, then, the objective benefits are considered and only if the resulting cost-value ratio 1 is almost the same then the subjective benefits value is used.

The system has been implemented as a number of interrelated Excel®-worksheets. The different steps in calculating total costs, objective and subjective benefits and cost-value ratios are done automatically. The system is flexible in the sense that changes can be applied whenener necessary.

	ATM (38 MBit/s) [sFr.]		ISDN (384 Kbit/s) [sFr]	
	Total	**per hour**	**Total**	**per hour**
Equipment:				
Audio	143'507.--		143'507.--

Transmission:				
Basic charge	70'200.--		1'917.--	
per hour		83.57		2.28
Bandwidth		37.62		90.00
Manpower:				
In- & Deinstallation/Guidance (h à sFr. 100,--)	x 1.5	150.--	X 1.33	133.33
Total costs per hour		543.09		477.77
Total costs per student/hour		13.58		11.86

Table 1: Costs Figures for Telepoly- and ISDN-System

	ATM	**ISDN system**
Costs per hour	sFr. 543.09	sFr. 474.77
Objective benefits	4.24	4.08
Cost-value ratio 1	**128.09**	**116.37**
Subjective benefits	4.51	4.05
Cost-value ratio 2	**28.40**	**28.73**

(Assumptions: 840 hours/year, 1 remote classroom)

Table 2: Cost-Value-Ratio 1 and 2 for Telepoly and ISDN system

We have used the system for an a posteriori evaluation of our own teleteaching system Telepoly. We have done a cost analysis to find out the actual costs of a teleteaching session. Furthermore, we have performed an evaluation of our system against an ISDN-based system. Although total transmission and operation costs are higher for Telepoly than for the other, the cost-value ratios of Telepoly are almost equally well. The cost-value evaluation system is still under development. In particular, the information on the objective and subjective benefits needs to be further justified.

Abstract: In this paper the object oriented design is combined with the hypertext mode to achieve an efficient system's structure which help the learner to navigate freely and stay in a certain context. Within this novel framework, tools and approaches can be shared or used while designing educational systems for different topics or didactic methodologies. Furthermore, the parallel design of educational systems for two different topics, history and physics, using the combined formation is presented. We have investigated the dependencies of objects and the sharing of tools used during the development of the two prototypes. Both systems are engaging, expandable and transferrable.

Introduction

The user interface design and the content's exploration are key issues, especially in educational applications. The interface is required to engage the user and offer aesthetic information presentation. The communication and interaction for the content's exploration should lead to knowledge aquisition. Adaptation to learner's selections and flexibility for different scenarios' execution are highly recommended. The disorientation that is created by the adaptation and the flexibility, should be eliminated (Shneiderman 1992), (Metaxaki et al. 1991a), (Kouroupetroglou et al. 1995).

The design, implementation and content development in multimedia systems are quite expensive. Thus, resuability of the content and/or a sucescfull former design approach is a requirement. In some applications, the re-use of a piece of content in the same or different format realizes educational aspects or didactic procedures (Metaxaki et al. 1991b), (Metaxaki et al. 1994).

In this paper, we present a novel approach to meet the mentioned needs. The structure of the proposed system is a combination of the hypertext mode and the object oriented architecture, implemented by embedded objects or components. There can be a design approach including objects descriptions which can be enriched by operation functions to face various needs. These functions can be interchanged by learner's selection to help him navigate freely without losing the context of the exploration (Rumbaugh et al. 1991), (Fayad and Schmidt 1997), (Aedo et al. 1996), (Wisnudel 1994).

Two applications using the same methodology have been desogned and developed to explore the dependence and the transferability of the object's description and presentation. The sharing of tools was investigated, too.

Aspects of the Combined Methodology

The extensively used hypertext mode has two main problems: the increasing number of connections over a topic and the disorientation these connections can create after some navigation steps. A novel method is required which could add connections of data and tools to eliminate this disorientation. The object oriented architecture can be used for this purpose.

Our decision was to design, implement and investigate according to the Component Display Theory (CDT) defined by Merill as: "The CDT is comprised of three parts: a two-dimensional performance-content classification system, a taxonomy of presentation forms, and a set of prescriptions relating the classification system to the presentation forms. CDT assumes that all instructional presentations are comprised of a series of discrete displays or presentation forms. Any presentation can be described as a sequence of such presentation forms, together with the interelationships between these forms" (Merill 1984), (Merill 1983).

A main notion of the embedded component (EC) structure is the independence between the objects used for presentation and the ones used for the information presented. This allows the appearance of the same information in multiple locations and in different forms. Moreover, new objects can be created in succession, the previously constructed ones can be re-used and the new ones are easily integrated in the system. An object can be plain or enriched, active (sound, video, motion) or inactive (plain text). Objects can be concrete or embedded on other objects. The objects can be interconnected through links pre-existing or created by user queries. Using the embedded objects we can succeed in the integration of information, the integration of media, the re-use of information and the flexibility of the presentation of information on a display (Spitzer 1997), (Baecker et al. 1995), (De Diana et al. 1994).

The Design Approach

System's Objects and Modules

The Objects

The objects are differentiated as *data objects* (dao) and display objects (dio). The *dao* are enfolding the data, the implementation of the possible links, and the execution of queries. They are of two different types, the *main* and *the instance data objects (mdao, idao)*. The *mdao* include the required information for the definition of an entity. The content of the *dao* can be a maximum or minimum depending on the topic or the didactic procedure i.e. *mdao* for the lesson on physics include the maximum content for a physical phaenomenon or a minimum to be further combined. The ones for the lesson of history are usually of a minimum content and are combined to form a historical event. Each *mdao* is connected with one or more *idao*, containing data and format information.

The *dio* include all parameters needed for the formation of a presentation on the display. Their parameters depend mainly on the type and format of information. They contain, too, the interactivity functions. The execution of *dio* performs the *dao*'s presentation. We emphasize that the *dio* do not define the interconnections of this presentation.

We can say that the system communication is organized in two layers. The presentation layer and the data layer. The user interacts with the presentation layer. At this layer the learner's requests and actions are interpreted and transferred to the data layer. The data layer processes the interpreted requests and a presentation appears on the display.

The Modules

We can assume that the system consists of three types of modules (Fig. 1): the Objects Module (OM), the Navigation Tools Module (NTM) and the Main Pages Module (MPM). The Objects Module contains all the objects of the system we have already described. The NTM supports the selected navigation and contains all the constantly presented elements of the display (chapters, menus etc). The MPM includes the main thematic pages of the system. These pages are the starting point for the user's exploration. They form the base for the orientation and the structuring of user's reactions and the selected objects' presentation. The pages are intercommunicating.

Both the hypertext navigation mode and the embedded object architecture co-exist in the system. The hypertext based interaction is realised in the communication between the MPM and the NTM. The objects-based interaction is realised in: (a) the communication inter-MPM, between the MPM and the OM, (b) the intercommunication of the OM.

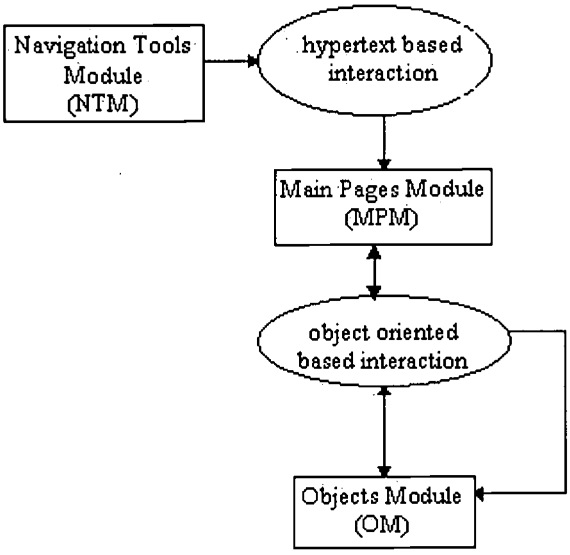

Figure 1: The General Design Approach

The combination of the two modes and the creation of the modules content create a frame in which various didactic procedures can be realized. The system can be adapted to the learner's needs.

Structure of the System and Applications

In order to design, structure the system and investigate the methodology we have decided to prototype in parallel on two different topics with which we had already a good familiarity (physics, history). The two topics concerning their implementation were differentiated by the type of exploration depth-width and the format of the presented information. The type of the exercises, too, were different. The base of reference was to keep elements of an electronic hypermedia book (Laurel et al. 1990), (Thuering et al. 1995), (Mullin 1990), (Metaxaki et al. 1995).

Both systems include links (for direct or nonsequential access), embedded objects, navigation bars or menus, wedges (areas offering additional information by direct access), floating windows (wedges enriched by functional characteristics), indexes and recapitulatory nodes.

In Fig.2 we present the structure of the applications. The structure is common although the outlook is different. There exist on the display the constantly shown fields and the changing ones. The constantly shown ones (menu, navigation bar, chapters etc) assist the user's orientation in a context. The user selects (links, buttons) a sub-topic, moves directly to it (main pages) and starts the exploration.

The exploration can be continued in depth or width by queries, indexes etc. The one in depth will occur by selection (links, hotspot areas etc) and the presentation of embedded objects in wedges or floating windows format. The other in width will occur by direct returns to the main pages and/or the extensive formation of interconnecting embedded objects. Windows or wedges can be opened concurrently or in sequence, overlayed or not.

Discussion and Results

The design of the two systems in parallel was proved quite succesful and spared development time. The topic of the nuclear physics needed a large amount of simulated and animated information. The topic of history was about the Emperor Carolus Magnus and needed texts and the reproduction of images. Our great difficulty was the presentation of the objects, which was developed in a parametric way so that we could share programming tools. The definition of the changing areas and the floating windows outlook as well as the connections of texts and pictures was scheduled in our system for the pictorial communication research (Metaxaki et al. 1996), (Kouroupetroglou et al. 1994). We can conclude that the information content was developed independently but for the presentation development we have used the same parametric tools. The object definitions were quite short for the history in comparison with the ones for physics but they contained more data. The inteconnections between objects were less extensive for nuclear physics. This means that the objects were more concrete. The in depth exploration of the topic was achievable by the system as well as the in width exploration for history.

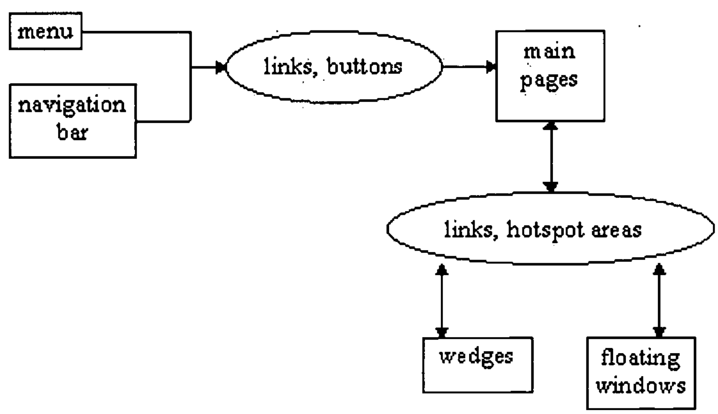

Figure 2: The common structure and communication for both prototypes

We work further using the same methodology and transferring tools and experience to the topic of human sciences.

Conclusions

The use of object oriented design in connection with the hypermedia mode to design educational systems is a quite successful approach. It helps the learner to navigate through the system feeling free but staying in the context. The learner can choose his own way to explore the system. The teacher or tutor can realize different scenarios taken advantage of the system's flexibility. The system can be explored in depth or width or both sequentially depending on the learning process.

The implementation of the approach needs expert programmers but the system is expandable and includes a large amount of transferability. When the system's content is existing in an intra-net server this type of design is much more powerful.

Abstract: This paper discusses a goal-oriented project called Distance Learning in Multimedia Networks (ETÄKAMU) <URL: http://matwww.ee.tut.fi/kamu/> that is a part of the Finnish Multimedia Programme (FMP). The project started on the 1st of February 1996 and lasted until January 1999. The project combined the efforts of Finnish telecommunication companies, content providers, publishing houses, hardware companies and educational institutions in the field of distance learning. One of the main goals of the project was to develop and pilot pedagogically appropriate and technically functional open learning environments. In this paper we present the main results of the project.

Introduction

The Distance Learning in Multimedia Networks Project <URL: http://matwww.ee.tut.fi/kamu/> combined Finnish technical and pedagogical research centres and institutions in the field of distance learning, hardware and software producers, publishing houses and telecommunication companies in an extensive joint project. In 1998 the budget of the project was approximately 4,7 million Finnish marks (900 000 USD). The project was funded jointly by the Technology Development Centre of Finland (TEKES) and by 32 Finnish enterprises. It was coordinated by the Hypermedia Laboratory of the Digital Media Institute at Tampere University of Technology. (Pohjolainen & Ruokamo 1998.)

The aim of the Distance Learning in Multimedia Networks Project was to research and develop pedagogically appropriate and technically functional open learning environments for distance learning based on computer networks. The design of the learning environments is based on the rapid development of information technology, especially on broadband computer networks and hypermedia-based learning materials. The learning environments were studied and developed from telecommunications (hardware), hypermedia material (courseware) (Nykänen & Ala-Rantala 1998, Pohjolainen, Ala-Rantala, Nykänen & Ruokamo 1999) and pedagogical points of view (Ruokamo & Pohjolainen 1998).

Distance learning using multimedia is exploited by schools, educational institutions, and enterprises for all ages ranging from children to adult learners. Various pilot projects and teaching experiments was set up in ten pilot areas to gain feedback from the methods and solutions developed. The purpose of the teaching experiments was to test both the technical and pedagogical functionality of the distance learning solutions developed.

Collaborating Partners

The Distance Learning in Multimedia Networks Project was divided between research and enterprise partners. The universities were the research partners in the project. The Digital Media Institute (DMI) operating at Tampere University of Technology was the project coordinator and the other units functioned as subcontractors to it. Research partners were

- Tampere University of Technology / DMI / Hypermedia Laboratory,
- Helsinki University of Technology / Centre for Educational Technologies,
- University of Tampere / Hypermedia Laboratory,
- University of Tampere / Institute for Extension Studies,

- University of Jyväskylä / Information Technology Research Institute,
- University of Helsinki / Lahti Research and Training Centre.

The project's enterprise partners were divided into steering enterprises and follow-up enterprises. Steering enterprises were as follows: City of Jyväskylä, City of Tampere, Data Network Institute, Edita Group, Finnet/HPY Ltd., Helsinki Institute of Physics, Helsinki Media Company Ltd., Jyväskylä Science Park Ltd., Lifelong Learning Institute Dipoli/Helsinki University of Technology, Nokia Mobile Phones, Otava Ltd., Sonera Ltd., Sun Microsystems Ltd., Tampere Technology Centre Hermia, WSOY Ltd., and Xenex Ltd. ETÄKAMU's follow-up enterprises were AAC-Institute, Centre for Technical Training AEL, City of Nokia, CSC - The Center for Scientific Computing, Finnet/TPO Ltd., Finnish Association of Adult Education Centres KTOL, KVS-Institute, Mänttä Regional Education Center, Promanet Ltd., Promentor Solutions Ltd., STAKES (National Research and Development Centre for Welfare and Health), Teleste Educational Ltd., The Folk High School for Finns in Sweden, The Subregion of South-East Central Finland, Valmet Ltd., and WM-data Kasanen.

The Project's Organization and Research Activities

The organization of the Distance Learning in Multimedia Networks Project was divided into a steering committee, a supporting group, research groups and pilot areas. The *steering committee* decided on general plans and coordinated the activities between industry and academia. *The supporting group* was composed of all the researchers of the project and staff from research units that were responsible for the project. The research activities of the ETÄKAMU project were divided into two parts, i.e. into research conducted by research groups whose objective was to produce knowledge in support of project activities, function as a support for pilots, organize necessary training, and analyze experiences gained from the pilots. The three *research groups* were concentrating on: development of a prototype of an open learning environment, development of criteria for technical functionality and structure for hypermedia-based materials, and development of methods for distance learning and pedagogical evaluation criteria for open learning environments.

In addition to the three research groups several *pilots* were set up in various areas via which distance learning solutions in multimedia networks were carried out in practice and feedback on the performance of technical and pedagogical solutions was obtained. The participants in the *pilots* were project researchers and staff of enterprises, and teachers and students of educational institutions. The pilots were divided into the following pilot areas: 1. Broadband networks and technical experiments, 2. Natural sciences, 3. Language learning, 4. Education, 5. Communication, 6. In-house education for enterprises, 7. History and civics, 8. New school learning materials (KUOMA), 9. Finnish children abroad, and 10. Web university (WU) (see Rinta-Filppula 1998).

During the three years project expanded in many ways. Participants included pupils, university students, adult learners and employees of enterprises - the idea of lifelong learning was adopted. Distance learning was seen not only as a matter for educational institutions but also enterprises were interested in utilizing it. Distance Learning in Multimedia Networks Project grew into a significant co-operative effort between research institutes, educational institutions and enterprises.

During the last year of the ETÄKAMU project the main emphasis was on analyzing and reporting the final results of the project. The project's development and research work during the third year was divided as follows:

- Collecting the data from a number of teaching experiments that were arranged during spring and autumn 1998.
- Analyzing of the results were done using pedagogical and technical evaluation criteria.
- Development of the prototype of an open learning environment has continued until the end of January 1999.
- Project's final results have been analyzed and will be published as a book (Ruokamo & Pohjolainen 1999) and on the web.
- In January 1999 the project arranged a closing seminar "Pedagogical Methods and Technical Solutions for Distance Learning IV".

Pedagogical Research Problems

The ETÄKAMU project applied seven important qualities of meaningful learning - based on the list presented by Jonassen (1995) - as guidelines in the design, implementation, and evaluation of the open learning environments (see Pohjolainen & Ruokamo 1998; Ruokamo & Pohjolainen 1998, 1999). On the basis of the qualities of meaningful learning, the following research problems for the pedagogical evaluation of learning environments were set:

1. Does the learning environment support learner-centered learning?

1.1. Does the learning environment support learners' active construction of new knowledge on the basis of prior knowledge in interaction with the surrounding reality (Constructivity)?

1.2. Is the learner's role active and are the learners responsible actors in the learning environment (Activity)?

1.3. Can learners work together and construct new knowledge with one another while utilizing each other's skills (Collaborativity)?

1.4. Has the learning environment taken due heed of learners' goals and does it support the achievement of their knowledge objectives (Intentionality)?

1.5. Are the learning tasks located in meaningful, real-world tasks from the perspective of the learner or is there simulation of this through certain case-based and problem-based real-life examples (Contextuality)?

1.6. Can learners transfer what they have learnt from that situation and context and apply that knowledge in other situations? Can learners utilize formerly learned knowledge and skills in the learning of new things? (Transferability)?

1.7. Is it possible for learners to articulate what the have learned and reflect on the thought processes entailed in the learning process and the decisions taken (Reflectivity)?

The foregoing pedagogical research problems served as the basis for the evaluation framework for the pedagogical evaluation of the learning environments. This is intended for the scrutiny of learning environments and learning from the learner-centered perspective, with consideration for the perspectives of both the learner and the teacher.

Main Results

Pilot projects in various fields constituted an important part of the ETÄKAMU activity. It was the aim of pilot work to try out the methods developed and elicit feedback on the technical and pedagogical functionality of the systems. In the field of piloting the focus was on the further development of the learning environments, on data collection and evaluation work. Pilot studies were implemented in ten fields in over twenty pilot projects. The following presents an overview of the main results from certain pilot projects.

A&O Open Learning Environment. The A&O learning environment is based on a space model that is divided into the following spaces: 1) *Office*, via which all administrative matters related to studies are carried out, 2) *Study* for students, teachers and other actors, 3) *Media Center*, where all the additional and reference materials are located and 4) *Gallery* where all the final works of the students can be set up to be available for all the Internet users. The system architecture of A&O consists of data management facilities including data acquisition tools, tools for communication and collaboration, course-dependent cognitive tools and authoring tools for producing hypermedia courseware. Since A&O is now just a research and development version, the authors have not yet been able to test the A&O learning environment in teaching experiments and user trials. These will be arranged in the future. (see Pohjolainen, Ruokamo & Nykänen 1999.)

Network PC. The pilot project Java in distance learning was implemented in the DMI Hypermedia Laboratory. It comprised TUT and three Tampere schools on the ATM network. Kaukajärvi School, Tampere Teacher Training School and Pyynikki School and also the joint network computer experimental environment. of Ylöjärvi Upper Secondary School. JavaStation was used to carry out teaching experiments in which it was noted that JavaStation is well-suited to use in educational institutions. (see Häkkinen in Ruokamo & Pohjolainen 1999.)

Pythagoras. The Pythagoras environment for statistics <URL: http://matriisi.ee.tut.fi/pythagoras/> is targeted at pupils of the secondary and upper secondary school. Experiments were carried out in numerous schools in the Tampere and Ylöjärvi areas. The outcomes of the experiments show that Pythagoras is viable as a learning environment for the study of statistics. The questionnaire-tool in Pythagoras was felt to be particularly good in that it enables users to publish their own questions on subjects which interest them on the web and also to collect answers from other users of the environment. It was possible for users to utilise the data they had themselves collected for subsequent project work. (see Mäenpää in Ruokamo & Pohjolainen 1999.)

New learning materials for schools (The KUOMA Pilot). The KUOMA learning environment and Environment Net <URL: http://matwww.ee.tut.fi/ymparistoverkko> were developed from the pilot project for the study of environmental subjects. EnvironmentNet was tried out in 1998 in Pyynikki School and in Ylöjärvi Upper Secondary School. The experiences gained from the experiment indicate that EnvironmentNet provides good opportunities for learner-centred learning. In order that optimal advantage be derived from these, more technical and pedagogical education would be necessary for teachers in using EnvironmentNet. Pupils, too, would require more orientation before beginning to study through EnvironmentNet. (Piiksi & Muhonen in Ruokamo & Pohjolainen 1999; Piiksi 1999.) On the same KUOMA pilot project the learning environment for elementary Russian was developed called Russian on the Net <URL: http://matwww.ee.tut.fi/venaja>. Russian on the Net was tried out in the Tampere Teacher Training School and Ylöjärvi Upper Secondary School. Results indicate that Russian on the Net brought variety and interest to the study of Russian, for teachers and pupils alike. Pupils reported that the environment was useful for learning, but there was still room for improvement. (Hämäläinen & Muhonen in Ruokamo & Pohjolainen 1999; Hämäläinen 1999.)

Web University (WU). On ETÄKAMU the international pilot Web University (WU) was developed. Web University pilot <URL: http://wwwcs.cern.ch/> operated as a virtual university through which it was possible to participate in real time and interactively in lectures of the Academic Training Programme by CERN and in CERN Colloquium seminars. International interest, and the further development and expansion of the pilot have shown that transmitting lectures by top experts is appropriate using broadband network-based, videoconferencing technique, and multimedia services. Distance learners have participated for a total of over 100 hours in two years in contact teaching realised through WU-mediated CERN contact teaching. Transmissions were in real time and were interactive. However, they were also recorded digitally on FUNET multimedia server <URL: http://mbase.funet.fi/>. (Rinta-Filppula 1998; Rinta-Filppula & Penttilä in Ruokamo & Pohjolainen 1999.)

Conclusions

The ETÄKAMU project developed many different learning environments for different target groups and learning contents; it also conducted a considerable number of teaching experiments. Most of the learning environments were available on the Internet. They utilized WWW hypermedia properties, the opportunities provided for situations and simulations. Communication and co-operation tools were also built into the environments, likewise cognitive and materials production tools. The activities and the experimental use made of the learning environments were successful and demonstrated the use and importance of technology in education. It was seen that technology can be used to aid the construction of pedagogically relevant environments and tools which support learning.

The rapid development in technology has been accompanied by certain problems. With the rapid development in browsers, plug-ins, script and programming languages and applications the computer network environment is not yet stable from the technical point of view. In consequence of this the existing learning environments must be constantly updated so that their operationality may be guaranteed. This problem may cause less trouble in the future, when the development in some respects reaches a plateau and commercial software dominates the markets.

Although hypermedia enables the construction and adaptability of documents there are as yet no systematic models of the structure of didactically appropriate learning material to be used more extensively. Standardization of the document structure would enable the use of content in different environments and facilitate both flexible combination of contents and information seeking. Material generated by both materials producers and learners constitutes an important part of the learning environment. Materials production would increase considerably if producers had at their disposal a user-friendly, structured tools for the production of multimedia material.

One obstacle to the expansion of the use of learning environments is the problems with use. Such problems are manifest in difficulty in use and the need for maintenance. For all actors a more user-friendly result could be achieved through better user connections and the integration of all necessary tools into the same learning environment.

In distance learning achieving objectives entails not only sophisticated technology but also appropriate pedagogy and contents - these must serve the same end of learner-centered learning. The new technology also provides scope for pedagogical progress and for the realization of pedagogical innovations. Efficient application of the existing technological options requires pedagogical research. An optimally efficient and meaningful learning environment commits the learners to active construction of knowledge instead of reproducing this. It further commits learners to discussion, interaction, co-operation and reflection of the parties in the learning process as opposed to the one-sided reception of knowledge or replication. The content of the learning environment should engage learners in meaningful contexts and situations in which it is possible to utilise knowledge and skills already acquired and to transfer these to further situations.

The pedagogical evaluation framework developed in the ETÄKAMU project proved functional in the evaluation of learning environments. It is also applicable in the planning and implementation of learning environments and in supporting learning. Of the seven qualities of learner-centred learning it was constructivity, intentionality and reflectivity which were found to be best realised in learning environments enabling project work. The learning environments were also found to enable contextuality and transferability. Activity and collaborativity were seen to pose challenges in many environments: what turned out to be problematic was how to get learners motivated and committed to the learning task and also to make active use each other's skills and knowledge.

The technologies available today enable totally new learning processes. In addition to the participation of traditional actors (teachers, educational institutions etc.) there are many kinds of new actors and producers of services such as teleoperators, producers of technical support services, producers of net materials, etc. The efficient and pedagogically sound use of learning environments requires overall control of the learning process. The dissemination of educational technology services developed in pilots and scaling them for more widespread use is a worldwide problem. The efficient dissemination of educational technology, contents and services requires that common rules of play be agreed on. This could be achieved by the dissemination of best practices and flexible standardising.

The efficient use of information technology (IT) in teaching in Finland is still at the experimental and pilot stages. Good experiments have been conducted but they need support in order to be realised. The risk exists that after experimentation, once the technical and pedagogical support personnel have departed, the environments used during the experiment will not continue to be part of the everyday practice of the educational institution or enterprise. The environments used in the experiments were neither technically nor pedagogically perfected products. There is a need for more user-friendly technologies to support learning, likewise appropriate content and more widely applicable models. Introducing and using learning environments should be easy, and not require great effort. Individual experiments should progress to more extensive nation wide trials and action models.

At schools resources should be invested in basic and further education for teachers so that they acquire the necessary competence to use take pedagogical and technical advantage of the learning environments and derive benefit from them. Those responsible for education in enterprises should also receive training through courses tailor made to suit their needs. At the present time the exploitation of IT in educational institutions is the responsibility of too small a number of active teachers. Maintenance of the schools' computer classes has proved problematic as there is a discrepancy between the time needed for this kind of work and the remuneration. Society should contribute adequately to improving the circumstances under which the new technology operates so that it can be introduced more rapidly.

The major developmental trends in education (see Carley & Dailey 1998) are: 1) sophisticated technology will play a greater role in education, 2) the role of commercialisation will increase, 3) the demands of lifelong learning and for educational services will be greater and 4) there will be redevelopment and reorganisation of education systems. The work on the research, development and evaluation of distance learning on the multimedia networks has served to promote these general trends, with a particular advance in the combination of technology and education. The increased demand for varied educational services has come strongly to the fore. With the help of learning environments which are independent of time and place it is possible to break out of limitations imposed by the classroom and individual educational institutions an offer new opportunities for training for companies and adults. Making these new opportunities a reality requires that in the long term the educational systems will be reformed. Due to the nature of the research and development project the role of commercial considerations was not accorded so much attention in the present research. Nevertheless the research findings of the ETÄKAMU project give good cause to make the transition from the phase of research and experimentation to product development which will be significant for international markets.

The activity of the project on distance learning in multimedia networks served as proof of the necessity of co-operation among the various actors in the development of educational technology and its exploitation. Co-operation between research units, educational institutions and enterprises, software and hardware manufacturers, content provider and teleoperators has been fruitful and has served to open new vistas. This valuable experience serves as a good point of departure for possible initiation of national and international projects in the future.

An Intelligent Multimedia Tutor for English as a Second Language

MARIA VIRVOU, DIMITRIS MARAS
Department of Computer Science,
University of Piraeus,
Piraeus 18534, Greece
E-mail: mvirvou@unipi.gr | seagle@compulink.gr

Abstract: This paper is about an intelligent multimedia tutoring system of the passive voice of the English grammar. The system may be used to present theoretical issues about the passive voice and to provide exercises that the student may solve. While the student types the solution to an exercise, the system examines whether the answer has been correct and if not it attempts to diagnose what the cause of the mistake has been. The student's progress and usual mistakes are recorded to the student model. This kind of information may be used in the individualised error diagnosis of the student in subsequent sessions.

Key words: Intelligent Tutoring System, multimedia, student modelling, error diagnosis, language learning.

Overview

Students who learn English as a second language often experience problems in learning and consolidating the English grammar. The passive voice is an important topic which often seems difficult to students to use correctly. The problem is even greater in cases when the passive voice is not used extensively as a matter of style in the first language of students.

A multimedia tutor of the passive voice can be very useful if it incorporates intelligence so that it can help the student in correcting his/her mistakes and offer an individualised explanation for the cause of them. Many researchers point out (e.g. McGraw, 1994) that the integration of AI technologies and hypermedia may offer better support to students than any of these alone. The multimedia tutor that we have developed has been based on the techniques used in Intelligent Tutoring Systems (ITSs) (Wegner, 1987). Our system focuses on student error diagnosis in common with other systems in the domain of language teaching such as (Bos and Van De Plassche, 1994), (Heift, 1998) and (Kunichike et al., 1998).

In particular, the passive voice tutor constructs a student model which serves as a source of information that can be used for the interpretation of the student's actions and possible mistakes in solving exercises. The underlying cause of a mistake may be difficult for a tutoring system to spot. For example, Hollnagel (1991; 1993) makes an important distinction between the underlying cause or genotype of an error and the observable manifestation or phenotype of the error.

In the case of the passive tutor, error diagnosis is based on the student model where there have been recorded previous mistakes that the particular user has made and the progress that s/he has made since previous sessions. For example, if a student has been recorded to have been prone to spelling mistakes, then the system may use this piece of information for the interpretation of a mistake by favouring the cause of wrong spelling rather than lack of grammar knowledge at some points of the interaction.

Architecture of the Passive Voice Tutor

The architecture of the passive voice tutor follows the main line of Intelligent Tutoring Systems (ITS) architectures. Researchers in the area of ITSs (Hartley and Sleeman, 1973; Burton and Brown 1976; Wenger 1987) largely agree on the major functional components constituting an ITS architecture, namely the Domain Knowledge, the Student Modeller, the Advice Generator and the User Interface.

The domain knowledge of the passive voice tutor contains knowledge about how to convert a sentence from active to passive voice and vice versa. In addition, it contains knowledge about the dynamic construction of new sentences that can be used as exercises. The construction of new sentences is done using several lists of words, three of which are the most important. One for possible subjects, one for possible verbs and one for possible objects. All lists are semantically related among them so that sentences that do not make sense are not allowed. This kind of knowledge is used by the system so that the user is not shown the same exercises while running the program. The same kind of knowledge can also be used by the student or teacher for the creation of new exercises that can be answered by the system as an example or can be used as new homework for the students.

The student modeller compares the solution that a student has given to that of the system and if these do not match it performs error diagnosis. There are several categories of error that may be recognised, for example spelling mistakes, accidental slips, mistakes in the actual conversion of passive to active voice, mistakes in the use of tenses, etc. The student modeller is also responsible for recording statistics about each student's performance. For example, the system records the percentage of the exercises that have been correctly answered, the percentage of spelling mistakes etc. This kind of information is also used in error diagnosis to create an individualised interpretation of a user's error.

The advice generator is responsible for acting in the most appropriate way in every situation. For example, if a student has made a mistake which is relevant to the use of verb tenses then the advice generator will show to the student the part of the theory that deals with this subject.

Finally, the multimedia user interface involves animations, sounds and a limited form of natural language so that it can attract the student's interest in the subject.

Overall Performance

The overall performance of the passive voice tutor may be summarised in the following functions which may be selected from the main menu of the system:

- **Theory:** At this point the student may read the theoretical issues that are relevant to passive voice.
- **Solving Exercises:** At this point the student may start interacting with the system in solving exercises. The student is given four types of exercise to select from:

  1) Multiple choice exercises.
  2) Exercises where the user is asked to rewrite a sentence using passive voice.
  3) Exercises where the user is asked to rewrite a sentence using active voice.
  4) A puzzle.

The way that multiple choice exercises have been constructed is based on an empirical study that has been conducted in real classrooms and through interviews with students and teachers. The results of this particular study have shown what the most common students' mistakes are. This kind of information has been used throughout the creation of the erroneous answers that have been incorporated in the multiple choice questions development. Furthermore, the above results have been used for the analysis of possible students' mistakes in the design of the diagnostic component of the student modeller.

In the case of exercises where the student is asked to rewrite a sentence using passive voice, the student is given a sentence in the active voice and s/he is asked to retype the sentence in the passive voice. At this kind of exercise, the system ignores trivial typographic errors such as the absence of a fullstop at the end of the sentence, absence of any space between words, redundant spaces or commas, etc. If the student has made an error other than a trivial typographic errors, then the system performs error diagnosis taking into account information that has been collected about the specific user in previous interactions as well as common mistakes that have been classified in several categories of error. There are seven types of errors that may be recognised by the system:

1) **Accidental slips**
   For example, the student may have deleted some words and may have forgotten to complete the sentence.
2) **Spelling mistakes**
   A spelling mistake occurs when the user has typed the expected word so that one letter is redundant or missing or two neighbouring letters have been interchanged. For example, the student has typed "mather" instead of "mother".
3) **Article mistakes**
   For example, the user may have used "a" instead of "an".
4) **Conversion mistakes**
   For example, the user may have not converted the active verb "write" to the past participle "written".
5) **Irregular verb mistakes**
   The user may have used the usual ending "-ed" to create the past participle of an irregular verb (for example s/he may have typed "buyed" instead of "bought").
6) **Noun mistakes**
   For example the user may have typed "book" instead of "books".
7) **Verb tense mistakes**
   For example the user may have typed "been" instead of "being".

In some cases a mistake of the user may be attributed to more than one categories of error. For example, if a student has not typed the word "by" in the converted sentence, this could be either accidental slip or a conversion mistake. In this case, the former is rather superficial whereas the latter is deeper and shows that the student has not consolidated the knowledge about passive voice. In cases like this the system takes into account the individual features of the user, that have been recorded in previous interactions, in order to formulate the kind of advice to give to the student. For example, if the particular student has not previously made conversion mistakes but has made carelessness mistakes then the system favours carelessness as the most probable cause of the mistake.

Examples of interactions involving students' errors are the following:

First Example

System exercise:	My sister has bought this book.
Student's answer:	This book has been bouht by my sister.
System:	You have made a spelling mistake in the past participle. You should have written "bought" instead of "bouht". Please try again.

Second Example

System exercise:	My sister has bought this book.
Student's answer:	This book has been bought my sister.
System:	Neither "by" nor "with" was found in your sentence. Please notice that we use one of these words in passive voice for the agent. Please read again the theory and try again.

In this example the system has considered the error as a conversion mistake. Alternatively, it could have considered the same mistake as a carelessness error. However, in this case it must not have had sufficient information that the student knows how to use "by" or "with".

Third Example

System exercise:	My sister will buy this book.
Student's answer:	My sister will be bought by a book.
System:	You have made a serious conversion error. Please notice that in passive voice the subject and object should exchange places. Please read again the theory and try again.

In the case of exercises where the user is asked to rewrite a sentence using active voice the function of the system is similar to that of exercises that were explained above. The only difference is that the initial sentence is given in passive voice this time.

Finally, the type of exercise called "puzzle" is a kind of game that the student may play, so that s/he can consolidate knowledge while having fun. This feature is quite important pedagogically because it stimulates student's interest. As (Amory et al., 1998) point out while students learn equally from playing games and traditional practical material, they find playing games more enjoyable and hence they attempt more interactions.

- **Creating Exercises/Examples:** At this point the student is shown exercises again, only this time s/he is the one who creates the exercises and the system solves them as an example. The student may create sentences in active voice by selecting subjects, verbs and objects from three lists respectively. Then the student may select articles or pronouns, singular or plural for the subject and object as well as tense for the verb. If the created sentence does not make sense or is not correct then the system gives a message to the user to let him/her know about the problem. If the sentence is fine then the system rewrites the sentence using passive voice, so that the student can see how this is done.
- **Statistics:** The student is allowed to see the statistics about his/her performance, which have been recorded by the system. In addition, s/he may ask to have a printed report. The student can see the statistics about his/her overall performance in all the sessions that s/he has attempted or just in the current session. S/he may also see the comparison between his/her overall performance and the performance in the current session or the comparison between performances in the current session and the previous one.

An example of statistics about a user's overall performance is the following:

Student name: John
In a total of 25 exercises:

Correct sentences:	65.5%
Sentences having spelling mistakes:	12.5%
Sentences having mistakes due to carelessness:	25%
Conversion mistakes:	0%

In the case of the above example in a subsequent session of the student called John, the system will favour the cause of carelessness for a mistake rather than lack of grammar knowledge in cases where either of them could be considered.

Conclusions

The passive voice tutor is a multimedia system that combines user-friendliness with intelligence in interaction. It offers individualised advice to users when they make errors after it has performed error diagnosis. It has a mechanism for choosing between different possible causes underlying an error which vary from trivial typographic errors to deeper misconceptions concerning the main topic that is being taught. The design of the diagnostic component has been based on an empirical study that has been held in real classrooms and has shown what the most common students' mistakes are.

EasyMath: A multimedia Tutoring System for Algebra

Maria Virvou, Victoria Tsiriga
Department of Computer Science,
University of Piraeus,
Piraeus 18534, Greece
E-mail: {mvirvou | vtsir}@unipi.gr

Abstract: This paper describes a multimedia tutoring system for Algebra. The system is called "EasyMath" and it incorporates intelligence. One of the primary aims of EasyMath is its usefulness in school classrooms, therefore school teachers of mathematics have been involved throughout the life cycle of EasyMath. The design of EasyMath has been based on the results of an empirical study that was conducted at schools and the resulting product was evaluated by school-teachers as well as students. EasyMath incorporates techniques from Intelligent Tutoring Systems. In particular, it takes a reconstructive approach to student modelling and error diagnosis, which uses a generic model of the domain for the reconstruction of correct and incorrect solutions to exercises. EasyMath provides a facility for the dynamic construction of new exercises for students on which it can perform error diagnosis and provide appropriate advice. EasyMath has been evaluated by school teachers and students. The results of the evaluation show that the multimedia interface provides a user-friendly interactive environment which seems more attractive to students than conventional teaching methods. In addition, EasyMath's intelligence guarantees more individualised advice with high relevance to the context and problems of the students.

Key words: Intelligent Tutoring Systems, Multimedia, Student Modelling, Error Diagnosis.

Overview

This paper describes a multimedia educational system for Algebra. The system is called EasyMath. One of the main aims of EasyMath is its usefulness in the environment of school classrooms in common with other projects such as (Alexandris et al., 1998). Therefore school teachers have been involved in the phases of requirements analysis and evaluation of EasyMath's life cycle.

In particular, during the requirements analysis, an empirical study was conducted involving 4 school teachers and 240 students of 8 different classes of the same grade. The results of the empirical study showed what the most common misconceptions of students have been concerning Algebraic powers. These misconceptions have served as the basis for the design of the student modelling component of EasyMath. The empirical study is described in more detail in the next section.

The evaluation phase of EasyMath involved 4 school teachers who were different from the ones involved in the empirical study. EasyMath was also evaluated by a total of 180 students of 6 different classes of the same grade. The evaluation is described in more detail in a subsequent section.

EasyMath incorporates techniques from Intelligent Tutoring Systems (Wenger, 1987). It follows the main line of an ITS architecture which consists of four major components, namely the domain knowledge, the student modeller, the advice generator and the user interface. ITSs have often been criticized that in spite of their superiority to traditional stand up training they may miss the mark in terms of task reality, feasibility and effectiveness (McGraw, 1994). However, there have been quite a lot of successful evaluations of ITSs (e.g. Marks & Greer, 1991) and reports on the successful use in classrooms of ITSs (e.g. Koedinger & Anderson, 1993).

The design of EasyMath has been based on techniques of ITSs that can be useful to the improvement of the quality of multimedia educational software both for the student and the teacher. In particular, the student modelling component has been based on reconstructive approaches to error diagnosis which have been used in many ITSs such as (Langley et al., 1987; Sleeman et al., 1990; Hope, 1994). These systems reconstruct the problem solving process and generate mal-rules from hypothesized faulty solution paths which are used for the modelling of students' misconceptions or procedural bugs. In the case of EasyMath, the most common faulty solution procedures, which were identified in students' transcripts during the empirical study, have been encoded in the student modelling component.

These faulty solution procedures are used for two purposes:

1) For the construction of new multiple choice tests where the wrong answers have been generated by the use of these faulty procedures.
2) For diagnosing what the cause of a student error may have been while s/he is solving an exercise.

Finally, EasyMath's multimedia interface renders the system quite attractive to students. The evaluation results have shown that students particularly liked an educational game that EasyMath incorporates and which makes full use of multimedia facilities such as animations, sounds, etc.

Empirical Study

EasyMath's design has been based, to a large extent, on the results of an empirical study that involved school-teachers and students. These results were particularly useful for the requirements analysis of EasyMath as they showed what teachers would like the software to do to help them in the class. In addition, they showed what particular pieces of the domain knowledge seem difficult to students to comprehend fully and what misconceptions they may have while learning.

Educational software should be used to supplement human teachers and not substitute them, therefore human teachers should be involved in the development process. Besides, as Mark and Greer (1993) point out, the accuracy of ITS components such as domain knowledge should be ensured before a system is completed and assumed thereafter. One good way of ensuring this accuracy is to involve human teachers in the early stages of the development process.

The empirical study involved 4 school-teachers. Each school-teacher taught 2 different classes of the same grade. Each class consisted of 30 students. All students of every class were involved in the empirical study. This gave a total of 240 students who were involved in the empirical study.

All students were given the same tests which were made by the 4 teachers in collaboration. These tests covered all the material taught in Algebraic powers. The results of these tests were analysed so that as many as possible errors could be categorized. As a result of the analysis, the most common categories of error were identified and the cause of them was diagnosed by the human teachers.

For example, for the multiplication of powers, the following most common categories of error were identified:

- If both powers have positive bases as well as exponents, the user may multiply instead of adding the exponents. For example, $4^3 * 4^6 = 4^{18}$ instead of 4^9.
- In the case when both powers have positive bases as well as exponents, the user may multiply the bases instead of leaving the same base. For example, $3^4 * 3^5 = 9^9$ instead of 3^9.
- When both powers have positive bases as well as exponents, the user may multiply the bases instead of leaving the same base in addition to multiplying instead of adding the exponents. For example, $2^3 * 2^5 = 4^{15}$ instead of 2^8.
- If one of the powers has a negative exponent and the other has a positive exponent, but both of them have the same bases, the student may subtract instead of adding the exponents. For example, $5^3 * 5^{-4} = 5^7$ instead of 5^{-1}.
- The user may make a careless mistake either in entering the base or the exponent of the answer. For example, $4^3 * 4^6 = 5^9$ instead of 4^9.
- When the student is asked to multiply a power with a number that can be converted to a power, s/he may make mistakes both while converting the number into a power as well as while multiplying the two powers. For example $2^3 * 8 = 16^3$ or $2^3 * 8 = 2^9$ instead of 2^6.

The identified most common categories of error, their causes and appropriate advice for each category were encoded to EasyMath's domain knowledge, student modeller and advice generator.

Overall design of EasyMath

EasyMath has been designed to be used by students and/or teachers. Students may use EasyMath to read theoretical lessons about Algebraic powers and solve exercises. Teachers can use EasyMath as an assisting tool for the creation of new exercises, which can serve as student tests.

The various ways that a student and/or a teacher can use EasyMath are represented as different modes of function:

- **Lecturing mode:** In this mode, the student is able to read theoretical issues concerning algebraic powers.
- **Solving exercises mode:** In this mode, the student is presented several exercises to solve. EasyMath constructs dynamically new exercises of different levels of difficulty, starting from the first level to higher levels.

  For example, in the multiplication of powers, the first level of difficulty comprises exercises where the student is asked to convert to a power a number which is multiplied by itself several times. For example, $3 * 3 * 3 * 3 * 3 = 3^5$. The number which is multiplied as well as the number of factors of the multiplication are generated randomly and they are different each time a student attempts this type of exercise.

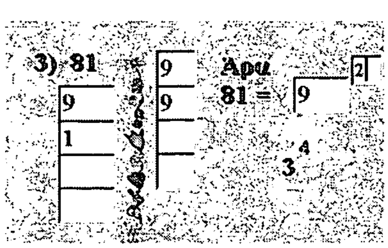
  A higher level of difficulty includes exercises where the multiplication factors are negative numbers. The different sign of factors renders this type of exercise more difficult than that of the first level and so on.

  For every type of exercise, EasyMath contains knowledge about how to solve it correctly and how to solve it in several faulty ways that represent the most common errors that were identified in the empirical study for the particular type of exercise.

  If a student gives an answer which is correct then EasyMath congratulates him/her and allows him/her to proceed to next level of difficulty. If a student gives an erroneous answer then EasyMath tries to perform error diagnosis by generating the faulty procedures of solution. If one of them is found to match the student's answer then EasyMath shows to the user the appropriate kind of advice and records the type of error identified in the student's personal record so that it can have the history of his/her progress.

  The way that EasyMath performs error diagnosis is based on reconstructive methods of student modelling. For example, while a student converts a number into a power, s/he may make the following types of error:

1. Error in the factorization of a number to prime numbers. This error can occur due to an erroneous conduction of the needed divisions as well as a division with a number that is not the smallest prime number. For example, while factorizing the number 81 to its prime numbers, the student may divide the number by 9, which is not a prime number. As a consequence of this type of an error, the base of the power that is given as an answer is wrong, 9 instead of 3 in the example. An example of this kind is shown in [Figure 1a] where the student's answer is 9^2 instead of 3^4 which is the correct answer.
2. Correct factorization of the number but erroneous transformation to a power. For example, the student after factorizing correctly the number 125 to its prime numbers, s/he has a misconception in identifying which of the numbers is the base and which is the exponent. This may result in a mistake such as entering a base different from 5 or an exponent different from 3. An example of this kind is shown in [Figure 1b] where the student's answer is 5^2 instead of 5^3 which is the correct answer.



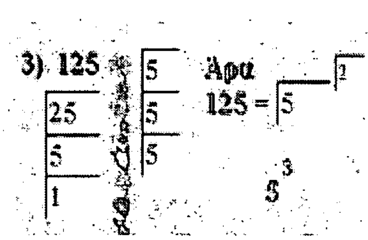


Figure 1a: One case of erroneous answer **Figure 1b:** Another case of erroneous answer

In the case when the student's answer is of the type that is illustrated in [Figure 1a], the system's answer is: "*There has been an error in the factorization procedure, because the number used as a base is not a prime number.*"

In the case when the student's answer is of the type that is illustrated in [Figure 1b], the system's answer is: "*The factorization procedure is correctly completed, but there has been an error while constructing the power.*"

- **Answering multiple choice questions:** In this mode, EasyMath constructs dynamically a new set of multiple choice questions which are presented to the user. The construction of multiple choice questions is based on domain knowledge and the student model.

  Numbers that serve as bases or exponents are generated randomly. For each type of question there is one procedure that solves the exercise correctly and there is a number of faulty procedures that have been encoded to the system, which represent common students' mistakes. The result of the correct procedure is used as the correct answer in the multiple choice. Erroneous answers are generated from the faulty procedures that are encoded into the system. For each question, a number of faulty procedures are selected randomly from the whole set of faulty procedures.

  For example, when the system issues a question concerning the multiplication of powers, it performs the following steps:

  1) A number within the range [1, 9] is generated randomly, in order to serve as the base of the two powers to be multiplied.
  2) Two numbers within the range [1, 9] are generated randomly, in order to form the exponents of the two powers.

  After the generation of the question that will be shown to the student, the system chooses randomly two out of the seven possible erroneous procedures and based on them, it constructs the two wrong answers that would serve as alternative answers to the problem that the user has to solve.

  An example of a multiple choice question is the following:

  $6^3 * 6^{-5} = ?$
  a. 36^{-2}
  b. 6^{-2}
  c. 6^{-15}

  In this case, the correct answer is b. However, if the student selects a, then EasyMath prompts him/her with the message:

  "Identified problem in the multiplication of powers: you have multiplied the bases instead of leaving the same base."

  If the student selects c, then EasyMath prompts him/her with the message:

  "Identified problem in the multiplication of powers: you have multiplied instead of adding the exponents."

- **Game playing mode:** In this mode, the student is given a game which is relevant to algebraic powers. This mode is quite important pedagogically. As (Amory et al., 1998) point out, games appear to motivate students intrinsically and represent one of the best uses of multimedia in education.
- **Assistance in the creation of new exercises:** In this mode, the teacher can profit from the domain knowledge and student modeller to create new multiple choice exercises and other exercises concerning algebraic powers. For example, the teacher types in a new question which is solved by the system correctly and in all possible faulty ways that EasyMath knows. Then the teacher is

presented with faulty results and algorithms so that s/he can select the erroneous answers for the multiple choice question.

Evaluation

EasyMath was evaluated by 4 school-teachers and a total of 180 students. The 4 teachers who participated in the evaluation were different from the teachers who were involved in the empirical study. They were asked to use EasyMath and then answer a questionnaire. Students constituted 6 different classes of the same grade. Each class consisted of 30 students. The evaluation by students was done in two phases. In the first phase 120 students of 3 different classes of the same grade were asked to use the software and then answer a questionnaire which included questions that are illustrated in [Table 1].

Question	Agreement	Lack of preference	Disagreement
1. Do you think that using EasyMath makes learning more like a game?	95%	1%	4%
2. Were graphics of EasyMath attractive?	97%	0%	3%
3. Were the colors and text used by EasyMath convenient?	90%	3%	7%
4. Has the use of sounds in EasyMath enhanced attention?	92%	2%	6%
5. Were you satisfied with the responses to students' errors?	98%	1%	1%
6. Do you believe that the domain of Algebraic powers was fully covered?	66%	15%	19%
7. Was the amount of different exercises enough?	93%	3%	4%
8. Were you pleased by the way student's progress has been recorded and used?	89%	3%	8%
9. Was it easy to get familiar to using EasyMath?	94%	4%	2%
10. Was it easy to trick EasyMath?	84%	1%	15%

Table 1: Questionnaire.

EasyMath's quality features evaluated	Corresponding questions from questionnaire	Average Score
Friendliness and Attractiveness of the Graphical User Interface	1, 2, 3, 4, 9	93.6%
Completeness of the Domain Knowledge	6, 10	75%
Correctness of the interactive student solution checker	8, 10	86.5%
Relevance of the advice provided when solving exercises	5, 10	91%
Sufficiency of range of exercises provided	7	93%

Table 2: Summary of results of evaluation.

Answers to the questions of the questionnaire (Table 1) were used to evaluate certain quality features of EasyMath as shown in Table 2. In this table the first column illustrates the quality features evaluated. In the second column we give the corresponding questions from the questionnaire which were used for the evaluation of the respective quality features. Finally, in the third column we give the score which has resulted from the average of the provided answers to the corresponding questions, as it appears in the "Agreement" column of Table 1. For example, in the friendliness and attractiveness of the GUI we take the average of the answers that represent the agreement percentage for questions 1, 2, 3, 4 and 9, namely 95%, 97%, 90%, 92% and 94% respectively. The resulted average score is 93.6%.

In the second phase 120 students, other than the 120 students who participated in the first phase, were taught half of the syllabus in algebraic powers without the use of EasyMath and they were given a written test. Then they used EasyMath while being taught the rest of the syllabus. In the end they were given another written test and the grades of their first and second test were compared. 46% of the students obtained a better grade in the second test, 43% obtained the same grade and only 11% obtained a lower grade in the second test.

Conclusions

Multimedia interfaces when combined with the reasoning capabilities of Intelligent Tutoring Systems can provide attractive, user-friendly environments for learning, which can interact with the student in an individualized way. This kind of educational software can be useful to classrooms if it provides assistance to teachers and helps students in the learning process. These qualities can be achieved to a high degree if school-teachers participate in the development of educational software.

Acknowledgements

The authors wish to thank the school-teachers who participated in the project and especially Mr. Stavros Drosakis.

Abstract: The Intelligent Essay Assessor (IEA) is a set of software tools for scoring the quality of essay content. The IEA uses Latent Semantic Analysis (LSA), which is both a computational model of human knowledge representation and a method for extracting semantic similarity of words and passages from text. Simulations of psycholinguistic phenomena show that LSA reflects similarities of human meaning effectively. To assess essay quality, LSA is first trained on domain-representative text. Then student essays are characterized by LSA representations of the meaning of their contained words and compared with essays of known quality on degree of conceptual relevance and amount of relevant content. Over many diverse topics, the IEA scores agreed with human experts as accurately as expert scores agreed with each other. Implications are discussed for incorporating automatic essay scoring in more general forms of educational technology.

Introduction

While writing is an essential part of the educational process, many instructors find it difficult to incorporate large numbers of writing assignments in their courses due to the effort required to evaluate them. However, the ability to convey information verbally is an important educational achievement in its own right, and one that is not sufficiently well assessed by other kinds of tests. In addition, essay-based testing is thought to encourage a better conceptual understanding of the material on the part of students and to reflect a deeper, more useful level of knowledge and application by students. Thus grading and criticizing written products is important not only as an assessment method, but also as a feedback device to help students better learn both content and the skills of thinking and writing. Nevertheless, essays have been neglected in many computer-based assessment applications since there exist few techniques to score essays directly by computer. In this paper we describe a method for performing automated essay scoring of the conceptual content of essays. Based on a statistical approach to analyzing the essays and content information from the domain, the technique can provide scores that prove to be an accurate measure of the quality of essays.

The text analysis underlying the essay grading schemes is based on Latent Semantic Analysis (LSA). Detailed treatments of LSA, both as a theory of aspects of human knowledge acquisition and representation, and as a method for the extraction of semantic content of text are beyond the scope of this article. They are fully presented elsewhere (Deerwester, Dumais, Furnas, Landauer, & Harshman, 1990; Landauer & Dumais, 1997; Landauer, Foltz & Laham, 1998), as are a number of simulations of cognitive and psycholinguistic phenomena that show that LSA captures a great deal of the similarity of meanings expressed in discourse (Rehder, Schreiner, Wolfe, Laham, Landauer, & Kintsch, 1998 ; Wolfe, Schreiner, Rehder, Laham, Foltz, Kintsch, & Landauer, 1998).

Based on a statistical analysis of a large amount of text (typically thousands to millions of words), LSA derives a high-dimensional semantic space which permits comparisons of the semantic similarity of words and passages. Words and passages are represented as vectors in the space and their similarity is measured by the cosine of their contained angle in the semantic space. The LSA measured similarities have shown to closely mimic human judgments of meaning similarity and human performance based on such similarity in a variety of ways. For example, after training on about 2,000 pages of English text, it scored as well as average test-takers on the synonym portion of TOEFL—the ETS Test of English as a Foreign Language (Landauer & Dumais, 1997). After training on an introductory psychology textbook, it achieved passing scores on two different multiple-choice exams used in introductory psychology courses (Landauer, Foltz & Laham, in preparation). This similarity comparison made by LSA is the basis for performing automated scoring of essays through comparing the similarity of meaning between essays.

Automated scoring with LSA

While much of the emphasis on evaluating written work has examined mechanical features, such as grammar, spelling and punctuation, there are other factors involved in writing a good essay. For example at an abstract level, one can distinguish three properties of a student essay that are desirable to assess; the correctness and completeness of its contained conceptual knowledge, the soundness of arguments that it presents in discussion of issues, and the fluency, elegance, and comprehensibility of its writing. Evaluation of superficial mechanical and syntactical features is fairly easy to separate from the other factors, but the rest—content, argument, comprehensibility, and aesthetic style—are likely to be difficult to pull apart because each influences the other, if only because each depends on the choice of words.

Although previous attempts to develop computational techniques for scoring essays have focused primarily on measures of style (e.g., Page, 1994), indices of content have remained secondary, indirect and superficial. In contrast to earlier approaches, LSA methods concentrate on the conceptual content, the knowledge conveyed in an essay, rather than its style, or even its syntax or argument structure.

To assess the quality of essays, LSA is first trained on domain-representative text. Examples of domain-representative texts include textbooks, articles or samples of writing that a student would encounter during learning in that domain. Based on this training, LSA derives a high-dimensional semantic representation of the information contained in the domain. Words can be represented as vectors in this semantic space, with the semantic similarity between words characterized by the cosine of the angle between the vectors for those words. Similarly, student essays can be characterized by LSA vectors based on the combination of all their words. These vectors can then be compared with vectors for essays or for texts of known content quality. The angle between the two vectors represents the degree to which the two essays discuss information in a similar manner. For example, an ungraded essay can be compared to essays that have already been graded. If the angle between two essays is small then those essays should be similar in content. Thus, the semantic or conceptual content of two essays can be compared and a score derived based on their similarity. Note that two essays can be considered to have almost identical content, even if they contain few or none of the same words, as long as they convey the same meaning. This feature of the comparison illustrates that LSA is doing more than just keyword matching; it is matching based on the conceptual content in the essays.

Evaluating the effectiveness of automated scoring

Based on comparing conceptual content, several techniques have been developed for assessing essays. Details of these techniques have been published elsewhere and summaries of particular results will be provided below. One technique is to compare essays to ones that have been previously graded. A score for each essay is determined by comparing the essay against all previously graded essays. The scores from some number of those pre-graded essays (typically 10) that are most similar to the essay are weighted by their cosine similarity to the essay and used determine the score for the essay This technique provides a "holistic" score measuring the overall similarity of content (Laham, 1997; Landauer, Laham, Rehder, & Schreiner, 1997). The score is holistic in that the grade for an essay is determined based on how well the overall meaning of an essay matches that of previously graded essays.

The holistic method has been tested on a large number of essays over a diverse set of topics. The essays have ranged in grade level, including middle school, high school, college and college graduate level essays. The topics have included essays from classes in introductory psychology, biology, history, as well as essays from standardized tests, such as analyses of arguments, and analyses of issues from the Educational Testing Service (ETS) Graduate Management Achievement Test (GMAT). For each of these sets of essays, LSA is first trained on a set of texts related to the domain. Then the content of each of the new essays is compared against the content of a set of pre-graded essays on the topic. In each case, the essays were also graded by at least two course instructors or expert graders, for example professional readers from Educational Testing Service, or other national testing organizations. Across the datasets, LSA's performance produced reliabilities within the range of their comparable inter-rater reliabilities and within the generally accepted guidelines for minimum reliability coefficients. For example, in a set of 188 essays written on the functioning of the human heart, the average correlation between two graders was 0.83, while the correlation of LSA's scores with the graders was 0.80. A summary of the performance of LSA's scoring compared to the grader-to-grader performance across a diverse set of 1205 essays on 12 topics is shown in Figure 1. The results indicate that LSA's reliability in scoring is equivalent to that of human graders.

In a more recent study, the holistic method was used to grade two additional questions from the GMAT standardized test. The performance was compared against two trained ETS graders. For one question, a set of 695 opinion essays, the correlation between the two graders was 0.86, while LSA's correlation with the ETS grades was also 0.86. For the second question, a set of 668 analysis of argument essays, the correlation between the two graders was 0.87, while LSA's correlation to the ETS grades was 0.86. Thus, LSA was able to perform at the same reliability levels as the trained ETS graders.

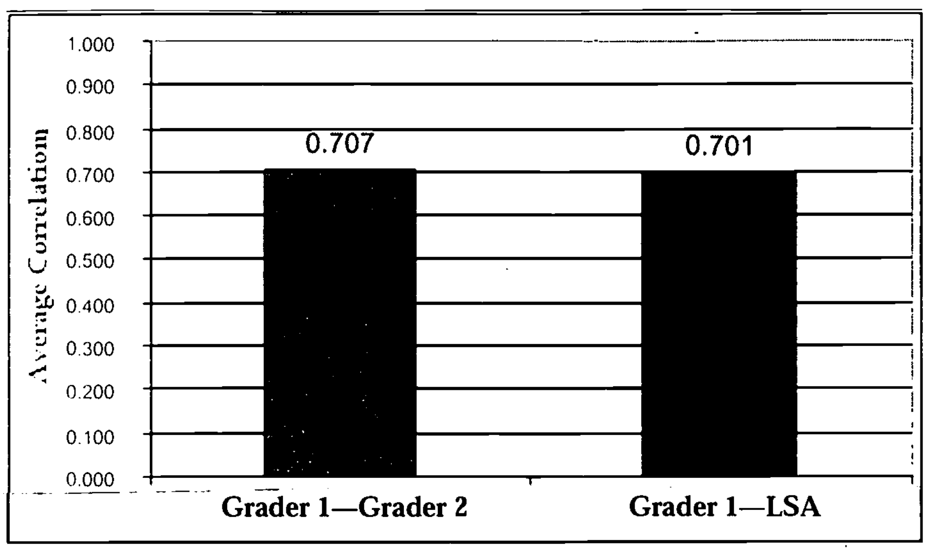

Figure 1. Summary of reliability results (N = 1205 Essays on 12 Diverse Topics)

While the holistic technique relies on comparing essays against a set of pre-graded essays, other techniques have been developed that also effectively characterize the quality of essays. A second technique is to compare essays to an ideal essay, or "gold standard" (Wolfe et al., 1998). In this case, a teacher can write his or her ideal essay and all student essays are then judged based on how close they are to the teacher's essay. In two final techniques, essays can be compared to portions of the original text, or compared to sub-components of texts or essays (Foltz, 1996; Foltz, Britt & Perfetti, 1996). In this final componential approach, individual sentences from a student's essay can be compared against a set of predetermined subtopics. This permits the determination of whether an essay sufficiently covers those subtopics. LSA derived scores based on the degree of coverage of subtopics in essays show equivalent correlations with human graders as graders correlate with each other

Anomalous essay checking

While it is important to verify the effectiveness of computer-based essay grading, it is also important that such a grader be able to determine if it can not grade an essay reliably. Thus, a number of additional techniques have been developed that can detect "anomalous" essays. If an essay is sufficiently different from the essays for which it has been trained, the computer can flag it for human evaluation. We currently flag ones that are highly creative, off topic, or violate standard formats or structures for essays. In addition, the computer can determine whether any essay is too similar to other essays or to the textbook. The program is thus able to detect different levels of plagiarism. If an essay is detected as being anomalous for any reason, the essay can be automatically forwarded to the instructor for additional evaluation.

Experiences in the classroom: grading and feedback

Over the past two years, the Intelligent Essay Assessor has been used in a course in Psycholinguistics at New Mexico State University. Designed as a web-based application, it permits students to submit essays on a particular topic from their web browsers. Within about 20 seconds, students receive feedback with an estimated grade for their essay and a set of questions and statements of additional subtopics that are missing from their essays. Students can revise their essays immediately and resubmit. A demonstration is available at: http://psych.nmsu.edu/essay

To create this system, LSA was trained on portion (four chapters) of the psycholinguistics textbook used in the class. The holistic grading method was used to provide an overall grade for any essay. In this method, each essay was compared against 40 essays from previous years that had been graded by three different graders. To verify the effectiveness of this approach for providing accurate grades, the average correlation among the three human graders was 0.73 while the average correlation of LSA's holistic grade to the individual graders was 0.80. To provide feedback about missing information in each essay, individual sentences in each essay were compared against sentences that corresponded to subtopics of the essay topic. If no sentence was found that matched a subtopic then the student received feedback about the fact that their essay did not properly cover that subtopic.

Students were permitted to use the system independently to write their essay and were encouraged to revise their essays and resubmit them to the computer as many times as they wanted until they were satisfied with their grades. The average grade for the students' first essays was 85 (out of 100). By the last revision, the average grade was 92. Students' essays improved from revision to revision, with the improvements in scores ranging from 0 to 33 points over an average of 3 revisions. An additional trial is underway with a similar system in a Boulder Colorado middle school in which students summarize texts on sources of energy. Preliminary results indicate that two-thirds of the students were able to improve their summaries based on the IEA's feedback.

In both the undergraduate and middle school trials, students and teachers have enjoyed and valued using the system. A survey of usability and preferences for/against the system in the psycholinguistics course showed that 98 percent of the students indicated that they would definitely or probably use such a system if it were available for their other classes. Overall, the results show that the IEA is successful at helping students improve the quality of their essays through providing immediate and accurate feedback.

Implications of computer-based essay grading for education

There exist a variety of applications within education to which the IEA can be applied. At a minimal level, the IEA can be used as a consistency checker, in which the teacher grades the essays and then the IEA re-grades the essays and indicates discrepancies between the two grades. Because the IEA is not influenced by fatigue, deadlines, or biases, it can provide a consistent and objective view of the quality of the essays. The IEA can further be used in large scale standardized testing or large classes, by either providing consistency checks or serving as an automatic grader.

At a more interactive level, the IEA can be used to help students improve their writing through assessing and commenting on their essays. By providing instantaneous feedback about the quality of their essays, as well as indications of information missing from their essays, students can use the IEA as a tool to practice writing content-based essays. Due to a lack of sufficient teachers and aides in many large section courses, writing assignments and essay exams have often been replaced by multiple choice questions. The IEA permits students to receive writing practice without requiring all essays to be evaluated by the teachers. Because the IEA's evaluations are immediate, students can receive feedback and make multiple revisions over the course of one session. This overall approach is consistent with the goals of the "Writing across the Curriculum" approach by allowing the introduction of more writing assignments in courses outside of English or the humanities. Thus, the IEA can serve to improve learning through writing.

Finally, the IEA can be integrated with other software tools for education. In most software for distance education, tools for administering writing assignments are often neglected in favor of tools for creating and grading multiple choice exams. The IEA permits writing to be a more central focus. For example, in web-based training systems, the IEA can be incorporated as an additional module which would permit teachers to add writing assignments for their web courses. Essays can be evaluated on a secure server and scores can be returned directly either to the students or to the teachers along with the essays. Textbook supplements can similarly use the IEA for automated study guides. At the end of chapters, students can be asked to write essay questions addressing topics covered in the chapter. Based on an analysis of their essays, the software can suggest sections of the textbook that the students needs to review before they take their exams.

Conclusions

To summarize the process of grading with the IEA, the IEA is first trained on some domain representative text such as a textbook, samples of writings, or even a large number (300 or more) essays on a topic. Second, the IEA is provided with one or more pre-graded essays on the topic to be graded. Once these pieces of information are processed, the IEA is able to provide accurate characterizations of the quality of essays on the same topic. Domain representative texts are easily available in electronic form and essays can now be easily converted or directly entered by students in electronic form. Thus, it is highly feasible to develop automated essay graders for a large number of topics across many domains. Although the IEA requires a large amount of computer processing power, it can be run from a centralized server, allowing students to access it from any web browser.

The Intelligent Essay Assessor presents a novel technique for assessing the quality of content knowledge expressed in essays. It permits the automatic scoring of short essays that would be used in any kind of content-based courses. Based on evaluations of the IEA over a wide range of essay topics and levels, the IEA proves as reliable at evaluating essay quality as human graders. Its scores are also highly consistent and objective. While the IEA is not designed for assessing creative writing, it can detect whether an essay is sufficiently different that it should be graded by the instructor. The IEA can be applied for both distance education and for training in the classroom. In both cases it may be used for assessing students content knowledge as well as providing feedback to students to help improve their learning. Overall, the IEA permits increasing the amount of writing assignments without overly increasing the grading load on the teacher. Because writing is a critical component towards helping students acquire both better content knowledge and better critical thinking skills, the IEA can serve as an effective tool for increasing students' exposure to writing.

Visualizing Navigation in Educational WWW Hypertext by Introducing Partial Order and Hierarchy

Ossi Nykänen
Digital Media Institute / Hypermedia Laboratory
Tampere University of Technology
Finland
ossi.nykanen@cc.tut.fi

Abstract: Building a visual navigation aid system for WWW-based hypertext is difficult due to the implicitly structured nature of associative hypertext. The task can be made significantly easier by identifying and explicitly stating the latent hierarchical and pre-set reading order of hypertext and by reducing the number of relations presented. A simple formalism and a method of constructing a visual graph-based navigation tutoring system for WWW is presented. The work is demonstrated in practice by briefly introducing a visual navigation system prototype, the Navtutor applet, that can be used with existing Web learning materials with little extra work.

Introduction

Today World Wide Web (WWW) is filled with information presented in hypertext format. Thanks to the global identification and retrieval mechanisms of documents and the standard hypertext markup language (HTML), WWW potentially offers means to create well-structured global hypermedia. From the authors' point of view, however, to date the syntax of HTML has not really supported nor been used for, e.g., explicitly defining document categories or linking semantics needed for creating navigation tools visualizing logical contents. This has led developers to search for different types of *ad hoc* solutions for structuring and coding their WWW material.

Structured hypertext is typically captured in a shape of different-looking WWW sites with (picture-based) link lists and overview diagrams similar to the navigation structures proposed in the early 90's (Nielsen, 1994). Systematic use of dynamic, visual graph-based navigation methods has been little, most of the educational navigation systems rely on text-based linking and image map techniques (Turau, 1998). Due to the enormous amount of references, visualizing complex associative linking is generally considered impractical as a navigation metaphor. Educational material is still at largely presented using the book or desktop metaphors which, in effect, provide little basis building structural mental models of the fundamentally non-linear (structured) hypertext. The straightforward use of book metaphor with linked keywords, for instance, adds little to using well-written conventional paper materials. Similarly, target-oriented learning is very difficult if it is simply based on flat associative hypertext. A dynamic, map-based navigation metaphor should help users building concise mental models to construct knowledge of the structure and relations of the hypertext at hand (Preece *et al*, 1994).

Motivation for us finding general solutions for providing students visual graph-based navigation tools arose when developing Web-based learning material for undergraduate-level mathematics (see, e.g., (Pohjolainen *et al*, 1996), (Nykänen & Pohjolainen, 1998) and (Luodeslampi *et al*, 1998)). Simply producing hierarchical, associatively linked WWW pages seemed to fail to achieve the latent potential of using computers to present structured learning material. We felt that in order to make the chosen structure "live", we should effectively promote the use of the fundamentally non-linear yet logical structure of hypertext. We hoped to achieve this by providing students maps to visualize the "expert's" view on the structure of mathematics (within a given course). There already exists case studies and tools of visualizing navigation and searching in (educational) contents (see, e.g., (Chavero *et al*, 1998) and (Akoulchina & Ganascia, 1997)) but our goal was to investigate and design a general WWW-based navigation system to be used in parallel with our prototype of a Web-based open learning environment in the future (Nykänen & Ala-Rantala, 1997).

During the process of structuring our learning material, we learned two major lessons. First, more detailed structure to supporting navigation we hoped to construct, more problems we encountered in practice. The "goodness" of a definition and granularity of hypertext depends on many things since structuring material can be based on a number of perspectives. Historical, purely logical or pedagogical approaches do not necessarily yield to the same structure. The second and the more important observation was, however, that after a guideline general enough for structuring material sufficient for our purposes was found, it was rapidly applicable to number of other subjects, besides mathematics, as well. To us the solution was to identify and clarify the implicit structure of (educational) hypertext. The main idea is to recognize and explicitly state the logical reading order of "key" pages and to cluster them into hierarchical groups.

After finding a simple syntactical way to clarify the essential structure of hypertext, we designed and implemented a simple prototype navigation tutoring system to exploit and test our ideas. Our software prototype, the Navtutor applet, was designed to function in parallel with existing Web clients.

The purpose of this paper is to motivate and present the idea of constructing a visual graph-based navigation tutoring system for WWW, and to suggest means to do this both in theory and in practice.

Introducing Partial Order and Hierarchy to Hypertext

Creating a good general navigation system for HTML-based hypertext is very difficult. The basic linking method using associative linking is extremely general by definition and introduces little structure to base a navigation support system on. In order to construct a general device for aiding navigation, an abstracted reference structure of hypertext is needed. In this chapter we will briefly describe the syntax of a *hierarchical prerequisite graph* (HPG) that is used to model the hierarchical and ordered structure of a given hypertext.

Implicit Structure of (Educational) Hypertext

The obvious method for developing syntax for practical visualizing of hypertext is to try to reduce the number of relations presented. Motivation for this is found from the contemporary WWW hypertext. In practice most of the educational WWW sites implicitly add two types of additional semantic relations to hypertext

1) by grouping individual pages of hypertext into hierarchical clusters, and
2) by introducing a partial reading order between different pages of hypertext.

For example, most WWW sites provide users a front page that divides information into various sections each of which consisting of a number or WWW which include information which is sensible only when read in some appropriate order. Obviously other types of link semantics are used also, including references, notes, examples, etc.

The important notice is that the seemingly arbitrary linking does not essentially reflect the logical structure of the WWW site. From the "definition" of hypertext we know that the structure of hypertext actually predefines the conceptual limits of the associative structure of hypertext by providing users links to follow. Similarly, logical reading order precedes the associative structure of hypertext. This implies that the associative structure of hypertext itself must have a backbone, *a core structure*, which lays down the basic pre-set logical structure of the hypertext. After all, if this wasn't true, the hypertext would actually consist of some sort of an associative database of completely independent records of the same level without any specific reading order(s).

Thus the associative structure of hypertext is associative only from the viewpoint of the users' limited dynamic control, not from the viewpoint of the core structure of hypertext itself. The core structure of hypertext is essentially hierarchical and pre-set. It turns out, that since our goal is to introduce a navigation aid for (educational) hypermedia, this observation is very useful to us.

Hierarchical Prerequisite Graph

Technically HPG is a semantic network consisting of vertices corresponding to each of the pages of hypertext and directed labeled edges defining two types of relations between vertices. These relations, *partial order* and *hierarchical inclusion*, are selected according to the desired logical structure of hypertext and do not necessarily include all the associative relations between the pages of original hypertext nor consist only of them. Figure 1 presents an example of a HPG consisting of nine vertices and fifteen edges or relations between vertices.

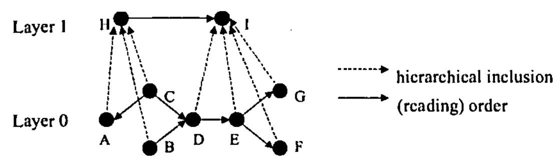

Figure 1: An example of a hierarchical prerequisite graph.

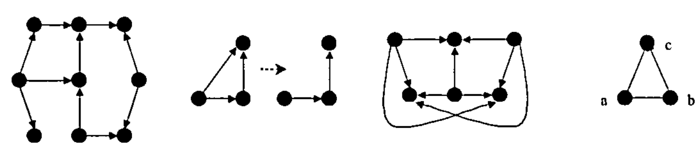
The example should be interpreted as following: the referred hypertext consists of two logical groups of pages, H and I (vertex sets {A,B,C} and {D,E,F,G} on layer 0) that have a definite prerequisite order in which pages are assumed to be read. The pages H and I are also assigned a prerequisite order on layer 1. In practice the example could model, e.g., a hypertext of two "sections" with introductions, each of consisting of number of "topics".

The structure of an HPG is straightforwardly generalized from this by adding more hierarchical layers (for instance in the previous example by further grouping H and I to some group J on layer 2). Relations of HPG are constrained as following: vertices on each layer form a directed acyclic graph (not necessarily connected) according to the order relations. Each vertex on a layer i is connected to exactly one vertex on layer i+1 or to nothing ("top layer") according to the hierarchical inclusion relations. In addition, each layer includes only the minimum number of edges needed to present the order relations which are assumed to be transitive. If the prerequisite structure is consistent, the direction of associative reference links should typically be against the direction of prerequisite links (order relations). Similarly references to concepts of higher or lower levels should refer to different layers (hierarchical relations) of the HPG.

Construction of Hierarchical Prerequisite Graphs

From the formal point of view a HPG can be described as a collection of directed acylic graphs $G=(G_0, G_1, ..., G_i, .. ,G_N)$ where each G_i corresponds to the *prerequisite graph* at layer i (see figure 1). Each graph G_i consists of a set of vertices $V(G_i)$, $V(G) = V(G_0) \cup V(G_1) \cup .. .\cup V(G_N)$, a set of edges $E(G_i)$, $E(G) = E(G_0) \cup E(G_1) \cup ... \cup E(G_N)$, and a set of hierarchical references $H(G_i) \subset V(G_{i+1})$ to layer i+1. For G_N, $H(G_N)=\emptyset$ because the vertices on layer N have no hierarchical parents. Note that an arbitrary G_i is not assumed to be connected. This implies that it may consist of several components; an arbitrary vertex $a \in V(G_i)$ may not be accessible from vertex $b \in V(G_i)$.

Prerequisite graph G_i is simple, i.e., it includes no parallel arcs nor loops. It also agreed that prerequisite semantics define no directed cycles. From the definition of a HPG it also directly follows that for each G_i no vertex is both the start- and endpoint of a directed walk. Graph G_i needs not necessarily to be a rooted tree, however, since it may include more than one root vertices. Figure 2a presents an example of a simple prerequisite graph.



(a) (b) (c) (d)

Figure 2: The structure of a prerequisite graph, an idea of a method for reducing redundant semantic information, non-planar $K_{3,3}$, and clique T_3.

Constructing prerequisite graphs based on a given directed acyclic graph is easy. The prerequisite (order) relation is transitive, which provides a straightforward method of removing semantically redundant edges (see figure 2b). Edges are removed if and only if the accessibility of vertices does not change.

Unfortunately, from the viewpoint of visual presentation of (even small portions of) prerequisite graphs, the given prerequisite graph G_i is not necessarily planar (like the example in the figure 2a), that is, it's sometimes impossible to draw an (isomorphic) 2D presentation of the graph with no crossing edges. Figure 2c demonstrates this with a counter-example of a directed graph $K_{3,3}$. The prerequisite graph has, however, some nice properties that can help parsing clear visual presentations of the graph. For example, it follows from the definition that a prerequisite graph does not include the (directed) clique T_3 (see figure 2d) as a sub-graph. This motivates finding appealing local isomorphic representations of the prerequisite graph.

Formulating Visualizations

Our goal is to provide a visual navigation aid for navigating hypertext that can be modeled using some appropriate HPG. For simplicity, we choose to visualize the given HPG as one layer at a time, by dynamically parsing a *visualization graph* S of a subgraph of the G_i selected.

The main idea to visualize the structure and context of the prerequisite graph is to use *direction metaphor*, our intuitive notion of physical direction, to encode the semantic information. The portion of the G_i to be visualized is drawn on a (bound) 2D surface with the selected vertex in the middle. Adjacent vertices are "grown" in north and south directions, according to the prerequisite relations in G_i. Figure 3a presents an example of a such visualization.

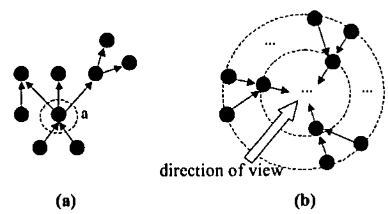


Figure 3: Example of visualizing a subgraph of G_i (selected location vertex a is marked with a dashed circle) and illustration of the direction metaphor

In the example above, the semantic interpretation of the order relation is clear. Vertices prerequisite (and close) to the selected vertex a are positioned south and vertices accessed from a north from a. Because S includes no cliques T_3, crossing edges (if any) will be appear in S only from two vertices away from a given vertex.

Direction and location metaphors try to provide the idea of direction and context for the user by dynamically generating a sequence of visualization graphs during the navigation. Each time a new location vertex is selected, each visualization "points" to the "center" of the given prerequisite graph (see figure 3b). During the navigation, the view "rotates" around the "center" according to the prerequisite relations. The visualization graph also naturally provides graphical encoding for "closeness" by including only vertices "close" to the selected vertex (in the sense of the explicit prerequisite relations).

However, in order to provide user a intuitive method for navigating, further remarks are needed. Merely creating a balanced 2D presentation of G_i would probably just confuse the user: navigation process is typically a sequence of selecting adjacent location vertices that should be visualized in the navigation process as moving to a certain (abstract) direction. Presenting user a sequence of rapidly-changing visualizations will not help developing a mental (structural) model of the relations of the graph because by doing so the visualization would change dramatically during each navigation step. Navigation systems ought not to create a set of independent balanced graphs but to process an animated sequence of dynamic graphs instead.

In practice this suggests that the visualization should be parsed dynamically according to the user's location and navigation history at the hypertext. Formally this is done by defining a *visualization function* v_P which, according to the user's current location in the hypertext and some parameters P, fixes a subgraph of G_i to be visualized as a visualization graph $S=v_P(a)$. When user navigates in the hypertext, visiting nodes a_1, a_2, ...a_j, ..., a_M, that make up the *total navigation history*, the process generates *a sequence of visualization graphs* S_1, S_2, ..., S_j, ..., S_M to be show to the user. Now each S_j is a graphical presentation of selected subgraph of some G_i with fixed relative vertex positions, color coding etc. set in P. Typically S_j would, e.g., include (provide a one-to-one mapping) only the vertices $b_k \in G_i$ such that the distance from b_k to a_j is less than some fixed value, positioned to a plane with descriptive labels, according to some balanced graph drawing algorithm satisfying the idea presented in the figure 3a. Note that the vertices of different visualization graphs need not to belong to the same layer.

Each transition is then visualized by using in-between animation frames from one visualization graph to another. Plane transitions along the "partial order" edges are visualized by moving and transforming S_j to S_{j+1} by moving, hiding and showing appropriate vertices. Vertical transitions along the "hierarchical inclusion" edges are visualized by conventional zoom in and out metaphors.

This scheme can be further developed by making additions to the visualization process. We connect the last step of the total navigation history to the visualization function v_P by exploiting the latest visualization graph S_{j-1} (j>1) which makes it possible to locally optimize the sequence of visualization graphs in order to keep the sequence of visualization graphs as smooth as possible during navigation. This way the user has two fundamentally alternative options for visualizing the navigation process:

1) the user can choose each $S_j=v_P(a_i)$ to be first globally optimized and then presented by using animated in-between frames from S_{j-1} (if possible, that is, $j>1$), or
2) the user can choose each $S_j=v'_P(a_i,S_{j-1})$ to be locally optimized to match S_{j-1} as closely as possible (if possible, that is, $j>1$) and then presented by using animated in-between frames from S_{j-1}.

The two options introduce two different ways of navigating. The former navigation method is *transition invariant* always producing the same visualization $S_j=v_P(a)$ no matter the path the user took to get to a. The latter navigation method, however, is *transition variant*. In this case, the path the user takes to get to the vertex a may cause visualization $S_j=v'_P(a_i,S_{j-1})$ to look different, according to the previous vertex a_{j-1} in the total navigation history. Note that both types of visualizations should be isomorphic to each other; the essential difference between different S's produced is the calculated vertex positions on a plane.

The decision between transition invariant and variant navigation modes is a trade-off between smooth in-between animation and global appearance of visualization graphs. The former provides user intuitive navigation sequences, but can sometimes confuse the user by introducing different layouts for visualizations depending on the navigation history. The latter, on the other hand, forces the visualizations always to look similar, but can sometimes make the in-between transitions to look complicated.

Demonstration: Navtutor Applet

To test the idea of exploiting order and hierarchy information in WWW sites, a prototype navigation support system, Navtutor, was written and tested with our existing WWW-based learning material (see figure 4). Test material consists of our experimental learning material of elementary matrix algebra (in Finnish).

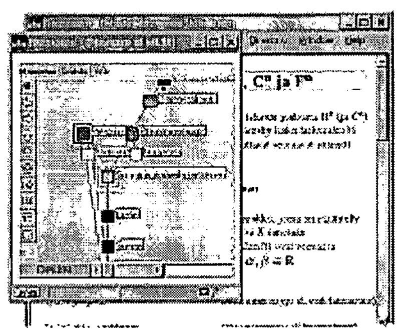

Figure 4: Navtutor window on top of a Netscape browser window.

The basic idea is to describe a educational WWW site in the terms of a HPG description file providing structural data for the Navtutor applet. For demonstration purposes we designed a small "learning structure" for the introduction of a matrix algebra course by defining the prerequisite and hierarchical order in which we thought different concepts should be studied.

The basic navigation is carried out with a standard Web browser. Browser process provides user the basic navigation functionality essentially by fetching and presenting HTML-encoded documents from the WWW, based on the browser's graphical user interface. When stumbled across a WWW site including appropriate Navtutor structural information, the browser process loads and initializes the Navtutor applet and provides it information about the browser windowing system references (in order to display pages at request and notify events) and instructs what hypertext HPG description to use.

The graphical user interface of the Navtutor applet consists of two parts: map view and control toolbars. The map view presents a dynamic visualization of the selected portion of the HPG describing the core structure of the hypertext (see figure 3a). When user selects a vertex, the map view smoothly animates to the selected vertex according to direction metaphor (see figure 3b). In each navigation step the visualization is dynamically parsed to reflect the contextual state of the users "location" in the HPG model. Vertical navigation from HPG layer to another is visualized by zooming in or out from the selected vertex.

In addition to the basic navigation functionality, Navtutor provides also basic methods for more structural navigation by using explicit *navigation modes*. Three modes of navigation are supported: *explore* *mode*, *local mode*, and *target mode*. In the explore mode, the visualization graph is constructed from all of the vertices (pages) "close" to the selected node by using simple breadth-first search. In the local mode, only vertices within the current cluster (hierarchical group) are displayed, and finally, in the target mode, only vertices on a path to a previously selected *target vertex*, are displayed. In practice this means that users are able to limit the information present in the map view to meet their needs when using different navigation (and learning) strategies.

Discussion

Finding a all-round format for describing educational hypertext structure is very difficult. Based on our experiences, designing structures for educational material is hard, but producing (or converting) learning material within the given format can be equally hard, or even harder. As a rule of thumb it would seem, that instead of re-writing existing WWW material, using relatively light additional information structures may turn out to be a "good enough" solution in practice. So far our experiences from Navtutor strongly support this point of view. With very little structuring, most of our educational WWW material should benefit from the single navigation support system implemented.

Of course, one should never apply new methods blindly. At this time of development, we are gathering experiences, based of which our ideas are later revised and systems further developed. One very interesting aspect of the Navtutor software is the interface with our software platform prototype of an open learning environment (see (Nykänen & Ala-Rantala, 1997)).

Finally it should be heavily emphasized that we are not implying that existing navigation systems should be replaced with Navtutor-like applications and thrown away, but rather suggest a parallel and a general alternative for effective and context-based navigation. Empirical research supports the view that map-based navigation aids are at their best when used in together with, e.g., book metaphors, not alone (Leader & Klein, 1996).

Experience Improving WWW based Courseware through Usability Studies

Vincent P. Wade, Dept. of Computer Science, Trinity College, Dublin 2, Ireland
Mary Lyng, Dept of P & Q, Waterford Institute of Technology, Waterford, Ireland

Abstract: The World Wide Web (WWW) has been heralded as a significant opportunity to deliver successful tele-educational courseware and learning experiences. The central tenant of the WWW being that everyone (educationalists) can become a publisher of educational material. However, although possessing technical or educational skills, WWW user interface design, usability and good pedagogical layout of WWW based content, are skills which are frequently weak amongst many of this community. This paper researches and proposes an easy to use 'usability' criteria and questionnaire, which facilitates the evaluation of educational WWW courseware. The paper describes the implementation of a WWW based server system for the questionnaire. The paper also describes how the system was trialled on an already proven WWW courseware system and still provided indications where improvements could be performed. The paper concludes with an assessment of the benefits of iteratively utilising such a system to improve WWW courseware.

1 Introduction

The last three years has seen a rapid increase in the use of WWW based educational tools, courseware and environments (Wade et al. 98). The applicability of WWW as a medium for educational experiences has been well documented as it's ubiquity of presence, it rendering capability for graphics, text, animation, video and audio, and it's potential for interactivity (both between participant and educational content as well as participant to participant) (Maurer 97), (Turoff 95). However, it is also well accepted that educational technology, over the last thirty years, has failed to achieve the revolutions that were initially forecast (Bates 95). There have been many reasons proposed for the failures of various educational systems, the two most widely reported being (i) the lack of pedagogical support within the educational systems (ii) the difficulties experienced by learners in using such systems. This paper addresses this second most common cause of failure. Usability as defined by the International Standards Organisation (ISO) is the effectiveness, efficiency and satisfaction with which specified users can achieve specified goals in particular environments. The paper focuses on evaluating the users' satisfaction of working with WWW educational systems and highlights the important issues when addressing the design of WWW courseware.

2 Usability for Educational Systems

This section identifies the users' satisfaction requirements / user interface requirements for WWW courseware which are derived from the pedagogic theory imperatives.

2.1 The Learning Environment

A learning environment must provide the learner with four key requirements (Duchastel 97). These are information, interactivity, structure, and communication. The learning environment must also implement key interface design concepts (Jones et al. 95). These key concepts can be loosely categorised by research facilities, presentation details, integration across various media, appropriate use of tools, and help facilities.

2.2 Layout requirements of a Learning Interface

When planning the layout of the interface, many factors will require consideration.

Engaging the User: The main consideration when deciding upon the layout of a screen is to assist learners in focusing their attention on the key aspects of instructional material while maintaining interest in the overall lesson content and activities. The intent is to draw attention to the relevant lesson content by adopting conventions that draw proportionately more attention to the selected information than the remainder of the lesson (Hannafin et al. 89).

HCI Principles: The interface of the instructional material must adhere to the HCI principles that have emerged through the years (Macauley 95). These are: the interface must be natural for the user to use; the interface must provide user support; the interface must be consistent; the interface must be non redundant; and the interface must be flexible.

There are also two categories of design rule: standards which are high in authority and limited in application, and guidelines which are lower in authority and more general in application.

Interface Structure: The structure of the interface must have at least two areas for the instructional material (Brooks 93). These are a navigation area and a presentation area.

Layout of the instructional material: It is not sufficient to place the information from a previous source on the Web and expect it to work as a presentation (Brooks 93). Many suggestions have been specified over the years about the layout of instructional material. The following suggestions could be considered. The provision of a menu in some guise, which is available at all times (Rambally et al. 87). The location of material of the same type should not vary from one screen to the next (Rovick 85). There should be consistency in the use of backgrounds, fonts, and colour (Brooks 93). Any special effects used and icons should be tested with users first to check their appropriateness (McFarland 95). The document should not be too large for two reasons. It will take longer to download, and not all learners may like scrolling (Nielsen 97). Scrolling can leave a learner disoriented (Berners-Lee 95).

2.3 Presentation of Instructional material components

The components that are required to produce instructional material can be a combination of text, graphics, video images, etc. so many factors require considering. Another issue of concern here is the inclusion of colour.

Textual Material: When deciding on how to present text, there are guidelines that need to be adhered to (Rambally et al. 87). These include: placing key information such as urgent messages and instructions in a prominent and consistent location; standardising the terminology used; establishing prompt-string conventions (captions) in order to provide a systematic, predictable visual correlation between prompts and their corresponding data input fields; and positioning captions in a natural and consistent physical relationship to the corresponding data fields. It has also been suggested that screens are easier to read if the text is structured in natural eye sequences, such as from top to bottom (Hazen 85).

When writing textual educational material, guidelines on how to lay it out should be adhered to (Bailey et al. 91). These include: distinctly separating paragraphs on the screen to promote cohesive groupings; left justifying the body text and ensuring that it is right ragged; ensuring that hyphens are not be used to break words at the end of a line; using sentence case rather than upper case as it speeds up the reading process; using UPPER CASE to draw attention; and using one font consistently, with point size greater than 12.

Non textual material: Interactive graphing, windowing, and animation differentiate the computer as a medium from most other media (Hazen 85). Tables can be used to graphically represent complex relationships (Schlegal 96). Graphics should be used when they contribute to the understanding of the text (McFarland 95). However, considerations of the size of the graphic should be made, as it should be able to fit into the graphical browser's window in order to provide the learner with the whole picture, and note also that a large graphic can take a long time to download. Slow graphics can become tiresome and/or interrupt lesson flow (Hazen 85). The key point with non textual material is not to let available equipment or technology determine the presentation of the instructional material (Brooks 93).

Colour: Colour has some uses when presenting material (Rambally et al. 87). These include: linking logically related data; differentiating between required and optional data; highlighting errors; separating various screen areas such as prompts and commands; emphasising key points; and communicating the overall structure.
When applying colour, the following guidelines have been recommended (Macauley 95): use colour coding consistent with user expectations; similar colours should denote similar meaning; avoid use of extreme colour pairs to avoid frequent refocusing and visual fatigue; adults may need higher brightness levels to distinguish colours; colour blind users must be considered, as they may not be able to distinguish some colour

combinations; use background colours in large blocks; group related elements by using a common background colour; use bright colour for emphasis and weaker colours for background areas; and brightness and saturation draw attention. In relation to WBI, there have been recommendations made (Jones et al. 97). These include: selectable areas should be clearly identified by a royal blue colour; interactivity is apparent by changes in the cursor as the cursor is moved to a hot spot; when a selection is made, the HTML standard is to immediately change to a dark red selection; and to indicate progress made, accessed links become a light red colour. In contrast, another view held on the colour of visited links is that they should signal the fact they are "exhausted" by being a darker colour than non-visited links (Kirsanov 97).

3 Evaluation Criteria and Implementing WWW based usability evaluation system.

The objective of the evaluation was to evaluate whether the present learning environment's user interface is conducive to learning, i.e. measure the users' satisfaction in terms of the their experience with the system. In order to carry out this evaluation, goals had to be specified but goals on their own are not measurable. Therefore from these goals, objectives were derived (Mandel 97). The concentration of the evaluation was on subjective measures rather on performance measures because it was required to address particular aspects of the system performance and thus required focusing on certain tasks (Whitefield et al. 91). The goals and resultant criteria reflected the performance levels required from the system from a learner viewpoint. These included the aesthetic appeal, ease of reading, ease of navigation, and the effort required reading through the material and navigating through the system. The goals are shown at HREF 1, and resulting evaluation criteria are shown at HREF 2.

The goals and resulting criteria produced a long list of items, which it was felt would be too detailed for a questionnaire. It was decided to structure the questionnaire into five sections, one for each of the HCI principles. The items from the evaluation criteria were examined and placed into one of the sections. Not all evaluation criteria were explicitly included in the questionnaire as some items were combined with other items or were deemed to have been redundant. The questionnaire is shown at HREF 3.

The questionnaire was placed on the Web so that the user could fill it in during the evaluation. Therefore, the design of the questionnaire involved producing five web pages, one for each HCI principle. There was a statement given for each question, and the User was asked to respond to each statement by choosing a point from 1 to 5 which determines whether they Strongly disagreed, Disagreed, Strongly agreed, Agreed or were Neutral with the statement. It was decided to read in the questions dynamically when the HTML file was being published rather than specify the questions in the HTML file. This ensures that any changes that are to be made to the questions only require a change to the text file of questions rather than a change to the HTML file. In order to provide this facility, an HTML file is not adequate, so a Common Gateway Interface (CGI) program written in PERL was used. The program opens and reads the entire contents of the text file of questionnaire statements and places them into an array. For each element of the array, it is displayed as a statement followed by the five radio buttons representing the five possible responses. When all elements of the array have been displayed, the User is then requested to Send or Clear the data. The second PERL program elicits the responses and stores them in text file separated by tabs. This procedure is described in Fig 1.

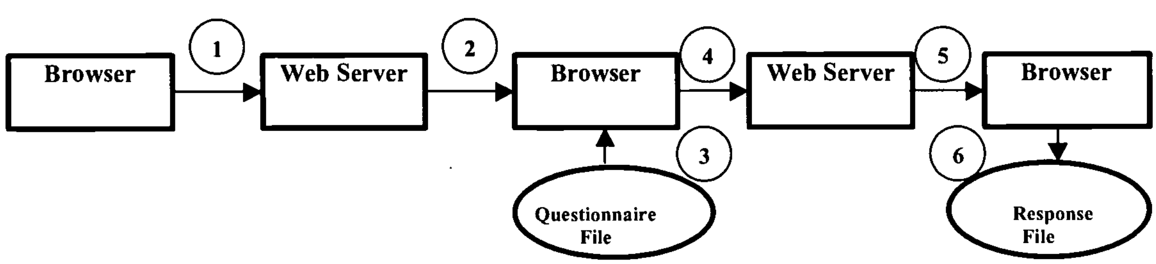

Figure 1: WWW questionnaire procedure

1. Browser requests CGI program from web server.
2. Web server recognises CGI request and initiates the CGI program.

3. CGI program reads questions from questionnaire file and displays the questions, and requests responses from the participant.
4. CGI program requests access to another CGI Program for data processing.
5. Web server recognises CGI request and initiates the CGI program.
6. CGI program transfers responses to Data file.

When the questionnaires are filled in, programs that can be run on the Web make an assessment of the responses. In order to produce any feedback/results from the evaluation, five programs were designed to produce five Web pages of results. In each program, the file of responses for the respective HCI principle is opened, read and processed. Processing of the file involves accumulating the number of times a response value (1 .. 5) was chosen by a participant in the evaluation. Then for each question pertaining to this HCI principle, the question is displayed and the accumulated values are displayed as percentages in a table. When all questions have been displayed, the overall accumulated values for each possible response is displayed. Also, an overall assessment is made which determines if 70% or more Agree or Strongly Agree with all statements then it is very satisfactory. If 50% or more Agree or Strongly Agree with all statements then it is satisfactory. If 70% or more Disagree or Strongly Disagree with all statements then it is very unsatisfactory. If 50% or more Disagree or Strongly Disagree with all statements then it is unsatisfactory. This procedure is described in Fig 2.

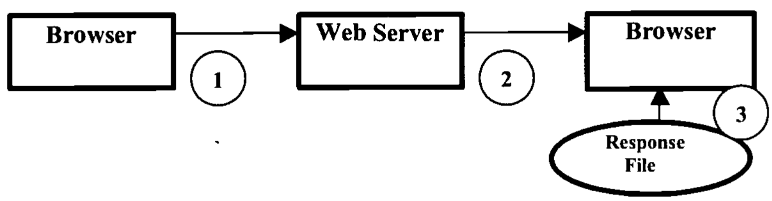

Figure 2: WWW evaluation results procedure

1. Browser requests CGI program from web server.
2. Web server recognises CGI request and initiates the CGI program.
3. CGI program reads responses from Response file, processes the responses and produces an assessment of results.

4 Case Study – Improving RDBMS Courseware

There is a WWW based self learning course, which has been designed and implemented successfully in Trinity College, Dublin. A subsection of the course was chosen and used to test and validate this evaluation. The modules chosen were the modules pertaining to the Select statement, which is one of SQL's data manipulation statements.

The participants for the evaluation were fourteen fourth year students on the BSc in Commercial Software Development, in Waterford Institute of Technology.

The feedback on the users' satisfaction of the RDBMS course produced some positive and negative comments.

Naturalness: The questions that provided negative feedback were concerned with colour and scrolling. Examples of some of the points made with regards to colour included that highlighted words and link items have the same colour, which is confusing; and that words are highlighted using different colours. Scrolling is a facility that cannot be avoided on the Web, however too much of it can irritate users. The participants felt that the material was too far indented and so the user had to scroll across the screen to read the material as well as scroll downwards. Another point made was that spelling errors exist and some words are joined together in the instructional material. Positive comments were also given which included that the instructional material provided was very clear to read and understand, and the instructions identified and described each icon sufficiently.

User Support: The first question about error messages provided some negative feedback but one of reasons for this was there were no errors incurred by the participants. The other area where there was some negative feedback was on the examples used. There needs to be more examples and exercises provided for the

User. Other points noted were that the instructions provided were clear and well presented, and that the Bookmarking and Notetaking facility was a good idea, but when a bookmark is recorded, some feedback should be provided to let the User know that it is actually recorded. Another interesting point made was that a forward button should be included as well as a back button. The main reason for this comment was that the participants felt that when you got to the end of a module, it was not easy to know where to go next. Some used the back button to go to the Roadmap menu; others used the Main menu button and then proceeded to the Roadmap menu.

Consistency: The responses were positive except for the question on error messages. The same reason as above can be concluded for this response. The main comments provided were that there was an inconsistent use of sentence case, italics, spacing and colour.

Non Redundancy : The responses were positive. However, the main concern of the participants was the repetition of the menu throughout the instructional material as well as providing it in the left frame. It was felt that the menu provided in the left frame would be sufficient on its own.

Flexibility: Again the responses were positive. The comments provided included the reference to proceeding from a module to the roadmap, which it was felt was not very clear.

4.1 Changes indicated and implemented

After reviewing the questionnaire results and interviewing the participants, the evaluation identified some changes to improve the users' satisfaction of the courseware, which were implemented. These included the following:

1. The colour of links, active links and visited links were changed to differentiate them from text. A consistent colour was chosen used to highlight words, which is also different than the link colours used. The background colour of the left frame is different to the colour of the right frame so it provides a contrast.
2. Scrolling across the screen was eliminated.
3. More examples and dynamic exercises are included.
4. Spelling errors were eliminated. Consistency in the use of italics, sentence case, and spacing is ensured.
5. The provision of menu items with the instructional material was eliminated, as it is confusing for the User.
6. In the left frame, a link back to the Roadmap menu is provided to allow the User to choose their next module.
7. The left frame was reduced in size to increase the size of instructional material presentation frame.
8. A check is made to ensure that when the learner attempts to bookmark a page that it is not bookmarked already, and when a page is successfully bookmarked a message is displayed informing the learner. The information displayed in the Bookmark window informs the learner of the Module and Page titles stored.
9. A status bar message is displayed each time the mouse moves over a link to clarify for the learner what the link is for.

A second trial using the modified courseware was conducted recently and early analysis of the results indicate an improvement of all five sections.

5 Conclusions and Summary

The use of such an evaluation system is a vital component in the delivery of successful WWW courseware, and may be as important as courseware authoring tools and communication tools. The criteria and questionnaire provide an explicit, easy to use method of evaluating users' satisfaction for educational systems.

The WWW based implementation provides three important features:

1. It greatly reduces the overhead in processing the evaluation.
2. It provides semi automatic assessment of the study results. E.g. if 70% or more Agree or Strongly Agree with all statements for a particular HCI principle then the adherence to that principle is very satisfactory.
3. It promotes and encourages learner feedback and evaluation as it greatly reduces their effort in completing the questionnaire. The system also provides its learners with the results of their efforts.

The overall user satisfaction was enhanced.

Abstract: A continuous improvement team is a group of people who work together on the same project and are committed to continuous improvement of their work processes. In order to support continuous improvement teams in a virtual corporation, a comprehensive system is needed to support integrated collaborative work and collaborative learning processes. In this paper, the SCOPE system is presented, which provides support for the definition, modification and execution of session-based collaborative processes for continuous improvement teams.

1 Introduction

A virtual corporation is a temporary network of independent operating units such as creative designers, manufacturers, suppliers, customers, and other experts in marketing and finance linked by interactive multimedia networks to share skills, production facilities, resources, to decrease costs and to increase access to each other's markets. In virtual corporations, the definition of a task is continually changing, and its product is a so-called virtual product that adapts in real time to the customer's changing needs [Davidow & Malone 93]. Excelling in a dynamic business environment requires more common understanding and agreement among team members than individuals' expertise and experience provides. In the life cycle of a virtual corporation, cross-functional teams need to continually expand their capacity to improve their work, processes, relationships and environment. Such a team, called a continuous improvement team (CIT), is a group of people who work together on the same project or who come together to solve a common problem, and are committed to continuously improve the processes on which they depend to get their work done [Hutchings et al. 93].

In order to support CITs in virtual corporations, a comprehensive environment is needed to overcome the barriers of physical separation and to support integrated collaborative work and collaborative learning processes. Existing learning support systems are designed according to one of three metaphors: session, process and place. Systems that rely on a sole metaphor provide insufficient support for continuous improvement processes [Hutchings et al. 93]. In addition, most collaborative learning support systems are separate from collaborative work support environments. In this paper, we present our approach to support an integrated collaborative learning and collaborative work process. The prototype system, session-based collaborative process-centered environment (SCOPE) integrates process support technologies into a collaborative support environment. A *session* is defined as follows: in a period of time activities are performed by multiple actors with different roles in a shared information space to achieve an elementary goal. A *session-based collaborative process* (SCP) denotes a process that consists of a set of coordinated sessions [Miao & Haake 98a]. SCOPE provides support for the specification, modification, and execution of session-based, integrated collaborative work and collaborative learning.

The remainder of this paper is organized as follows: In the next section, characteristics of continuous improvement processes and major requirements are identified. Section 3 presents related work. Section 4 describes how SCOPE supports continuous improvement processes. Finally, we present our conclusions and future work.

2 Requirements for the Support of Continuous Improvement Teams

In order to identify the characteristics of continuous improvement processes and the major requirements of the support system, a scenario in a virtual corporation is developed, which is based on a real scenario presented in

[Hutchings et al. 93].

2.1 A Scenario

Seven members of a team in a virtual software corporation are responsible for designing a software product. The team consists of software engineers and requirement analysts who are geographically distributed. The team wishes to learn how to perform continuous improvement. The team and software process consultants jointly determine what is needed to improve the team's capabilities. Then, training consultants design a training course for the team. They create and customize necessary materials. Such a course takes into account the team's total work situation, team's present job tasks and their social environment. The training course consists of a series of sessions. The sessions take place in working hours and are conducted in the same environment as collaborative work. In the first lecture session, the team learns sound decision-making strategies and principles. After the lecture, the team practices separately in two groups (function design group and interface design group) and sets up the strategies for how they would like to make group decisions. Then, they switch to their collaborative work processes and follow the strategies to make decision for their design. During work processes, the data collected and practice results achieved will be transferred into collaborative learning processes as parts of materials of the following sessions. In the succeeding learning session, the teacher guides the team to analyze and evaluate the currently used decision-making strategies. After that, the team will learn and try to improve their decision-making strategies and use the improved strategies to get their work done. That is, collaborative learning and collaborative work in virtual corporations form a process in which the team as a whole continuously reflects upon events, gains knowledge about job tasks and work processes, improves product quality and work processes, and discovers their learning needs in the workplace - continuously.

2.2 Characteristics of Continuous Improvement Processes

Based on an analysis of the scenario described in the previous sub-section and a reference of design principles presented in [Hutchings et al. 93], the characteristics of continuous improvement processes can be identified.

- *Modularity for flexibility*: Information and materials used and produced in learning activities or working activities are documented as modules. They are constructed as typed and self-contained units of information -- artifacts. Modularized, structured artifact models are beneficial for the team's common understanding and communication.
- *Team-based collaborative learning and collaborative work activities*: Interventions are delivered in team sessions, and emphasize collaboration and shared responsibility. Sessions are designed for team members to gain new skills and knowledge together. In addition, team members collaboratively perform job tasks also in sessions. Team members may adapt or improve collaboration strategies to conduct sessions according to their learning.
- *Phased delivery*: Interventions are phased in their delivery over time. Intervals between learning sessions provide opportunities for the team to apply learning in work. The data collected and test results achieved in working sessions will be transferred to the succeeding learning session. Team members have to schedule an integrated collaborative learning and collaborative work plan to help communication, understanding, and coordination among team members. There are dependencies among sessions, such as temporal sequencing, as well as among participants and artifacts.
- *"Just-in-time" effort*: Learning and its application occur almost simultaneously. In a virtual corporation, the external environment and customer demands are dynamic and changeable. In turn, team's business goals and needs related to a team's mission should be adapted to the changing environment.

2.3 Major Requirements

In order to design an integrated computer-supported environment, according to the analysis of characteristics, the major requirements are identified as follows:

(R1) *Support for dealing with artifacts*: The artifacts are modularized and structured, and should be adjusted and tailored dynamically according to the team's progress.

(R2) *Support for session activities*: The system should support team members with different roles to perform collaborative activities in a shared information space. In addition, the system should provide facilities for team members to define and modify collaboration protocols, a computational description of a collaboration policy or co-decision strategy.

(R3) *Support for definition and execution of SCPs*: A SCP model is a computational description of a project plan or a curriculum. The system should enable team members to define process models. It is desirable that process models can be used to coordinate group work and learning activities automatically.
(R4) *Support for dynamical and collaborative change of process models by teams*: The system should support team members to modify SCPs on the fly. Instead of a single-user process modeling tool, the modeling tool should be able to be used jointly by teams.

3 Related Work

In this section, we investigate existing systems in two aspects, system development and integrated collaborative work and collaborative learning support environments.

3.1 Development Approaches of Learning Systems

Most existing learning systems or environments are based on one of three metaphors: *session, process and place.*

Session-based systems support team members to collaborate within single sessions or meetings. They provide an environment for sharing information and performing collaborative activities at the same time. These systems, such as Microsoft NetMeeting [http://www.microsoft.com/netmeeting], provide support for dealing with artifacts (R1) and for session activities (R2), but have no support for the remaining requirements.

Process-based systems provide support for structuring stages according to the content structure in a overall learning process. Learners can progress at different speeds in the learning process. These systems focus on individual learning. Obviously, these systems have no sufficient facilities to support session activities (R2).

Place-based systems provide virtual places to hold meetings or to perform activities asynchronously. All of the artifacts produced in meetings or individually are left in the places to be reused in the succeeding activities. However, the sequencing of activities performed in places and the transferring of artifacts has to be done manually. A lot of place-based learning systems have been developed recently, such as Virtual Places [http://www.virtualplaces.com], CSILE [Scardamalia et al. 94], VITAL [Pfister et al. 98]. These systems also provide support for dealing with artifacts (R1) and for session activities (R2). However, they can not meet the requirements related to support for SCPs (R3 and R4).

Mixed approach: Some information sharing systems (session-based systems and place-based systems) add means for embedding the group's overall work process into a general collaborative learning environment. For example, CLARE [Wan & Johnson 94] is developed based on a model of three-phase collaborative learning processes. The process can be regarded as a SCP to some extent. However, it offers no support for dynamical and collaborative change of SCPs (R4), because it supports a fixed, domain-specific process model.

3.2 Integrated Collaborative Work and Collaborative Learning Support Environment

Most collaborative learning support systems can not support learning in work settings. They normally support open-enrollment styles of training which focus on improving individuals. Learners may successfully gain knowledge in courses and then they will apply their learning at different places. Such courses rarely take into account learners' present job tasks and their social environment. Some systems can be used to support both collaborative learning and collaborative work separately, because they only provide general communication support. However, to the best of the authors' knowledge, no system can support learners to define and modify a computational description of their work processes as learning practices, and to coordinate their collaborative work by using the computational description of their work processes. No system can support automatically transferring the data collected and the practice results achieved in work processes into learning processes as part of learning materials.

4 The SCOPE System

In this section we present our approach to support CITs. This approach can be characterized by

- using hypermedia to represent artifacts in a flexible way,
- providing shared hypermedia workspaces for sessions,
- using hypertext structures to specify and modify organizational structure, collaboration protocols, and SCPs,

- facilitating the execution of SCPs and collaboration protocols.

This approach has been tested in the SCOPE system [Miao & Haake 98a]. Next, we discuss how to support the specification of SCPs. Then support for continuous improvement processes at run time is presented.

4.1 Specification of SCPs

In this sub-section, we present our approach to specify SCPs. We discuss how to specify sessions first and then present how to specify a SCP.

4.1.1 Specification of a Session

In SCOPE, a session is created for a CIT to learn or perform job tasks collaboratively. In a session, the common information space is potentially accessible by all team members involved in this session. Team members can perform operations synchronously or asynchronously to construct shared artifacts together, and to perform actions to change the state of collaboration. It is important to notice that a CIT consists of members who may have different privileges and responsibilities to deal with artifacts and to coordinate their efforts. To define a new session, team members are required to set values of attributes for the session. Without being exhaustive these attributes include: session name, session type, session creator, session description, collaborative mode, artifact models, collaboration protocol, mapping from organizational to functional roles, scheduled start and end times, etc. Some attributes used in specifying a session are defined by using specific tools: organizational structure definition tool, artifact definition tool, and collaboration protocol definition tool.

Definition of members and teams: Members and teams are defined by using the organizational structure definition tool. With this tool, a member, an organizational-role or an organizational-unit is represented as a node with a type, a unique name and a set of attributes to describe properties. The typed links are represented as direct arrows between suitable nodes. A description of an organizational structure is represented as a Directed Acyclic Graph.

Definition of the artifact model: An artifact model is defined in terms of task-specific typed hypertext objects (nodes and links) together with operations on them to support a certain activity [Streitz et al. 89][Wang & Haake 97]. Artifacts are organized into these node and link types according to their structure, function, and behavior properties. An artifact may be hierarchically structured, and the structure of aggregated artifacts can be defined in an artifact definition tool, which is a part of the COWFISH system [Wang & Haake 97].

Definition of collaboration protocols: A collaboration protocol is described like a state-transition diagram where a node may contain a sub diagram describing the state represented by that node in more detail. A state node in a diagram represents a state within the collaboration protocol. A link in a diagram represents an event. The occurrence of an event causes a transition between the two states connected by the link. Each state of the collaboration is associated with a set of behavior rules. A behavior rule specifies which roles are permitted to perform which operation on what type of artifacts. A link is associated with a behavior rule or a logical expression. The detailed description of collaboration protocols is presented in [Miao & Haake 98b].

4.1.2 Specification of SCPs

Every SCP is represented by its description, which is called a process model. This description specifies all sessions embedded in the process and the relationships among these sessions. SCOPE provides a visual process model language for process definition. A process model is described as a hypertext document consisting of nodes that are connected via links. A process can be decomposed into sub-processes. The components and the structure of a (sub)process are described inside the (sub)process node. Session nodes, the elements of processes, are specified in the way described above.

The process models are specified in SCOPE by using the process definition tool (see Fig. 1). The tool shows a window title bar listing the name of the overall process model and the tool type. Below that is a list of icons showing the current users of the tool, followed by a button bar with generic functions for editing, navigating hypertext documents, and specific functions for editing process models, followed by a palette of components of the visual process model language (left side) and the content pane (right side) displaying a process model. In Fig. 1, an example of a process model is presented, which describes the collaborative learning process explained in the scenario (see Chapter 2.1). This part of process model consists of a session for collaboratively customizing materials, a lecture, two practice sessions, and a workshop. They are connected by temporal links, such as "finish-trigger" and "AND-split", and by artifact links with named artifact buffers. It is important to note that the artifact input/output buffers are used to exchange artifacts across (sub)processes. For example, in practice sessions, decision-making strategies are defined as collaboration protocols that will be transferred to the collaborative work process. The defined collaboration protocols will be initiated in groups' collaborative work sessions, and guide and control group decision-making processes for design. The feedback from the collaborative work process will be imported into the workshop via an artifact-input node. After a process model is defined, it can be stored in a process model base and can be instantiated and reused. Next, we will discuss the run-time features of SCOPE.

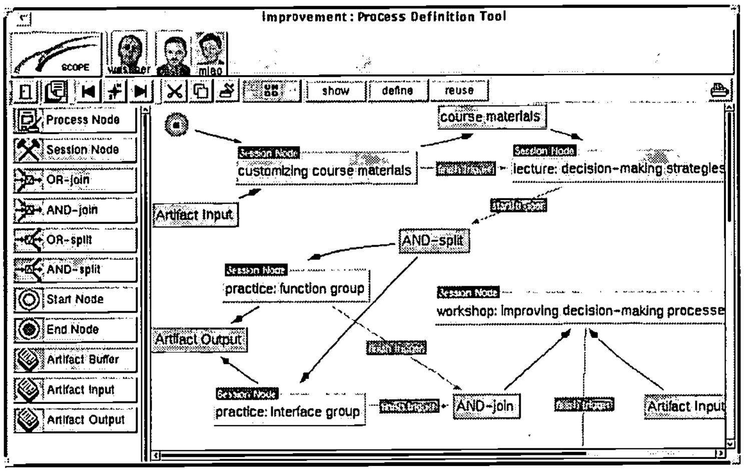

Figure 1: An example of a process model

4.2 Support for Continuous Improvement Processes at Run Time

Process execution is concerned with the enactment of a process following the previously defined process model. Now, we discuss process execution from the users' perspective.

Team members can select a pre-defined process model from the process model base as their initial process model. If no suitable process model exists, they can define a new one. When they start to execute the process model, an instance of this process model is created. This process instance will progress according to its process model.

Support for execution of session activities: Each team member has a personal information panel. In this panel, information is listed about processes and sessions in which he/she should be involved. He/she can join a session by selecting it from the session list. When he/she joins a session, the top-level of the shared information space of the session is displayed in the session browser and he/she can browse through the artifacts following the recorded dependencies. In this browser there is a palette that lists the artifact types, which are allowed to be created in the current state according to the rules defined in the collaboration protocol of this session. The shared artifacts can be viewed and edited simultaneously by team members working in the session depending on their access rights. When a user performs an operation on an artifact, the system will check whether this member has the access right to execute the operation according to rules defined at this state of collaboration. If the check is successful, the change will be propagated to all sites. To maintain consistency for concurrent changes at different sites, a fully replicated concurrency control mechanism is provided by COAST [Schuckmann et al. 96]. Transitions from one state of collaboration to another may be carried out by team members who have the right to perform actions. Allowed actions are also listed in a palette in the session browser. Each session has an autonomous agent that monitors the status of collaboration periodically by evaluating the transition conditions. If a condition is met, the system changes the state according to the collaboration protocol.

Support for execution of SCPs: Changes of the state of collaboration in one session may result in changes of the state of related sessions according to the process model. In the case of two sessions connected by a "finish-trigger" link, once the source session is finished, the state of the destination session will change. In SCPs, artifacts will be automatically transferred between sessions according to the process model.

Support for dynamical change of SCPs: Even when a process instance has already been created, parts of the process model can be modified. That is, the values of attributes of the related sessions can be modified and the model of a sub-process can be altered.

5 Conclusions and Future Work

In this paper, we described the major requirements for supporting CITs in virtual corporations. Based on the concept of session-based collaborative processes, we developed a modeling methodology and an environment, SCOPE. The system can support definition and execution of session-based collaborative processes. This is realized by maintaining shared hypermedia workspaces with the aid of data level control mechanisms, such as access control and fully replicated concurrency control, and user level control mechanisms, such as collaboration protocols and SCP models. In addition, the SCOPE system provides a high level of flexibility for team members to adapt artifact models and to modify process models at run time. By using the facilities provided in the SCOPE, members of continuous improvement teams can define and execute integrated collaborative work and collaborative learning processes. They can improve their work processes through applying their learning and identify learning issues at work to fit the changes inside and outside of virtual corporations.

SCOPE is a prototype system of our ongoing research project and is currently being tested in our group. Most of our work to date has been focused on demonstrating the feasibility of implementing and using the system. We will develop more collaborative tools required by software development and total quality management. We will further test and evaluate the usefulness of the system in more real-world settings.

Designing a Distance Curriculum to Harness the Potential of Asynchronous Computer Conferencing: an Example from a Masters Programme in Continuing Professional Development (CPD).

Gillian Jordan, School of Health, University of Greenwich, London, UK
G.G.Jordan@Greenwich.ac.uk

Malcolm Ryan, School of P.C.E.T., University of Greenwich, London UK
M.Ryan@Greenwich.ac.uk

Abstract: There are many reasons why an adult may choose to undertake a distance programme and in recent years there has been considerable interest in off-campus learning and an increase in the availability of such opportunities. The University of Greenwich (UK), a long time provider of distance learning opportunities, is offering, through its School of Health in the Faculty of Human Sciences, an MSc. in Continuing Professional Development (CPD) for health professionals. Computer Mediated Communication (CMC) is at the core of the curriculum process in which off-line, asynchronous conferencing ensures participants have opportunities for critical evaluation and reflection before formulating and sending considered responses. This paper considers elements of the curriculum design in order to reveal the extent to which the embedding of communications technology has provided a unique teaching and learning experience. It will demonstrate how a multi-disciplinary group of health professionals are working collaboratively at a distance, through computer conferencing, to enhance both individual and professional development.

Introduction

The use of communications technology clearly has enormous potential in a number of educational areas; some of these are already being realised and many others are in the process of development. Communications technologies embrace an extremely wide range of resources, from simple e-mail to sophisticated multi-media applications. In this paper we discuss the use of relatively low-level technology, asynchronous computer conferencing, as a delivery and support tool for health professionals participating in a MSc. in Continuing Professional Development (CPD).

The Concept of CMC

Computer Mediated Communication (CMC) is not a new concept nor does it need to use state of the art technology. Whilst some research has been undertaken into the medium, much still remains to be discovered and understood about its impact on teaching and learning. Until this knowledge is available it will not be possible to exploit the technology fully. At the University of Greenwich we run several courses using CMC and are now in a position to begin an evaluation of its potential. In particular we can begin an analysis of its effectiveness as a curriculum tool in the delivery of the MSc. CPD (Health).

We define CMC as, *"the use of computers, telephone lines and specialist software to facilitate interaction between students and tutors irrespective of geographical location or time zone"* (Ryan, 1997). It is this interaction which we consider one of the key aspects of CMC because, *"where opportunities exist for interaction in learning situations at a distance, it helps learners to make leaps in their understanding that are unlikely to occur when working in isolation"*. (Owusu-Sekyere & Branch, 1996)

Synchronous Versus Asynchronous Systems

There is no doubt that modern, synchronous communications systems such as Video Conferencing and Internet Relay Chat are both attractive and powerful but produce technology-driven environments which are in a constant state of flux. They also require participants to be available at the same time, albeit in different places, in order to interact and collaborate. Such 'real-time' technologies are time-location dependent and whilst their appeal can not be denied there is evidence to suggest that asynchronous technologies are better able to facilitate the reflective models (Mason & Kaye, 1990) embraced by many CPD programmes.

Computer conferencing which uses asynchronous media is time-location independent and provides greater flexibility and student autonomy (Harasim, 1989). This asynchronicity facilitates a spirit of co-operative enquiry (Heron, 1985) leading to active dialogue through which participants share ideas and information (Gundry, 1992). The resultant peer-to-peer collaborative interactions have been shown to increase learner satisfaction (Kaye 1992) and involvement in the development of theories of professionalism and professional practice (Richardson, 1993). Our experience indicates that this asynchronous CMC environment provides real opportunities for collaborative and multi-disciplinary discussion, brainstorming, problem solving and networking, which we hope to demonstrate in this paper.

Many adult distance learners engaged in CPD programmes are known to study at home and accessing the Internet would normally require them to subscribe to a commercial service. To benefit fully from time-location independence, students should not be required to work synchronously and in the current financial climate they should not have to bear the additional costs incurred by working on-line or paying subscriptions to Internet providers.

The Context of the MSc. in CPD

The context of this development is a MSc. in CPD for health professionals. Although presently being delivered to health professionals it is the conviction of the course developers that the model itself is generic and has the potential to be transferred to other professions and groups.

Distance learning had to be the mode of delivery for this MSc. so that the potential participants, identified through market research and enquiry, would be able to access the appropriate learning opportunities they needed. It was clear from the start of the development that the curriculum model selected would have to offer much more than that available on a traditional paper-based distance learning programme where even the production of learning materials can take many months or years. This would be inappropriate for a topic as dynamic and diverse as CPD.

The development team holds a strong philosophy that professionals, such as the ones for whom the programme was developed, have much to offer their fellow students from their previous learning and experience. Learning processes selected for the programme would have to acknowledge and make the most of this knowledge, *"the richest resources for learning lie in the adult learners themselves"*. (Knowles, 1990). Thus it was decided to utilise a computer-mediated communication technology which would facilitate the realisation of the potential each student had as a learning resource.

Everyone in a multi-professional group of students would be, at different times, colleague, peer, learner and expert and it was considered that significant deep-level learning could result from the discussion, conversation, debate and argument between these groups which CMC would facilitate. For the students to see themselves, as important and crucial resources would not only ensure that the content and context of every unit would be relevant for each and every participant but also that the group process that would be fostered would result in an atmosphere of collaboration and co-operation. We think we are achieving this; - one student recently wrote in a conference area *"...may we continue to bounce our ideas off each other like light and reflect images in a mirror or window in our world in our efforts to illuminate the subject from all angles"*.

The Concept of CPD

The issue of continuing professional development is of major importance in many professions, including the health professions where evidence of ongoing participation in continuing professional development (CPD) activities is likely to become a requirement for re-registration to practice. CPD is an umbrella term for a wide range of activities relating to professional competence, some practice or clinically based and occurring in the workplace and others more academically based and initiated and run in Higher Education Institutions (HEIs). Methods of assessing CPD activity are also diverse and it is clear that the evaluation of the relevance and quality of an individual's CPD is not an easy task. However, that CPD should occur is not in doubt as maintenance of professional competence is essential for the protection of the public. Grant (1994) suggests that professional knowledge has a half-life of five years and that obsolescence will occur if no new knowledge is assimilated and incorporated into practice within that time.

In the present climate of economic constraint, in the UK National Health Service in particular, it has become increasingly difficult in terms of both finance and study time for many health professionals to fulfil their CPD requirements. We are in a situation, in which health professionals must have evidence of CPD to maintain a licence to practice but at a time when they are finding it more and more difficult to participate in suitable CPD activity. It is in this context that the MSc. in Continuing Professional Development (Health) (Collaborative Learning through Reflective Practice and Computer Mediated Communication) was conceived and developed.

The programme is now in its third year and has three cohorts of students. They represent almost all the health professions and encompass a wide geographic spectrum including Austria, Canada, Cyprus, Malaysia, Malta, New Zealand, South Africa and the UK.

The Choice of a CMC System - Why Lotus Notes?

Having decided to use asynchronous, text based computer conferencing on the basis of its fitness for purpose (Laurillard, 1993) the software chosen was the groupware product Lotus Notes. Groupware is essentially any computer application that runs over a network, and/or is accessed by direct dial means, allowing the user group to increase their communication, collaboration, and co-ordination. Lotus Notes is currently the only software on the market that captures these processes in one product, with the potential for customisation.

The immediate advantages of Notes appeared to be its availability on multiple platforms in both server and client forms. It is an industry-standard package with a massive international user-base providing sophisticated E-mail and conferencing facilities. We felt it would appeal to novice users of communications technologies but with infinite possibilities for expansion and development. It was supplied with a number of templates that were customisable to enable the development of a range of databases to support conferencing and workflow applications. Unlike many of its competitors, Notes allows off-line working with replicas of conferences and mailboxes using a remote, direct dial facility with the option of networking and connectivity via TCP/IP.

It was perhaps this apparent ease of use, the attractiveness of the interface and the facility to work completely off-line that appealed most. In this paper it is not our intention to promote a particular brand of software but to examine the concept and impact of CMC on distance learning. What we have experienced whilst using our chosen product may be replicable with other software.

Unique Features of CMC Supported Learning

In developing a CMC system we began by trying to reproduce our experiences of classroom-based teaching but soon realised that computer conferencing impacts on the dynamics of the group and changes the nature of face-to-face (F2F) activities. Additionally, we discovered that communications technologies provide some unique opportunities for interaction which should be exploited (Anderson, 1996).

Ongoing evaluation has revealed that students appreciate the opportunity to be able to ask for and receive almost immediate support from tutors. They welcome the interactive and collaborative nature of the environment, get to know their peers and tutors as recognisable personalities despite the absence of non-verbal cues. They comment on feeling as if they are actually attending the institution (virtually) and make reference to being part of a community. This twenty four-hour access to the learning community and the automatic archiving of all discussion, a feature of the software, produces two highly valued resources. These two features alone establish a novel identity for CMC supported distance education in that neither aspect is normally available in traditional F2F or distance models of learning. (Ryan, 1997)

As indicated by the literature, we found the asynchronous and archived exchanges between participants aid the reflective process and students gain considerably from access to a team of staff who are able to provide different perspectives on issues and problems. Team-teaching, long since abandoned in f2f classrooms, becomes a financially viable method of delivery by CMC. This virtual environment appears to provide more opportunities for students to determine the pace, direction and focus of discussions, which results in a more learner-centred approach to the curriculum. Based upon what has been learnt we have now developed a customised Notes desktop with databases that combine together to give the impression of a virtual integrated learning environment (Ryan and Culwick, 1997). Our experience of using CMC has raised a number of questions and identified several issues for curriculum developers and learning technologists. Of significance is the undoubted impact that using CMC has on teaching and learning.

Impact on Learning and Teaching

The themes of the MSc. in CPD (Health) are collaborative learning, reflective practice, critical thinking and research. They are explored in each of the five units of the programme, which are followed sequentially. Each cohort of students stay together throughout the programme and Accreditation of Prior Learning (APL) is not used to provide exemptions from any part of the programme. Although this might indicate a less flexible approach, it is an essential element that supports our philosophy. The responsibilities inherent in being a member of an active group enhance the sharing of individual experiences and perspectives for the benefit of the group as a whole, *"...individual learning as part of a group process"* (Kaye, 1992). The flexibility arises from the asynchronous nature of the programme, giving the participants opportunities to connect to the system at any time of day or night from anywhere in the world, and being able to study off-line, without the pressures associated with on-line working.

Collaborative Learning

Professional development does not occur in isolation but through collaborative learning and working. Within a health profession environment it is essential that participants learn about each other's professions and are helped to develop inter-professional working practices. One student described how this approach was appropriate for her, *"I have always held near to my heart the potential that peer-to-peer collaboration has for individual and multi-professional CPD."*

The UK Government (1997) has clearly articulated its intention that in the modern National Health Service (NHS) a foundation for a changing health care system must be formulated in which the barriers between professions are removed. This allows collaboration with other agencies concerned with the health, social well being and economic development of the population to occur. As each profession strives to ensure that its practice is evidence-based, cost-effective and can be clearly shown to benefit the patients or clients it is important that professional boundaries are identified and clarified so that areas of overlap are redefined and restructured. In the multi-disciplinary, collaborative environment of the MSc. CPD (Health) the 'learning community' which is formed enables participants to explore their paradigms of practice as they share experiences and draw on communal knowledge. This was eloquently summarised by one student commenting on her impression of a computer conference, *"... discussion is available to the whole group - and we can build on each other's contributions in the conference area which provides opportunities for collaborative decision making through negotiation at all times."*

The multi-disciplinary approach enhances a deeper understanding of the theoretical and practical concepts in the context of the diverse social, economic and political health environments in which the participants work. From an educational perspective there is evidence that through collaboration significant and deep-level learning occurs. In the CMC environment discussion between peers, colleagues and experts is a major feature of the learning process. This discussion is archived and available for re-examination and reconsideration, and it is possible to see in the interactions how the participants are actively searching for the deeper meanings in the debates and arguments presented by their colleagues. Is this the beginning of virtual ethnography? Perhaps this is a question we will soon be able to set about answering.

Reflective Practice

Reflective practice, described by Thorpe (1993) as, *"...the key process in professional learning,"* is a fundamental concept within the programme. This is in line with current moves in all the health professions towards evidence-based health care that advocates reflection on practice to ensure that such practice does not become merely routine. That this is happening is borne out by a comment from one student, *"reflection in/on action since beginning the MSc. has influenced any tendency to be prescriptive..."* Reflective practice is a complex process of learning from experience and involves challenging the taken-for-granted assumptions, values and norms of practice. Participants work individually applying different models of reflection to their own practice and collaborate in the computer conferences to question the purposes of reflection and to examine the extent to which reflection can shape, improve or enhance professional practice. They achieve deeper understanding of whether or not reflection can lead to better practice and whether reflective practitioners are more effective in practice. Another student wrote, *"For me it was the collaborative/shared learning experiences which helped me to at least begin to unravel the reflective process at an academic level as distinct from what the majority of us would, I suspect, claim to have already been doing within our professional practice."*

Critical Thinking

The ability to think critically is fundamental to work at Masters level. Students need to be able to interpret and evaluate sources of information, not only text and research findings but also conversation, discussion and argument. Critical thinking is reasoning in which problems are formulated, assumptions are identified and challenged, alternatives are explored and facts and values that result in credible actions and beliefs are justified. In the computer conferences the students are encouraged to apply their critical reasoning skills with a positive and non-judgmental attitude. One student commented, *"... this critical thinking and analysing of findings is vital for healthcare professionals to enable us to stake out our own professional autonomy."*

Research

At the end of the Masters programme the students produce an individual piece of research relevant to their own practice. The evidence we are collecting suggests that their collaborative and reflective work in the conference areas enhances their acquisition of research skills and adds an extra dimension to their development as researchers. One student wrote, *"... I thought the bit on qualitative statistics and analysis was well-led and therefore it inspired more collaboration,"* which is not the usual sort of comment heard on a research methodology unit! This (lengthy) quote from another student encapsulates what we hope to achieve, *"... in the unusual nature of CMC classrooms, it is fascinating to watch the evolution of students' research ideas from first thoughts to the final version of the research project. It is unusual because, following a traditional degree pathway, students and tutors would not have intimate insight into the development of each of our research projects. In effect we are baring our souls for all to see and opening ourselves up to constructive criticism. The evolution and the shaping of our research ideas gives us, students and tutors, an extremely rich source of information: indeed this information is privileged, would students and tutors on other degree pathways have this opportunity to share such information? I doubt this very much."*

Conclusion

In this paper we have attempted to show how we have begun to harness some of the potential of communications technology to facilitate the continuing professional development of health professionals undertaking a Masters programme. We have demonstrated the use of relatively low-level technology and discussed the merits and advantages of this approach. We have not dwelt on the disadvantages. We are certainly not suggesting that there are no disadvantages, but our experience so far indicates that these are far outweighed by the advantages. We hope that we have been able to show the potential transferability of our chosen model to other professional groups and welcome the discussion this paper might initiate.

Bringing Asynchronous Learning Networks into the Mainstream at NVCC

John Sener
Extended Learning Institute
Northern Virginia Community College, USA
jsener@nv.cc.va.us

Abstract: Northern Virginia Community College (NVCC)'s Extended Learning Institute (ELI) is currently bringing online learning 'into the mainstream' at NVCC through a large-scale deployment of Web-based courses in key disciplines. This diffusion strategy includes developing online Associate in Science (AAS) degrees in high demand (Information Systems Technology, Business Management) or of special interest (Public Management), and also on-campus courses with ALN components at all five NVCC campuses. The project addresses Northern Virginia's needs for access to "anywhere, anytime" educational opportunities, particularly for information technology and public sector workers. Incorporating asynchronous learning networks (ALNs) into courses enables utilization of rich content resources and levels of interaction among learning participants comparable to classroom-based courses. The project thus far has enabled significant opportunities for innovative and effective Web course design, including use of several Web-based development and delivery tools, use of publisher-created content resources, affordable Web-based transmission of mathematical expressions, and cross-course content linkage.

Project Background and Significance

ELI as a Distance Education Provider

Northern Virginia Community College (NVCC) is the 2nd largest multi-campus community college in the United States and the largest educational institution in Virginia. NVCC currently (Fall 1998 semester) enrolls over 37,000 students. As NVCC's distance learning administrative unit, ELI is one of the nation's oldest, largest, and most successful distance education programs. Since 1975, ELI has enrolled over 160,000 students in its courses; ELI currently offers over 140 courses and enrolls over 10,000 students annually. ELI offers entire distance education degree programs in General Studies and Business Administration and has also developed the first and only Associate in Science (AS) in Engineering degree program available in the United States through home study distance education.

Since it primarily serves students who cannot or prefer not to attend regular classes on campus, ELI has relied largely on asynchronous, or time-independent, forms of distance education delivery such as print materials, computer conferencing, voice mail, and pre-recorded telecourses or other video programs. ELI students highly value self-paced, independent study because of its flexibility and convenience. However, most of ELI's learners live within 20 miles of one of NVCC's five campuses and can handle occasional campus visits for exams, laboratory exercises, or other course-related activities. Most ELI courses also offer continuous enrollment, enabling students to register on any day of the year.

Consistent with the community college mission to provide maximum access for learners, ELI has generally relied on proven, reliable, inexpensive, and easy-to-use technologies which minimize access barriers (Sener 1997a). Accordingly, ELI's entry into development of Web-based courses has been relatively recent, coinciding with a sufficiently large market penetration of home computers and Internet access.

The project's major activities address the following needs: the need for accessible, anywhere, anytime learning, for information technology workers, and for expanded education opportunities related to public sector employment in Northern Virginia. Different strategies are being used to address each of these needs based on their particular characteristics.

Need for Accessible, Anywhere, Anytime Learning

This project addresses the problem of providing accessible educational opportunities to the growing "new majority" of potential students who seek to further their education and attain degrees but have significant obstacles preventing them from attending traditionally-structured on-campus classes. Community college programs in the U.S. are increasingly attractive to adults of all educational attainment levels who wish to enhance their prospects for promotion, find new jobs, or even change careers. Community college students also often have other demands on their time such as work and family responsibilities, making it more difficult for them to attain a degree by attending regularly scheduled classes on campus. These factors help explain the increasing popularity of asynchronous learning networks (ALNs) and other forms of accessible, anywhere, anytime learning delivery systems. ALNs provide access to remote learning resources at the learner's convenience, not dependent on synchronous, real-time communication. This includes 'people resources' who participate in the learning process (e.g., faculty, tutors, peers, guest experts) and the wide variety of possible content resources (e.g., lectures on demand, libraries, computer simulations, collaborative work products, et al.). Assuming that learning follows from supporting access and interaction, ALNs increase opportunities for interaction and collaboration among learning participants (Mayadas 1994).

This project will result in the development of at least 40 courses which utilize ALN in a variety of formats, including entirely online, Web-based ALN courses, largely online courses with one or several face-to-face meetings, and on-campus courses with Web-based ALN components. Half of these courses will enable online offering of AAS degrees in Information Systems Technology (IST), Business Management, and Public Management; the remainder of the courses are being selected for development in a wide variety of disciplines within all major divisions at each of NVCC's five campuses, assuring a widespread diffusion of 'model' Web-based courses throughout the College. As the largest and most far-reaching such initiative at NVCC, this project is creating a critical mass of distance education and on-campus offerings which will establish Web-based ALN courses as a self-perpetuating norm at the College.

Need for Information Technology Workers

The AAS IST degree program is designed to address the critical shortage of information technology (IT) workers in Northern Virginia and the resulting high demand for IST courses at the College. The demand for workers in IT-related fields in the U.S. has grown at an unprecedented rate during the past decade, with recent estimates ranging as high as 346,000 unfilled IT jobs in the U.S. in 1998 (Information Technology Association of America 1999). High technology firms are a major component of the economy of the Northern Virginia region which comprises NVCC's service area. Northern Virginia now has the 2nd highest concentration of high technology industries in the U.S., ranking only behind Silicon Valley in California. Not surprisingly, the nationwide shortage of IT workers is particularly acute in Northern Virginia. According to recent estimates, almost 23,000 high tech jobs in the region are unfilled (Stough and Trice 1999) and 112,000 additional jobs will be available over the next five years (Ryan McGinn Samples Research, Inc. 1997).

The great demand in Northern Virginia for IT-related education and training opportunities is reflected in the demand for NVCC's IST courses. The IST program is designed for persons who need knowledge and skills in business computer information systems to enter or advance in the field, or for persons who wish to apply IST to their current fields. IST is one of the largest programs at the College with over 2,200 program-placed students. Accordingly, the IST and related courses are being designed to accommodate moderate to high enrollments, as this program is expected to produce at least 1000 course enrollments per semester when development is completed in Spring 2000.

Need for Education Opportunities Related to Public Sector Employment

The AAS degree program in Business Management, including the Public Management specialization, addresses the need for education and training opportunities relevant to public sector employment in Northern Virginia, with its high concentration of federal, county, and state government employees. Although federal government employment in the region has not grown in recent years, employment at the county and state levels has grown. There is a particular need for education and training for historically underserved populations such as public safety and support employees. These populations have been overlooked since most public administration programs of study in the U.S. focus on producing Bachelor's and Master's level graduates. However, community colleges are highly suitable institutions to provide opportunities for these populations to obtain a successful and rewarding education experience in the field of public administration (Banas and Emory 1998).

Although the Business Management degree program is well established, the Public Administration specialization is a new one with relatively low enrollments thus far. Accordingly, several strategies are being employed to increase program enrollments. These include designing all of the related program courses for nationwide availability; making versions of the courses available in a variety of formats, including online, compressed video, classroom, and on-site delivery; and developing customized certificate programs on demand for employers and other clients with a sufficient cadre of employees with specialized needs. When completed, the Public Administration specialization will be one of only two such Associate degree programs available in the U.S. through distance education.

Program Implementation Issues

Any large-scale program implementation is accompanied by a number of related issues. Some of the key program implementation issues in this project include ensuring accessibility and affordability, selecting software and technology, promoting learner interactivity, providing adequate support services, and ensuring effective program evaluation. Of particular interest here are those issues related to software and technology implementation.

Software and Technology Implementation

One important set of decisions which must be made in any large-scale implementation of Web-delivered courses is what software and technology to use. Such decisions include the following:

Off-the-shelf tools or make your own? This was an easy decision to make for this project: NVCC/ELI does not have the resources to make its own Web-based instructional development or delivery products, so commercial software products are being used.

Standardize on one product set or allow many? Although there are many advantages to requiring faculty to use one set of Web-based development and delivery products, ELI decided to support many such products for several reasons:

- In our opinion, none of the currently available commercial products are so superior to the others that they merited exclusive selection.
- Because of ELI's "faculty-centered" course development model which gives faculty primary responsibility for and 'psychological ownership' of course development and delivery, it makes more sense to give faculty more freedom to select the tools they will use. Given the current state of

evolution of Web-based products, any selected product set is likely to dissatisfy many faculty who do not like that particular set of features.

- Much faculty course development is "textbook-driven," i.e., faculty instructional design decisions determine which textbook is selected for the course, which in turn drives software and technology selection. This is because more and more textbook publishers are supplying Web-based software and content as an enhancement to their textbooks. Some publishers are creating their own Web content and/or integrating external Web sites into their textbook content available in CD-ROM format. Many other publishers are also bundling Web development and delivery tools with their textbooks, with or without accompanying content. For example, McGraw-Hill Learning Architecture uses TopClass™ (McGraw-Hill 1999), Course Technology uses CyberClass™ (Course Technology 1999), etc.

Consequently, ELI is currently using a variety Web-based development, delivery, and management software tools, including Web Course in a Box™, CyberClass, and Serf™. Other faculty are choosing to build their own Web pages using many of the currently available tools such as Netscape Composer™, Microsoft Front Page™, AOL Press℠, et al. ELI also uses Allaire Forums™ as a Web-based conferencing software tool for faculty who wish to integrate discussion forums into their courses.

Strategies for Innovative Web Course Design

A common criticism of many Web-based courses is that they are little more than "page-flipping" courses containing computer-based information with little use of the Web's special capabilities for enhancing instruction. This project is providing the opportunity to apply several effective strategies for innovative Web course design.

Rich Content

Incorporating ALNs into course design provides an effective framework for developing effective learning environments because it requires integration of substantial content resources as well as activities which promote interactivity among learning participants (Sener 1997b). The quantity of Web-based content of instructional value has rapidly increased, as have ways to organize and use this content effectively. For instance, the textbook to be used in ELI's Introduction to Speech Communication course includes hundreds of content-related Web sites which is directly referenced to textbook content by page number; the publisher's web site even uses software which "regenerates" dead Web links by automatically identifying a suitable alternate link when a referenced Web link becomes inactive (Allyn & Bacon 1999). Similarly, there are numerous non-commercial sites such as The Electronic Hallway (University of Washington 1999), which has a repository of case studies suitable for use in course assignments, as is done in ELI's public administration courses.

Promoting Interactivity among Learning Participants

In designing ELI's Web-based courses, the standard of desired level and quality of interactivity among learning participants is that the opportunities for interaction are equal to or greater than those available in the comparable classroom course. In some cases, this is a relatively modest standard to meet, as many classroom courses do not necessarily generate much interaction among learners or between learners and other learning participants (instructor, tutor, etc.). Consequently, some courses rely more on optional interactivity, i.e., available upon demand, while other courses integrate mandatory interactivity into their assignments (e.g., collaborative projects, homework assignment review, etc).

Mathematics on the Web

Enabling two-way electronic transmission of graphics, equations, and formulas has always been a particularly vexing problem. ELI previously developed a serviceable means of accomplishing this by using Expressionist and FirstClass™ (Sener 1997a), enabling electronic transmission of mathematical expressions using a remote server accessible via local telephone service. However, this solution was not technologically feasible for Web-based courses, so a new solution had to be found.

The current Mathematics for the Liberal Arts I course uses Scientific Notebook™ (SN) as the means of mathematical communication with students. The instructor and students use the software to transmit quizzes, homework problems, and general questions and answers to each other. The software is priced very affordably (currently <$30US/copy) as it is bundled with the course textbook. SN can be used as an equation editor; it also has a lot of computational power as is it incorporates the symbolic engine from Maple™, and it has one of the easiest user interfaces of the available math software packages. Since it is not currently possible to post SN files directly on the web, the instructor uses MSWord™ with MathType™, the full version of the Equation Editor that comes with Word to post Web pages with mathematical content (Goral 1999). This procedure is much easier and quicker to download than the previous common practice of embedding mathematical expressions within graphics on Web pages.

Cross-Course Content Linkage

One particularly exciting set of possibilities enabled by a large array of Web-based courses is linkage of content across courses. The instructional possibilities of cross-course content linkage are just beginning to be explored; one strategy which ELI is using is to link "helper" courses to other academic courses. One of ELI's new courses, Library Skills for Research (LBR 105) is a one-credit course designed to teach students basic library research skills, including online research (Egan, Delmore, and Wharff 1999). The course includes mandatory participation in discussion forums which are monitored by librarians at each of NVCC's five campuses. Other Web-based courses with a research component are starting to use the library research skills course as a resource by including a link in their Web pages to the LBR 105 course for students who need additional assistance in completing their research assignments. Students can use the linked LBR 105 content as a refresher or reference resource, while students who need more extensive assistance can sign up for the course and receive online assistance from the librarians.

Project Status

Currently (Spring 1999 semester), seven courses are being offered with over 280 enrollments; an additional ten courses will be available in the Summer 1999 semester. When the project is completed in the Spring 2000 semester, the complete AAS degree programs in IST, Business Management, and Public Management will be available. A complete Associate in Arts degree in Liberal Arts will also be available starting in the Fall 1999 semester.

For more current information on this project, visit the "Bringing ALN into the Mainstream at NVCC' project website link at http://elisp.nv.cc.va.us/.

New Tools for Synchronous and Asynchronous Teaching and Learning in the Internet

Volker Hilt
Christoph Kuhmünch
Lehrstuhl für Praktische Informatik IV
University of Mannheim
Germany
{hilt,cjk} @pi4.informatik.uni-mannheim.de

Abstract: In this paper we describe the new tools for synchronous and asynchronous learning developed within the context of the TeleTeaching Projects at the University of Mannheim. With our tools, students are enabled to follow lectures not only in the lecture halls of the connected universities but also at home. The innovative processing of course material allows the production of educational documents that consider the requirements of synchronous and asynchronous learning modes out of a single primary document. Course material is provided within a Web-based training unit designed specifically to support asynchronous student learning.

1. Introduction

In the Fall of 1995 the University of Mannheim initialized a joint Teleteaching project with several partner universities (Eckert et al. 97) in Germany. Three different synchronous Teleteaching scenarios were implemented and evaluated. In these synchronous learning scenarios, production and consumption of the educational material takes place at the same time. The first scenario is called the ``*Remote Lecture Room Scenario*'' (RLR). Lectures are transmitted live via the Internet to lecture rooms at the partner universities. Transmission is entirely based on the Internet protocols so that students from anywhere can participate easily. The second scenario we explored is called the ``*Remote Interactive Seminar*'' (RIS). In contrast to the RLR scenario, a seminar is much more interactive since a discussion between the three sides usually takes place after each talk. The third scenario is called ``*Interactive Home-Learning*'' (IHL). Its target users are students running Linux or Windows 95/98 on their PC at home having an Internet connection via ISDN. This scenario is the most widely distributed among its members. The Goal of the IHL project is the provision and interactive usage of multimedia teachware within the bounds of academic education over digital networks in order to gain experience. From a pedagogical point of view information about the acceptance and learning success of such a scenario should be retrieved.

In addition to the synchronous scenarios, *asynchronous* learning is supported. In the asynchronous scenario, the student is provided with course material for the lectures and seminars. This material can be reviewed at any time and at the speed the student desires. Especially in the preparation for an exam, access to course material is viable for the students. Besides the material used in the lecture (slides etc.) additional documents are handed to the students in the asynchronous scenario. E.g. the video and audio recordings of the lectures provide access to the explanations by the professor of a specific topic. Further educational material (texts, animations etc.) may provide background information on selected topics of the lecture.

Many other related projects in the area of distance education exist (Bacher et al. 97) (Baehring et al. 98) (Schill et al. 98) (Parnes 97) (Maly et al. 97). Howerver in contrast to the other projects, our approach integrates synchronous and asynchronous forms of learning. The main features are the automatic production of educational material for both forms of learning from a single primary document. Furthermore we provide students access to the synchrounous and asynchronous learning scenarios from their home.

2. Synchronous Scenario

Our main goal in the synchronous scenario was to gain experience in the transmission of lectures to student households via ISDN. Thus an infrastructure had to be established and software components designed and implemented. From an pedagogical point of view information about the acceptance and the learning success of the scenario had to be obtained. (Fig. 1) depicts the synchronous IHL scenario. Lectures were transmitted via high-bandwidth ATM connections to the remote lecture rooms and simultaneously to the student PC at home via a low-bandwidth ISDN connection.

2.1. Implementation

During the summer semester 1998 we evaluated the scenario. Four groups of participants were selected and equipped in order to attend to our teleteaching lectures. The first group of participants attended the lectures directly in the classroom where the lecture took place. The second group of participants was located at a partner university, connected via ATM links with a reserved bandwidth. The reserved link allowed the transmission of high-quality video of the lecturer. The third group consisted of participants who attended the lectures individually at various universities in Germany, connected via the public MBone, i.e. they depended on the best effort IP protocol for packet delivery without bandwidth reservation. The fourth group consisted of students who attended the lectures individually at home. These participants were connected via ISDN and used multimedia PCs running Linux or Windows 95/98 or NT. Since ISDN provides a reserved bandwidth of 64 kbit/s or 128kbit/s (if two channels are combined) the students could depend on a relatively reliable connection, although the bandwidth available is relatively low.

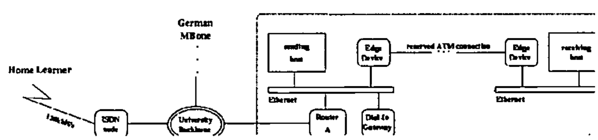

Figure : The Integrated Home Learning - Teleteaching Scenario

It proved to be a complex task to set up a multicast connection among these different groups of participants. (Fig. 1) depicts our solution: The reserved ATM connection to the participants of the second group was provided as a Permanent Virtual Circuit with a peak bitrate of 3 MBit/s. Upon this PVC a LAN emulation was set up: At both sites Edge Devices were installed which acted similar to remote repeaters. Ethernet frames were transmitted over ATM connections. Since participating hosts could be connected through conventional ethernet this solution allowed a flexible integration of new hosts into the virtual LAN. A dedicated router equipped with two Ethernet interfaces acted as multicast gateway to the MBone (router A in (Fig. 1)).

The simultaneous transmission of multicast streams through high-bandwidth ATM connections and low-bandwidth ISDN connections creates two technical problems: At first, the transmission of high-quality video requires a high bandwidth of at least 600kbit/s but ISDN provides only 128kbit/s. . Second, broadcasting networks like Ethernet inherently allow multicasting. Since ISDN is not a broadcasting channel, a tunnel must be set up dynamically in order to transmit multicast data.

The *Dial-In Multicast Gateway* allows the transmission of selected teleteaching lectures sent via IP multicast, over dial-in connections such as ISDN. It sets up tunnels dynamically; thus selected multicast sessions can be transmitted through channels without multicast capabilities. Furthermore it includes a simple filtering mechanism that scales the bandwidth needs of transmitted streams according to given priorities. For each selected media stream of the lecture the desired quality of service parameters can be set interactively, e.g. a certain share of the available bandwidth can be reserved. In order to allow a graceful scaling of video we integrated a simple scaling mechanism for H.261 video streams that controls the temporal resolution of the video.

In principle the gateway works in the following manner: Users connect to the server through the client application. Once a user has logged in the client will receive a list of lectures available for transmission. The user will then choose which lecture to join. A request for each selected media streams of this lecture will be sent to the server, which then will transmit and rescale the media stream according to the bandwidth available. A more extensive description of the Dial-In Gateway can be found in (Kuhmünch 98).

2.2. Evaluation results

During the summer semester 1998 a lecture on Multimedia Technology by Professor Effelsberg was implemented with the technology described above. The remote classroom was located at the University of Freiburg. A Web-based questionnaire was used for the evaluation of the synchronous scenario. Besides sozio-demographic information it assessed aspects of motivation, the technical, organizational and didactical quality of the scenario and several aspects of the subjective bearing and perception during the teleteaching lessons. The questionnaire was similar to the standardized questionnaire HILVE (Rindermann et al. 94). Also assessed was information on the software tools for the ISDN users.

A total number of 65 students attended the lectures. 43 students participated directly in the classroom, 12 students studied at home and 10 students in the remote classroom, connected through the virtual LAN. Since the number of participants in each group is small and differs widely we had to dispense with inference-statistical evaluations. The following evaluations therefore are purely descriptive but we refer to related evaluations of other projects where possible in order to buttress our interpretation of the evaluation data.

Comparisons between the ``remote situation" and the ``local situation" showed that the students always gave a higher rating to the ``local situation". The Home Learning students as well as those in the remote classroom rated perception in a ``normal" face-to-face lecture higher. The reasons mentioned were the unfamiliarity of the video on the screen or the video beamer and the poor audio quality combined with the merely sufficient visual quality of the slides in the whiteboard. Additionally students in remote situations do not feel themselves to be perceived by the lecturer as well as they would have been in the local situation. They also reported difficulties concentrating for a full, uninterrupted 90-minute lecture. In order to overcome this problem, we introduced a 5-minute break after the first 45 minutes. These evaluation results coincide with those in (Eckert et al. 97).

We evaluated how the students assessed the quality of the three media types audio, video and whiteboard with respect to their importance in the learning process. Since Home Learning students and those in the remote classroom received the lecture in differing qualities the interpretation of their results are discussed separately. (1.) Home Learning students: The evaluation data gives reason to the hypothesis that video is only of minor importance in computer science lectures, although the received quality was rated as merely sufficient. In contrast the importance of audio and whiteboard was rated high. While the whiteboard quality received good ratings the audio again was perceived as merely sufficient. (2.) Students in the remote classroom: Obviously the students in the remote classroom demanded higher quality of the video. They rated to the importance of video average and the importance of whiteboard and audio as high. While the video and whiteboard quality fulfilled the student demand the audio quality was rated as needing improvement.

Specific questions designed for the evaluation of the Home Learning scenario indicated that the participants were partly motivated by technical interest in ISDN and partly by personal contact to the department. Additionally some students found it advantageous that they did not have to commute to the university. Frequent problems with the gateway router (router A in (Fig. 1)) caused the reliability of the connection to receive only an average ranking. Nevertheless all students would participate in the experiment again, especially if higher bandwidth (provided for example over ADSL) were available.

An important finding is that the Home Learning scenario is generally accepted by students although higher bandwidth is obviously necessary. Nevertheless students in the remote classroom as well as the home learning students reported a less personal atmosphere. This result coincides with other evaluations (Eckert et al. 97).

3. Asynchronous Scenario

3.1. Objectives

One of the main goals of the asynchronous scenario is to provide the student with educational material that can be visited selectively depending on one's personal learning process. The material usually accompanies a lecture that is held in the synchronous scenario. In contrast to the synchronous scenario, where content is *pushed* towards students, the asynchronous scenario enables a student to selectively *pull* the desired material. Due to this fundamental conceptual difference, the range and the amount of material presented in the asynchronous scenario may be much greater than in the synchronous scenario. Additional material may also be used to explore certain topics of the lecture in more depth or to address different needs of learners by providing compact explanations for fast learners and full texts for slower ones. Since students interact directly with the material, highly interactive material like animations and simulations can be handed to them.

3.2. Preparation of Course Material

The lecture material of the course on Multimedia Technology given in the summer semester of 1998 was presented not only during the synchronous lectures but was also provided for asynchronous learning. Since the demand of lecture material in both scenarios differ, a novel authoring process was developed that allows efficient production of material for both. We also set up a system which allows the material to be captured that was created during the synchronous lecture.

3.2.1 Authored Material

For the material authored by hand (e.g. the slides of a lecture) we found it to be a great advantage to leave the choice of the authoring tool to the lecturer. This enabled the lecturer to efficiently create the course material because no time was needed to learn the operation of a new tool. The lecturer may also reuse any material he has created previously with his favorite authoring tool. This will tremendously reduce the amount of time required to prepare a lecture, especially if material from previous semesters is used. The documents produced with the chosen authoring tool are in a tool-specific document format (e.g. Microsoft Word format) which is usually not appropriate for the presentation of the material. We call this document format a *primary format.*

As mentioned above, the lecture material in the synchronous scenario is presented using the MBone whiteboard wb (Jacobson 92) which is able to process documents in postscript format. Within the asynchronous scenario, the course material is provided on the teachware Web server. Since both scenarios must be considered during the authoring process, a conversion from the primary format to multiple *presentation formats* is required. This conversion process should be executable with minimal user interaction. In particular, it should not be necessary to edit the conversion results, because these changes would be lost if the conversion process is repeated.

The authoring process we have implemented allows to produce the presentation formats postscript, PDF and HTML out of a single primary format document. The authoring process is subdivided into three steps. In the first step, the document is edited using the desired authoring tool (in our case, Microsoft Word). In the second step, the document is converted to the presentation format. In contrast to postscript and PDF, the conversion to HTML proved to be very difficult. Our experiments with HTML export filters showed that the resulting HTML documents often could not be post-processed any further. Very good results were achieved by exporting a document to the RTF format and converting the RTF document to HTML. This process is suitable for all authoring tools that are able to export RTF documents and therefore does not restrict the flexibility in the choice of the authoring tool.

In the third step of the authoring process, the HTML document resulting from step two is post-processed for its actual presentation. Using a Perl script, the WBT described in Section 3.3 is automatically generated. To accomplish this task, the script reads a configuration file in which the linking structure of the WBT is specified and inserts appropriate links into the HTML documents. The configuration file can be edited by the author to specify further material that should be integrated into the WBT.

3.2.2 Captured Material

Course material can be gathered during the live lecture by recording the audio and video data. In our case, we recorded audio and video using the MBone VCR recorder (Holfelder 97).

Besides audio and video, an important source of material are the slides that are presented by the lecturer using the wb. In contrast to the audio and video data, wb data cannot be recorded with a state-of-the-art recorders like the

MBone VCR. But even if the data of the wb could not be recorded directly in the past semester, it proved to be a good source of information for assigning parts of the recorded audio and video to the corresponding slides of the lecture. The recording of a lecture comprises the full 90 minutes. In order to determine the parts which belong to a single slide, the recording must be indexed. This indexing is done automatically during the recording of the lecture by our tool *listenwb*. This tool examines the data stream produced by the wb. It records the time at which a slide is changed in the wb. This point in time is converted to a timestamp relative to the start-time of the video and audio recording by subtracting an offset. At the end of a recording, an index is created by listenwb which contains the timestamps of page changes relative to the beginning of the video and audio recording. This index is the foundation of the configuration file used by the perl script in the generation of the WBT.

3.3. Web-Based Training (WBT) Unit

The complete course material of the 1998 Multimedia Technology course was combined into a WBT (Effelsberg 98). This WBT integrates all the material (hand-authored and captured) and provides access through the common user interface of a Web browser (Fig. 3).

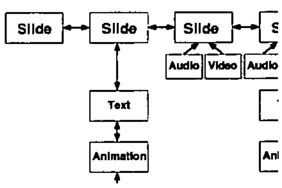

Figure 2: Instructional design of the WBT

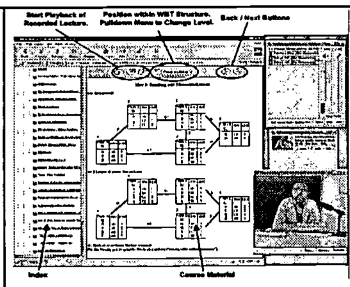

Figure 3: Screenshot of the WBT

3.3.1 Applying an Instructional Design

A very important aspect of a WBT is the appropriate structuring of the material it contains. For this reason, the instructional design of the WBT (Fig. 2) was developed in cooperation with a research group at the Department of Psychology at the University of Heidelberg under the direction of Professor Reimann. The foundation of the WBT consists of the slides of the lecture. These slides are linked in the order in which they were presented during the lecture. Each slide contains a forward and a backward button in the *navigation bar* on top of the screen (Fig. 3). This allows a student to successively walk through the complete course. Additionally, a self-expanding index enables a student to access material on a specific topic. Each slide contains a link to the corresponding part of the video and audio recording of the lecture. Some of the slides contain links to additional material. This additional material is structured in multiple layers where each layer contains different material (full text, animations and exercises) on the same topic as the slide. Thus, a student may descend through different layers until the topic has been completely understood. Afterwards, the student ascends to the upmost level and continues with the next slide. Currently we have integrated Java animations and exercises into the WBT; the integration of full text will follow

4. Conclusions

In this paper we summarized our synchronous and asynchronous teaching and learning scenarios. We described details of the technical implementation and presented initial evaluation results which prove that teleteaching in its synchronous mode is generally accepted by the students although they expect high technical and organizational quality. For the asynchronous scenario, we presented an innovative course material processing scheme that enables the production of educational documents considering the requirements of different learning modes out of a single primary document.

Future work aims to add interactive media such as VRML or Java animations and simulations as new educational paradigms to our asynchronous and synchronous teleteaching scenarios. This comprises the development of a general framework for the transmission and recording of interactive media (Mauve et al. 98).

Acknowledgments

We would like to thank Professor Reimann at the University of Heidelberg for his assistance in the instructional design of our WBT unit and Andreas Eckert at the University of Mannheim for his help in the evaluation of our teleteaching scenario. Part of this work was supported by the ``Deutsche Forschungsgemeinschaft" within the ``V3D2 Digital Library Initiative".

Project Clio: Tools for tracking student use of course webs

Raphen Becker, Kevin McLaughlin, and Samuel A. Rebelsky
Department of Mathematics and Computer Science
Grinnell College
Grinnell, Iowa 50112
{beckerr,mclaughl,rebelsky}@cs.grin.edu

Abstract: In this paper, we present *Project Clio*, a Web logging system that permits instructors, instructional designers, Web designers, and course web architects to better garner information that helps them understand how students use course webs, and therefore how to improve course webs. In particular, the system allows one to determine the path(s) individual users follow through a site, the time they spend on each page, and their simultaneous use of multiple pages. While there are now a number of systems for logging Web use, ours is able to provide more targeted and more individualized information than typical systems.

1. Introduction

Students at most universities now have access to the World-Wide Web, putting the Web in a position to be the common medium of hypermedia for class materials. Hypermedia has many advantages over a paper-based presentation of information. Of primary importance are that hypermedia (1) permits the easy integration of media other than text and (2) supports a structure quite different from the linear presentation of textbooks. Links allow students to access related material easily, from various nodes in the course web.

At the same time, this new technology requires analysis of its use and usefulness. Instructors need to know how students actually use Web materials so that they can better learn how the Web and their course webs affect students' understanding of information and their performance in class. Such analysis requires careful and regular gathering of information on how individual students use course webs.

The Web was not originally designed to provide a great deal of specific information on how readers use individual sites and pages. The log files generated by most Web servers, such as the NCSA HTTPd (NCSA 1997) are inadequate for careful analyses. In particular, log files list only pages accessed, the time the page was accessed, and the machine that issued the request, but not the individual that accessed the pages, the previous and next pages on that individual's exploration of the Web, or the amount of time the person spent on the page. Successful acquisition of more detailed data requires working around this original design decision. Recently, new technologies such as cookies, Java, and Javascript have extended the opportunities not just for hypertext on the web, but also for tracking and analyzing use of the Web. Using these technologies it is now possible to track students more closely as they move within and beyond the course web. In particular, we can log the path of each particular student and record the time each student spends on each page.

2. Improving Understanding of Site Usage

Why analyze course webs? The primary goal of course web analysis is to help teachers, site designers, and instructional designers as they evaluate the use and usefulness of course webs. By "evaluate use", we mean an analysis of what pages students use, how long they use them, how they get to them, how they leave them, and what other pages they use in conjunction with those pages. By "evaluate usefulness", we mean a consideration of the effects of pages and use patterns on learning, based not just on the preliminary analysis, but also with additional information such as records of student performance or targeted interviews, as in (Jones et al. 1996).

There are many potential benefits from more thorough analysis of course web usage. These include a better understanding of student learning patterns, justification for the time and effort spent developing a site; and support for improving the site. While such benefits can also be gained in careful study of commercial sites, the focus of our tool is on understanding student patterns.

Information presented with hypermedia does not need to appear in linear format as in a lecture or in a text book. This change can have a dramatic effect on how well students learn and retain course material. An analysis system can allow instructors, instructional designers, and course web architects to correlate viewing information on the Web with related test questions (Trochim 1996), student interviews (Jones et al. 1996), or student perceptions of their own web use (Rebelsky 1998).

With more detailed usage logs, one can also ask questions like

- What are the more popular parts of the course web, and are those parts used more for their links (short time on page) or content (long time on page)?
- How do readers reach particular pages? Can they quickly reach the pages they want?
- How do better and worse students use the web? Can all students benefit from the strategies of the best students?
- Which pages do students seem to leave active, perhaps as a reference in a background window, while visiting other pages? Are there ways to improve the use of reference pages in such situations?

To permit these sorts of analyses, a logging system must identify students, keep track of the paths they take through the course web, and identify the amount of time they spend on individual pages. This means the system needs to log when a reader loads a web page, how they found the page, how long the page is open, and which link (if any) is followed next. Because the web permits readers to open multiple "windows" on the same site, we also need to be able to determine when they have several pages open concurrently.

3. Architecture

Project Clio is based on a number of interconnected systems, each of which provides a different role in tracking or helping analyze student use.

- An *identification system* (described in section 3.1) identifies individual users and provides this information to the other parts of the system.
- A *page transducer* acts as an intermediary, fetching requested pages and extending them so that (1) they can be tracked with the tracking system, (2) links from the page use the transducer for subsequent requests, and (3) additional activities can be performed during the fetch.
- A *tracking system* (described in section 3.2) records simple events which are then used to develop usage information. This system includes:
  - an *event logger* which logs individual events to a file for later analysis;
  - a *request analyzer* (server side) which garners information from the initial page request; and
  - a *page observer* (client side) which garners information from the client, such as whether the student is still on the page.
- A *synthesis system* which translates the "raw events" (such as "the user has loaded page *X* ... the user is still on page *X* ... the user has left page *X*") to a more usable form (such as "the user was on page *X* for five minutes").
- An *analysis system* which permits interactive analysis of the translated usage information and supports questions like those given above.

In this paper, we focus on how the system tracks users with an identification system and a tracking system.

3.1. The identification system

The identification system is loosely modeled after the Unix model of users and groups. Each user entry contains a single line in a file that contains all of the information for a user. Each entry contains the *account* name of the user, an encrypted *password*, the *groups* that the user belongs to, the *real name* the real name of the user (or anonymous, for users who do not wish their name to be known), and an *email* address for contacting the user.

We use a group model so that different types of tracking are possible. For example, one might want to compare different classes using the same web site or only log members of a particular group. The group model is also appropriate for related uses of the system, such as an annotation system which takes advantage of this system (Luebke and Mason 1998) (Luebke, Mason, Rebelsky 1998).

When users first access pages that are logged, they are prompted by a form that asks for account and password. Once the user has logged in, a session and session identification number are created for that user. As the user continues throughout the logged pages the session identification number is carried with them via query strings and cookies. Once the user exits the logged pages or leaves the browser the session number is expired and they must login again if they choose to return to logged pages. In this way, only registered users of the system may view the logged pages. This can easily be circumvented by allowing a guest account. In the future it should also be possible to restrict certain pages for certain groups or to restrict logging to certain Internet domains (so that, for example, internal users might be logged but external users would not be).

The identification system is not only essential in providing access control to pages. It is also essential in keeping track of users as they move around the logged pages with the tracking system. With the identification system, each time a user enters a page, both the user name and session number can be immediately identified. These pieces of data are used in constructing the log files for each user.

3.2. The tracking system

The tracking/logging system is used to record events for each user as they move around the logged webpages. To improve the accuracy of the tracking, *tracking events* are gathered in a variety of ways. The tracking system includes a server, a Java applet, Javascript scripts, and several CGI scripts written in Perl. These various components report events to the server for each session. Selected events are describe in Table 1.

Event #	Sent by	Event type	Data sent
00	observer: applet	left page	page left
01	request analyzer	loaded page	page loaded; previous page
02	request analyzer	from page	last page
03	observer: Javascript	Javascript enabled	current page
04	observer: applet	Java enabled	current page
05	observer: applet	stay on page	current page

Table 1: Events recorded by the tracking system.

As the user browses through the logged pages these events are generated and sent to a *log server* which writes them to a log file. Because it is traditionally difficult to determine when someone leaves a page (e.g., if the user switches to a page on another server, the current server gets no notice), the *stay on page* event helps us determine the amount of time on the page. One might also or instead record the time when the user leaves the page (Davis and Jain 1998).

Since we rely on Java and Javascript, problems may occur when the user disables them in the browser. This is the reason we record events 3 and 4. In the synthesis system, these events are looked for. If they are not found we know that Java or Javascript was not functioning properly and that we must use a different (and less accurate) mechanism for evaluating some aspects of traversal. Thus, analysis component accounts for this and tries to determine some synthesized events based on a wide variety of other events.

4. Anonymous Browsing

The question of anonymity with regard to the World-Wide Web is a common question. Is it acceptable for sites to track users paths through the web? We considered this issue in great detail while designing the logging system. For example, would students be less likely to use web pages if they knew their use was being logged, or would they "simulate browsing" to make it appear that they were using the system more than they were? In addition, what should be done about non-student readers of the course web? In some cases, such readers should be discouraged from using the web, but in many cases, use by non-students is certainly acceptable. How can one make it appropriately accessible to such users without hindering their own attempts to benefit from the materials.

It is clear that careful studies and interviews need to be done to determine all of the potential effects. As a temporary stopgap, we decided to provide two mechanisms that help alleviate some of these concerns. One is a permissions system incorporated in the identification system that allows the instructor to specify which domains require accounts, which domains do not require accounts, and which domains should be denied access. A second mechanism was to permit the instructor to specify that *anonymous* accounts are acceptable. Let us consider some details of anonymous accounts.

There are a number of options for anonymous browsing: one might use a single "anonymous" account, one might use multiple anonymous accounts (one for each user), or one might allow users to turn off logging. In the case of a single account, the administrator might distribute the password to all users with privileges to browse the logged pages. This method, however, has a distinct disadvantage. One purpose of the logging system is to determine paths for each student across sessions and not just in a single session. With a group guest account it is unknown what student is reading the web at a particular time. In addition, some students might use the guest account some of the time and their own account at other times, leading to unreliable data collection. Turning off logging is similarly unacceptable.

A better system for allowing anonymous browsing is to create accounts for all desired users and let the account names, real names, and email addresses be blank or pseudonyms. Such accounts may be distributed anonymously (e.g., with slips of paper in a hat). In this manner we can create distinct paths for each particular pseudonym and thus, each user. Regular analysis can be performed without any loss of accuracy. This is the preferred way to handle anonymous logging.

For many purposes, such as marketing and other corporate uses, the name of the user is the desired information. For our logging system, however, it is frequently not the name, but the the path taken by any particular user. Hence the actual name of the user is only useful for record keeping and is not needed to actually perform many analyses. Names are useful only when usage and success in learning are correlated in one of many possible analyses.

5. Related Work

There are a wide variety of systems for Web analysis. For example, the Internet Product Watch listed 116 "Analysis products" on March 25, 1999 (Internet Product Watch 1999). Of these, perhaps half are intended to gather and report site usage in some form or another. Many provide a wide range of reports. For example, Accrue Insight (Accrue Software, Inc. 1998) provides approximately fifty different types of reports. Is another reporting system needed?

Because many existing systems are targeted toward commercial webs, the answer is *yes, course webs require different systems*. One reason is simple: most instructors (and even institutions) cannot afford the commercial products, which are priced toward industry and not towards academia.

More importantly, existing products tend to focus on group data, rather than on individuals. For example, consider the eight "visitor" reports provided by Accrue Insight (Accrue Software, Inc. 1998): total visits, total visitors, new visitors, registered visitors, unregistered visitors, visitor types, visitor types, and average pages per visit. None of these reports give details about individual visitors; rather, they are mass statistics of number of "things" per "time unit". Similarly, consider the sixteen reports generated by FlashStats (Maximized Software, Inc. 1999): summary, top URLs requested, top referrers to your site, search phrases, most common browsers, bad URLs, bad referrers, user domain analysis, types of domains, daily totals, hits per day of week, and hits per hour. Again, these are primarily counts that reflect compound rather than individualized data. (FlashStats is limited to the information in standard log files; Accrue Insight uses a number of other technologies, including cookies, to gather additional data. Neither provides information on single users.)

By providing information on *paths* (including entry to web and exit from web), we are able to provide course web architects with the smaller-scale and more individualized information that they need. In fact, while some commercial software can track paths, that paths are used only as a means of collecting more general data, such as the first and last pages readers visit at the site (Page 1997).

There are also client-side technologies that can more closely observe users interactions with their browsers. We have chosen not to explore such technologies because (1) they require more effort on the part of the student; (2) they typically assume a one user/computer model that is not applicable in the academic setting; and (3) they are more difficult to implement and maintain in the typically heterogeneous academic environment. By relying on server-side tracking along with lightweight client technologies (e.g., Java), we are able to support a variety of browsers and computer platforms.

6. Future Work

We have developed working identification and tracking systems that have been been used for simple experiments during Summer 1998 and Fall 1998. Development of a sophisticated analysis tool for using the logs and a more robust tracking system is underway. When completed the tracking and analysis tools will provide the means to track users and answer questions about student usage, such as "How often and how much do students use particular pages?" and "How do students typically reach the most useful pages?". With the answers to these questions one can design more usable and more useful course webs.

One issue that is of particular concern for tracking paths through WWW sites is that a student may have multiple windows open on the same site at the same time. This is in stark contrast to the "one view" hypertexts that are typically analyzed, such as in (Jones et al. 1996). We plan to consider a number of possible static and dynamic mechanisms for visualizing the multiple *simultaneous* paths students take through course webs.

The identification and tracking systems are also being used to support additional facilities for course webs. The identification system has been used to support a group annotation system (Luebke and Mason 1998) (Luebke, Mason, and Rebelsky 1999) and will be used to support a system for building *trails* from both local and non-local pages. The tracking system may also be used to support a form of adaptive hypermedia in which pages can be modified based on prior use.

Acknowledgements

We thank Grinnell College, the Robert N. Noyce Faculty Study Program, the Robert N. Noyce Prize Program Summer Student Fellowship Program, and the Grinnell College Noyce Science Summer Research Fund for their support of this research. We also thank Sarah Luebke and Hilary Mason for their critiques and suggestions throughout the entire project. Their use and extensions of Project Clio helped us improve its design and architecture.

Abstract: Research in the information society is undergoing radical change. The new challenges make it necessary to rethink research and the ways of educating researchers so that they can cope with them. We show that research has to be considered as skilled practice, consisting of numerous component skills which have to be trained so that future knowledge workers can successfully deal with unstable, uncertain and complex situations. As a practical application of this argument, we outline a project for an integrated Internet service, called BASES - Basic Support for Educational Study and Research.

1. Training researchers

It is not possible and, in fact, not sensible anymore to provide learners with pre-given answers to pre-defined generalized situations. What they rather need are the skills for investigating themselves the complex, new and uncertain situation they have to deal with. This kind of work is what is usually called "research", or, using a modern term, "knowledge work". This demand a radical re-thinking and re-design of teaching and learning, cf. e.g. (Schön, 1987; Schön, 1983).

Knowledge workers typically have to "consume" and "digest" information from widely varying, dispersed and uncategorized sources. They are being changed by information and seek to change others by it.
Changing context is characteristic of the situations knowledge workers have to deal with. Buckingham Shum (Buckingham Shum, 1997p.902) calls these situations "wicked problems", as they cannot be solved by known methods and pre-defined procedures. The process of identification and definition (or, as we would say: construction) of the problem is itself the main task at hand, requiring complex judgment and negotiation among the stakeholders. In this process of framing the problem, the goals, constraints and possible solutions change permanently, as does the need for and use made of information.

Research as a professional activity is, in our understanding, not restricted to the research professionals at universities and in R&E departments in industry, but rather a basic and essential skill for knowledge workers in the information society. But in our case we decided to specialize on educational research.

2. Research as skilled practice

Research work is neither an art that cannot be taught or learned, nor a set of rules and regulations to follow. It is a skill, or better a set of skills, that can be acquired (at least to a certain degree) and whose acquisition can be supported by training.

The mastery of a skill is not a question of "all-or-none": it is not the case that one day we are unskilled in a field and the next day we are experts. There certainly are steps and phases in the acquisition of skills, i.e. in the emergence of the capacity. Following the model proposed by Dreyfus and Dreyfus (Dreyfus, Dreyfus, 1986), who distinguished five steps in the process of passing from novice to expert, Baumgartner/Payr (Baumgartner, Payr, 1993) have outlined a three-dimensional heuristic model of teaching and learning with three different styles of teaching. These different teaching modes have important impacts of the adequate types of learning interactions:

FIGURE NOT AVAILABLE

Figure 1: Three-dimensional heuristic model of teaching and learning

The social perspectives and implications of these styles of teaching are substantially different. The knowledge transfer model is based on the belief that there exist people who know the right answer to a pre-defined question (e.g. the teacher). It is heir to a positivist tradition and corresponds to a hierarchical career model with competition at its center.

FIGURE NOT AVAILABLE

Figure 2:

The "situated learning" model, on the contrary, subscribes to the constructivist viewpoint where the coach collaborates with the learner to cope with a complex real situation for which neither of them has a ready solution. At the beginning of their concerted action, learners legitimately participate only peripherally (Lave, Wenger, 1991). During the learning process, their responsibility grows continuously until the learners can themselves act as coach for other, new learners.

The difference between commonsense knowledge and scientific knowledge is not the quality of knowledge itself. Both types of knowledge are structured experiences that one has to develop, acquire, examine and apply for a viable (successful) action. The quality of knowledge does not depend on the difference in range and object domain (Meehan, 1991). Scientific research develops (or should develop) knowledge in a systematic way and uses a meta-language (second order language) to describe the ongoing procedures and activities (Laurillard, 1993).

Whatever skill we want to train, we need a second order language which functions as a training language. The lack of a meta-language in scientific thinking is the biggest problem we have to confront in training research skills. The existing meta-language describes mainly the products of research but not the activity, the process itself. In training the knowledge worker, we find ourselves in a position where we can only judge if the product fulfills the scientific standards but not the skills that have to be improved. We are like football trainers who can only comment the outcome of a game, qualifying a won game as "good" and a lost one as "bad", without being able to specify what was good or bad, what should be improved and how this could be done. A prerequisite for training research is therefore to develop this meta-language, starting with identifying relevant actions and processes that make up the complex practice of doing research.

3. Training research skills with Internet support – BASES project

The logical consequence of this change for learning in context ("situated learning" (Chaiklin., Lave, 1993; Lave, 1991) is that the support for training these skills itself should make use of the new media that are able to integrate information, interaction and tools.

We follow this approach with the BASES (BAsic Support for Educational Study and Research) project, an Internet service for supporting and training research skills. It is the hands-on complement to a book on the subject that we are currently finishing. With BASES we support the training of research skills in three different ways:

a) *Cognitive Apprenticeship* (Collins, Brown, Newman, 1990): We provide different kinds and qualities of guided practice:

- general information and resources permanently updated and verified. These include links to libraries, grants; reviewed software tools (freeware or demo versions) for research work (e.g. mind-mapping software, bibliography packages); sample macros, stylesheets, forms etc.
- training modules for research-relevant Internet techniques (e.g. searching for and in online databases, assessing the quality of resources)
- interactive tele-learning modules with "human backing" for general research skills like research design, writing, argumentation, referencing.

b) *Anchored instruction* (Vanderbilt, 1990): Starting with common authentical problem situations, BASES offers a wide range of activities to tackle them:

- FAQ collections
- moderated and guided discussions
- online interconnections among users
- modular tele-learning courses for different authentical problems (how to limit the hits of search engines, how to quote Internet resources, ...)

c) *Cognitive flexibility theory* (Spiro, Jehng, 1990): Learning to defend different points of view and to take multiple perspectives:

- giving different examples of the same task (e.g. paraphrasing a certain quotation, constructing the same argument on different logical bases ...)
- defending different points of view (e.g. presenting the arguments of an author and of his/her critics, summarizing advantages and disadvantages of a certain procedure, product ...)
- choosing different methods on the same subject (taking a commonsense approach and a scientific approach, proposing a pragmatic and a theoretical solution, seeing a problem in short and long term development ...)

We call this integrated site for research support a service, not a server, because we acknowledge that it can only function optimally with "human backing". Beside the need for constant updating and for dealing with requests, problems, contributions and suggestions, there are different situations where support is necessary and new requirements arise. These could range from university teachers using the resources as complementary material for their courses to students who need a last-minute brush-up for presenting their thesis.

Making resources and training offers for research skills permanently available also addresses the need for learning on demand. Skills cannot be acquired on store and in one step, but require permanent training and refinement. With the help of BASES, learners can train their research skills whenever they need them and in unison with their growing competence and the increasing complexity of their research tasks.

Contrary to the book that we have been working on with little financial support, the design and implementation of the BASES service requires more personpower than we have available at the moment. The project is currently (End of October 1998) submitted to national funding program by the Austrian ministry of science. We are now shortlisted and have a final hearing in the middle of November in Vienna. We hope to start with the end of the year. A prototype of some of our ideas can be found under

http://www.uni-klu.ac.at/~pbaumgar/deutsch/medien/html/21.htm

4. Summary

Interconnected problems, rapidly changing unstable environments, and an indeterminate future of our society challenge our traditional education system. What is needed is not only factual and procedural knowledge for solving pre-defined problems but the active skill of framing problems, designing desirable changes and inventing ways to bring these changes about.

Research is not a gift based on "talent", "intuition" or "art" but a skilled social practice that can be learned and trained. What we need is a second order language for this training process that satisfies the following criteria:

- definition and isolation of different kinds of research skills and training of these skills
- development of a program to progressively chunk these different kinds of isolated skills to
- acquire a gestalt view of the research process
- integration of the challenges raised by new technologies in a self-study socio-technological environment.

We propose the BASES project as a small step in this direction.

Telecommunications: Using Combined Technologies to Deliver Courses and Training--Lessons Learned from Montana State University-Bozeman Distance Learning Projects

Janis H. Bruwelheide, Ed.D.
Professor
Project Director, Montana University System Distributed Learning Pilot Project
Project Director, US WEST Montana Teacher Network
College of Education, Health, and Human Development
Montana State University-Bozeman
United States
janisb@montana.edu

Abstract: Three distributed learning projects involving various applications of telecommunications technologies are briefly discussed in this paper. The projects were conducted with Montana State University-Bozeman as the administrative and fiscal agent. Two of the projects were designed for higher education and both involved collaborative efforts. The third project was designed for k-12 teachers and involved peer coaching over 1300 Montana educators to use the Web and telecommunications in their classes.

Introduction

An article by Gibson and Gibson in *Adult Learning*, identified several lessons learned from over 100 years of experience with distance learning. Lesson one states that distance learning is different from that in the traditional classroom setting and traditional models should not be the base against which success or failure is measured. Lesson two stressed training for faculty, administrators, and support staff. Lack of training is identified as one of the biggest failures in distance learning. The third lesson is that learnersÆ needs must be continually supported during the learning experience.

Technology used effectively has the potential to link faculty and learners in order to overcome distance and to enhance sharing of institutional resources among units of the university system. Technologies can be used to reinvent the means by which instruction is delivered and the kinds of activities in which learners engage. Technology can assist in meeting increasing demands from potential learners who cannot afford to leave a job and/or family to pursue an advanced degree on a college campus.

These lessons serve as a framework to identify the multi-faceted issues in these projects. First, there is a need is to restructure and move faculty away from thinking that the traditional classroom model will work with distance learning. Second, it is necessary is to provide extensive faculty development and support for faculty so courses can be developed or adapted for appropriate distance learning formats and new teaching skills acquired and tested. Third, is the need to develop an adequate support system for learners who are engaging in distance learning activities and to enhance learner/faculty interaction. Finally, the impact that distance learning has on issues such as faculty work loads, salary, advising, promotion/tenure decisions, intellectual property concerns, and learner support must be determined.

Materials listed in the References and Web Resources section can provide readers with many additional considerations for designing distance learning courses and learning opportunities. There is much to consider in addition to a course itself. Institutions, faculty, and course designers must deal with intellectual property issues (copyright, patent, and trademarks) as well as technical support, library resources, faculty development, and student support. There are also many inter and intra institutional challenges which can make or break a course. In addition, there may be concerns from faculty and institutions about faculty rights, course ownership, and the effectiveness of distance learning courses. Inter and intra institutional issues which must be considered include application paperwork, registration fees and procedures, ease of registration, financial aid, transferability of courses, learner support and access to materials and library resources

This paper will briefly discuss three telecommunications distance learning training projects in the College of Education, Health, and Human Development at Montana State University-Bozeman and share some of the lessons learned as well as some of the challenges.

Telecommunications Faculty Development Project

During 1993, the first interactive television (compressed video) phase of the Montana Educational Telecommunications Network (METNET) was implemented and it consisted of compressed video codec (interactive television) units installed in four locations. This technology made available many distance education opportunities for delivery of course work, staff development, and videoconferencing which has previously been difficult. In order to demonstrate need and applications for the video network, courses and training had to be developed and delivered in order to convince the institutions of higher education, state offices, and the legislature that funding for additional sites should be continued. Officials of the Office of the Commissioner of Higher Education and the Telecommunications Division of the State Department of Administration were anxious to see demonstrations of educational applications between and among institutions. They also wanted to see demonstrations of the integrated use of the technologies with audioconferencing and Internet. To date, twelve sights are now operational and another video network, Visionet, has been installed due to a grant from the TIIAP program. It isnow possible to link to a medical telemedicine network and another video network installed in eastern Montana. Thus, the state is quite well covered with interactive television although communications costs are still relatively high. The METNET is very heavily booked with courses, training, and meetings. This project provided some early input and demonstration of effectiveness which has been shared with subsequent efforts.

Description of Project

The director was given the charge to design and deliver courses and staff development for faculty and teachers using the METNET technologies of compressed video and the bulletin board system during the 1993-1995 academic years at the Montana State University. Interested faculty were solicited and mini grants available for the design and delivery of courses or staff development using the system. Formative and summative evaluation was conducted with the idea of refining and learning as much as possible about instructional design for distance education courses and faculty development. This information was then applied by the director to future courses and shared with interested College faculty in the System. The Office of the Commissioner of Higher Education had established a goal of using telecommunications and distance education to facilitate intra institutional courses. The Montana State University (now the Montana State University-Bozeman) as a land grant university has a strong commitment to utilizing the METNET distance learning technologies for the State through course delivery to college students, K-12 students and lifelong learners as well as other applications.

Short Term Objectives

1. A faculty distance education resource person and possibly a cadre of faculty would be trained to use METNET and distance learning technologies as relevant to Montana. A "train the trainers" concept was used to facilitate program development and applications.
2. The METNET technology would be used to teach use of the system over the system.
3. Faculty from different higher education institutions would demonstrate a team teaching approach to a course using the network and possibly combining technologies.

Long Term Objectives

1. The METNET would become ingrained into education at all levels in Montana. The METNET interactive television system and bulletin board would be used as an instructional tool and conferencing tool by all three groups of users.

2. A well trained group of users would have developed a substantial amount of program applications materials for use on METNET.

3. The METNET would provide Montanans with opportunities for economic development and career options by workshops through Business, Extended Studies, degree granting and certification courses, licensing programs and various other activities.

Summary

The project proved to be very successful. The director designed and delivered the first two courses over the METNET to five sites including an onsite class at the Bozeman campus. At that time, the broadcast studio was primitive and presented many challenges for all concerned. The instructor had to run and manage the equipment while also teaching a live class to five sites. During the semester, some assistance was provided with camera support and the experience of managing the environment provided useful information about teaching a course over live television to the College as well as the Division of Extended Studies for Montana State University. It also provided information concerning teaching techniques and what types of additional equipment such as microphones, graphics camera, monitors, and furniture was needed as well as information about room arrangement and camera placement. During the second phase of the project, a course taught by instructors at two Montana institutions of higher education was designed and delivered. It dealt with telecommunications and was an experimental graduate course in teaching telecommunications using telecommunications. It used the interactive television network to deliver a weekly two-hour evening class and the campus computer networks were used for an online component to apply class content and complete assignments.

Several pieces of information were gathered from the project. Permission slips granting use of images were gathered from each student at sites where the course was delivered and students were informed that each class would be videotaped for research purposes. Each session of the course had a brief formative questionnaire administered which asked students a few questions about the nightÆs class. During the course of the semester, instructors experimented with varying the rates of transmission from quarter T1, and lower, to full T1 which at the time provided ônear broadcastö quality video. An interesting finding was that the students tolerated poorer quality video with no difficulty. However, they were insistent that the audio quality be excellent. Students were also sensitive to feeling involved in the class so that the instructors had to make sure that each class and student had a fair share of air time and that we learned their names. It was also important that remote students be sent materials ahead of time as they did not like to see the site with the instructor receive materials prior to them. Another interesting finding was that after the first session or two, students learned to ignore the technology. At one point, one instructor created a virtual computer lab using an audio conference for a remote site having trouble with a particular Internet navigation tool. It was surprising to find that the instructorÆs presence by audio with both she and the class looking at the same computer screen so that she could guide them through use of the tool was more important for student learning than using video without a hands on experience.

Other lessons learned from the project emphasized the intense early planning which must occur to prepare for a interactive television class delivered to several sites. Students must be able to receive course materials in a timely fashion and they must have a way to contact faculty by phone if something is not operative at the remote site. Having a way to contact remote students personally is important using traditional mailings as well as electronic mail is needed. Technical assistance for faculty and students was found to be an imperative. We also found that having a person at each site to handle the equipment and trouble shoot was also a necessity when funding allows.

Montana University System Distributed Learning Pilot Project

This project began during May, 1998 and was funded by a competitive, incentive grant from the Office of the Commissioner of Higher Education, Montana University System. The project involved designing and delivering five graduate education classes to be delivered through computer conferencing during the 1998-1999 academic year. Institutions involved were: College of Education, Health, and Human Development, Montana State University--Bozeman (administrative and fiscal agent); College of Education and Human Services, Montana State University--Billings; Department of Education and Graduate Programs; Montana State University--Northern; School of Education, University of Montana-Missoula.

To date, three courses have been delivered with two to be completed in May, 1999. Evaluation will be completed by June, 1999.

Objectives

1. A core of courses in the graduate MasterÆs Degree in Education was selected to be used as the focus for distributed learning delivery efforts in the College of Education, Health, and Human Development at Montana State University-Bozeman, the College of Education and Human Services at Montana State University-Billings, the Department of Education and Graduate Studies at Montana State University-Northern, and the School of Education at the University of Montana. Software used was the First Class Intranet Client housed on servers at the METNET and MSULINK, Burns Telecommunication Center at the Montana State University -Bozeman.
2. Through faculty development and support, it was hoped that faculty in these programs would collaboratively explore program design as well as adapt, design, and deliver courses suitable for delivery to distant learners.
3. Distant learners were to receive support regarding access to faculty, library resources, and information based on delivery of courses and services. Information gained and shared will further enhance and improve future offerings.
4. Coordination of course offerings would result in better distribution of programs in Montana and utilization of scarce resources.
5. Distant learners and faculty would benefit from a systematic, focused approach to course design and delivery.

Twelve faculty from the four institutions were selected to work on the project. A two day faculty development workshop was held at the Bozeman site in May, 1998, to begin work on the courses. An experienced, outside distance learning consultant was hired to work with the faculty in the workshop. Faculty received summer stipends to design and deliver the five courses during the academic year.

Challenges and Summary

This project has provided a lot of evidence which exposes inter and intra institutional challenges and obstacles to distributed learning efforts which need resolution before projects can proceed smoothly. The easy part was working with the faculty and students. Challenges included advertising, policies and procedures involving course registration, fees, transferability of courses and monies, and compliance with letters of agreement. Students using certain Internet service providers had difficulties using the First Class Intranet Client initially. The project also demonstrated some of the challenges in working collaboratively across institutional lines. Preliminary data from students shows a high degree of satisfaction with the courses and they felt that there was no lack of quality or rigor in the classes. Most students would have preferred at least one or two face to face meetings which could have been accomplished using interactive television or an on site session. Final evaluation of the project will become available in June and will be shared during the live presentation of this paper.

US WEST Montana Teacher Network

Challenges and Summary

Funded by a grant from US WEST and developed in cooperation with the Montana Education Association, an affiliate of the National Education Association, the Montana Teacher Network is currently providing peer coaching in telecommunications training and Web applications to over 1300 Montana Educators. The paper in the ED-MEDIA 99 proceedings on session 2483 provides information on the project so only a brief summary is included in this paper. The project involved distribution of notebook computers to an initial 132 teachers representing one percent of the Montana teaching force. The computers will remain with the teachers as long as they are teachers in Montana. Participants were selected through an application process and agreed to participate in an on site summer workshop, an online training course to be held during 1997-1998, and then to execute a training plan to peer coach at least ten colleagues during 1998-1999 thus impacting over 1300 Montana educators. The online course was conducted using First Class Intranet Client software housed on a server at the Montana State University-Bozeman Burns Telecommunication Center server. The second year of the project used the same software housed at the Montana Office of Public Instruction server for the METNET.

The project has been very successful and reports and anecdotes received from the coaches have been positive. They definitely see growth in their schools in using the Web and telecommunications. However, there have been challenges. One problem has been that some school districts were not able to provide the Internet access which was promised to participants selected for the project and this made it difficult for the teachers to fulfill their coaching requirement in a timely fashion. Four teachers were unable to complete the project and their notebook computers were recalled. It has proved difficult to keep track of the second group of teachers receiving the coaching. Having the ability to offer a credit option for the second wave of teachers would have been helpful but this proved to be impossible. Had it not been for the geographical challenges presented by the size and population of Montana, it would have been helpful to convene the teachers in groups two or three times during the project. Instead, the METNET bulletin board was used as the primary gathering place. Plans are underway to continue the Montana Teacher Network and expand it to a community approach. Additional funding and partnerships to take the project forward into 2000 are being sought.

A Few Ideas to Consider When Planning Distributed Learning Projects

1. Conduct a needs assessment to determine the target population and consider the needs of the group including level of technology literacy.

2. Determine who are the stake holders in the project and their agenda.

3. Decide in advance how to distribute instructional materials and obtain copyright clearance and permissions when needed.

4. Select the technologies to be used and consider a combined approach

5. Consider all financing aspects and any hidden costs.

6. Determine whether courses will be in-load or taught for extra pay.

7. Consider all possible policies and procedures which might impede the project.

8. Determine how faculty and remote learners be supported.

9. Determine how the course and effort will be evaluated for feedback as well as promotion and tenure considerations.

Abstract: To establish a new studying course extensive researches have to be done. Government of Slovenia - Ministry for Education and Sport sponsored the research for the new studying course "Multimedia for Teachers". Fundamental research was conducted to verify positive effect to the learning process. Research of written materials and know-how of similar projects was done to define objective of the project. Later the project plan to implement the studying course was made and; verification of the project plan was not left out. The project is now at the beginning of the implementation. First populations of students - future teachers are experience new approach to the teaching by learning multimedia with computers.

Introduction:

The research projects to find potentials of the multimedia in various branches of enterprises were conduct a long time before the technology was available at acceptable price. In the 90's technology becomes available. Now is the time to use the results of research projects once conducted and research of the things that were not apparent till now.

Government of Slovenia - Ministry for Education and Sport funded the project to improve computer technology at primary and secondary schools named RO (Computer Literacy). As the schools get better equipped teacher was educated to use the potential of equipment. One of the five strategic research subprojects in project RO is "Multimedia in Education". In the research work for a project "Multimedia in Education" three parties are involved: Republic of Slovenia - Institution for Education and Sport, Faculty of Computer Science in Ljubljana and Faculty of Education in Maribor.

Using statistical analysis of the gathered data it becomes clear that multimedia in the teaching process increases effect of learning. By combining the entertainment and education the pupils finds fun in absorbing the educational material and the time necessary to remember the certain information was significantly shorter in compared with the traditional educational materials.

We were not satisfied with results of statistical analysis. In the search for artifacts that would clearly support the statistical analysis we started fundamental research of effects of multimedia material to the brain activity. It was found that a larger portion of the brain is active if multimedia educational material is used (Jausovec, 1998). Statistical analysis was confirmed.

The new step was taken to study the market available multimedia supported educational materials. The majority of these materials is in English language and not always suitable for use in the primary and secondary level of education. There are doubts if these materials can be used in the large scale even at the university level. The conclusion is simple. We need to prepare the multimedia supported educational material in such a way to be easily translated to any language.

As a test the multimedia supported educational material for the physics was prepared. The users very well accepted these educational materials. Using this material we find that the most appropriate media for distribution is CD-ROM. The bitrate of current communication network does not allow Internet distribution. Materials have large amount of video clips and can be use on LAN but is almost impossible to transmit them to students'

computers over telephone lines. On the other hand we are also members of European project COLOS (see COLOS) where the interactive computer materials is accessible over the Internet.
When we gain experience we find out that teachers have to be prepared to use this material as a valuable support in their work. This is the goal of the project "Multimedia for teachers".

Project Goal:

Curriculum:

Subject: **MULTIMEDIA**
Time span: 60 hr; 30 hr lectures, 30 hr practical experiments
Year: 2. or. 3.

Goals:

Students will:

- become aware of the importance of mono/multimedia system in education;
- become aware where and how they can use mono/multimedia systems in their work;
- get qualified and motivated for creative problem solution in primary and secondary schools using mono/multimedia systems;
- get qualified for use of mono/multimedia system during their studying and research & development activities.
- get acquainted with methods and rules for making of simple mono/multimedia systems in their classes and basic laws of special didactics for that field.

Contents:

1. *educational technology basics*: terms, classification, history, mono/multimedia in education;
2. *monomedia systems*: technical didactical characteristics of visual and audio monomedia systems;
3. *application of computer in education and educational information system*: cybernetics, systems theory, information theory, communication theory, information systems;
4. *multimedia systems*: terms, classification, history, technical didactical characteristics of multimedia elements/systems and;
5. *planning the appliance of mono/multimedia system in education.*

Project Plan:

IMAGE NOT AVAILABLE

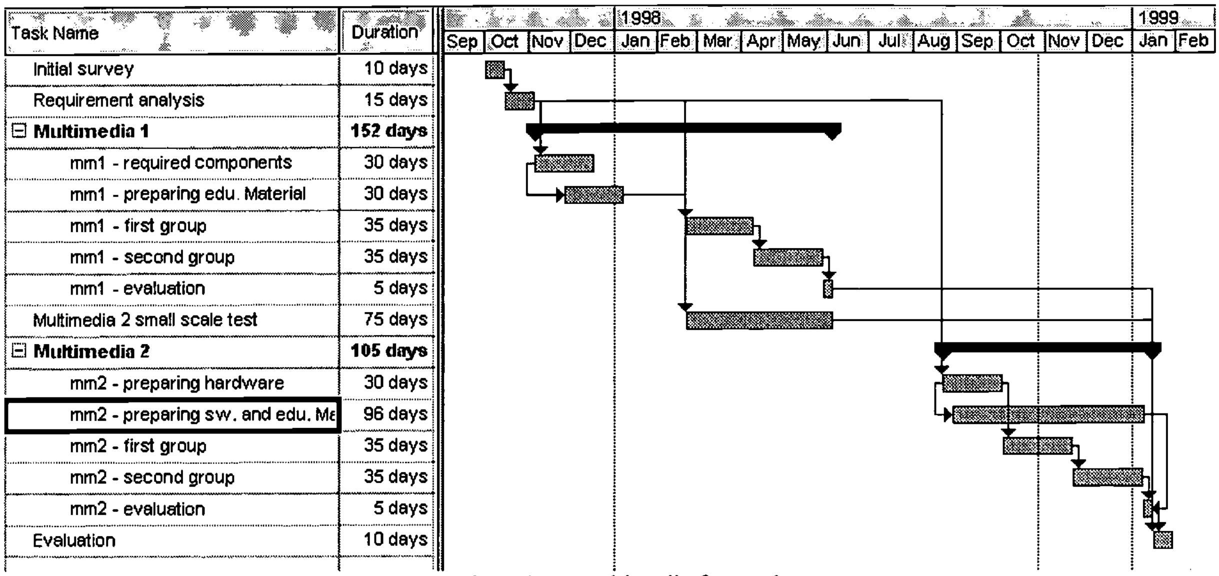

Figure 1: project plan - multimedia for teachers

Description of the Plan:

In the "*initial survey*" we gain the agreement of the different participants of the project. It was decided to separate multimedia into two courses. First course "Multimedia 1" would gives students initial knowledge to the traditional multimedia systems (radio, CD players, cassette recorders, minidisks, TV studio equipment, VCR's, camcorders, presentation techniques). The student course having elements of multimedia 1 was held even before. It was called "*Educational technology*". Now it was reorganized and renamed into multimedia 1. The second course "Multimedia 2" would extend students knowledge to the computer technology. Objective for the project is two level of knowledge. In the lowest level students would learn what the new technology is capable to do. In the highest level students would be capable to fully utilize the new technology. With these levels we provide individualization and differentiation.

In the "*requirement analysis*" we were to make a rough list of required equipment, hardware, software and educational material for each of the working place. Most of the traditional multimedia systems were already presented at the faculty but computers were not. The project could easily be jeopardized if we could not gain enough funds to equip a new computer multimedia room. It was decided that no previous knowledge would be required for course "Multimedia 1" but for course "Multimedia 2" a knowledge of use of computers operating system (MS Windows); wordprocessor (MS Word); presentation program (MS PowerPoint) and; Internet browsers would be required. Education material for the "Multimedia 1" would be prepared; printed and put to every working place but for the "Multimedia 2" education material and descriptions for every working place would be on the Internet. We were capable to do this since every working place would have a computer connected to the Internet.

The phase "*Multimedia 1*" was divided into several tasks. The first task "*mm1 - required components*" was to establish the working places; put equipment to that working places and; check how things work. It also includes the detailed learning of tutors how to use every single equipment. When task "*mm1 - required components*" starts we could start second task "*mm1 - preparing edu. material*". Education materials were consist of manuals; description of the working place and required work to do at the specific working place.

"*mm1 - first group*" and "*mm1 - second group*" are tasks where Multimedia 1 becomes operational. 429 students in the second year passed this course. Informations we get from them were satisfying. Most of the students really enjoyed working with audio, video and presentation equipment.

At the same time we start with elements of Multimedia 2 - "*Multimedia 2 small scale test*". The test group was the students of computer and mathematics teachers' course. We got valuable responses from them what can we expect from other students. They help us prepare better educational material and establish the working places.

In the task "*mm2 - preparing hardware*" not only computers needs to become operational. A new LAN with UTP technology has to be made and furnished the whole room. The task "*mm2 - preparing sw. and edu. material*" takes a lot of time because preparing web pages with instructions and lectures takes a lot of effort. (Ambron, S.,& Hooper, K. 1990), (Bergman, R. E., Moore, T., V. 1991), (Frater, H.,& Paulissen, D. 1994), (Gerlic, I.

1991), (Jereb, J.,& Jug, J. 1991), (Tauber, H. 1993), (Wodaski, R 1992). Now we are at the point where first student group are learning multimedia with the computer.

Description of Multimedia course

It was easy to establish first part of multimedia course "Multimedia 1". We have many years of experience with similar course "Educational technology". Preparing students to the course "Multimedia 2" was primary objective of course "Multimedia 1". Most of the students have sufficient level of knowledge even prior attending this course and most of them just love working with the latest technology. For most inquisitive students we also have video studio equipment. Students have to pass through every working place except video studio.

Multimedia 2 was completely new course. We had skilled personnel but no experiences with students for this course. Preparation of working places and working instructions required paramount attention. Everything was designed to be easily changed. Now we could increase or decrease required work in a matter of hours. Since everything is accessible on the Internet and students can prepare themselves before they actually come to work with equipment.

We will explain procedures of course "Multimedia 2" in more details. The course "Multimedia 2" has nine working places. Attending students have instant help from assistant and technical support person. Students are encouraged to pass through as many working places as they can during their course.

Description of working places:

- three are for processing audio signals (CD, tape, radio, voice, Internet ...);
- two are for image processing (scanning, digital photography, retouching, OCR ...);
- one is for animation (GIF, AVI, MPEG ..);
- one is for Internet (searching for multimedia web sites, educational software, downloading, installing, writing manuals for downloaded programs, ..);
- one is for video capturing and;
- the last one is for presentation (PowerPoint, DVD ...).

Problems

One of the greatest problems we encounter was the required knowledge of using a computer. Students should gain required knowledge in the secondary schools but in reality we find out that this is not true. Since every student have free access to faculties computes (Internet; e-mail account and; PPP) we assume that they will use these services. We were wrong. Faculty of Education has a lot of different student programs. We have to teach them all. We were aware that students from natural sciences programs would easily accept computer as a working tool than the other students. In order to solve the problem we have to remake the lessons and make them in such a way that it would satisfy diversities.

We also have a problem in the system itself. Special didactics course (didactics of physics, didactics of geography ...) does not prepare students for new technologies. Students are unaware of importance of multimedia educational material. To overcome this problem we need to change the way people think.

Among other problems we also face software problem when we find out that Slovenian Windows are not completely compatible with English version. We could not use Volume Control to change any settings of the sound card. Any attempt was stopped with error message and Volume Control termination. We solve this problem by installing English version of Windows.

Future plan

Our future plans are:

- making multimedia learning material to be used by students and teachers in primary and secondary schools;
- establish multimedia advisory service for primary and secondary schools;
- establish standards and quality control for multimedia education material;
- lobbying for improving national/university computer network to advanced high bandwidth computer network;

- establish multimedia student program;
- establish university on demand TV;
- establish connections with other universities and improve students and lecturers mobility and;
- we will be open minded.

Conclusion

In today's modern world we cannot allow time to pass by. Learning must become more effective and multimedia is the answer. So future education cannot be without multimedia. As this is true a lot of work needs to be done to produce enough multimedia educational material for every program and every course. Constant education of teachers and students is essential for this to become true. Multimedia education material and high bandwidth network must be accessible to every interested individual.

Intellectual Property and Copyright : Ideas for Managing Issues and Protecting Educational Interests

Janis H. Bruwelheide, Ed.D.
College of Education, Health, and Human Development
Montana State University-Bozeman
United States
janisb@montana.edu

Abstract: How do we create an innovative, supportive environment for teaching and learning in an electronic environment while attending to copyright and intellectual property concerns especially considering recent changes made to copyright law in the United States? The subject of intellectual property is one of importance to individuals involved in all aspects of Internet and Web based education globally. This session will set forth some intellectual property concerns and issues for faculty and institutions and suggest policy and content and audit points for consideration and discussion.

Introduction

The electronic environment is forcing educators at all levels to revisit issues concerning intellectual property. Quick availability of information and data electronically has changed the way the general public views information since it is in seeming less endless supply on anyone's desktop. Thus, faculty and students alike are faced with a figurative smorgasbord of materials in varied formats. A dilemma concerning intellectual property occurs when owners' rights collide with users' rights and the public need to access and use resources. Thought provoking papers about the Internet and intellectual property are becoming available on the World Wide Web. Esther Dyson has written a book, Release 2.0, and several articles dealing with intellectual property on the Internet and the intellectual value of property. An article by Vincent J. Roccia presents an interesting perspective on copyright law in the United States and possible changes or clarifications needed perhaps to enhance applicability to the Internet. Current copyright laws in the United States perhaps do not quite address the Internet per se because it represents a challenge to existing law and interpretations.

This paper will present a brief overview of several topics. The first is ideas and concerns as to why faculty and institutions in education, particularly higher education, have good reasons to ask questions concerning "who owns what" in a era where educational opportunities may be delivered through the World Wide Web and various distributed learning systems. Secondly, it will present issues relevant to learner support and student ownership. Lastly it will present sources of information, and sample policies, as well as ideas about ownership of intellectual property which institutions might consider. A copyright update for 1999 will be an inclusion of this brief paper on intellectual property concerns and issues. These issues include highlights of Digital Millenium Copyright Act signed into law in October, 1998, new provisions for library preservation copying, and distance learning guidelines currently under study by the Register of Copyrights.

Institutional and Faculty Concerns

Distribution mechanisms, format of materials, and traditional models of ownership are bringing increasing concerns about intellectual property development, use, and application to a new importance in academic conversations. University professors, under the old way of viewing ownership, were the single owners and authors of intellectual property with a few exceptions. However, in today's environment, ownership may be shared with several individuals or organizations as new technology encourages development of multimedia products using a variety of formats and pieces which may involve multiple layers of copyrighted materials.

The dilemma of "who owns what" is compounded when one considers matters such as how much support, use of facilities, and equipment involvement are used to produce a work using newer electronic technologies. Often the institution has invested a great deal of funds in a project or product before it is used for educational purposes. The author believes that basically four major issues concerning intellectual property need to be addressed by faculty and institutions through dialogues, policies, and communication:

1. Ownership of intellectual property
2. Rights to use intellectual property
3. Procedural issues concerning intellectual property
4. Special considerations concerning copyright

In most cases, an "audit" or checklist of what rights need to be acquired, cleared, or considered must be developed prior to design, production, and delivery of a course, for example, through the World Wide Web or through other distance learning distribution systems. Institutional personnel should think through what rights are needed for a course and what all future possible uses and distribution mechanisms of course content might be prior to release. If not accomplished prior to development, the entity could find itself having to retrace steps and renegotiate or acquire additional rights at more cost. Thus, planning ahead with a checklist approach could save a great deal of money, effort, and hassle for all involved.

Some authors and organizations have made information available which can encourage and guide discussions about intellectual property in the higher education environment. Many professional associations are discussing the issues but no definitive checklist or statement exists currently since ultimately each institution must deal with the volatile topic of intellectual property and issues concerning "who owns what" at the state or local level. A few examples of resource materials are included at the end of this paper. An interesting document entitled Ownership of New Works at the University: Unbundling of Rights and the Pursuit of Higher Learning by the Consortium for Educational Technology for University Systems, CETUS (www.cetus.org), suggests several points worth considering in a discussion. The group sets forth a viewpoint that simple, individual ownership of all rights which are associated with copyright may not now be the most desirable avenue as it may stifle creativity and new work unduly. Thus, it is time for higher education to revisit ownership of intellectual property in order to avoid contention, place the focus on optimal access and development of works, and reduce the emphasis on economics which often dominates discussions about intellectual property. CETUS sets forth the "three C approach," to conversations about intellectual property: creative initiative, control of content, and compensation concerning published as well as unpublished works. The approach is quite useful as it may be less intimidating and antagonistic than beginning with the economic issues and may apply more broadly to faculty engaged in producing materials but not necessarily receiving compensation for those materials.

The CETUS model for discussion, the "three C approach" presents the following points. The first point is creative initiative and poses discussion questions such as "who generated the idea for the work, whether published or unpublished, and who created the work and fixed it in a tangible medium? For example, a Department Chairperson might encourage faculty to publish but not dictate the ideas and content. The entities of initiator, creator, and fixator may not be the same. The second point for discussion deals with the control of content as to who controls creation, production, specifications, and authority for acceptance. The degree of control is something which might be negotiated. The third point is compensation and other support. The CETUS document suggests that unless the two were extraordinary--above what faculty are normally provided-- the faculty would most likely retain ownership of intellectual property they created. Again, there are many areas of negotiation under the third discussion point.

Another way of approaching ownership of intellectual property is presented in a paper by Dan L. Burk, an attorney and Associate Professor of Law at Seton Hall University. He presents a good overview of models for copyright ownership of electronic course materials between faculty and their sponsoring institutions. is paper presents detailed discussion of advantages and disadvantages of three sets of options and two models which might be considered by universities and colleges drafting documents for copyright.

Bruwelheide presents in her writings several issues concerning intellectual property and some materials specifically targeted to copyright, telecourses, and Internet.

In summary for this section, it is important for universities, colleges, and faculty to engage in dialogue concerning intellectual property so that ownership issues are clearly defined before products are developed by institutions, faculty, and even students. There is plenty of room for negotiation but faculty must be informed about policies and participate in the development. If not, both faculty and institutions stand to lose a great deal. Creation of new intellectual property is very important and the climate must be supportive for both sides.

Student and Learner Support Issues and Concerns

Students' rights to ownership of intellectual property they develop while students or student workers at a college or university need to be considered in addition to rights of faculty. In some instances, universities and colleges lay claim to all work produced by students. This issue needs to be addressed by institutions, policies developed, and ways found to inform students as in the catalogs for the institutions.

Learner support issues for courses delivered via distributed learning technologies bring new concerns to the discussion table. Included are topics such as electronic reserves for libraries and housing of course syllabi and materials on a university computer network. The author presents questions such as the following:

1. What rights need to be acquired and cleared prior to posting course materials including syllabi and readings on a closed versus an open network? The same question applies to courses delivered via the World Wide Web and other distributed learning networks such as video conferencing.

2. Is an online class treated the same or differently than a traditional "face-to-face" class when it comes to copyright issues? Many institutions are treating an online class such as one delivered via the Web or through computer conferencing software as a closed class which must be password protected. Thus, only students actually enrolled in the class could access materials with a password and not much material could be seen by non enrolled individuals.

3. What about posting student work to a class web site? It would seem certainly that clearances would have to be obtained from the students.

4. May students freely use materials they find via the World Wide Web for class projects? Does the format make a difference or are formats such as music, video, and graphics to be treated differently than print materials?

5. May library personnel scan articles for online class reserve systems? If so, must the network be closed except through students enrolled in a specific class?

Closing Statement

This paper has set forth some ideas to provoke discussion and perhaps policy development for intellectual property issues, particularly copyright, which need to be addressed by institutions of higher education and faculty in order to maintain the flow of good materials in a changing electronic environment. Failure to discuss and address these issues may result in a curbing of creativity and much antagonism on the parts of faculty and their institutions. Many models and points for discussion exist which can lead to successful negotiation of ownership issues.

Resource List

Materials dealing with intellectual property globally are abundant and quite easily located via the World Wide Web. The materials selected for inclusion in this list are by no means comprehensive and the list is not exhaustive. Sites were selected because they provide unique information and/or links to many additional resources on a variety of intellectual property topics issues, and perspectives. Readers may follow links in the resources to obtain more information. While the primary focus is on USA resources, some urls are provided for international perspectives and have links to hundreds of sites. Sources are current as of mid-1999.

AN ANALYSIS OF INTERNET-BASED COMMUNICATION AND COLLABORATION AMONG K-12 TEACHERS

Barbara Ohlund, Instruction and Research Support, Arizona State University, USA, barbara@earthvision.asu.edu
Angel Jannasch-Pennell, Ph. D., Instruction and Research Support, Arizona State University, USA, angel@asu.edu
Samuel A. DiGangi, Ph.D., Instruction and Research Support, Arizona State University, USA, sam@asu.edu
Sandra Andrews, Instruction and Research Support, Arizona State University, USA, ozma@asu.edu
Chong Ho Yu, Ph.D., Instruction and Research Support, Arizona State University, USA, alex.yu@asu.edu

Abstract: This study investigated the use of asynchronous (mailing lists) and synchronous (chat sessions) Internet-based communication and its impact on teachers' attitude toward collaboration, activity completion rate and test performance. Although in this study it was found that attitudes toward collaboration did not affect test performance, the data suggested a relationship between attitudes toward collaboration and use of Internet-based communication. Also, it was found that use of Internet-based communication increased the likelihood of completing the course activities.

OBJECTIVES

Cognitive models of learning stress that learners are active agents in constructing their own learning (Shaw, 1995; Biehler & Snowman, 1986). Asynchronous and synchronous communication provides users with opportunities to collaborate across distances through such technologies as mailing lists and chat sessions, respectively. It was hypothesized that these modes of communication provide unique features conducive to the development of a collaborative community of learners. The benefits of Internet-based communication and collaboration are not reflected solely in test performance. Behind the behavioral change is an attitudinal change. Gain in test performance might be short term; change in attitude could facilitate life-long learning (Yu, 1998). Therefore, this study investigated the use of asynchronous (mailing lists) and synchronous (chat sessions) Internet-based communication and its impact on teachers' attitude toward collaboration, activity completion rate and test performance.

THEORETICAL FRAMEWORK

Several theoretical perspectives suggest that peer interaction occurring in computer networked groups may be beneficial to learning. These perspectives include Vygotsky's (1978) and Piaget's (1963) emphasis on social construction of knowledge and Bandura's (1969) interpretation of peer modeling (King, 1989). From a social cognition point of view, when educators interact with peers they are faced with ideas, explanations and information inconsistent with prior knowledge and beliefs. Confronting these inconsistencies challenges one's current point of view; resolving such cognitive conflicts results in cognitive restructuring (Bearison, 1982). Group members presumably add detail to existing cognitive schemas, explore and correct misunderstandings, fill in gaps in their knowledge, and/or reorganize their knowledge structures (Bearison, 1982; Piaget, 1963; Vygotsky, 1978).

Collaborative learning is the acquisition by individuals of knowledge, skills or attitudes as a result of group interaction, where that specific learning could not have been derived individually (Schrage, 1990). Computer-mediated collaboration provides a medium for educators to learn to engage in collaboration with other educators at a distance. Alavi (1994) observes that those involved in collaboration can monitor individual thinking, opinions and beliefs and provide feedback for clarification and change.

Internet-based communication provides both asynchronous and synchronous environments for collaboration. Synchronous communication (such as chat) allows interaction to occur at the same time among learners, as in classroom discussions: but learners in the Internet environment use a keyboard to type messages. Local Internet accounts enable learners to engage in collaborative chat sessions with distant peers, expanding the collaborative environment from a single classroom to classrooms around the world. Asynchronous communication (mailing lists) allows interaction to occur at different times and locations between two or more learners. Learners need not be present to receive information, and may communicate when ready. Learning occurring as a result of group interaction may take place in a virtual community and may be adjusted to student need, schedule and educational goals. Both of these forms of Internet-based communication expand learners' access to information, resources, and collaboration, and may increase learners' attitude toward collaboration as well as achievement performance. In this study, we are interested in both forms of Internet-based communication as they relate to learner attitude toward collaboration and the completion rate and performance on Internet skill tests.

HYPOTHESES

Based on the above theoretical framework, the following hypotheses were formed:

(a) Use of Internet-based communication increases teachers' positive attitude toward collaboration on the Internet as measured by the *Stages of Concern Instrument: Attitudes Toward the Internet* (*ATI*; Hall, George, & Rutherford, 1977; Well and Anderson, 1997);
(b) Use of Internet-based communication increases course completion rate;
(c) Use of Internet-based communication increases test performance as measured by criterion-referenced Internet skills test;
(d) The more positive teachers' attitudes toward collaboration, the higher the increase in teacher performance as measured by criterion-referenced Internet skills test; and
(e) The more positive teachers' attitudes toward collaboration, the higher the course completion rate.

METHODS

PARTICPANTS

Participants in this study were one hundred sixty-one K-12 educators residing throughout a southwestern state. All participants took part in an interactive web-based course designed to enhance the collaborative teaching and learning communities for participating educators as they acquired Internet skills.

TREATMENT

The treatment was an interactive web-based course designed to enhance the collaborative teaching and learning communities for participating educators as they acquired Internet skills. Of particular interest were new outcomes made possible through use of advanced technologies in instruction. Therefore we looked at the engagement in Internet-based communication and increases in Internet skills.

PROCEDURE

Participants were part of a large collaborative community (the course) as well as of smaller communities focused on establishing professional relationships and on technical and course help. These smaller communities were facilitated by a group leader trained in the use of Internet technologies and in how to facilitate Internet-based communication. Participants had access to chats and were members of two course-related mailing lists, (a) course announcements, and (b) a group list headed by the group leader. Group leaders conducted at least one chat bimonthly and communicated with their participants via group mailing lists biweekly. Participation in chats was mandatory for group leaders and strongly encouraged for participants. Participants were encouraged to join other mailing lists within the course setting as well as outside of the course. Archives of eleven chat sessions and eleven mailing list groups were used in this investigation. The Internet skills that participants were to learn focused on searching techniques and the use of email. Participants completed a pretest assessing their Internet skills in these areas. Following the pretest, participants completed tutorials specific to these skill areas, then completed a posttest.

DATA COLLECTION

Two instruments were employed in this study. The first instrument was the *Stages of Concern Instrument: Attitudes Toward the Internet* (*ATI*; Hall, George, & Rutherford, 1977). This scale was developed to measure the evolving attitudes of learners exposed to an innovation. In this original scale, the variable word "innovation" may be substituted with the innovation of interest. Therefore, in a study regarding learner attitudes toward a new innovation, specifically the Internet, Wells and Anderson (1997) substituted the variable "innovation" with "Internet" to measure attitudes toward the Internet. Reliability of the instrument was reported as .91 (Reed, 1990), and discussed in detail by Wells and Anderson (1997). The second instrument was a performance test over the Internet skills learned that was developed by our research team. For both measurements, a pretest was administered prior to a web-based instruction program. Three months later a posttest was given. The interval was short in order to avoid the "maturation" effect in which subjects improve over time regardless of treatments (Cook & Campbell, 1979). All participants completed the pretest and 95 finished the posttest. One hundred and fifty-nine participants completed the ATI survey and fifty-six completed the post-survey.

A subscale of ATI was used to measure the attitude toward collaboration though the entire survey was administered to the participants. The survey was composed of 35 questions and could be divided into seven subscales, which indicated seven stages of concern with the Internet. The seven stages were awareness, informational, personal, management, consequence, collaboration, and refocusing (Wells & Anderson, 1997). Please see Table 1 for the items in the collaboration subscale.

Question 5:	I would like to help other faculty use the Internet.
Question 10:	I would like to work with present fellow workers and others who are using the Internet.
Question 18:	I would like to familiarize my colleagues about the Internet as I learn more about it and with it more.
Question 27:	I would like to coordinate my efforts in learning about the Internet with fellow workers.
Question 29:	I would like to know what other people are doing in relation to the Internet.

Table 1: Collaborative subscale in Stages of Concern Instrument: Attitude Toward Using the Internet

Factor analysis confirmed the factor structure of the instrument. Based on the pre-survey data, the survey items could be grouped as eight latent variables according to the Kaiser criterion (eigenvalue as one or larger). By examining the inflection point in the scree plot, seven factors could extract most of the eigenvalues. In the post-survey, Kaiser criterion also suggested eight factors while the scree plot implied five to seven factors.

Based upon the pre-survey data, the estimated reliability of the entire ATI survey in terms of Cronbach coefficient Alpha was .86 whereas the Cronbach coefficient Alpha for the collaboration subscale was .87. In the ATI post-survey data, the overall Alpha was .89 while the collaboration subscale Alpha was .79.

The second instrument in this study was a criterion-reference performance test, which consisted of 30 items. Cronbach coefficient Alpha of the pretest was .45 whereas that of the posttest was .86. The low Alpha in the pretest, which was expected, implied that participants were unfamiliar with the subject matter and random guessing of answers led to inconsistency. In the posttest the high Alpha denoted that the response pattern was internally consistent.

Finally, use of mailing lists and use of Internet chat were logged as a measure of engagement in Internet-based communication as a collaborative tool. Originally, engagement in collaboration was defined by the number of words in email/chat and the total number of messages. However, these distributions were highly skewed and thus violated the assumptions of parametric tests. Therefore, observations were re-coded into four binary variables: (a) use of mailing lists, (b) use of chat sessions, (c) use of both mailing lists and chat sessions, and (d) use of neither mailing lists or chat sessions.

RESULTS

Prior to addressing the hypotheses, two one-tailed dependent t-tests were employed to examine whether improvement in teacher scores on the Internet skills test and the ATI collaboration subscale occurred after the treatment. The dependent t-test for the difference between the pretest and posttest yielded a significant difference, $\underline{t}$

(94) = 16.33, p = .0001. Given that the effect size was .03, the alpha level was .05, and the sample size was 95, the power for this t-test was .90, which indicated a high probability that the null hypothesis was correctly rejected.

On the average participants had a decrease in the positive attitude toward collaboration after the treatment, M = -0.67. A dependent t-test showed that this decrease was not significant, t (42) = -0.88, p = 0.38. This result might be due to the lack of statistical power. Given that the effect size was .03, the alpha level was .05, and the sample size was 43, the power for this t-test was .61, which indicated that a true significant difference might be undetected.

To test the hypothesis regarding the relationship between engagement in Internet-based communication and attitude toward collaboration (hypothesis a), exploratory data analysis instead of ANOVA was performed to examine the relationships. The data structure did not conform to the parametric assumptions of ANOVA such as normality and homogeneity of variances, and this sample size was not large enough to run a robust ANOVA test. In the exploratory data analysis, it was found that users of chat and mail tended to center around the mean of the difference between collaboration pre-survey and post-survey, as shown in Figure 1. Participants who engaged in chat sessions had less variability on the change score of ATI (-7.5 to 1.5) than the general test population. Likewise, participants who posted messages on mailing lists also centered around the mean (-4.5 to 4.5). Therefore this might indicate that participants who engaged in chat sessions or mailing lists have less change in their attitude toward collaboration than those in the general test population, maintaining scores close to the mean.

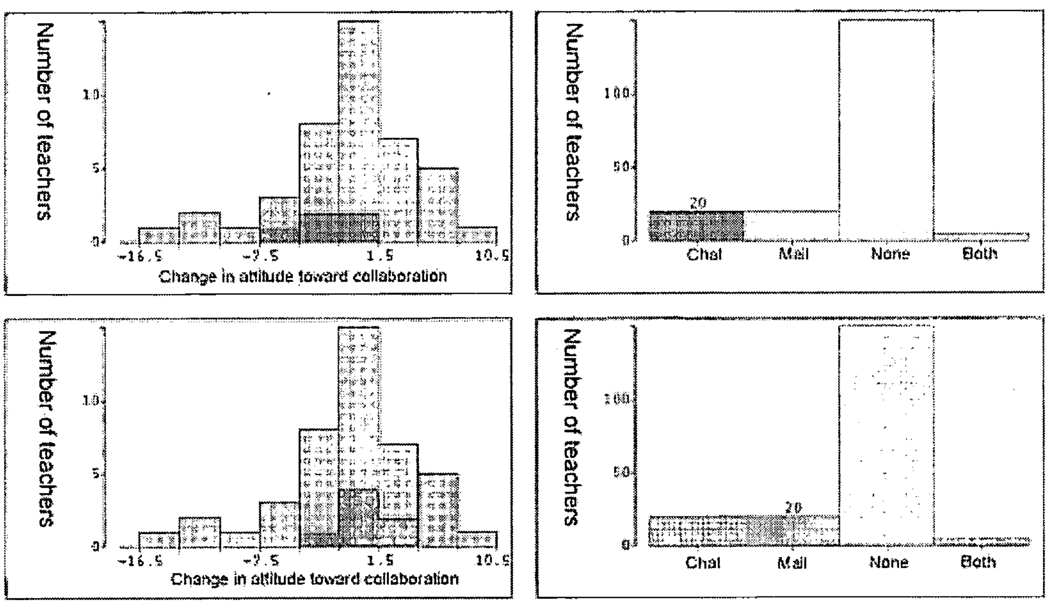

Figure 1: Linked observations between use of collaboration and changed scores in attitude toward collaboration

A Chi-square test of goodness of fit was applied to investigate whether engagement in Internet-based communication could increase the likelihood of completing the entire instructional module (hypothesis b). Likelihood ratio Chi-square was used because it is related to log-linear model and logistic regression model, and completion of module was a dichotomous variable. The Chi-square analysis yielded a significant result, Likelihood ratio $X^2 = 8.19$, p = .042. Because one of the cells had no subjects and some cell sizes were very uneven, a Chi-square test might not be valid. To rectify this shortcoming, an exact test was performed using StatXact (SPSS Inc., 1999). Both asymptotic inference and exact inference yielded significant results. In the former the one-sided p-value was .02 whereas in the latter the one-sided p-value was .03. These results indicate that engaging in Internet-based communication increases the likelihood of completing Internet activities.

As the data structure did not conform to the parametric assumptions of ANOVA, a one-tailed two-sample independent t-test was applied to examine hypothesis (c), regarding whether engagement in Internet-based communication could lead to improvement as measured by the difference between the pretest and the posttest.

Originally, use of Internet-based communication was classified into four groups, namely, use of chat, use of email, both, and none. For conducting a t-test, the first three groups were collapsed into one group. As a result, only two groups remained, namely, use of collaboration and no use of collaboration. The two-sample t-test did not yield a significant result, $t(28) = .61$, $p = .54$. Therefore, use of collaborative tools did not appear to have an impact on test performance.

Regression analysis was adopted to test hypothesis (d), which was concerned with the relationship between attitude toward collaboration and test performance. The assumption of random residual was checked by plotting predicted scores against residuals. The regression analysis disconfirmed use of Internet-based communication as a predictor to Internet skills test performance, R^2 (42) = .0005, $p = .88$. The scatterplot of the two variables did not display a pattern (Figure 2).

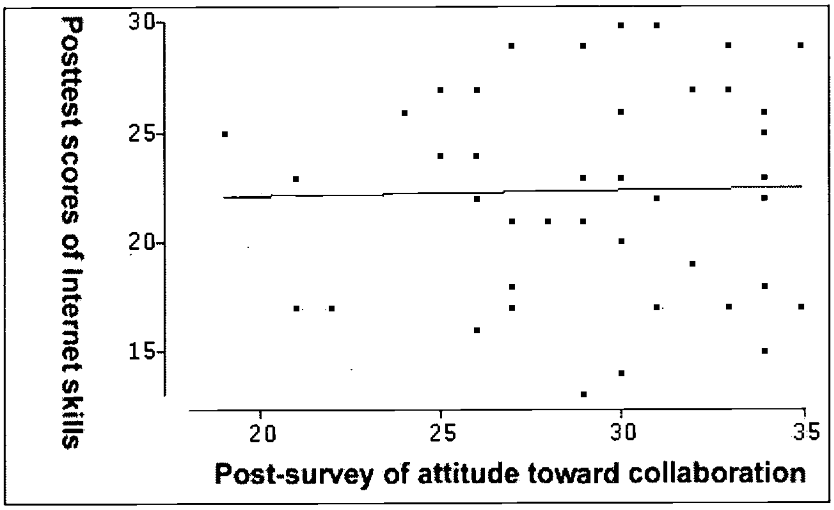

Figure 2: Scatterplot of attitude toward collaboration against posttest scores.

A logistic regression was employed to examine hypothesis (e), which addressed the relationship between activity completion and the attitude toward collaboration in the Internet. The logistic regression analysis did not yield a significant result, $p = .60$, odds ratio = .98, therefore scores on attitude toward collaboration did not predict course completion rate.

DISCUSSION

Collaboration provides a way for educators to form a virtual community of learners in which members can engage in individual thinking, share opinions and beliefs and provide one other with feedback for professional and personal growth and change. In the course studied, Internet-based communication allowed participants to engage in collaboration with others across the state. Although the Internet provides different types of environments for communication and collaboration among users, their effects are as yet unknown. In this study, it was hypothesized that asynchronous and synchronous Internet-based communication provides unique features that promote the development of collaborative communities. In addition, this environment would then impact participants' attitudes toward collaboration and performance on Internet skill tests.

Although in this study it was found that attitudes toward collaboration did not affect test performance, the data suggested a relationship between attitudes toward collaboration and use of Internet-based communication. It is encouraging that use of Internet-based communication increases the likelihood of completing the course activities, though no link by instructional theory was established between the two variables. It was speculated that those who used chat sessions and mailing lists were motivated by their peers, or self-motivated by their own engagement, but no measure of motivation was conducted in this study and thus the issue remains inconclusive.

The results do not substantiate the remaining hypotheses. Therefore it may be concluded that in this population, attitudes toward collaboration are little effected by engagement in an Internet-based course. In addition, using Internet-based communication such as chat sessions and mailing lists do not effect participant performance. Similarly, participants' attitudes toward collaboration do not predict performance on Internet skill tests.

Although not all results lead to positive conclusions, it is important to understand the aspects of Internet-based communication that may contribute to the development of collaboration among educators at a distance. Information about the characteristics of Internet-based communication and methods of implementing effective collaboration must be investigated to increase educators' effectiveness, to enhance achievement for all students and to promote systematic school improvement. This study provides a step toward such research.

Collaboration is not a context-free concept: its implementation is tied to specific types of communication provided by the medium and the specific application within the medium. As indicated in this paper, mailing lists and chat sessions represent two different modes of communication. Within these modes, there is further classification by application such as moderated and unmoderated groups. Findings in this study should not be over-generalized and different research studies for different modes and applications of Internet-based communication are recommended.

Due to the sample size and the distributional assumptions, variables in this study were examined in a pairwise manner. This research project serves as a preliminary study to identify relationships among variables. As relationships are identified, a coherent model specifying the inter-relationships among variables can be constructed. To achieve this goal, structural equation modeling with a large sample size will be employed.

Abstract: This paper describes the process of converting an interactive multimedia training program with laser disc video to a program incorporating MPEG-1 compressed video on CD-ROM. An overview of the hardware and software demonstrates how a conversion can be accomplished by taking a standard, well-equipped personal computer and adding less than $1500 of additional hardware and software. A detailed of process outlines how a quality video production can be obtained with minimal cost. Video capture and edit techniques are outlined to provide a workable template for developers to follow. Working at the "low end" of "high tech" can produce a very acceptable multimedia product.

Introduction

The original interactive multimedia program, *Managing Asthma*, was developed by personnel at Carle Foundation Hospital and Illinois State University. It was used to train staff how to teach asthmatic patients the effective use of inhalers and peak flow meters (Byers and Rhodes, 1998). This program, authored with Asymetrix ToolBook II Instructor 6.0, contained 179 computer screens and a total of 30 minutes of full-motion video edited into 43 separate files. The video was displayed with an overlay board directly on the microcomputer monitor. User control of the laser disc player was enabled through a custom-built program integrated into ToolBook II Instructor.

The multimedia system, i.e., microcomputer, touch-screen monitor, videodisc player and speakers were placed in a self-contained wheeled "traveling case." This traveling case was placed in four departments at Carle Foundation Hospital and at seven of the associated Carle Clinics in Illinois. The system was available in areas such as lunchrooms, break areas on the hospital floor, or staff lounges.

During program development, formative reviews were carried out by health care specialists and designers. These reviews helped ensure that the program incorporated principles basic to the design of successful multimedia training applications (Palmer and Rhodes, 1997). More than 200 health care personnel who used the program completed an evaluation form and selective interviews were also conducted. The response indicated that staff had a very positive experience using the interactive multimedia system and find it quite helpful. More than 70% of those surveyed rated the program as "excellent," and 25% rated it as "good."

Although the program itself had exceptional ratings by users, the logistics of moving the traveling case from location to location and related difficulties of system maintenance became significant problems for health care personnel. While additional programs on asthma management and other disease entities would be welcomed, an alternative to the laser disc format became necessary. Compressed video on CD-ROM would solve many of the problems identified, especially those of portability, system availability and cost. With the proliferation of CD-ROM technology, program distribution would not be limited to the traveling kiosk or only to locations with a similar multimedia workstation. Unlike laser discs, CD-ROMs could be duplicated almost immediately at minimal cost as additional institutional usage dictated. Other features, such as audio over text would be available. A determining factor, however, would be maintaining the quality of video scenes because this was a significant positive factor for users.

Video encoding

As the first step in the conversion process, during the winter of 1998 we examined demonstration versions of some two dozen commercial programs with CD-ROM video. The results were not encouraging, especially for playback on a Pentium 90mhz microcomputer with a 24x CD-ROM player comparable to many of the machines to be found in the heath care setting. The most successful of the program in terms of video quality were those in which the original scenes had been made with "artificial" (blue-screen) backgrounds that reduced the amount of information to be compressed. Since the *Managing Asthma* video had been filmed in a real hospital setting, this was not an option for us.

At one point we considered "leapfrogging" CD-ROM delivery and moving directly to a DVD format. We soon found that an initial startup and certification cost of $50,000, conflicting technical standards, lack of development hardware and software in the university setting and playback units in the healthcare setting made this technology impractical for us, at least for the present.

After considerable further investigation, we located a software program containing compression algorithms that are significantly advanced enough to support required video quality levels on CD-ROM. This program is the XingMPEG Encoder 2.2 from Xing Technologies [www.xingtech.com] at a cost of $249.00. The XingMPEG Encoder will compress 30 minutes of video (.AVI format) into MPG1 files that fit onto one CD-ROM. Screen image resolutions from 160 x120 pixels to 352 x 240 pixels are available.

We have found that both 256 x192 pixel and 352 x 240 pixel images both provide more than adequate video quality for interactive multimedia training purposes. Indeed, by scaling we enlarged the 352 x 240 pixel images to approximately 600 x 400 pixels without noticeable loss of video quality. This conclusion does not come from a controlled research study, but from observation of experienced PC users. We had planned such a formal study, but after receiving user comments such as "That's really great," and "I didn't know you could do that," we simply moved ahead with development. As audio and video are synchronized and there are no obvious computer artifacts with Xing files, video quality is not an issue for viewers.

For the developer, the XingMPEG Encoder has a batch-processing feature that will compress a list of .AVI files without operator attention. The task list feature enables one to reconstruct individual MPG files should changes be required. XingMPEG Encoder supports PAL, NTSC, and FILM formats, with a wide range of data rates from 128kbps to over 1200kbps. Video can thus be customized for various delivery environments such as hard drives, local area networks, or CD-ROMs.

The interface screen for XingMPEG Encoder is very intuitive, displaying the New, Edit, Delete and Encode buttons in the main interface window. For each entry the operator selects the video format desired and identifies the source file and destination file. This feature saves time and minimizes the possibility of errors. The compression process is not time-intensive; for example, we found that a 30 second .AVI file could be compressed into a .mpg file in about four minutes. Batch processing can be set up to run overnight without operator intervention. In this conversion project, 30 minutes of video in 43 .AVI files spanning 4.2GB of uncompressed data were compressed to an equal number of .mpg files spanning 481MB resulting in a compression ratio of 8.79 to 1. As a compact disc will hold 650MB of data, adequate storage for program, graphics, and audio files was still available.

Video capture and editing

Without quality digital .AVI files captured from analog video, compression to MPG1 is not a profitable venture. We have found that the Miro DC30 Plus capture card and associated software from Pinnacle Systems [www.pinnaclesys.com] at a cost of $900 has done everything that we require. The Miro DC30 card will capture NTSC (composite and S-Video) and PAL analog video at 7MBps with minimal frame loss, perhaps one frame for video minute on the PC employed. The software for Windows 95 comes bundled with the board; the user interface is simple and procedural. Software for Windows NT can be downloaded from Miro; the user interface is more sophisticated, with both introductory and advanced levels. We have used the Miro D30 card and software to successfully capture motion and still frame video from S-Video, Hi8, and VHS tape decks and, for the *Managing Asthma* program specifically, a Pioneer laser disc player.

The capture process was made much simpler by having the file names and entry and exit points on the laser disc defined before capture. All systems used the "capture to memory" feature with the overflow going to a hard disk. When capturing video from laser disc or S-Video tape, a thin bar of unsynchronized video appeared across the bottom of the capture window. This problem was resolved by selecting the "TV cropping" setting. We captured NTSC video, quarter screen, with square pixels at a rate of 29.97 frames per second. Once the process was mastered, which took less than a day, fewer than three minutes were required to setup each video sequence for capture.

Because the video scenes had already been prepared for the laser disc version of *Managing Asthma*, video editing was only a minor part of the conversion process. When capturing video, we began about a second before and ended a second after the designated segment. The excess frames were easily cropped during editing. We experimented with cropping files using two editing programs, Adobe Premier 4.2 and MGI VideoWave. Both were satisfactory for our purposes, though with differences: Premier has more editing features than Video Wave, but with its relatively complicated interface is more difficult to use.

PC hardware and software

The personal computer used in the conversion process was a Dell 300MHz Pentium II machine with 10GB of EIDE storage and 128MB of memory. SCSI hard drives would have been preferable to the EIDE drives in efforts to minimize frame loss during video capture, but the latter were adequate for performance in this project. The hard disk space required for video capture depends directly upon the amount of video to be captured. The .AVI files required approximately 1MB per second of video captured. Digital .AVI files are about 10 times the size of compressed .mpg files, and space for both is needed during the compression process. In the configuration we used in the capture process, the resulting .AVI files were uncompressed.

We were able to store the 43 video files of *Managing Asthma* in both formats with space to spare. A Gateway 200MHz Pentium Pro processor in another machine also proved to be satisfactory for video capture and compression, but a Gateway 100MHz Pentium did not. There was a significant loss of frames in the capture process when a Gateway 100MHz PC with 64MB of memory was used.

The compact disc recorder (CD-R) in the PC was the latest Sony model with bundled Adaptec Direct CD software. We upgraded the software to Adaptec Easy-CD Pro 95. There were a number of problems with this hardware/software combination. We could, with enough time and effort, make an acceptable CD-ROM containing video and ToolBook II Instructor program files, but eventually removed the Sony from our development system. We settled on a Hewlett-Packard 4020i CD-R and Adaptec Easy Creator Deluxe [$100]. Easy CD Creator Deluxe has more features than Easy-CD Pro 95, including CD duplication, and is very reliable.

Production

The procedures for capturing, compressing, and editing the video scenes were relatively straight-forward, and the learning curve associated with hardware and software described above was not particularly steep. Adventures at the low end of high tech began in earnest when the various components of the development system were combined to produce the new CD-ROM version of *Managing Asthma*.

ToolBook II Instructor was retained for authoring, since we believed that using it would minimize conversion cost and conversion time. As program designers, we had worked with versions of ToolBook since Release 1.53 and were familiar with its idiosyncrasies, or so we thought. Even after an upgrade from version

6.0 to version 6.1a, there was a steep learning curve for incorporating digital video in an MPEG format into *Managing Asthma*. It was necessary to make significant modifications in the original ToolBook II Instructor program to use CD-ROM rather than laser disc video.

In order to control playback of the video segments, the ActiveMovie Control Object extensions, a feature of Window 95, must be added to the ToolBook II Instructor environment. These extensions enable the developer to use drag and drop technology to insert, position and size the window in which the video is to be played. The next step is to set the ActiveMovie properties. Displaying the default video controls (play, pause, stop rewind and fast forward) can be enabled or disabled as desired. We developed a simplified set of customized controls for video control. Nearly 50 parameters, such as size, window placement, auto-play and auto-rewind, are configurable.

In ToolBook II Instructor, the properties can also be set using scripts. The ToolBook II Instructor search and replace feature makes this method easier to use when making a comprehensive change in parameters such as the video display window size. For example, the sample script displayed below sets the display area, file to be played, disables auto rewind, plays the video segment and stops at the end of the segment with the last video frame displayed.

```
set bounds of ActiveMovie "Video" to 2000,700,8000,5000
set extMovieWindowSize of ActiveMovie "Video" of page "videoIntro" to 3
set extFileName of ActiveMovie "Video" of page "videoIntro" to / vDrive&":\asthmaMpg\astintro.mpg"
set extAutoRewind of ActiveMovie "Video" of page "videoIntro" to false
get extRun() of ActiveMovie "Video"
```

While the process is not difficult to describe, it did not operate very smoothly in practice. Asymetrix does not have "native support" for playing .MPG video files; that is, ActiveMovie is an "add-in," not part of the ToolBook II Instructor environment. ActiveMovie is not documented or supported by Asymetrix and minimally documented by Microsoft. ActiveMovie properties such as screen size and video file name that were configured with object control extensions would not remain stable in ToolBook II Instructor. We found it beneficial to save the file after every change. The "drag and drop" function to set the screen size was not operational; changes were made by adjusting parameters in the ToolBook II Instructor script. Some ActiveMovie parameters were operational in the script; others did not seem to be.

Naming conventions for .AVI and .MPG files were limited to the 8.3 standard because of ActiveMovie and ToolBook II Instructor constraints; file names were also case-sensitive. Thorough documentation, formerly often an afterthought, became a necessity. Every programming session was indeed an adventure. Eventually we were able to determine the optimal, if not ideal, relationship between setting parameters through ActiveMovie object control and ToolBook II Instructor scripting.

Packaging

Once the program was converted we needed to package the application in a way that the end user could easily install the software. The AutoPackager utilities supplied by Asymetrix provide the ability to distribute a professional looking installation program for a ToolBook II Instructor application. This program gives the developer the option to select the target distribution media of CD-ROM, floppy disk or Internet and set default configuration selections for the installation of the program. One of the more useful options is the ability to have the installation process copy the assortment of ToolBook files to the hard disk and allow the large video files to remain on the CD-ROM. Unfortunately this option does not support add-ins such as the ActiveMovie extensions we used. Video files thus had to be added to the distribution disc separately. We did use the packaging option for storing the audio overlays used in *Managing Asthma*.

Further development

We have decided to reduce the amount of adventure in further development by shifting to Visual Basic as an alternative to ToolBook II Instructor, even though we have been very pleased with what we have been able to do with ToolBook over the years. Visual Basic will provide a more stable environment for programming in general and ActiveMovie specifically. ToolBook II Instructor does not have support in the settings in which we work; Visual Basic is fully supported. Furthermore, extensive online support, user groups and many third party add-in modules are available for Visual Basic. Special promotions for Visual Basic are often to be found in academic settings; these promotions may lower the cost by as much as 75% from advertised prices.

The CD-ROM version of the program will receive the same type of use in "real world" settings as did the laser disc version. We will be determining whether the projected savings of logistical and maintenance time and money can be realized. Of most importance will be the response of health care personnel to this new delivery system.

Abstract: Struggles over educational access to new communications technologies in the age of US radio and television provide insights into current struggles of educational access to the "information superhighway". Findings from an historical analysis of these earlier periods show that educational access to new communications technologies is often constrained or marginalized in 4 primary ways: 1) definitional distinctions in law and policy, 2) high costs and technical operating standards, 3) technical ghettoization in low-power, low-reach technologies, and 4) mid-stream legal and policy modifications including challenges to regulatory jurisdiction. Similar methods of constraint are identified in the current context of universal service e-rate discounts for K-12 access to the NII. It is suggested that educators should be excited about NII service discounts, but wary of regulatory constraints.

Introduction[1]

The information age is upon us and the Clinton Administration's 1993 policy mandate to connect all schools to the National Information Infrastructure (NII) by the year 2000 has placed the education community at center (Information Infrastructure Task Force 1993). Such connections are not only necessary for educational delivery and achievement, it is claimed, but also for building a publicly accessible advanced telecommunications network for the nation. The *Telecommunications Act of 1996* is the legislation recently enacted to usher in the promise of this new age. Its universal service "e- rate" provisions establish discounts and encourage public/private partnerships so that K-12 schools, public libraries, and rural health care systems across the nation can defray the costs of accessing advanced telecommunications services.

But should educators trust the promise of the universal service e-rate as a way to ensure their access to the NII? There can be no doubt that the NII's advanced telecommunications networks and information systems have much to offer our educational, local, national, and international communities. Likewise there is precedent in US communications history for tempering market forces by regulating for the public interest. If we consider the history of how radio and television were introduced and regulated for educational access and use, can we find insight into the current situation?

In this paper, I report findings from an historical analysis of struggles between 1912 and March 1999 over terms and efforts to regulatorily ensure educational access to radio, television, and networked computer technologies. By submitting policy documents and related academic and popular articles to methods of textual analysis and genealogical discourse analysis (Foucault, 1984), I found that education is consistently constrained from being afforded secure and autonomous access when new communications technologies are introduced. Although access is supported rhetorically, financially, and regulatorily –both by government and the private sector – it is limited regulatorily through 1) definitional distinctions in law and policy, 2) high costs and

[1] For the sake of space, I have not included references to legislation or regulatory decisions that can be found using the title and date references provided in the text.

technical operating standards, 3) technical marginalization in low-power, low-reach technologies, and 4) mid-stream legal and policy modifications including challenges to regulatory authority of the FCC.

I argue we are currently seeing these kinds of constraints in the case of universal service e-rate provisions. Thus, my analysis would seem to suggest that the education community should both embrace and be cautious about the promise of the NII. For while advanced communications networks offer possible solutions for problems relating to providing K-12 education to a highly diverse national population, as in the past, they also threaten to either impose significant economic and organizational hardship on schools and their communities, or saddle them with unusable or marginal technological capabilities and unfulfilled hopes.

Limiting Educational Access to Communications: The Case of Radio

New technologies create the need for new regulations. When radio was introduced, for example, US legislators felt it necessary to regulate it so that dedicated frequencies could be set-aside for defense uses. In the US's first communications regulation -- the *Communications Act of 1912* -- a system of licensure was established that allocated particular spectrum frequencies to particular licensees. These early laws and regulations were constitutive in education's marginalization in communications.

In the first place, the 1912 *Act*, defined licensees as "persons, companies, corporations", and successive amendments defined them as "individuals, firms, or corporations" (1927), and as "persons, corporations, and amateur stations" (1934). Nowhere did the language of these early laws deem public educational institutions viable licensees, unless tied to private or government research under the 1912 provision for "conducting experiments for the development of the science of radio communication".

Secondly, The 1927 *Communications Act* established costly licensing fees and required that stations operate with stronger signals, longer hours, facilities built to code, etc. In 1929, *General Order 40* re-allocated spectrum and placed educational stations in low-power, low-reach frequencies which, although they were more expensive to operate, were more difficult to receive. These legislative and technical decisions had a chilling effect on educational uses of new radio technologies. Without the deep pockets or the technical acumen of their commercial counterparts, educators were often unable to meet the new, significantly more taxing financial and technical commitments of the late 1920s. And, because their stations were low-power and low-reach, they had trouble developing markets. By the time the *Communications Act of 1934* was passed, reports like the following were not uncommon:

> Professor Jerome Davis of the Yale University Divinity School presented...the results achieved by the present radio law. When it went into effect there were ninety-four educational institutions engaged in broadcasting; today difficulties put in their way are so great that many, including Columbia University and the Massachusetts State Department of Education, have given up entirely, while many of the others are rendered almost useless by the policies of the government (The Nation 1934, p. 201).

Despite these developments, there was some financial and institutional support for educational broadcasting. For example, the Office of Education for established a Radio Section in 1929 to "initiate and assist with research studies of radio" for adult education (Saettler 1990, p.213). The Payne Fund continued its long-standing support of lobbying efforts to set-aside dedicated non-commercial channels by coalitions like the National Committee on Educational Radio (NCER) (McChesney 1993). President Roosevelt allocated $75,000 to the Office of Education in 1935 to develop educational programming (Arafeh 1998). And, radio corporations offered free air time for educational broadcasting as part of their "public interest" mandate (Studebaker 1936)[2].

While each of these efforts generously contributed to the cause of educational radio in their different ways, commercial stations had a particularly strong effect. Not only were their lobbies strong, their willingness to broadcast educational programming for free made it difficult to justify the more costly alternative of educators owning, making, and running their own stations and shows.

By 1936, then, the question was more one of how education could contribute to commercial broadcasting's "public interest" mandate than how it could gain dedicated station access and programming control. This quote by Commissioner Studebaker from the 1936 National Conference on Educational Broadcasting is instructive,

[2] US Commissioner of Education J.W. Studebaker (1936), noted that "the commercial sale value of the [radio] time used by the Office of Education during the last six months has been estimated at several hundred thousand dollars. That is an impressive amount of money...And yet these [private radio] companies provide free time on the air to the Office of Education and to other educational and non-commercial organizations" (p.3).

particularly in light of current efforts at public/private partnerships for advancing the NII:

> Suppose we state the problem this way: How can public enterprise use a utility which is privately controlled? Let me repeat that: How can public institutions (educational organizations) use the publicly owned airwaves which are controlled by private enterprises under federal licenses? Is this the basic question that confronts us?...[T]o gain our objectives, educational broadcasting requires that we pool our knowledge of educational purposes and of planned instruction with the practical experience of broadcasters schooled in the technical complexities of radio...Let us – educators and broadcasters – go forward together (Studebaker 1936, pp. 4-5).

Educators and broadcasters did go forward – often together – but push-me/pull-you frequency set-asides and spectrum re-allocations kept educators off balance. The 25 AM channels reserved by the FCC for in-school educational use were later transferred to FM spectrum where limitations in bandwidth left only 5 low-power channels intact (Sterling and Kitross 1990). By the end of 1941, there were only 2 FM education-run stations which grew in 1945 to 6, and then to 90 in 1952. Frequency relocation to the 88-108MHz bandwidth, and changes in FCC guidelines that allowed education-run stations to broadcast with only 10 watts of power (5-10 mile reach) contributed to this upswing in educational radio stations. While the positive impact of these regulatory technical changes can be seen by the dramatic increase in stations between 1941 and 1952, educational aspirations were likewise limited by low-power stations and regulatory uncertainty. This is the fourth method of educational constraint to which I want to draw attention: 4) mid-stream modifications and revisions in policy, legislation, or administration that either frustrate or erode legitimate access and positive activity.

These four specific regulatory techniques helped marginalize the education community's radio use, often resulting in reliance on, and collaboration with, commercial enterprise. Federal and state governments were pleased with such arrangements because it relieved them of funding and staffing a more robust educational radio sector. As well, the primary burden of communications infrastructure development was placed on private industry which benefited because it was assured control of the medium and income from government- and foundation-subsidized educational programming. The education community, however, was placed in a role of dependence. As the promise of television loomed on the horizon, little would change.

Limiting Educational Access to Communications: The Case of Educational Television

The mid-40s increase in educational radio channels was partly due to regulatory and technical modifications required by the advent of television in which education got a poor start. The War Production Board imposed a station construction freeze between 1942 and 1945, and the FCC a debilitating license freeze in 1948 that lasted 6 years. Education was unable to get its foot in the television door during these early boom years.

During 1950 and 1951 of this of this hiatus, the FCC held hearings to determine the new regulatory scheme for both radio and television channel assignments, as well as for color television standards and educational television set-asides (Saettler 1968). A combination of lobbying efforts by the Joint Council on Educational Television (JCET), research provided by the National Association of Educational Broadcasters (NAEB), and the active participation of FCC Commissioner Frieda Hennock did result in 242 channels (most in the UHF band) being set-aside in 1952 for the education community. Educational broadcasters were encouraged by this show of FCC support as well as the generous sponsorship for program development provided by the Ford Foundation's *Fund for the Advancement of Education* (TFAE) (Brinson 1998, DeVaney 1990, Saettler 1990).

As in the case of radio, however, channels were located in low-power UHF frequencies that were more expensive to operate and could not be picked up by all television receivers. Four years after UHF ETV channel WOSU broadcasting in Columbus Ohio, for example, 85% of the sets in its market were still unable to receive its signal (Baughman 1985). This devastated educational broadcasters who, now subject to more stringent ratings measurement schemes, were hard-pressed to justify station ownership and operation for such small markets. Even with the success of the 1952 channel reservations then, educational broadcasters once again faced structural barriers and technical marginalization that hindered their ability to provide consistent, wide-reaching, and receivable educational programming to the schools and communities in their particular areas.

Educators' struggles for more favorable circumstances took a distinctly different turn in 1962 when Congress passed the *ETV Facilities Act*. Partly a response to an increasingly uncontrollable commercial sector, and partly an attempt to bolster the goals of Johnson's Great Society program, this Act initiated federal funding and regulatory support for *public* broadcasting[3]. As a result of the Act, ETV channels increased from 52 in 1961 to 114 in 1966 and then to 252 in 1972 (Sterling and Kitross 1990) – still in the low-power frequencies.

Between 1962 and 1967, educators sought programming from the Ford Foundation's National Educational Television Center (NET)[4] and settled in to one of the most robust, autonomous educational broadcasting moments in US history. Stations were in place, funding was available, and programming was on the rise. When the Johnson Administration's appointed Carnegie Commission's recommendations on extending the *ETV Facilities Act* were enacted in the *Public Broadcasting Act* in 1967, however, such halcyon days were over.

This Act not only passed control and funding of educational broadcasting to a publicly-funded but semi-private Corporation for Public Broadcasting (CPB), it also definitionally changed the educational broadcasting charge from one of either "educational" or "instructional" programming (i.e. ETV or ITV) to one of "public" programming. Within this definitional shift, ETV's instructional mission – which included distance initiatives up to this point – were excluded from public broadcasting's mission. "Public" broadcasting intoned broadly "cultural" programming. Once again, definitional requirements resulted in a marginalization that not only barred educators from being able to pursue what they had perceived to be their primary program content domain but, this time, also resulted in a loss of their stations to a semi-private government agency. This left the lower-power, lower-reach stations – particularly the closed-circuit, microwave-distributed Instructional Television Fixed Service (ITFS) systems –for instructional use. In the best cases, municipalities and states have developed local and regional instructional networks from these facilities. However and again, here was another case where education was being definitionally and technically marginalized while simultaneously being kept off-balance by uncertainty in policy and legislative determinations.

Cable broadband technology produced a similar scenario. Early days of its regulation held educational promise as the FCC encouraged cable systems to provide "public access" (i.e. channels designated for autonomous public, educational, and government use) through an informal recommendation in 1969. In 1972, the FCC mandated that cable systems serving areas with 3500 or more subscribers provide PEG channels and educators found yet another opportunity to utilize new communications infrastructure for their curricular and pedagogical purposes (Engelman, 1990).

Unfortunately, the Supreme Court ruled that the FCC was not authorized to mandate PEG access in *FCC v. Midwest Video Corporation* in 1979. This, in combination with the *Cable Communications Policy Act of 1984's* statutory location of jurisdiction for negotiating PEG set-asides in municipalities, had two effects. First, it reduced the likelihood of establishing PEG channels and, second, it continued the trend of technical marginalization by virtue of PEG stations being available only to cable subscribers within a small geographically-bound system (Arafeh 1992). What the case of cable shows, however, is one more form of mid-stream modification to laws and regulation: annulment of regulatory determinations through formal challenges to the jurisdiction and authority of the regulating body – the FCC.

To date, schools and districts have had varying degrees of success using television for education. This is partly because they have had trouble gaining access to production equipment and facilities, partly because regulations continue to change, and partly because they do not have the financial and human resources. Some states and regions have been able to develop quite robust educational networks (i.e. Iowa, South Carolina, etc.). This outcome has been facilitated in more recent days by regulatory initiatives like the StarSchools program. It is safe to say, however, that educational broadcasting has, and continues to be, difficult for schools to undertake – especially elementary and secondary institutions.

Conclusion: Lessons from the Past and the Promise of Universal Service

Combining the informational and computational power of computers with the fast and wide-ranging distributive power of telecommunications networks presents an unprecedented opportunity for commercial, interpersonal, and educational interaction. Or does it? Do these limited insights on the past help provide perspective on the present and future?

It would seem so, for while networked communications hold possibility for education, so did radio and

[3] The Act also mandated that all television sets be manufactured with UHF and VHF reception capability.

[4] Originally the National Educational Television and Radio Center, which was founded in Ann Arbor, Michigan in 1954. A collective that developed educational programming, it changed its name in 1963 to the National Educational Television Center (NET) and received funding from the Ford Foundation (Sterling and Kitross 1990).

television. Once again, K-12 access to new communications technologies is controversial; and the four regulatory constraints that I have outlined above remain hard at work.

The universal service e-rate program has been very successful in some respects. Over $1.4 billion dollars in discounts have been allocated to 94% of the schools that applied, and 54% and 48% increase respectively in schools and classrooms from 1994 to 1998 has been reported. At this rate, connecting all K-12 schools to the NII by the year 2000 may be an attainable goal, that already seems to be decreasing the positive correlation of school connection to the NII with race (Digital Beat, 1999).

The e-rate program is also being contested, however. The *Telecommunications Act of 1996* has deemed K-12 schools as having no legitimate interest in networked telecommunications other than as service end-users needing service discounts through an e-rate – a definitional distinction that supports the historical information provided above. And, as in previous communications scenarios, schools may be marginalized, or even ghettoized, by their less-than-state-of-the-art technology and, ostensibly, increasingly low-technology connections. Already there are password- and technically-driven "levels" to the Internet which distinguish commercial and government users from public and public institutional users like k-12 schools. Legislation like the *Next Generation Internet Research Act of 1998* and the *Technology Administration Act of 1998* are already trying to establish the I-NET, a value-added Internet, which again threatens to create and justify new technologies and capabilities outside of K-12 education's reach. Not every NII application is appropriate for elementary and secondary schools. Yet, as our conceptions of what these technologies can and should do are formed in early research, development, and implementation phases; educational and public aspirations should not necessarily take a back seat. As my research shows, limits to sophisticated technology has been particularly damaging for explorations of innovative ways education can contribute to uses of new communications and, in doing so, contribute to the public and national interest.

Lastly, there have been sufficient mid-stream modifications to e-rate legislation and its administration to keep educators off-balance and unable to plan for their futures. Telecommunications service providers have filed suits claiming that the financial obligation is overly burdensome and that cost models are unreasonable (c.f. ALAWON 1999b). Industry has also chosen to "pass through" their universal service costs to customers', creating public stir and political anxiety (Atlanta Journal and Constitution 1998). Some federal legislators have challenged the FCC's authority to create a non-profit, quasi-public Schools and Libraries Corporation (SLC) to administer the funds (Simons 1998), as well as the FCC's authority to pursue social policy goals through its regulatory activities (Broadcasting and Cable 1999). These regulatory destabilizations have created a stunting period of uncertainty, chaos and, at times, paralysis as administrative jurisdiction continues to change and the FCC walks on egg-shells in order to keep legislators from dismantling it. Most recently, there has been proposed legislation to require that schools receiving e-rate discounts use filtering software[5], and that the e-rate program be "killed" altogether [6]. Such opposition to supporting educational access to networked communications will inevitably have devastating effects.

Should educators trust the promise of universal service? This history suggests that they probably should not. And this is bearing out as the universal service e-rate program – and the schools, students, and communities it is supposed to benefit – is close to drowning through regulatory measures once again. There is the potential that this will be just another unhappy chapter in education's long history of attempting to benefit from, and positively use, communications technologies in the course of its work of educating the nation's children. However, it is my hope that the insights regarding K-12 education's marginalization relative to new communications technologies provided in this paper urges education advocates to keep their eyes on high-level policy, legislative, and regulatory activity – particularly when new technologies emerge. Only in this way will the educational community – and the public-at-large – gain assured, robust access to new communications technologies now, and in the future.

The Development of a Multimedia Instructional CD-ROM/Web Page for Engineering Graphics

Stephen W. Crown
Department of Engineering
University of Texas – Pan American,
United States of America
scrown@panam.edu

Abstract: The positive response to a tutorial video tape developed for an engineering graphics class ultimately lead to the development of a comprehensive multimedia instructional CD-ROM/web page. The project in its current state consists of an integrated web site with links to hours of tutorial movies, lecture presentations of all class lectures, web-based games that reinforce significant course topics, and a series of interactive web-based quizzes. The through discussion of the specific methods and tools used to develop each component of the project is presented including a discussion of the many challenges encountered. A realistic picture is painted of how the project both positively and negatively has impacted the course and individual students. A detailed estimation of the overall time investment made in the development of the project provides a reference for those considering undertaking a similar project. The overall outcome of the project was positive and has led to an expansion of the project to include the offering of an on-line graphics course and the development of similar work for other engineering courses.

Background

Engineering Graphics is an introductory engineering course that teaches the fundamentals of graphical communication and how to use a specific computer aided design drafting (CADD) software package. The course is often the first engineering course that students take and many base their decision about their future as an engineering student on their experience in this course. A number of area high school students also take the graphics course each semester. A positive experience in this course commits students to the engineering program and motivates them toward completion of their degree.

Running counter to the objective of providing a positive experience in the engineering graphics course are several realities faced by all academic institutions. Economics dictate high student to teacher ratios even in a laboratory setting. Laboratory assistants do not have the same level of training or motivation as the professor. Students enter each course with varying backgrounds, learning abilities, and learning styles. Such realities often lead to a course that caters to the average student leaving slower students confused and brighter students bored.

In an attempt to provide a positive experience in engineering graphics for all students while addressing the issue of individual student needs a video taped tutorial session was developed. The tutorial was a compilation of staged individual tutorial sessions that addressed the most common problems which students encountered while completing the homework. The feedback from the experiment was very positive and required only a few hours of staged tutoring. One criticism of the video tutoring, however, was the separation of the tutoring and application. To address this student concern a screen capture program was used to record screen activity and audio for the staged tutorial sessions. The reception of these tutorials which could be viewed in the computer lab and run simultaneously with the CADD software was extremely positive. Encouraged by the results, the tutorial movies became the first step in the development of a comprehensive multimedia instructional CD/web page. The project to date includes hours of tutorial movies, lecture presentations of all class lectures for the semester, web based games to reinforce significant course topics, and a series of interactive web based quizzes that prepare students for class exams. Similar multimedia teaching projects have been developed for other courses and disciplines such as engineering (Haugsjaa & Woolf, 1996, Hill et al., 1998, Reed & Afjeh, 1998, Suni & Ross, 1997), mathematics (Antchev et al., 1996), and computer science (Marxhal & Hurley, 1996). The engineering graphics project has been successful to the point where students rarely seek individual tutoring during lab and almost never need help outside of lab. The CD/web page accommodates the different learning styles and abilities of students in the class by providing a wide range of instructional material (Carver et al., 1996, Ellis, 1996). What was only partially accomplished in the lab with the constant presence of an instructor and lab assistant is now accomplished with the CD and very limited lab assistance. The final stage of development will be to include a multimedia presentation of the lectures in the project. The entire course, lab and lecture, could then be offered as on on-line self-paced course with hours of interactive tutorial and review material that would give students a positive experience in engineering.

Methods and Tools

The selection of tools used in the development of the CD was initially based on the availability of and familiarity with particular software titles. As the project developed and certain obstacles were encountered a greater breadth of software was considered. The information contained on the CD project is accessed through a series of linked HTML pages highlighted with animated GIFS created in AutoCAD and AVI clips obtained with a video capture card. The lecture presentations are accessed through links to Microsoft PowerPoint presentations (Figure 1). The laboratory tutorial material is presented using Lotus Screen Cam movies. The games and quizzes are HTML files that use simple Java Script 1.2 code. The information was created and compiled on a 200mHz Pentium and then burned onto recordable CDs and uploaded to a public directory on a Unix based server. The entire project requires slightly more than 300MB, the Screen Cam movies taking the bulk of the disk space. The development of each element of the project was affected by the capabilities of the selected hardware and software. A prior understanding of the limitations and capabilities of hardware and software would have averted many of the obstacles encountered.

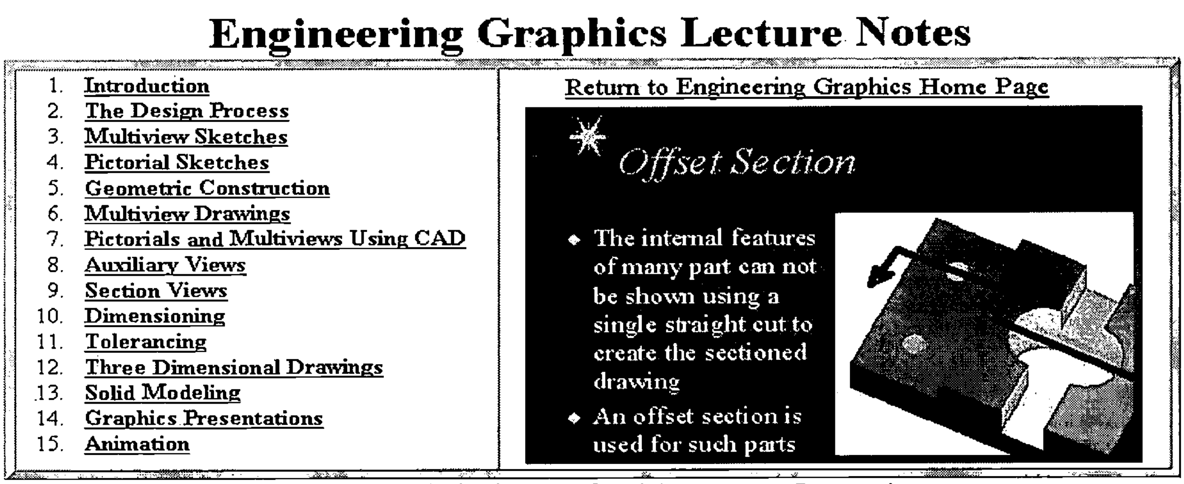

Figure 1: Web Navigation Page for Links to Lecture Presentations

Lecture presentations

The original lecture presentations were prepared using PowerPoint. The lecture material presented on the CD is simply a copy of the lecture presentations used in class. The essential capabilities of the presentation software for this project are: the ability to efficiently embed large high quality line drawings and images into slides; the availability of a free viewer for viewing the presentation; and simple but significant navigation capabilities in the viewer. Some limitations in the software that were encountered were the inability to embed animated GIFS or MPEG clips into the presentation and the absence of a web browser plug-in for earlier versions of browsers. These limitations with the exception of animated GIFS have been addressed with the latest versions of software.

The presentation software allows for the creation of HTML pages with control buttons and an index of all slides in the presentation. However, the HTML pages scale down the image size to a selected fixed resolution and use a significant portion of the screen for slide control. In addition, the HTML pages also do not allow for animation of slides. Because of these limitations the lectures were saved in the original presentation format and with links to the files from the web page. This requires that the browser is set up to launch the presentation viewer program based on the MIME type if the file is on a server or based on the file extension if the file is on the CD. An HTML page showing how to setup the computer and the web browser was added to the web site to address this issue.

Tutorial Movies

The tutorial movies were created with Lotus Smart Suite is Lotus Screen Cam. The program allows for real time screen capture synchronized with audio. This type of screen capture program allows for the simple creation of tutorial movies. The format used for the Engineering Graphics course was for the instructor to do each homework assignment using the CAD program while the screen capture program records the session. The accompanying audio could be recorded with the video or added later. The finished product is then a set of narrated tutorial movies that walk the student through each assignment.

The usefulness of the tutorial movies lies in the fact that they run on the same platform as the program that is being taught. The movie can be paused while the student completes a portion of the assignment and then continued. In this fashion students having difficulty with the homework will follow the tutorial step by step while more advanced students will watch the entire movie and then complete the assignment on their own. The movies can be broken into major segments that allow the user to jump forward or back to the start of each segment. The player also allows the user to fast forward through each segment. The movies require about 400-700kB/min (typically 60-70% for the audio) of storage for a 600X800 screen with 24 bit color and 8 bit mono sound sampled at 11kHz and compressed with a 2:1 compression ratio. The size of a typical 10-minute tutorial would be about 4mB.

There are several notable limitations to the software which affect the use and creation of the tutorial movies. The greatest challenge to creating the tutorial movies is to create a long movie that does not contain pauses or errors since the screen capture program does not allow for editing of movies. If a long pause or error is made during the recording the movie must be redone. Completing a ten-minute engineering drawing without pauses or errors requires planning and several attempts. One way to address this is to record the tutorial in segments saving each as a separate movie. The segments can then be compiled into a single tutorial movie. Therefore, if an error is made in the last segment, only the last portion needs to be re-recorded. The screen capture program is also sensitive to the video drivers used. When using the CAD program a portion of the cursor often disappears and occasionally the program would occasionally not refresh the video when objects were added or erased. The use of some drawing and editing commands had to be avoided to address this problem which was restrictive.

There are a two drawbacks with the program related to playback. First, the image size is fixed at the time of recording so a low level of resolution must be used to accommodate a variety of users. Second, the player does not allow the user to rewind the video except to the start of each segment. This can be frustrating to students and is their primary complaint about the tutorials.

Java Script Games and Quizzes

A game and quiz were written to supplement the material covered in each lecture and associated lab. The quizzes use forms with radio buttons to record answers to True/False and multiple choice questions. The answers are stored in an array and compared to the array containing the correct answers when the user selects the grade button. The number of questions missed are displayed using an alert window. The students can then change answers until they receive a perfect score. The quizzes give instant feedback to the student, are interactive, and are very simple to create. Once the format for the quiz page is set up it only takes a few minutes to adapt questions for another chapter. The JavaScript quizzes have given the best return given the limited investment of time.

The games give students exposure to images and animations that were created in the CAD program that they are learning to use. The games were all developed using JavaScript code to manipulate graphic images based on user input. .The simple manipulation of images based on user input allowed for the development of a wide variety of games which each effectively teach some element of engineering graphics. The first and simplest game gives an palette of images that must be placed on a grid in the proper order (as in a puzzle) to reveal a computer generated model of a utility van generated in CAD. On completion of the puzzle an animated GIF is displayed which shows the vehicle in motion and a simulated impact with an automobile. Another game allows the user to manipulate a 3-D object such that it will fit correctly into a hole. Two other games use image maps (Figure 2) to record input from the user while the graphics change according to their response. With the development of 5 different game formats a variety of other teaching games could easily be developed using the same formats.

The games were the most challenging and problematic endeavor on the project. The JavaScript is not as straight forward as the quizzes and requires more programming skill. More difficulties were also encountered with how different browsers and versions of browsers handled the placement of graphics images. The games do not work with Microsoft Internet Explorer 3.0 and earlier versions or with early versions of Netscape. The selection and placement of images with the mouse causes problems if the user tries to drag the image into place or moves the mouse while pressing the select button. Feedback from some students that the games don't work reveals that instructions to games would be helpful. The level of success achieved for someone with little programming experience and no JavaScript experience however was surprising. It can be assumed that an experienced programmer could address many of the obstacles encountered.

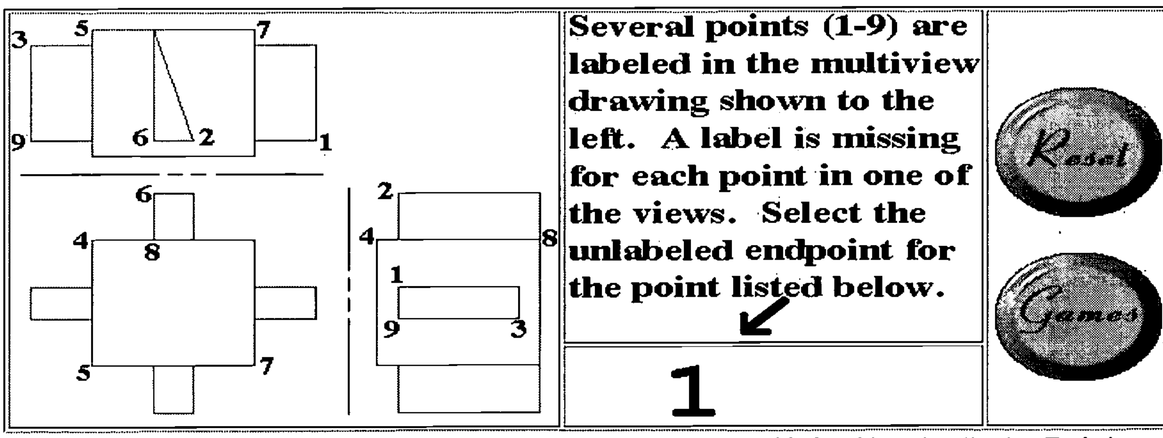

Figure 2: A JavaScript Game That Uses an Image Map to Aid Students With Graphics Visualization Techniques

How the Project Has Impacted the Course

The development of the CD has impacted the course in several significant ways. In the past engineering graphics was taught by a number of faculty and the lectures were presented in the lab to relatively small class sections. As the engineering program grew it became necessary to combine the lab sections for lecture and rely on teaching assistants for the lab. The positive impact of these changes relate primarily to the instructor. By combining sections the total lecture time has been reduced by 80%. The use of the CD in the lab has in many ways eliminated the need for the instructor in the lab. On the negative side large lectures (70-80 students) are less interactive and more impersonal. The laboratory environment has also become less interactive and more impersonal with the exception of student interaction with the computer. There is no longer a need for group teaching in the lab as each student is individually tutored on the computer. Since the tutoring uses audio the students wear headphones while in lab, which reduces interaction among students. The lab has transformed to become an environment of individual learning. A semester group design project has helped to reintroduce interpersonal communication in the lab.

As the students are provided with full presentations of the lecture notes, more material can be covered during the lecture time. Students don't need to spend as much time copying information of the lecture slides since they are all available to them on the computer. On the negative side some student forgo the lecture for an individual reading of the lecture notes. Rather than fight this trend, work toward adding audio and video clips to the lecture presentations is in progress giving the student complete access to all the lecture material on their own schedule. Some of the same dynamics occur in the lab where students work on their own time rather than during the scheduled lab time. Quizzes given each lab period motivate students to attend the lab where they feel some accountability for turning in homework and keeping caught up with assignments.

The development of the CD has also impacted the future of the course. As stated previously the project has made it possible for the course to be offered on-line. This will especially be helpful for area high school students who are taking the course to have full access to the course material from their individual campuses. Although an on-line course offers more flexibility for students it restricts the flexibility of the course material. Significant changes to the course that require redevelopment of the material are avoided because of the investment of time involved.

How the Project Has Impacted the Students

The greatest positive impact that the project has had on students is they now use their time more efficiently. Labs are no longer filled with students with hands raised waiting for an instructor to respond. Instead, students work quietly and independently on their homework using the tutorial movies to answer their questions. Bright students use the tutorials as a backup when they encounter a difficult problem and quickly complete the assignments. Slower students follow the tutorials step by step and rarely need to ask for assistance. Both, however, learn the material and complete the homework assignments. Students who don't finish the work during lab can return any time to complete the assignments while still receiving instruction. The number of students who don't complete the homework or complete the assignments with errors has dropped noticeably. This has led to a slight improvement in the performance on exams.

The greatest negative impact that the project has had on students is that they feel less connected to the instructor and the engineering program. Contact with the instructor is primarily during the large lecture sessions, which meet weekly for 50 minutes. One consequence of this lack of connection is that unmotivated students are not personally encouraged and eventually drop the course. Many students need personal encouragement from an instructor who knows their name and periodically checks on their performance to succeed in a course. This will likely be more pronounced with an on-line course. One of the motivating factors for offering the course to area high school students is do draw future students into an engineering program that they feel connected to. This aspect of the project works counter to that goal.

There are a number of other notable effects of the project on the students. A student who falls behind because of uncontrolled circumstances is much more likely to catch up and perform well in the course. In the past this required a significant effort from the instructor and special meeting times had to be scheduled with the student. The visualization tools that are developed by the student as they interact with the game pages are invaluable to the student and difficult to teach using other methods. As the students visualize objects repeatedly in the games with positive and negative feedback they exercise a developing skill that would otherwise be tedious if done using a printed worksheet. By the end of the course the students have been exposed to a breadth of examples using interactive graphics to teach and communicate. The students seem motivated and intrigued by use of engineering graphics as a powerful communication tool whereas in the past they had a much narrower focus for the application of engineering graphics.

The Cost of Development

The development of an interactive multimedia teaching tool requires a significant investment of time. Assuming that the developer is familiar with the tools needed to create the project, which is significant assumption, the time invested in a project of this magnitude would be on the order of several hundred hours. Such an endeavor requires an extreme commitment of resources and energy far above those required for the development of a course taught using a traditional approach. The costs and benefits need to be carefully assessed before undertaking the development of a project of this magnitude (Turner, 1997, Ward & Newlands, 1998). The 62 tutorial movies on the CD were each recorded several times and cover several hours of instruction. The planning and recording of the tutorials required more than 120 hours. Putting the lecture presentations into a computer presentation format required approximately 4-5 hours per lecture. The bulk of the time was used to generate graphics used in the presentations. Future development of the lectures into multimedia presentations with audio and video is expected to take 8-10 hours per lecture with the exception of the first lecture. The first multimedia lecture presentation has been completed and required more than 40 hours to complete. The games each took 5-8 hours to design, write the JavaScript code, and generate the graphics. The quizzes could each be developed in less than an hour. Setting up the overall structure of the web site and linking the information is a relatively simple task.

Reliance on previous experience can greatly reduce the required investment of time. The first project has been duplicated in a very limited way and applied to another engineering course (Measurements and Instrumentation). In less than 30 hours a significant portion of the structure of the original project has been recreated for the new course. Handwritten lecture notes were scanned and saved as PDF files that are readable with a browser plug-in. Old exams and homework solutions have also been added to the site to give many of the benefits of the interactive quizzes for a fraction of the invested time.

Conclusions

The overall effect of a major change in pedagogy on the average student has been positive. The average student has adapted to the use of the multimedia instructional approach quite well with minor improvements in overall performance and depth of knowledge gained in the course. The most notable changes however, are associated with those who fall outside the range of average. Advanced students are stimulated by the self-paced nature of the course and stay motivated throughout the semester. Slower students can work at their own pace and finish a course that they might otherwise drop. There does appear, however, to be a group of students from the full intellectual spectra who do not perform well in an environment with there is little interpersonal connectivity with the instructor. A small section using traditional instruction could be added to address this problem.

The overall impact on the course has also been positive with a significant increase in the breadth of material covered and flexibility of delivery. With the completion of the multimedia instructional material the course can be easily exported off campus to area high schools students and to those who wish to take the course on-line for convenience. The scheduling flexibility for students taking an on-line course will likely increase enrollment as the course is an introductory level course.

The cost of developing the project was significant. Several hundred hours were required to bring the project to its current level. Justification for such a tremendous individual effort was based on the promise of teaching multiple sections of the course over several semesters. A scaled down version of the project has since been successfully been developed for another engineering course with a fraction of total time invested indicating that the pedagogical approach can be successfully adapted to other courses.

From Algorithm Animations to Animation-embedded Hypermedia Visualizations

Steven Hansen, Daniel Schrimpsher and N. Hari Narayanan

ABSTRACT: The idea of using animations to illustrate dynamic behaviors of computer algorithms is over fifteen years old. Over a hundred algorithm animation systems have been built since then, with most developed in the belief that the animations would serve as effective learning aids for students. However, only recently have researchers started asking the question: Do algorithm animations really help? Unfortunately, results of experiments driven by this question have been disappointing. We believe that previous attempts at using animation to teach algorithm behavior were unsatisfactory not because of a flaw with animation as a technique, but because of the approach used to convey the animations. In this paper, we present a novel theoretical framework for the design of effective algorithm visualizations, one which espouses embedding interactive analogies and animations in a context and knowledge providing hypermedia environment. We then present the architecture of HalVis, an implemented system based on this framework, and results from five empirical studies that demonstrated the advantage of our framework over traditional means of instruction and extant algorithm animations.

Introduction

Over fifteen years ago, with the unveiling of the movie Sorting Out Sorting at SIGGRAPH-81, the idea of using graphics and animation to illustrate the dynamic behavior and functionality of computer algorithms was born. Algorithm animation appeared to hold great promise as an instructional aid, with many dozens having been built such as Balsa (Brown, 1988), Tango (Stasko, 1990) and their successors. Most were developed in the belief that algorithm animations would serve as effective supplements to lectures for students to learn about algorithms. This belief has a strong intuitive basis. Students have always had a relatively difficult time understanding abstract mathematical notions, especially when these included dynamics of how algorithms manipulate data, so concretizing these notions graphically and animating them to illustrate the dynamics ought to improve learning.

Though research on designing and deploying algorithm animations spans over 15 years, only recently have researchers started asking the question: do algorithm animations really help? Dozens of experiments have been conducted to test whether algorithm animations lead to improved understanding of algorithms. Hundhausen (1996) presents an excellent summary of the results of 29 empirical studies pertaining to the comprehension efficacy of algorithm animations and, more generally, software visualization. Unfortunately, all one can say about this accumulated evidence is that the results, at best, are mixed. While animations are enthusiastically received by the students, none of the studies has proven conclusively that these visual presentations actually *improve* learning (Badre, 1991; Byrne, 1993). The following quote succinctly expresses the frustration felt by researchers working in this area: "Unfortunately, the viability of algorithm animations as instructional aids remains rooted in intuition. No substantive empirical evidence has ever been presented to support these claims" (Stasko, 1993). Is this because animation is an ineffective teaching tool? Intuition tells us this is not likely.

Rethinking Algorithm Animations--From Animations To Visualizations

Research presented here is based on the premise that animations are indeed useful. We believe that previous attempts at using animation to teach algorithm behavior were unsatisfactory not because of a flaw with animation as a technique, but because of the approach used to convey the animations. Hence, a rethinking of algorithm animation design is required in order to harness its power to enhance learning.

Theoretical foundations of our approach to algorithm visualization are rooted in several areas: (i) a comprehension model derived from research on how humans reason using static diagrams to infer the dynamic behavior of mechanical devices and its application to the design of hypermedia machine manuals (Narayanan, 1998), (ii) recent research in cognitive and educational domains on how multimedia and hypermedia can improve student comprehension (Crosby, 1995; Daily, 1994; Kehoe, 1996), and (iii) extant research on the design and evaluation of algorithm animations (e.g., Byrne, 1996; Kehoe, 1996; Lawrence, 1994; Stasko, 1997; see Hundhausen, 1996 for a comprehensive overview). Drawing from these sources, we have developed a framework for the design of algorithm visualizations called HalVis (**Hy**permedia **Al**gorithm **Vis**ualizations) and a corresponding software system. The key idea is to embed algorithm animations at various levels of abstraction inside a hypermedia environment. Distinctive features of HalVis and their rationale are described below.

- Learning Objectives: Algorithm visualization design starts with a top-down process in which explicit learning objectives (e.g., understand the central metaphor such as that of values "bubbling up" in BubbleSort, understand core operations of the algorithm such as swapping data values during sorting or pivot picking in QuickSort, etc.) are used to divide, describe and deliver information. The approach is learner-centered ("what do students *need* to know") rather than technology-centered ("what *can* we show"). In HalVis, the focus is not on the animations but rather on the orchestration of various hypermedia elements to meet the educational objectives, leading to effective visualization.

- Scaffolding: The learning process begins using real world analogies (e.g., animated playing cards that illustrate sorting and merging in MergeSort) intended to provide a basic conceptual understanding of the essential elements of the algorithm. These analogies serve the purpose of "scaffolding" (Hmelo, 1996) and are a natural prelude to subsequent learning. Douglas (1995) and Stasko (1997) have shown that when students are asked to design algorithm animations, they employ real-world metaphors such as a football game or flying spacecraft. In HalVis, the analogy introduces the algorithm, and then the gap between the analogy, the abstract components of the algorithm, and the concrete graphical representations used in other modules to depict the algorithm's behavior is bridged. Bridging is intended to facilitate comprehension of algorithm animations by allowing the learner to internally connect the analogy and the animation. All this occurs *prior* to showing any algorithm animation. We believe analogies set the stage for subsequent detailed learning, help improve long-term retention, and lead to better visualization.

- Chunking: Given the big picture, learning can proceed to the details. Unfortunately, current algorithm animation systems present the detailed dynamics of the algorithm as a one-shot, stand-alone show that is entertaining to watch but tends to obscure the very details the student needs to learn. Research on cognitive media types (Recker, 1995) points to the importance of using different types of information (definitions, examples, etc.) in teaching algorithmic concepts. Kehoe (1996) have also pointed out the importance of multiple representations and media, concluding that text is important for precision, pseudocode is useful for conveying steps of the algorithm, and animations are good for depicting operational behavior. HalVis uses a technique called "animation chunking" in which animations are broken up into meaningful bite-sized pieces. Each chunk is presented in synchrony with other representations (e.g., feedback in a text window, pseudocode with relevant lines highlighted, aural explanations) of the specific actions taking place. These are embedded within a hypermedia structure that provides contextual knowledge using hyperlinks to additional explanations using text, audio and pictures. Combining, synchronizing, and presenting information in multiple media in discrete chunks is more than animation; it is visualization.

- Granularity: Three distinct kinds of animations provide views of algorithm behavior at different levels of granularity. One is an animated real-world analogy intended to function as a scaffold and a bridge by conveying the essence of the algorithm. The second is a detailed micro-level animation that focuses on specific algorithmic operations. The third is a broader macro-level animation that shows the algorithm's behavior on large data sets. The detailed animation is chunked at multiple levels (e.g., at the level of a single instruction execution, at the level of a "pass" for algorithms that make multiple passes over data). Each chunk is presented in tandem with pseudocode highlighting and textual/aural explanations. The learner can elect to see the animation at any of the available chunking levels. The micro-animation is presented before the macro-animation, both of which are seen by the learner only after the animated analogy. This sequential design is intended to address a particular difficulty uncovered by an earlier study that stated, "a paradoxical problem with the animation is that it shows the big picture or emergent qualities that might be appreciated only by those that already understand the algorithm at the mechanical level" (Byrne, 1996).

- Rich Interactivity: Most educators agree increased student interaction improves learning. Experiments conducted by Lawrence (1994) indicate a learning advantage for students who had active involvement in the creation of input values to algorithm animations. In contrast, research in different domains indicates that passively watching an animation may not facilitate learning (Rappin, 1997; Stasko, 1993). In HalVis, all animations allow active intervention by the learner. Besides the usual replay and speed controls, HalVis allows and even encourages students to alter the data and rerun the animations to see how the algorithm performs on data sets of their own choosing. Students can also make predictions about performance to compare with actual results. Increasing the level of interaction leads to better visualization.

- Critical Thinking: A potential problem with multimedia presentations is often stated as "hands-on, mind-off," where the interactions engage the user so much that analytical thought about the content of the presentation is inhibited. HalVis employs two kinds of probes to avoid this syndrome. One, called "ticklers," are questions that pop up in random order, but always in an appropriate context, and can be dismissed by the user. These are questions that require considerable mental effort in the form of self-explanations (which have been shown to promote comprehension (Chi, 1989), but the system makes no effort to enforce answering them. The other kind, which we call "articulation points" involves questions the user must answer before proceeding, and the system provides immediate feedback about the correctness of the answer. These questions are tied to learning objectives set out by the designer and help students self-diagnose their learning and allow them to reflect on what they know, what they don't, and where to find relevant information.

HalVis Architecture

We have created a prototype system, called HalVis, to test the components of the framework described above. HalVis is implemented using Asymmetrix Toolbook, and as of this writing, contains visualizations of four sorting algorithms and one graph algorithm. Each visualization in HalVis consists of the modules shown in Figure 1 and described below:

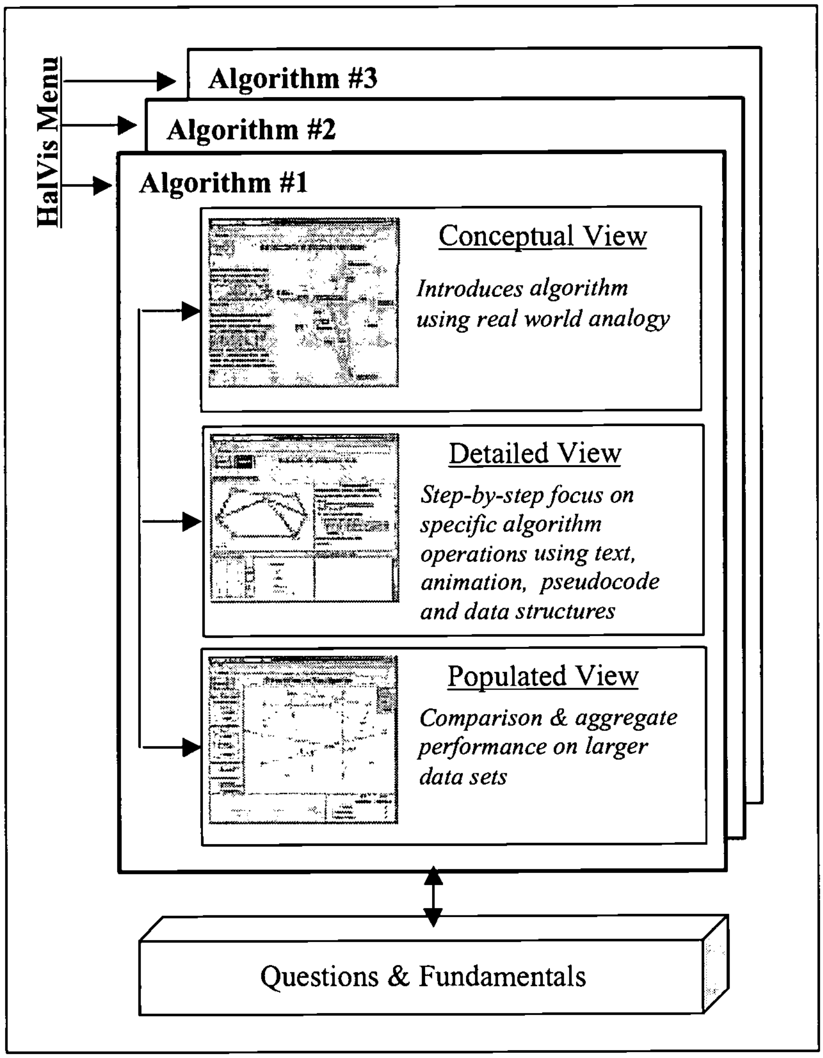

Figure 1. HalVis Architecture

- Conceptual View: This module introduces a specific algorithm in very general terms using a real world analogy. For instance, BubbleSort is introduced using a flask of water with bubbles that rise to the surface according to their size and the Shortest Path algorithm uses a simple game that allows the student to observe a map of airline fares through various cities and select the route with the cheapest fare to illustrate the basic working of the shortest path algorithm. This module uses animations, text and audio to provide the student with a general overview, a visual example to aid long-term retention, and sufficient bridging information to help learners proceed from the visual elements in the analogy to the data structures and algorithm operations in later modules.

- Detailed View: This module contains two screens. One consists of a detailed textual description of the algorithm alongside a pseudocode representation of it. Embedded in the text are hyperlinks to related information in the Fundamentals module. The second screen, shown in Figure 1, contains four windows that depict various aspects of the algorithm's behavior. The Execution Animation window shows how steps of the algorithm modify data structures using smooth animation. The animation is chunked at multiple levels of granularity corresponding to meaningful units of the algorithm's behavior, and can be altered by the learner. At the lowest level, the animation displays the execution of an individual statement, pausing for the learner's signal to proceed. The next level corresponds to a logical operation, like completion of a single pass in a loop. At the highest level, the animation proceeds to completion without pausing. The Execution Status Message window provides comments and textual feedback to the student about key events and actions during execution. This is also available as an audio commentary. The Pseudocode window shows the steps involved in the algorithm, which are highlighted synchronously with the animation. Finally, the Execution Variables window contains a scoreboard-like panorama of the variables involved in the algorithm and their changing values. Before launching the animation, students can change the data input to the algorithm as well as the speed and granularity of animation and feedback. Execution of each step of the algorithm affects the display in the four windows simultaneously. The thumbnail in Figure 1 shows a seven vertex graph used in the Shortest Path algorithm. HalVis intentionally limits the number of data items in the Execution Animation window to focus attention on the micro-behavior of the algorithm.

- Populated View: This module is intended to provide students with an animated view of the algorithm on large data sets to make its macro-behavior explicit. Many of the details presented in the detailed view are obscured to enhance the student's focus on the algorithm's performance. For example, the pseudocode is not shown, nor are variables. Animations in this module are similar to those in extant systems, but there are two novel features. One is a panel of counters that show pertinent performance-oriented information such as number of comparisons, swaps, recursive calls, and so on. Another is a facility for the student to make a prediction about different parameters of algorithm performance and then compare those against the actual performance when the animation is running. When the learner launches the animation, the system prompts for predictions, creates a random initial configuration, and proceeds to move the graphical representations accompanied by audio explanations and cues.

- Questions & Fundamentals: The Questions module presents the student with a combination of multiple choice, true-false, and algorithm debugging (by reordering the steps) questions to measure competency and comprehension, and the system provides immediate feedback on student responses. HalVis also pops up context-sensitive tickler questions to help focus student attention on key aspects of the algorithm. The Fundamentals module contains information about basic building block topics common to virtually all algorithms. Examples include Comparing & Swapping Data, Looping Operation, Recursion, and so on. Generally, this module is accessible only through hyperlinks from other modules, so that the basic information is presented *on demand* (in response to a learner request in the form of clicking on a hyperlink) and *in context* (of algorithm-specific information within which the hyperlink is embedded).

Experiments With Hypermedia Algorithm Visualizations

We conducted a series of five experiments to evaluate and substantiate the effectiveness of hypermedia visualizations of algorithms, specifically to validate our hypothesis that visualizations will be more effective than traditional teaching methods for students learning about algorithms. In each of the experiments, subjects took a pretest to measure prior knowledge, learned the algorithm using HalVis or a traditional method, then took a posttest that measured knowledge improvement. Students were tested on their ability to recognize and reorder pseudocode descriptions of algorithms, mentally simulate algorithmic operations, and predict resulting data structure changes. In these studies, we did not differentiate between visual and verbal learners since HalVis contains rich textual and visual presentations to support both kinds of learner dispositions.

Table 1 lists information about these experiments, showing the student level, the materials used by the two experimental groups, the algorithm(s) studied, and the statistical significance of results. The first two experiments were described in detail in (Hansen, 1998). Experiment I showed that hypermedia visualizations are more effective than textbooks for learning about algorithms. This result was successfully replicated in Experiment II using more advanced students. Experiment III compared learning from HalVis to learning from a compilation of the best algorithm descriptions (extracted from 19 textbooks published between 1974 and 1997) followed by problem solving activities. While the posttest averages favored the HalVis group, the difference is not statistically significant. This experiment indicated that interactive visualization can be as effective as learning from carefully crafted text, when that textual learning is *followed* by problem solving.

Experiment	Student Level	Comparison Groups (average posttest scores)		Algorithm(s) Studied	Statistical Significance
I	Sophomore	HalVis *(74%)*	Text *(43%)*	MergeSort	$F(1,27)=10.9$ $p<0.015$
II	Junior	HalVis *(63%)*	Text *(44%)*	MergeSort QuickSort	$F(1,21)=4.9$ $p<0.038$
III	Sophomore	HalVis *(61%)*	Text + Exercises (57%)	BubbleSort SelectionSort	$F(1,24)=0.3$ $p<0.57$
IV	Sophomore	HalVis *(70%)*	Lecture *(44%)*	SelectionSort MergeSort	$F(1,19)=5.3$ $p<0.033$
V	Junior	HalVis *(89%)*	Text + Animation *(71%)*	ShortestPath	$F(1,37)=12.8$ $p<0.001$

Table 1. Summary of Five Experiments Conducted in This Research

Experiment IV was designed to compare and evaluate how algorithm visualization (AV) and conventional classroom lectures interact and contribute to student learning. Our hypothesis was that AV alone would assist learning more than a lecture. If so, it follows that AV used in conjunction with lecture should assist learning even more. We used a 100 minute live classroom lecture by a computer science faculty known for his teaching ability, delivered in two consecutive class sessions. Participants were second year computer science students at Auburn University, divided into two matching groups. One group used HalVis before attending the lecture (called the visualization-lecture (VL) group) and the other group used HalVis after the lecture (called the lecture-visualization (LV) group). Having both groups attend the same lecture eliminated variations that can occur in different sessions, while allowing interactions with the teacher. A first posttest was given between the two phases, and a second posttest was given after both phases. The first posttest results indicated that the VL group learned significantly more than the LV group; following the session with HalVis, the VL group's average score was 70% compared to 44% for the LV group. However, the second posttest results showed that after receiving both the lecture and the visualization, both groups performed at the same level (72%). These results suggest that visualizations can have a significantly higher learning impact than a lecture, and that a combination of both is even better.

Experiment V compared the effectiveness of learning from HalVis to learning from an algorithm animation typical of extant research on this topic. One of the most mature, widely reported, and publicly available algorithm animation platforms is the Tango software suite developed by Stasko (1997). The Tango software distribution contains a library of animated algorithms, including eight animations of the Shortest Path algorithm. Of these eight, we selected one that appeared to be the most complete, easiest to understand, and which most closely matched the features of the HalVis system, as a representative animation. One group of students interacted with HalVis and the other group interacted with the Tango animation. The second group was also provided with a textual description of the algorithm, to which the HalVis group did not have access. On the posttest, the HalVis group averaged 89% while the Tango group averaged 71%, indicating that a hypermedia algorithm visualization is more effective than an algorithm animation.

Conclusion

Collectively, these experiments provide initial statistical validity to the hypothesis that hypermedia algorithm visualizations can be significantly more effective than traditional teaching methods considered in isolation. More details of these experiments are available in (Hansen, 1998). There are a number of possible reasons for this effectiveness. First, in comparison with previous animation systems that only presented animations with some textual feedback, HalVis allows the student to learn incrementally by starting from a real world analogy and transitioning to the algorithm itself. Second, the hypermedia structure allows a student access to fundamental building blocks of algorithmic knowledge in-context and on-demand. Third, the top-down learning objective based design approach and the hypermedia structure have allowed us to divide information into manageable pieces and present each chunk using the most appropriate media. Fourth, rather than providing an animation all in one piece as has been the typical approach, HalVis presents three kinds of animations in an analogical-detailed-abstract sequence. Fifth, animations are delivered at multiple levels of granularity. This animation chunking makes it easier for students to pause, repeat, reflect, or access other relevant information through hyperlinks while watching animations. Furthermore, animation chunks are presented in synchrony with other representations. These two unique features, we believe, result in the dynamic information being conveyed better in context, and therefore in a more comprehensible fashion. Sixth, animations allow both active intervention and performance prediction by learners, both of which can improve comprehension. Seventh, we believe that questions that pop up in context in different parts of HalVis promote reflection and self-explanation, contributing to learning. Future studies will selectively analyze these features in order to identify those that contribute most to learning. More information on this research is available at our group's web site: http://www.eng.auburn.edu/cse/research/vi3rg/vi3rg.html.

Learning Strategies: A Framework for Understanding Students Learning with Computers

Terry Di Paolo
Institute of Educational Technology
The Open University
Great Britain
t.dipaolo@open.ac.uk

Abstract

The last two decades have seen a significant increase in both the development and usage of computer based learning technology in tertiary education. Many researchers in the field of education have begun to develop an understanding of student learning in terms of learning strategies. Such constructs represent behaviours and thought processes adopted by the student and are believed to mediate learning. At present, however, little is known of the impact that computer based learning technologies have on these strategies.

This paper outlines various developments in our understanding of student learning in terms of styles and strategies that have occurred over the latter half of this century. The paper focuses on a learning strategies framework developed in the United States and its initial use as an evaluation tool for courseware in a distance education setting in the UK. Preliminary findings from this initial study designed to investigate the learning strategies users adopt when using a piece of courseware are also described along with plans for a future large scale study.

Introduction

Increasingly, educators and researchers acknowledge that learning strategies comprise some of the active processes that need to be examined to gain a better understanding of how students learn. At the same time educators are turning to software developers to offer computer based solutions to material that has proved difficult or unsuccessful in the traditional educational setting. In turn software developers are utilising more sophisticated forms of media (Jonassen, 1988). An increasingly popular option, especially with the natural sciences, is the computer simulation. Advances in both hardware and software, have meant increasingly sophisticated simulations becoming common computer-assisted learning (CAL) tools. Dating back to the late 1970's, simulations have provided the student with a meaningful environment within which they can interact with physical objects or scenarios from the real world (Thurman, 1993).

The research discussed in this paper examines a resource based learning tool, "The Human Brain" CD-ROM, which makes use of simulations. The research aims to explore this tool in terms of students' learning strategies. This form of evaluation, where students' learning strategies are the focus of the investigation, has almost exclusively been neglected in favour of one that determines the usability or effectiveness of the software. Yet, arguably, notions of usability and effectiveness are dependent on the learning strategies employed by students. The evaluation is intended to provide insight into the success and limitation of the software in terms of both usability and effectiveness. The research has also aimed to examine the stability of student learning strategies over the duration of an academic course and explore whether learning strategies differ as a function of the learning medium students use on the course, i.e. computer based versus non-computer based.

In the following sections the notions about and measurement of learning strategies will be described with a history of how educational researchers, predominantly in the States, have come to understand student learning in terms of such constructs. Evaluation at the UK Open University (OU) will then be outlined briefly, demonstrating the current consideration given to learning processes in CAL evaluation. The paper will then describe a pilot study undertaken in 1998 to investigate the learning strategies of student learning with a computerised resource based learning tool.

Background Literature

Learning Strategies

For many years educational researchers have sought to determine and understand the learning processes adopted by students in tertiary education. Much of this work has been influenced by psychological theory. In the last fifty years or so, the field of psychology has been dominated by an interest in cognitive processes. With this impetus and also an increasing understanding of personality and personality typologies, researchers began to investigate whether differences existed in the ways individuals approached everyday information processing. Differences were found which indicated a series of consistent approaches to the organisation and processing of information which came to be termed cognitive styles (Tennant, 1988). Attempts have been made to examine such differences in the context of the university setting. However, according to Messick (1981, 1984) they have generally proved unsuccessful because of problems associated with the definition and measure of cognitive style.

By the late 1960's researchers began to acknowledge that learning in the university setting differed from everyday learning processes. Work carried out predominantly in Europe during the 1960's and 1970's proposed the notion of student learning styles. As a construct, learning style generally referred to one of a finite number of learning dispositions that students adopted in their pursuit of a degree qualification. It also incorporated the notion of both cognitive and motivational processes impacting students' learning behaviour. For example, a student who was intent on gaining a high level understanding of the information being learnt and was motivated to do so by a personal interest in the subject matter could be categorised as adopting a deep learning style (Marton and Saljo, 1976). In contrast, a student who was preoccupied with meeting the assessment aims and requirements of the faculty and whose main concern was to learn the required information by methods of rehearsal or rote memorisation could be categorised as adopting a surface learning style.

The term "learning style" has come to be used both synonymously with, and in contrast to, the terms "learning approach" and "learning orientation". This confusion with regards to terminology is associated with problems of definition regarding what behaviours or processes the construct of learning style actually refers to. Terminology regarding learning style and definitions of the construct have become convoluted, in part, because of a common aim held by researchers in the field - to increase our understanding of student learning by determining individual differences in the manner in which students learn. Confusion has arisen because a great number of individual differences have been found to exist amongst learners, yet researchers report their findings as definitive and finite. Attempts have been made to classify the various findings in the field, but even these systems present little agreement over the classification of findings from over thirty years of work (see Murray-Harvey, 1994).

In recent years there has also been an increasing amount of debate about the benefit of learning style as a measure of learning behaviour in tertiary education (e.g. Mitchell, 1994). It has been proposed that such notions of learning preferences and habits may not take into account variation in the learning behaviours and processes that occur in response to university teaching (McKeachie, 1998). The work of McKeachie and his colleagues at the University of Michigan, like many others, represents a move away from the classification of learners towards the classification of learning according to a series of constructs termed learning strategies (Pintrich, McKeachie and Smith,1989). Pintrich et al propose a framework of learning strategies based in part on the work of Weinstein et al (1987).

Weinstein and Mayer (1986) provide a definition of learning strategies as:

> "behaviours and thoughts that a learner engages in during learning and that are intended to influence the learner's encoding process...the goal of any such strategy is to affect the learner's motivational or affective state, or the way in which the learner selects, acquires, organises, or integrates new knowledge" (p315)

Learning styles provide a classification of the student, for instance, as in the examples provided earlier. Learning strategies present a departure from this method, instead learning is seen as comprising a series of components or constructs that relate to motivational and cognitive aspects of learning behaviour. The student is seen as using each of these strategies to a varying degree, for example they might be highly extrinsically motivated and make good use of an organisational strategy. There is no categorisation of the student, merely a profile of their learning behaviour, a profile of the extent to which they use a particular set of strategies.

In attempting to measure student learning strategies Pintrich et al (op cit), have developed the Motivated Strategies for Learning Questionnaire (MSLQ). The MSLQ is based upon a theoretical framework comprising a series of assumptions about learning in both the academic and real world which assumes the use of a maxinum fifteen strategies (McKeachie, 1990).

The team claim that students construct knowledge on the basis of that which they already know. It is also suggested that students' ability to remember and utilise what they have been taught depends on the level to which they process the material they have learnt. Finally, they propose that human beings are inherently learning creatures but intrinsic interest can be weakened by a sense of hopelessness about one's competence as a learner.

Arguably, the MSLQ's most important and valuable attribute is that it acknowledges that strategies are subject to change amongst courses and sets out to measure strategies specific to courses and course components. For the purposes of the planned research, this is an extremely valuable attribute of the MSLQ. This research endeavours to assess the impact of educational software on students' learning strategies. It aims to examine the learning strategies students come to use when using a resource based learning tool - "The Human Brain" CD-ROM.

The framework for establishing the nature of these strategies has been informed by the constructs measured by the MSLQ. Comparisons and distinctions are intended to then be drawn between learning strategies used whilst working with the CD-ROM tool and other teaching materials, predominantly text-based, on the course. This comparison may appear problematic since the two comprise very different mediums, but the comparison being made is not one of learning outcome: whether there is a difference in the quantity or quality of information that is learnt between computer based and non-computer based materials. Rather, the research intends to ascertain whether a different or similar set of strategies mediate learning with computer-based and non-computer based learning materials. This is important, since learning strategies vary in the context of learning domains based upon the specific learning requirements of the domain and previous learning experience. To that end, one of the aims of this research is to determine whether the learning processes for the course overall feed into the learning strategies the students then come to use in using the CD-ROM.

The design of "The Human Brain" CD-ROM was prompted, in part, by the difficulties reported by past students in comprehending the material in traditional text or two-dimensional pictorial format. Generally, where educational software has been made available it forms an important course component, yet very little research has examined the technology in terms of students' learning strategies. At the Open University evaluation studies have embraced the study of users' learning processes but not included learning strategies in their assessments.

Most of the courseware developed at the UK Open University, like "The Human Brain" CD-ROM have been produced to supplement or complement various science courses (see Jones et al, 1996). For example, The Works Metallurgist has been designed to help students with problems experienced in interpreting phase diagrams. Another example, the Driven Pendulum assists students with their understanding of the physics of motion. Increasingly though, Arts based subjects are also drawing on computer based resource learning tools. One example, is the course: Charles Booth and Social Investigation in the Nineteenth Century which introduces the computer as a tool for historical research. It allows students the opportunity to use and construct their own historical databases from a number of archive resources digitised and stored on CD-ROM.

Evaluation experience from such courseware and other projects has framed the development of an evaluation framework, CIAO! (Context, Interactions, Attitudes and Outcomes), by the Computers and Learning Research Group at the OU(Jones et al, 1996). The framework is intended to provide the evaluator with a variety of methodological tools instead of a limiting set of prescriptive measures. The framework has been used to evaluate courseware on a number of courses taught at a distance by the OU. It proposes three facets, or dimensions that the evaluation process should come to incorporate and integrate: context, interactions and outcomes.

At present, the CIAO! framework proposes, in part, that the process of evaluation takes into account various learning behaviours students exhibit when using courseware. The notion of various learning strategies as proposed by Pintrich et al would provide definition and more importantly a framework for understanding precisely what these learning processes are.

The Pilot

The review above has sought to identify a need for viewing students' learning in terms of learning strategies and, with the growth of computer based resource learning tools, to examine learning with these tools in terms of learning strategies. In the past, student learning has been considered in terms of style, initially cognitive style and subsequently learning style. These conceptualisations view the learner as a creature of habit whose learning behaviour falls into a limited set of categories, e.g. deep approach, surface approach. Increasingly, though, this classification of learners is being replaced by an examination of their learning behaviour in terms of learning strategies.

The notion of learning strategies accepts that learning behaviour is subject to change in response to the demands of the learning situation, with the characterising feature of these constructs being not the classification of the learner but of their behaviour. Over the years a series of learning strategy frameworks have been developed. For the purposes of the research presented in this paper the framework developed by Pintrich and his colleagues has been chosen as the method by which to identify the learning strategies that students on SD206:Biology: Brain and Behaviour course come to use. The framework identifies fifteen learning strategies and measurement is made of the extent to which each of these is utilised or adopted by the learner. What results is a learning profile of the learner as opposed to the characteristic classification of the learner that occurs with cognitive style and learning style measures. This profile is relevant only to the learning situation in question, i.e. the study of a particular course that forms part of the degree award, since learning strategies are sensitive to learning contexts and different courses present different learning contexts.

The use of computer assisted learning (CAL) tools also presents a different learning context and the purpose of the current research is to examine the impact of that context on student learning processes - their learning strategies. The research proposed here is thus framed by a series of issues which arise from the literature examined in the previous sections. Firstly, much of the work on learning strategies and the resulting frameworks have been carried out in the US on students studying in traditional tertiary education. The research has sought to examine, in part, how comparable those findings are to a British sample studying at a distance.

There has also been little work on the stability of learning strategies over a short period of time. The constructs are said to be sensitive to context, but over the period of a course there may be other factors, for example assignments or the onset of assessment, that impact the strategies that students come to use. Thus, the research has also sought to examine the stability of students' learning strategies. This idea of context impacting upon learning processes leads to the important question of whether students' learning strategies change as a function of the medium that they come to use whilst learning? That is, would the option of using a computer based learning resource bring about changes or differences in the strategies students use when learning with traditional text, video and audio material. The answer to this question, however, is dependent on knowing what learning strategies students employ whilst learning with a computer assisted learning (CAL) tool. For the purposes of this study a piece of courseware developed at OU has been chosen as the piece of software to be investigated in terms of students' learning strategies. The pilot is intended to provide an understanding of the learning strategies used by students undertaking a course at the OU where there is the option of using a CAL tool to complement traditional teaching materials. The aims of the intended research are two-fold and comprise two research phases. The first phase serves to apply the MSLQ to a distance education setting and to examine the stability of the learning strategy measures over a distance of approximately two months.

Developed in America, the MSLQ is a self-report instrument designed to assess college students' motivational orientations and their use of different learning strategies for a specfic college course. The questionnaire comprises 81 items, each scored on a seven point Likert (1=not at all true of me and 7=very true of me). Motivation is measured by six subscales: intrinsic goal orientation, extrinsic goal orientation, task value, control of learning beliefs, self-efficacy for learning and performance, and test anxiety. Learning strategies are measured by nine subscales: rehearsal, elaboration, organisation, critical thinking, metacognitive self-regulation, time and study environment management, effort regulation, peer learning and help-seeking. The fifteen subscales are designed to be modular, that is measurement of all or specific strategies can be made dependent on the needs of the researcher or instructor for the course in question.

In this study the course that students have been selected from is a second level 60 credit course run at the OU - SD206: Biology: brain and behaviour. The course aims to teach students neurobiological structure and functioning and was chosen because students have the option of using a computer based resource learning tool - The "Human Brain" CD-ROM. The CD-ROM has been developed in-house at the OU by the Biology Multimedia Group. Its main purpose is to marry together the teaching of neurobiological functioning and structure in a medium that is able to present detailed information in a format that is easy to use and affords understanding. The tool is anticipated to provide approximately 30 hours of study time. It makes use of various features including narration, text, video, animations. Navigation is such that each topic is organised into three levels of increasing complexity. The topics the tool covers include: general aspects of the central nervous system, the cerebral cortex, the spinal cord, vision, hearing and speech. The tool also allows the student to assess their knowledge via a series of multiple choice questions. The second phase aims to examine the learning strategies students adopt when using the CD-ROM produced for SD206.

In June of 1998 an amended version of the MSLQ, measuring all fifteen subscales, was posted to a sample of 471 students studying the SD206 course. After a period of two months those that responded to the first questionnaire, 306 students, were sent the questionnaire again. From this second posting 96 cases have been matched; of these, approximately half are using the CD-ROM. This exercise, in part, aimed to explore the learning strategies of students in their general study of the course. Amendments made to the questionnaire included changes in terminology (e.g. class, instructor) to make the questions applicable to students studying at a distance. Also each question incorporated the course code, the common referencing term for the course being studied. It was intended that this tactic would direct the responses of students to the course in question in lieu of the cues suggested by Pintrich and Garcia. For example:

> Original Question - *In a class like this, I prefer course material that really challenges me so that I can learn new things*
>
> Revised Question - *I prefer course material for SD206 that really challenges me so that I can learn new things*

From this intial phase the results indicate relatively high correlations between the subscales on both questionnaires. This would seem to indicate a fair degree of reliability and stability in the subscale measures. In examining the subscale scores, findings indicated that students taking the course are highly motivated and making good use of learning strategies in their study. In many respects the results of this distance education sample mirror the results of students studying via traditional methods in American colleges. Also, at this early stage, those using the CD-ROM indicate that the tool is easy to use and praise its development.

The second phase of the research is intended to build on the intial phase and its findings and explore the strategies that students adopt in using the CD-ROM. This next step will be to observe and interview students using the tool and identify the strategies they come to use based on the framework developed by Pintrich et al.

Conclusion

Our understanding of student learning has undergone a series of changes, from initial notions of cognitive style and learning style to the present day emphasis on examining student learning strategies. Measures of style are still common today but the extent to which they help us understand the complexity of student learning remains uncertain. Learning strategies present a move away from the classification of learners towards a classification of learning. Currently, evaluation practice fails to adequately understand the nature of the user's learning processes. The current research serves to remedy this by implementing a learning strategies framework in the evaluation of learning processes that occur whilst learning with a computer. It is intended that the subsequent research findings will inform not only evaluation practice but also courseware design.

A Process for Improving Web Site Accessibility for People With Disabilities

Eric G. Hansen
ehansen@ets.org
Douglas C. Forer
dforer@ets.org
Daniel H. Jacquemin
djacquemin@ets.org
Educational Testing Service, Princeton, New Jersey
United States

Abstract: There is a great need to improve the accessibility of Web sites for people with disabilities. This paper suggests a five-step process, drawing upon our experience at Educational Testing Service (ETS). For each step, we offer suggestions. The steps are: (1) Initiate a Web accessibility project; (2) Identify accessibility problems using automated tools and human evaluators; (3) Identify possible solutions, such as providing education and training, making available templates and examples, utilizing new technologies, and forging relationships with outside experts; (4) Select and implement a solution; (5) Obtain support for continuous improvement. In practice, these five steps may be somewhat concurrent and may be repeated.

Introduction

Many Web sites are partially or completely inaccessible to people with disabilities. For example, many Web pages implement graphics and audio clips in ways that are inaccessible to people with visual and hearing disabilities. Also, the written text on many Web sites uses language that is unclear or unnecessarily complex, making it inaccessible to some people who have language-related disabilities, such as cognitive disabilities, learning disabilities, and deafness.

Fortunately, Web developers can make their sites accessible to people with disabilities. For example, pages with images can be made accessible to people who are blind if appropriate text alternatives are provided. For instance, if a Web page uses an image of a flower, the Web developer can insert a text description of the flower into the "alt" attribute of an image (IMG) element. The Web user who is blind can then use speech output technology to hear the text alternative. By making this and other provisions, Web developers can ensure that Web sites are accessible to people with a variety of disabilities, including blindness, deafness, deaf-blindness, and many other disabilities.

However, it is not necessarily easy to change current Web development practices within an organization. Web site development in many organizations is a complex undertaking involving many individuals and teams.

Individuals who take the role of change agent need to be aware of the how best to balance the technical, educational, and advocacy aspects of the role. Such individuals can benefit from learning how others have attempted to address the challenge of improving Web site accessibility within their organizations.

Background

The main Web site of Educational Testing Service (ETS), "ETS Net" (www.ets.org), became available to the public in May 1996. The site includes links to other sites, such as those of the Graduate Record Examinations® (GRE®) program, the Advanced Placement Program® (AP®), the Graduate Management Admission Test® (GMAT®) program, the College Board®, and others. These sites provide information on how to prepare for tests, how to register for them, and how to obtain special accommodations (extra time, a sign language interpreter, etc.). Other features of ETS sites may include online registration, practice tests, and financial aid information.

Several ETS staff expressed an interest in ensuring that our Web sites were accessible to all users. We did not possess, individually or collectively, all the expertise needed to guide the corporation in achieving this goal. We determined that it would take a specific project to pull together the expertise and resources with which to ensure the accessibility of our Web sites.

In mid-1996 we sought and obtained internal corporate support for the ETS Web Access Project and began organizing our team. From then until now (March 1999) we have carried out a number of activities. On the basis of our experience with these activities, we feel that we can offer suggestions that may be useful to others who see similar needs in their organizations.

Purpose

The purpose of this paper is to describe a process that an organization can follow to improve the accessibility of its Web sites.

Method

The method for describing the process is to break it down into five steps, as follows: (1) Initiate a project; (2) Identify accessibility problems; (3) Identify possible solutions; (4) Select and implement a solution; (5) Obtain support for continuous improvement.

At what point in this process is ETS's Web Access Project? It is difficult to say. Since the project is under consideration for its third year of funding (from ETS Research), one would judge that we are in step five. The fact that we are beginning to implement some solutions suggests that we are in step four. Yet in other areas we feel that we are very much at the beginning (step one). Thus it is difficult to characterize the entire project as being at a single point in the process. We hope that, notwithstanding these ambiguities, the five-step process will serve as a useful framework for organizing our suggestions.

The Process

1. Initiate a Web Accessibility Project

There are several activities that may help an organization launch a Web accessibility project.

Communicate the Benefits

Making Web sites accessible is a practical step toward providing "equity" and "access" in the delivery of products and services. Improving accessibility of Web sites will also benefit many individuals, beyond those who have disabilities. An example of "side-benefits" for nondisabled people is found in the case of curbcuts on sidewalks. They were intended primarily to benefit individuals with wheelchairs, but they also benefit parents pushing strollers, people temporarily on crutches, and older people for whom stepping on or off a curb is difficult. Following accessibility guidelines in Web sites will similarly benefit many individuals who do not have disabilities, including individuals with slow modems (who often use the Web with the graphics turned off), text-only Web browsers, or telephone-based browsers (which use Touch-Tone signals for input and provide audio output). The work would also benefit individuals who use search engines, which generally rely on indexing of text to find Web content. Thus, in addition to just being the right thing to do, improving accessibility of Web sites can increase the base of clients who are able to use an organization's products and services.

Obtain Organizational Support

Obtain support from the organization. Our project has received internal research -area funds for the past two years and will, hopefully, do so for a third year. As the effort continues, we hope to find additional sources.

Ensure Wide Representation on the Project Team

Ensure that the project team includes individuals with a variety of expertise and backgrounds. The Web Access Project team has included members from different areas within ETS. Areas of expertise represented include publishing (paper and electronic), systems analysis, instructional design, disability access, research design, and other domains. Individuals with disabilities , such as those with blindness, serve as team members and consultants on the project.

Review Existing Accessibility Guidelines

Review existing guidelines for Web accessibility. The most authoritative document on the subject is the "Web Content Accessibility Guidelines," which is a proposed recommendation of the World Wide Web Consortium (W3C) (Chisolm, Vanderheiden, & Jacobs, 1999).

2. Identify Accessibility Problems

Identify and document accessibility problems according to a systematic evaluation methodology, using both human evaluators and automated tools. Human and automated methods for identifying accessibility problems complement each other. Human evaluators are more expensive to use but can help researchers identify problems that automated tools generally cannot, such as unclear labeling of links, unnecessarily difficult vocabulary and grammar, inconvenient page layout, distracting visual stimuli, ineffective search capabilities, cumbersome navigation, and privacy concerns. Automated tools, on the other hand, are able to identify some of the most critical problems (e.g., lack of alternative text for graphics) very quickly and at a low cost.

Use Human Evaluators

Have human evaluators go through the Web site. These evaluators should include (a) individuals with disabilities and (b) experts in disability access. ETS has engaged people with disabilities to evaluate the accessibility of its Web pages. An evaluation methodology called "heuristic evaluation" was a useful starting point in our work with human evaluators (Hansen, Forer, & Jacequemin, 1998; Levi & Conrad, 1996; Nielson, 1994).

Use Automated Methods

Use automated tools for validating accessibility. For example, "Bobby" is a software tool that automatically evaluates the accessibility of Web pages. Bobby has features that make it an essential tool for Web developers who want to ensure accessibility of their Web sites.

One can begin using Bobby by going to the site for the Center for Applied Special Technology (CAST), www.cast.org/bobby/. (The name "Bobby" appears to be associated with the site's graphic of a British police officer, commonly known as a bobby.) The user types in the URL of the page that he or she wants to analyze and then clicks the submit button (or simply presses Enter). Usually within half a minute, Bobby analyzes the page and returns a report listing accessibility problems and showing their locations on the page. Bobby is especially effective at identifying problems that hinder the effective use of speech output technology (e.g., "screen readers") by people who are blind or have other language-related disabilities.

A downloadable version of Bobby has some special advantages. It can be used to evaluate accessibility of Web pages that are behind organizational firewalls. One can also analyze many pages at a time rather than one at a time. ETS staff have used this version to analyze thousands of pages (Hansen, 1998).

3. Identify Possible Solutions

Identify possible solutions or elements of a solution to the problems that have been identified. Generally, a workable solution will involve a combination of elements. Depending on the particular set of problems being addressed, each of the following could represent either a solution or, more often, an element of a solution.

Educate and Train Staff

Ensure that staff who work with Web development receive training that acquaints them with the problems faced by individuals with disabilities who are using Web sites. Technical staff can additionally benefit from seeing actual examples of HTML code that address these problems. One source in which to refer is the W3C/WAI "Web Accessibility Content Guidelines" (Chisolm, Vanderheiden, & Jacobs, 1999).

Staff who are members of a Web accessibility project team should receive significant opportunities as well. Some ETS Web Access Project staff have received opportunities to both provide and receive instruction on accessibility issues. They have gained expertise and have shared their knowledge with other ETS staff through talks, presentations, and consultations. Some project team members have also presented material on the subject at national conferences (Hansen, Forer, Jacquemin, 1998; Hansen, Katz, & Forer, 1997; Katz, 1997). Thus, project staff are gaining expertise that will allow them to become resources to the organization and to others.

Make Available Templates and Examples

Make available templates and examples of accessible Web site components. On our ETS Web Access Project Web site, we have accessible versions of Web components, such as practice test questions that provide text descriptions for graphics (e.g., charts, tables, graphs) and that eliminate certain problems caused by use of tables and form buttons. We have implemented one version of an accessible, alternative version of the ETS front door (www.ets.org) and have helped develop templates that will be used in many other pages.

New Technologies

Conduct ongoing investigation into new technologies that may provide important accessibility benefits. Among the most important are HTML 4.0, Cascading Style Sheets (CSS), SMIL, Extensible Markup Language (XML), Synchronized Multimedia Integration Language (SMIL), and Mathematical Markup Language (MathML).

Forge Relationships With Outside Experts

Forge relationships with outside experts and their organizations. Many organizations wishing to improve Web site accessibility will benefit from hiring outside consultants. Members of the Web Access Project worked with a number of outside experts.

4. Select and Implement a Solution

Select and implement a solution that is ambitious yet recognizes limitations of time, expertise, and resources. Develop a strategy for making a significant difference, but realize that not every positive change can take place immediately. For example, certain lower-priority problems may need to go unfixed for a while in order to allow staff to focus on preventing problems in new Web content. Other tradeoffs may involve determining how to take advantage of new technologies while providing adequate support for users of older technologies.

Persistence in the accessibility effort is important. The design, development, and maintenance of Web sites involve many parts of an organization, and change may be slower than desired or expected. Changes to some sites may be frequent, so it is important to check sites frequently for accessibility.

5. Obtain Support for Continuous Improvement

Obtain support for continuous improvement. The following are a few ways to help achieve and maintain continuous improvement.

Share and Celebrate Successes

In a recent article that appeared last year our ETS corporate newsletter ("Project aims at accessible websites"), the Web Access Project team members shared their successes and discussed areas that need improvement. This article has helped raise staff consciousness of the accessibility issue and at the same time credited project staff for their efforts. The team has been discussing ways of publicly recognizing ETS Web sites that achieve a high level of accessibility, and hopes that doing so will help make striving for accessibility something that is motivating and fun rather than a burden.

Conduct Ongoing Training and Education

Conduct ongoing training and education in technology and accessibility issues. We are confident that with Web-related technology and markets changing so rapidly, ETS staff will need to receive ongoing training and education to ensure improving levels of accessibility of Web-based products and services. From time to time, if large-scale changes or improvements are needed, it may be necessary to repeat all five steps of the cycle.

A desirable outcome of such training and education would be for people developing products and services to ask themselves, "How would a user interact with the system if he or she had a visual, hearing, learning, physical, or other disability?" After answering this question, developers would then try to provide alternative media or methods to allow individuals with disabilities to obtain information from a given site.

Involve Individuals With Disabilities

We strongly recommend directly involving individuals with disabilities in all aspects of Web accessibility projects, making them project leaders as well as participants or evaluators. Individuals with disabilities encounter real accessibility problems when using Web sites. While many of the problems are documented, being able to witness the difficulties or to interact directly with individuals who have faced difficulties will add motivation and understanding to your effort.

Maintain a Win-Win Philosophy

Avoid developing an "us versus them" mentality. As we have attempted to facilitate change in the organization, we have tried to avoid placing blame for our current Web accessibility problems. The technologies are new, the standards are new, and we are only beginning to understand how to make Web sites more accessible. We emphasize the fact that we are all in this together, that we are all learning, and that by working together we can make a positive difference in the lives of many people. We take the approach that we will all be winners if our Web sites are accessible. Beyond simply doing the right thing, making Web sites accessible can generate good will and appreciation from customers and also may create a competitive advantage when dealing with the increasing number of clients and potential clients who value accessibility in information products and services.

Develop Consensus to Establish Organizational Policies

Develop consensus among relevant constituencies to establish an organizational Web accessibility policy. This policy should define minimum requirements for accessibility of Web sites. ETS project staff are now working with the corporate Office of Disability Policy and representatives from across the corporation to prepare a corporate Web accessibility policy document. We plan to continue to survey the accessibility of ETS's Web sites periodically with both human and automated raters in order to track our progress and provide feedback to Web developers and others. We believe that, with proper support and learning opportunities, the programs will try to exceed the minimum standards when possible.

Conclusion

A highly effective Web accessibility project will find that elusive balance among research, development, and communication. Conducting research to identify problems using both human evaluators and automated methods such as Bobby has been enormously helpful. Development of accessible Web components and sites (our own accessible Web Access Project intranet site) has been important because it helps demonstrate that we can do what we are saying others ought to do. Communication of findings and results is an important challenge. One ought not work for long periods without presenting results that can be understood and appreciated by individuals outside the project.

Efforts to improve the accessibility of the Web for people with disabilities can make a difference for millions of people throughout the world. Even with the problems that individuals with disabilities encounter with our Web sites, we found that they generally loved the fact that they had ready access to so much information. Our current efforts will help consolidate and extend the benefits that Web users with disabilities have been receiving.

Abstract: In researching educational applications of virtual reality, it is now possible to place several students within a single virtual environment (VE) simultaneously. This raises questions regarding the impact of collaboration within virtual environments on overall learning processes. A preliminary study of 110 sixth and ninth grade students was conducted for the purpose of examining peer collaboration within a VE. Students worked in pairs while investigating the concept of global warming within a fully immersive, 3-D, virtual reality based model of the city of Seattle, Washington, called Global Change World (GCW). It is concluded that most students thoroughly enjoyed and valued their experience with GCW. Continuing research will focus more closely upon the impact of peer collaboration on preconceived or "naive" scientific concepts as well as the possible conceptual change inspired by collaboration within GCW. This preliminary study has successfully demonstrated the potential for GCW to facilitate collaborative learning experiences.

INTRODUCTION

The application of virtual reality (VR) to the educational process is becoming more commonplace, with large numbers of students of all ages experiencing virtual environments (VEs) in educational settings. For example, Youngblut (1998) identifies over forty examples of VR applications that are specifically designed to support learning. These learning experiences can come in many forms, from virtual worlds created via VRML to fully immersive VEs that utilize stereoscopic headmounted display systems. Moreover, with ever-increasing computational processing power, the rapid growth of the World Wide Web, and the ongoing construction of a digital communications infrastructure, the creation of distributed fully immersive, multi-participant VEs running on the Internet are on the technological horizon. Given the growing interest in distance learning and distributed education among educators, it is fair to assume that many fully immersive, multi-participant, educational VEs will come on line as the technology becomes less expensive and more readily available.

Most educational applications of VR are designed to make use of its unique features. These features provide opportunities for students to gain a greater understanding of abstract concepts through the creation of visual metaphors or representations and the ability to scale and manipulate these representations. Working with these representations allows students to investigate relationships between objects in VEs which are unbounded by distance, time, or safety concerns. Designers of educational VEs believe that students retain, master and generalize new knowledge better when given the opportunity to become actively involved in constructing that knowledge through a coherent, firsthand interaction with knowledge domain representations (Winn, 1993).

As it becomes possible to place more than one student within a VE, questions arise regarding the potential impact of collaboration on learning. The purpose of this paper is to report the progress of a proof-of-concept project which is being conducted by members of the University of Washington's College of Education and the Learning Center at the Human Interface Technology Laboratory (HITL) at the University of Washington. Funded by a grant from the UW Royalty Research Fund, this project seeks to investigate the nature of peer collaboration within VEs. We describe an investigation that looked at how easily school children adapted to working together towards the ultimate goal of developing and testing hypotheses regarding environmental factors that affect climate change in a VE designed for use in science education.

BACKGROUND

Arriving at an understanding of exactly how to use immersive VR to support the teaching and learning of abstract concepts continues to be a challenging and elusive goal for researchers of virtual learning environments (VLEs). The potential for VR to benefit education is widely recognized and a number of studies have been conducted that have demonstrated a capability to teach content using VR under certain prescribed conditions (e.g. Byrne, 1996; Dede, 1995; McLellan, 1996; Osberg, 1997; Winn, 1997; Youngblut, 1998). A significant challenge, however, remains in fusing of the affordances of VLEs and educational methods of exploiting them into a demonstrable theory of learning for VR.

Zeltzer (1992) refers to the three attributes of autonomy, presence, and interaction in describing the affordances VR provides. Autonomy refers to the notion that a virtual environment (VE) is to some extent capable of performing its own actions, independent of user intervention. An autonomous VE follows its own path to goals and may or may not change course in response to user actions. Presence is simply the experience the user has of being in a real place when immersed within a VE. Zeltzer claims that for presence to be high, the user must be allowed to interact with the VE both naturally and intuitively; when presence is high the computer interface disappears. Finally, interaction involves the ability of the user to perform actions in the VE according to a logical rationale. Even though the user may have to learn how to function appropriately within the environment, the laws that govern the VE should become apparent over time, allowing for a meaningful interactive experience.

Most educational applications for VR are designed to make use of these and other unique features and affordances. Other affordances include: 1. Allowing students to gain a greater understanding of abstract concepts through the creation of visual metaphors, 2. Allowing students to directly manipulate and scale virtual objects or environments for clearer understandings, and 3. Allowing students to visit places and interact with events that distance, time, or safety concerns would normally prohibit (Winn, 1993, Youngblut, 1998). Designers of VLEs tend to believe that students retain, master and generalize new knowledge better when given the opportunity to become actively involved in constructing that knowledge through a coherent, firsthand interaction with knowledge domain representations.

Much of the appeal for applying VR in education is derived from the observations of educational theorists like Bruner (1986) and Piaget (1929) who have long stressed the value of actualizing learning through making it more real for students. VR technology allows for the creation of a VLEs where students can learn by interacting with virtual objects similar to how they would interact with real objects. Through immersion in a VE, students become a part of the phenomena that surround them. Learning is facilitated through the construction of concepts built from the intuitions that arise out of their direct experience of the environment. More recently, research (Clancey, 1993; Bricken, 1990) has supported the notion that VLEs, by their very nature, increase the human capacity for certain types of learning by allowing users to cross the boundary between third and first person experience, negating the need for a highly abstract symbol system. In traditional education, learning the symbol system of a particular knowledge domain is often a prerequisite to learning its content, as in the case of mathematics or music (Winn, 1993). The problem with this type of learning is that mastery of the symbol system can often be mistaken for mastery of the content, and teaching may end well before students make the link between the two.

First person, or direct, interaction within a VE allows students to construct knowledge out of their own experience without relying on symbol systems. This concept of knowledge construction among learners is more generally referred to as constructivism (Duffy & Jonassen, 1992). Self-constructed knowledge is highly individualized and may represent an improvement over similar knowledge learned by other methods because the learners shape the learning experience themselves. In other words, instead of relying on third-person instructor or text-based accounts of how things occur in the world, students immersed within VLEs can directly experience and interact with the concepts, principles, rules, and procedures found in the domain. VLEs designed from the constructivist approach are seen by some as having great potential for providing powerful learning experiences (Bricken, 1990).

Constructivism has entertained a long history in education and philosophy and is representative of a wide diversity of views that may be summed up in the following points: 1. Learning is an active process of constructing rather than acquiring knowledge, and 2. Instruction is a process of supporting that construction rather than communicating knowledge (Duffy & Cunningham, 1996). While constructivism is seen to imply that there is a tangible world, it argues that it is individuals who impose meaning on that world. Consequently, there can be many meanings or perspectives for any event or concept and the goal of education can no longer be one of instilling an absolute, correct meaning (Duffy & Jonassen, 1992). More importantly, constructivism brings with it the underlying assumption of a learner-centered approach to instruction. Constructivist arguments are often used to defend the design and implementation of VLEs.

Traditionally, most VLEs have placed a single student within the VE. However, as the technology becomes available educators are becoming interested in investigating the potential for collaborative learning in VEs. There has been considerable research on the value of collaborative learning. O'Malley (1995) found that much of the research on collaborative learning has evolved from the works of Piaget (1985) and Vygotsky (1978). Crook (1994), for example, views peer collaboration as having three basic cognitive benefits; articulation, conflict, and co-construction. According to Crook, peer collaboration forces students to make their ideas explicit and public. To do so, they need to learn to clearly articulate their opinions, predictions, and interpretations. Conflict may arise when students disagree in regards to their interpretations. To resolve the conflict engendered by collaboration, they must justify and defend their positions and are thus forced into reflection. Piaget (1985) offered a similar view, noting that socio-cognitive conflict often arises when students holding inadequate or differing views work collaboratively. As these differing views are sorted out, students are forced to reflect upon their own conceptions. Crook's concept of co-construction is based upon Vygotsky's (1978) belief that learning is the sharing of meaning in a social context. Students collaboratively co-construct shared knowledge and understanding by building upon each other's ideas. Given the ability of VLEs to support multi-participant activities, it is easy to see why educators are very interested in examining the potential for using them to support collaborative learning.

GLOBAL CHANGE WORLD

Global Change World (GCW) is a VLE that was designed and programmed by the Learning Center of the Human Interface Technology Lab (HITL) on the University of Washington campus. The GCW environment is created by two networked Hewlett-Packard 9000 workstations running DVISE VR software. Hardware manufactured by Division provides the physical user-interface and consists of an audio/visual rendering system connected to a headmounted display helmet (HMD), a navigation and control wand, and a position tracking system. GCW is capable of supporting peer collaboration by allowing more than one student to be immersed and interactive within the same VE at the same time.

In GCW, student pairs enter a virtual model of Seattle in the current year. They are able to navigate their way around the world using the wand while viewing the world through the stereoscopic HMD. Within the world, the virtual representation of each of the participants appears to the other as a cartoonish pair of large eyes, spiral ears, a triangular-shaped mouth, and a singular cyber hand with which they can manipulate objects. In addition, students are able to speak to and hear each other by means of an intercom system that is built into the HMD. In order to perform tasks within GCW, students access a virtual tool kit that allows them to measure air temperature, amount of greenhouse gasses in parts per million, and yearly rainfall. They are able to adjust such variables as the amount of green plant biomass as symbolized by trees, the number of factories, and the number of automobiles present in the world. After making measurements and adjustments, they can then use a "time portal" to go to a selected year in the future and repeat their measurements in order to determine the impact of their actions on the climate of the future.

In preliminary studies, GCW has been taken to College Place Elementary School in Edmonds, Washington, and Redmond Junior High School in Redmond, Washington where a total of 110 students have participated in collaborative VLE activities. Through these visits we hoped to gather information concerning the educational effectiveness of employing a multi-participant VE as a science education tool. Our subjects were eighteen 11 and 12 year-old boys and girls (9 female, 9 male) from a single sixth-grade class and ninety-two 14 and 15 year-old boys and girls (47 female, 45 male) from three ninth-grade class sections. Differences in navigation and general task performance abilities between the older students and the younger students did not appear to be substantial.

Our first task was simply to familiarize the students with the interface, scientific measuring tasks, and basic nature of GCW. The goal of this first phase of the GCW peer collaboration investigation was to observe and record the student interactions with each other in both world navigation and in performing specific tasks. As noted earlier, the HMDs were fitted with microphones so that the students could speak to each other from within the world. This allowed the students to communicate with each other in their normal voice and appeared to improve communication, facilitate collaboration and enhance feelings of presence. Each student pair spent an average of 20 minutes in GCW.

RESULTS

Upon exiting GCW, students were given a nine-question survey that employed a Likert-type scale. The questionnaire asked them to rate the quality of their experiences within the VE. The results of the survey indicated that the students found the experience to be highly enjoyable and most students said they would like to repeat the experience. About 5% of the students reported malaise (dizziness or disorientation). A few students reported problems with using the wand and seeing clearly in the HMD. Ratings of presence were high for most respondents.

Clearly, the overwhelming majority of students thoroughly enjoyed their experience with GCW and most of the students felt highly immersed within the VE. It was apparent that peer collaboration played a significant role in regards to the level of student engagement within the VE. The ability of the students to speak clearly to each other while in the VE seemed to greatly facilitate peer collaboration. Many pairs of students were highly communicative. As they navigated through the world or performed the requested tasks, they were engaged in near constant conversation regarding where to go, what to do next, and how to do things.

Observation revealed substantial peer collaboration among almost all pairings of students, though some pairs needed initial prompting and encouragement to begin conversing with their partner. Expert/expert pairs of females, who were comfortable with the interface, were the most vocally communicative. Novice/expert and novice/novice pairings of all gender combinations were somewhat less communicative. Expert/expert male pairings appeared to involve more action, such as racing, but still incorporated a significant amount of conversation, as well as the inclusion of vocal "sound-effects" that were related to actions being made, particularly among the younger students.

Male/female expert/expert pairings, as well as male/female expert/novice parings, resulted in what appeared to be a more self-reflective, thinking out loud style of conversation with the experts doing far more talking. These pairs would play hide-and-seek, in the case of experts, or simply try to keep track of each other by talking about what they were seeing. Most groups developed strategies for finding each other by identifying prominent landmarks and agreeing to meet at them. Some individuals picked up and carried large brightly colored objects, such as cars or boats, and waved them around or carried them along with them so the other at a distance could see them.

Though students can fly through the world with their hand controller, many of them were physically active as well. Many students were observed to be pointing at virtual objects with their free hand in the real world while talking to their companion in the virtual world. Several students were quite surprised that they had walked almost halfway across the room when we removed the HMD; they had assumed that they stood fairly still while they were flying around the VE. The students who were the most at ease with the interface were the most animated in their physical movements while immersed within GCW.

A number of students found GCW to be easy to use and made full use of the tools provided. These subjects quickly mastered navigational skills and the use of the environment measuring tools that allowed them to view the VE's current temperature, the amount of greenhouse gases present, and the amount of annual rainfall. While in the world, they were instructed on the use of the wheels controlling the quantity of the VE variables of cars, factories, and biomass. These students flew through the time portal, time and time again, in efforts to determine what the impacts of their changes would be and test theories regarding what changing the variables would do to the environment over time. These students typically rated the experience highly and reported a strong sensation of immersion.

Other students, however, had more difficulty mastering the use of the environmental tool kit and in trying to come up with theories for future environmental outcomes based upon changes made to the variables. Some dyads never got to the point of being comfortable enough with the interface to successfully investigate the environmental research elements of GCW. Those who did often disagreed on the expected outcomes. Time, as well as the scope of this preliminary study, did not allow us to perform a further investigation into the existence or nature of hypothesis generation and testing within GCW. We do know that the students were highly motivated, very willing to work in pairs, interested in exploring virtual space, and capable of performing investigative tasks within GCW. Further research that focuses more closely on the impact of peer collaboration on preconceived or "naive" scientific concepts and the possible conceptual change inspired by collaboration within GCW is planned and data collection will be underway throughout 1999.

CONCLUDING REMARKS

While the potential for VR to facilitate collaborative learning experiences appears to be great, much more research is needed before effective collaborative learning strategies can be developed. It is anticipated that these strategies will vary, depending on the kind of educational experience desired and the learning environment employed. However, for this potential to be realized, designers of hardware, software, and instruction must make sure that it is easy for multiple participants to collaboratively navigate and perform within VEs. This requires improvements of today's input devices including improvements in spatialized audio systems, less cumbersome HMDs, simpler wands, and the eventual introduction of haptic (force feedback) devices. The need for these technical advances is essential, considering that the networking of multi-participant, collaborative virtual environments appears to represent a significant trend for future applications of VR both within and outside of the educational domain.

Abstract: This paper reports the preliminary findings of an investigation into the use of internet voice technology to support community building for distance language learners. It is asserted that such technology, when chosen in accord with the pedagogical aims of the learning activity designers adds value to the overall learning experience. It empowers and enables such learners, realigns the tutor's role in the direction of co-learner and allows both tutors and learners to participate equally in the learning process.

Introduction

The Open University is the UK's largest modern foreign language learning provider with a current enrolment of approximately 8000 students, all of whom study individually at home, at a distance from each other and their tutors. While the traditional Open University methods of delivery – print, video, audio and face-to-face tutorials - are used by the majority of students, alternative methods of delivery are being actively investigated for those students who require or would prefer them by virtue of their geographical location (they may be in an area which is geographically remote from face-to-face provision) or circumstances (they may be unable to attend face-to-face tutorials because they are, for example, physically disabled in some way, in hospital or in prison). We describe these investigations, outline the learning environments and internet-based tools offered to learners and tutors and examine the outcomes of the initial trials in terms of the features we have found to be necessary to support and maintain an online community of students who are located at a geographical distance from each other.

Background

The research described in this paper comprises part of a larger, long-term project seeking to establish a framework for the use of networking technologies in distance language learning with a particular emphasis on the development of oral – and, as a consequence of this, aural – skills in the target language. During the lifetime of the larger project, technologies from telephone conferencing to voice conferencing on the internet have been employed in order to provide learners with increased opportunities for speaking and listening practice.
Initially, learning activities were designed for use with telephone conferencing systems. These were first

implemented in 1995. Groups of 6-9 students met at weekly intervals in order jointly to use the target language to participate in role-plays or other pre-arranged learning activities and thus to practise their communication skills in tasks requiring collaborative interaction. This framework was subsequently widened to incorporate both telephone conferencing and e-mail to allow students to prepare the broad content of what they were going to say (without writing a script), to refine their positions for the role-plays, and to negotiate with each other in the target foreign language about how to address the fictitious problem which had been posed for the activity.

Results from these trials [Hewer & Kötter forthcoming] suggest that student behaviour is modified according to the tools offered by the learning environment: for example, it was found that learners utilised e-mail to plan and rehearse their oral contributions in a way which was not possible to them when only telephone conferencing without e-mail support was available. Analysis of data collected during the course of that research has also led to the hypothesis that learner performance in the foreign language improves when learners are able to collaborate with each other between scheduled events. For example, students used e-mail to form small groups whose members supported each other in a way that went well beyond what a tutor could offer – in other words, students use such learning environments not only to carry out the required task, but also autonomously to form self-help groups. They employed e-mail for the following purposes: to enhance their knowledge of the vocabulary of a certain speech register and, in order to find out whether other students were able to make sense of their language output, to experiment with various syntactic and lexical forms of the target language that were, as yet, beyond their level of competence (this latter behaviour was also observable in the synchronous oral exchanges). In this environment, learners were able to receive rapid feedback from their peers, and this led to an increased willingness to take risks in the foreign language and so to develop fluency at a much quicker pace than might be expected to result from individual studies carried out in isolation.

A feature which is notably absent from most distance language learning settings is the option for learners to collaborate with each other outside inflexible, scheduled meeting times. While the use of telephone conferencing and e-mail addressed this problem to some extent by encouraging students to exchange e-mail, there was still no affordable way for them to participate in synchronous interactions which were flexible as to time, frequency and the number and composition of participating groups. With the recent increased robustness of Internet audio technology, however, it has now become possible to offer learners this improved access and flexibility, and it was as a result of such technological developments that the current investigations were implemented.

Previous uses of audio applications

A survey of the literature and the contents of listservs concerning the pedagogic uses of Internet-Audio, suggests that research into *on-line* use of audio applications is still very limited. There is streamed radio (via RealAudio) and a small number of homepages from which the visitor can download short audio clips (there are several on-line dictionaries that incorporate the ability to allow learners to listen to the pronunciation of a given entry), one prominent example being Randall Davis' *Randall's ESL Cyber Listening Lab* where it is possible to listen to pre-recorded "chunks" of language. (This site also includes a feature called "Randall's Voice Mailbox" which "gives visitors an opportunity to ask questions via e-mail and then to listen to their responses over the Internet"[Davis 1998b]. In other words, visitors may leave e-mail and then listen to the pre-recorded response to their question once this has been uploaded to the web page.

None of these applications uses audio in a truly interactive form. That is to say, none employs it in a two-way fashion. Streamed audio is very much uni-directional, as is listening to sound files which have to be downloaded from the Internet. The only exception to this seems to lie in a case study reported by Elske Heeren in 1995. This "...was carried out to investigate small-group collaborative learning through real-time"[Heeren 1995]. As a result of this study, Heeren reports that "audio-conferencing plus a shared workspace led to equal task performance as audio-conferencing without such an additional tool"[Heeren 1995]. Even this investigation differs from the research reported here in at least two important ways: firstly, whereas its focus was on assessing the technology's potential to foster decision-making, the current investigation deployed the technology in real language learning activities and secondly, participants in Heeren's investigation were students of philosophy rather than language learners.

In the light of the learner behaviours observed during the activities using telephone conferencing and email then, the current study set out to examine whether the new, Internet-based learning environment would support and encourage not only these behaviours, but also if the increased flexibility it offered would modify learner behaviour still further, encouraging increased collaboration and peer support and thus improving the learning experience as a whole.

The FLUENT[1] project

In the summer of 1998, volunteers from two language courses – first level German and final level French - were asked to participate in a series of training activities, followed by three language learning activities. The entire project lasted from October 1998 until January 1999. Learners were told all these activities, would use Internet audio conferencing software and would give them voice access to each other at any time of day for the cost of a local telephone call, regardless of their geographical location. 30 German students and 26 French students volunteered to take part in the trials after receiving detailed information further to their initial expression of interest. Of these volunteers, thirty students participated in all three activities while approximately three per group dropped out after each of the first two activities.

The learning environment which was developed included not only the audio client, but also e-mail and a website which contained both technical and pedagogical information. Learners were encouraged, both by email and during their audio tutorials, to consult the website to obtain information about how to use the audio client and about the content of each activity. The former information was provided via a Frequently Asked Questions list, whilst the latter was posted to the appropriate webpage on a 'need to know basis'. In effect, students were given information about each activity as and when the tutor believed this to be appropriate. The web-page environment allowed dynamic responses to student requests for further information – whether such requests were technically-based or activity-related.

The Internet audio conferencing software that was used provided very low-bandwidth transport of voice using state-of-the-art encoding. While there are subtle artefacts perceptible to the attentive listener, the voice quality is sufficient for the task of providing students with listening and speaking practice in western European languages. The technology is optimised for relatively low-speed exchange, i.e. using V.34/bis (28.8 or 33.6 kbps) modems. It works with de facto standard sound subsystems; while desktop microphone and speakers can be used, headphones with a powered microphone (widely available at low cost) are recommended. The encoding and decoding algorithms are simple enough to permit the client to work well on mid-range computers (a 100Mhz 32-bit processor with 16Mb of memory is adequate). The server software, which groups users in virtual 'rooms', can run on affordable, mid-range computers – we have been using a desktop 200MHz Pentium machine with 64Mbytes of memory. The server must be able to manage multiple Internet connections, i.e. have an industrial-grade TCP/IP facility (supplied with most operating systems designed for server support). The server for this project was connected to a standard campus Ethernet LAN at 10Mbps.

Students were able to load and configure the software with relative ease. Where difficulties did arise, they could obtain help in the form of telephone and email access to technical specialists on the research team. Those problems which occurred were in two major areas: some students – approximately 15% of the overall total - dropped out of the trials because they could not get the client installed or running on their machines, but the majority experienced few problems. Another area of difficulty concerned latency and reliability of the network connecting students to the server. These connections were provided by a number of commercial ISPs and were not under the research project's control. Thanks to expertise provided by the Open University's Knowledge Media Institute, which has extensive experience in telepresence research and practice, it was possible to inform students of the source and extent of the trouble very rapidly, often as conditions changed "in real time." This ability to reassure students that their own computers were not necessarily at fault helped them to remain confident and engaged, even during temporary "rough patches" due to network conditions. However, these difficulties were exceptional – the vast majority of participants experienced no problems during months of activity.

Findings

[1] Framework for Language Use in Environments embedded in New Technologies

An analysis of preliminary results suggests that the type of audio-support offered to students during the course of these trials is what many distance language learners who are unable to attend face-to-face tutorials and/or who want to learn at their own pace have been looking for. Various participants confirmed that part of what made the project so attractive to them was that they did "not leave home and travel miles for a tutorial", as one student put it. Another major asset was the fact that the servers were constantly available, or, in other words, that students could arrange to meet either on a one-to-one basis *and/or* in group whenever they pleased, thus supplementing the scheduled internet-audio tutorials and occasionally even making them superfluous.

One very important outcome of this study was that it appears that it does not suffice simply to provide the software and to leave the rest to the learner. In fact, the first few weeks of the project required researchers to work long hours to ensure that both the technical and the pedagogical sides of the project were well developed. On the technical side, students reacted in very different ways to the learning environment; for example, one student reported needing to "overcome still high level of nerves" while another reported exactly the opposite, claiming to feel "a little more relaxed than face to face which is good". The project's supporting website had to be maintained and updated on a regular basis and a weekly surgery was provided to offer technical trouble-shooting advice on a one-to-one basis. From the pedagogical point of view, not only did tutors have to develop meaningful, motivating and engaging learning activities, but it was also necessary to lay the foundations to encourage learners to form self-help study groups - that is, to develop as autonomous learners.

A key figure to the success of the whole project was the tutor. The embarrassment several students reported experiencing when they sat alone by their computers, finger on the mouse-button, listening to others' voices from the headset, made it crucial for tutors to provide them with a fairly high degree of encouragement or "back channel cues", such as *uh*, *yeah, really*, etc, or the equivalent in the target language. As the participants' familiarity with the medium grew, they became more confident in using it and their self-consciousness waned. It was crucial, though, to steer them through these initial difficulties and also to allow and encourage them to take their time in composing utterances in the target language rather than to exert pressure on them to speak in order to fill the sometimes lengthy gaps between turns. It is also important to note that, initially, tutors found long pauses difficult to cope with, but, like the students, as they became more familiar with the medium, they adapted their teaching style to provide learners with a learning experience optimally suited to the learning environment.

Yet another essential component of this virtual learning environment is the learning activity. As in 'traditional' learning environments like the real-life classroom, task-design is vital to the success or failure of the experience. It would be wrong to assume that every activity that works in a face-to-face-setting can simply be transferred to a virtual, audio-conferencing environment. The findings of the current research support the hypothesis that "...more explicit structuring of the task content, of the already agreed-on issues, and of the planning and progress was needed to maintain a shared understanding and a shared focus"[Heeren 1995]. Given that the present project is explicitly concerned with language learning, we would like to cite one of our students who, in a different context from Heeren, noted: "The level of concentration required for on-line communication is extremely high and this should enable enhanced focus on the expression of the language as well as enhancing the understanding of the sense of what is being received." This, then, is exactly what we had hoped to achieve – the learning environment allowed learners to concentrate their efforts on using their listening and speaking skills to communicate and interact in the foreign language and thus improving their confidence in the use of the target language.

To summarise, what is asserted here is the following: this project enables and empowers learners to interact with each other via synchronous audio and to form autonomous learning communities whose members are located at a distance from each other. The learning environment changes the role of the tutor to that of facilitator, co-learner and activity co-ordinator and allows learners and tutors to participate equally in the design process. Finally, the technology itself was chosen precisely because it can be used in accord with the pedagogical aims of the activity designers and is thus deployed in a pedagogically- rather than technologically-driven manner - thereby adding value to the overall learning experience.

Abstract : The *Vicarious Learner* project is looking broadly at issues concerning the development of a multimedia database system to promote and enhance the role of dialogue in learning. A specific interest, and the origin of the project's name, is in the question of whether and how dialogue can be helpfully "re-used". What benefits can students gain from dialogue as observers, not just as participants? We describe our initial attempts to generate and capture educationally effective discourse exchanges amongst and between students and tutors. Problems encountered with available CMC discourse formats led to our development of a set of Task Directed Discussions (TDDs). A medium sized corpus of discourse exchanges was collected using the TDDs. A selection of two hundred of these TDD exchanges formed the multimedia discourse database to the implemented prototype system, Dissemination. Initial results from a large scale controlled experiment and evaluation of Dissemination are outlined.

The Vicarious Learner Project

Attempts to develop CMC environments that could support appropriate educational discourse has tended to simply result in designers repeatedly making the same mistakes (Graddol, 1989). Motivated by this observation Mayes (1995) has developed the 'Groundhog Day' model of educational courseware in which the roles and interaction between the three types of learning technology are explained; these being referred to as Primary, Secondary and Tertiary Courseware. Primary Courseware is the technology to support the presentation of content, Secondary Courseware the technology that provides the support for the doing of learning tasks and, finally, Tertiary Courseware is the technology that supports learning dialogues, through communication. The present paper looks at how the value of dialogue in learning depends on the structure of the environment in which it takes place. In particular, we consider dialogue which takes place in a "computer-supported communication" (CMC) environment, an approach which is being adopted in many courses from primary schools through postgraduate university courses and continuing education, often uncritically and without fully understanding all the issues which arise from these methods.

Motivated by our own experience in developing web-based CBL environments we describe the reasons for developing a multimedia database of discourse exchanges as a means to promote better discussions (Greeno, Benke, Engle, Lachapelle and Wiebe, 1998). The development of this multimedia system, Dissemination, has been motivated by a wish to exploit technology as a means to promote patterns of discussion and enquiry that have proved difficult or problematic to initiate in traditional educational contexts (Bligh, 1986; Gibbs, 1992). We begin by looking at the Vicarious Learner projects initial attempts to generate good educational discourse and consider the various roles of the environment, the participants and the decisions of the course organisers as some of the determinants of the kind of dialogue that results. These issues underlie dialogue in learning, face-to-face as well as on-line (Newman, Webb and Cochrane, 1995).

Attempts to Encourage Appropriate Pedagogical Discourse

Dialogue is an essential component of learning, particularly in complex, discursive domains. This has been noted by many researchers (Voss, 1996; Laurillard, 1993), but with increasing class sizes and the move toward more and more computer-based courses, this component is ever-decreasing and in danger of disappearing completely. The role of technology must be to push back the threshold imposed by these constraints, this being achieved by opening up new media for discourse that are not subject to the same delivery bottlenecks as traditional methods.

The Vicarious Learner project propose a new type of courseware that aims to support understanding of primary course content (notes, lectures...) by distilling the experience of other learners captured as discourse. Initial attempts to exploit CMC technologies led us to adopt a range of web-based discussion tools, principally the "HyperNews" system (LaLiberte, 1995) -- a tool that manages a collection of HTML pages to provide a forum maintaining persistent discussion threads accessible through a normal Web browser such as Netscape. In the first Computers in Teaching and Learning course (CTL1), this environment was used relatively loosely. Students were prompted by a few seed questions, but then were left to develop the discussion as they chose, with arbitrary but usually quite sparse contributions from the course tutors. Thus HyperNews, as used in CTL1, acted as a form of 'discretionary database' (Connelly and Thorn, 1991), growing and developing only under the motivation of the students themselves.

Based on feedback from the first course and suggestions in the literature on conducting on-line discussions (Sproull and Keisler, 1993), we made the discussions in the second CTL course more structured and participation compulsory. We had tutors post specific questions and participate more, particularly by summarising the main points at the end of each week's discussion.

These changes, which in good 'user-centred' style were based on the comments and observation of real users in a real setting were not successful in improving the discussions. Two effects were particularly striking. On the one hand, all students participated in the discussion in CTL2, whereas in CTL1 only a half of the students made any contribution, though only half of these again (i.e. a quarter of the class) on a regular basis. On the other hand, the number of questions raised in the HyperNews discussion in a given week in CTL1, was typically four times greater than in CTL2. A content analysis of these questions showed those generated in CTL1 to have been 'knowledge-based' questions arising from students' interests and attempts to engage more deeply in the problems underlying the course content (Scardamalia et al., 1992). That is, they were engaging in discussion on the theoretical assumptions and motivations defining the knowledge domain. In contrast, students in CTL2 all participated, but in a generally much more subdued manner, restricting their questions to a more shallow 'text-based' level (Rosenshine and Chapman, 1990).

Turning Discussions into Learning Tasks

In response to our own experience we have developed a series of Task Directed Discussions (TDDs) which encourage students to engage in meaningful structured discussion tasks. The series of tasks gradually demand students to engage in deeper thinking about the domain concepts and 'ease students in' to discussions. These TDDs are a first step both toward developing methods which will be useful for any student population and also toward testing and refining our model of educational dialogues.

In themselves each TDD is a discrete language activity with a set goal, with all discussions being based upon discursive manipulations of a common set of domain concepts. Altogether eleven Task Directed Discussions have been proposed ranging in discursive focus from single concepts to groups of concepts, with varying manipulations of these. Thus, the discussions vary in their coverage of the knowledge domain, the specificity of discussions and the types of epistemic structures that they aim to elicit and make exoteric to others. This is where TDDs have gained a great deal from the lessons learnt in work on second language acquisition, where there is over thirty years of work in using and embedding complex cognitive tasks in structured discussion groups (Skehan, 1998).

For each discussion task the idea is to focus attention on to an explicit and shared set of concepts that have been derived from the Primary Courseware (i.e. the course content). Thus the Primary Courseware remains the target for each discussion task, but the form and scope of each discussion is controlled through specified manipulations of these concepts. So, each discussion form is based around a simple cognitive task and acts as an example of Secondary Courseware. Finally, Tertiary Courseware is produced as an outcome of these TDDs in the form of recorded discussions about the course content. These discussion can then be indexed into a multimedia database to compliment the Primary Courseware. The eleven Task Directed Discussions are :

1. *Amphibolic TDD* : the goal is to examine the multiple interpretations offered by the organisation and Primary Courseware.
2. *Common Denominator TDD* : given a concept, name examples of its application.
3. *Comparison TDD* : describe the connection between two concepts relative to a given criterion.
4. *Defining Terms TDD* : one student attempts describes a concept well enough for another to guess what this concept is.
5. *Depiction TDD* : explore the multiple representational structures, styles or media in which a concept or argument may be depicted (e.g. charts, text, graphs...).
6. *Gestalt TDD* : the explicit goal is to highlight the underlying assumptions made by another student as part of one of their explanations of a concept or argument using a given concept.
7. *Hypothetical TDD* : Encourage learners to reason to and from precepts, conjecturing to and from 'possible worlds.' Examples would be a counterfactual arguments.
8. *Ranking TDD* : rank a given set of concepts in terms of level of importance along a given dimension.
9. *Reconstruct TDD* : have learners re-organise the order and propositional structure of sections of the Primary Courseware to explore the conceptual and functional structure implicit.
10. *Repertory Grid TDD* : select three concepts and describe in what way two are similar, but different from the other one along a common dimension (construct)
11. *Scanning TDD* : select from a designated section of the Primary Courseware a specified number of factors that are the most relevant examples of a given criterion.

TDDs have a number of goals, but foremost is the requirement that through taking part in them learners are implicitly helped in structuring their understanding and developing their knowledge, i.e. that learners are helped in developing their cognitive '*epistemic fluency*' (Morrison and Collins, 1995).

As mentioned above, as a means to explore such issues relating to multimedia indexing and modality presentation of pedagogical discourse we have developed and implemented an indexed multimedia database of these TDDs in the 'Dissemination' tutoring system. A logical representation of the interface structure of Dissemination can be seen in Fig. 1, while an example of the actual system is shown in Fig. 2, below.

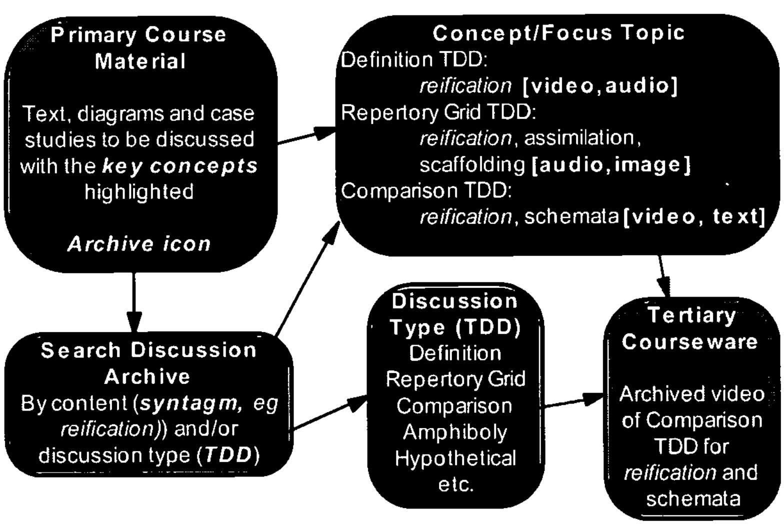

Figure 1 : The 'Dissemination' Tutoring System

Dissemination : An Indexed Multimedia Database of Tertiary Courseware

From a potential resource of over 30 hours of videod discussions Dissemination has been populated with an initial number of 200 media clips as video, audio-graphic, and text transcripts. Further, using Dissemination a large-scale study was undertaken in which 37 subjects were required to undergo a 10 hour learning experiment. The subjects' goal was to learn and understand the Primary Courseware ('The Role of Computers in Teaching and Learning', as in the CTL 1 and 2 courses) well enough to achieve 70% on a test about it (the subjects were told that anyone achieving this score would be awarded a financial bonus). In addition one set a subjects had access to the Tertiary Courseware in Dissemination. However, there was no explicit requirement that these subjects make use of the Tertiary Courseware during the experiment. In fact, given the incentive of the financial bonus it is reasonable to assume - in addition to the subjects own stated comments - that they only made use of this material when they found it useful to do so. As a result we a confident that in using the Tertiary Courseware the subjects were attempting to retrieve those examples of multimedia discourse from the database that would best help them in the interpretation and understanding of the primary course content. Each media clip entered in the system could be retrieved along three orthogonal dimensions :

1. The concept or focus topic of the TDD;
2. The form of the discourse as determined by the discourse goal specified in the TDD;
3. The medium of discourse. This is the dimension along which the discourse is captured and entered into the database (video, audio, text, graphic).

The relationship of the Primary Courseware to the Tertiary Courseware can be seen in Fig. 1. In reading the course notes the learner can access Dissemination through an indexed set of key concepts highlighted directly (top left), or they can access an archived TDD indirectly through a search of the database (bottom left). For each key concept the learner is presented with the indexed set of all TDDs for that key concept in various media (top right). In selecting one of these along the three orthogonal dimensions the learner is shown the desired piece of Tertiary Courseware (bottom right).

are needed to see this picture.

Figure 2 : A Screenshot of the 'Dissemination' Tutoring System, showing the Primary Courseware (centre), the indexed database of TDDs for the concept 'reflection' (top left) and Tertiary Courseware presented as a text transcript (bottom left) and digitised video clip (bottom right)

Tertiary Courseware as a Vicarious Learning Resource

The results from the experiment are extremely rich in data. Giving us information on the cognitive, affective, linguistic and behavioural impact of Tertiary material on learners. At the time of writing we are conducting a series of structured interviews using Repertory Grid techniques on the RepGrid II programme (Gaines and Shaw, 1993). In addition we are analysing the computer logs to look at the media access patterns in relation to the content of the Tertiary and Primary Courseware. Some preliminary data that is of interest in its own right is data showing that there are patterns of preference and individual differences in subjects' retrieval strategies, and that these preferences for Tertiary Courseware develop over time.

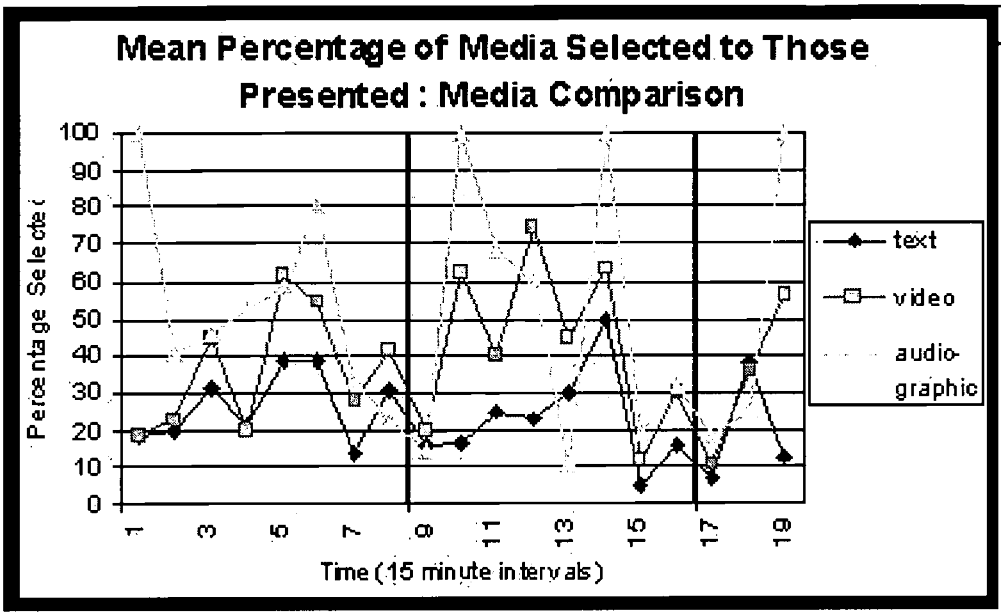

Figure 3: Graph of comparative mean rates of media use for each quarter hour.

The pattern of media use during the course of the experiment can be seen in Fig. 3. Certainly there are a number of surprising patterns suggested by this data. The audio-graphic medium is clearly the preferred medium of retrieval for the Tertiary Courseware. In addition, it was surprising to the experimenters that the textual medium was used at all, as these were verbatim transcription of the conversants' speech (hums and stutters included). One explanation is to understand these results in terms of the 'grounding' of the discourse available in each medium (Clark and Brennan, 1993). Yet the concept of communicational grounding does not adequately explain why subjects would access the same data in different media or would show a preference for one media at one time and another later. This problem is clearly highlighted when one looks at the data on individual differences. For each individual there were marked patterns of preference for one medium over another, though these preferences often changed over time. Additionally, the subjects varied greatly in the volume of material browsed through to the number of clips they viewed or read in their entirety.

Finally, the data on the mean number of clips viewed in their entirety also pose a problem to be explained. Over the course of a single session individuals were less likely to listen or watch a clip in its entirety, the decline being gradual from an mean of 2 per quarter hour to less than 1; with this pattern being repeated during each session. It may be that this is an indication of subjects' improvement in their ability to retrieve the information. Or that their growing understanding of the course notes allowed them to confirm their working hypotheses more quickly. Basically, as your understanding of a subject grows do you simply get better at retrieving the information you need or need to retrieve less information?

Conclusion

In coming to exploit and fully understand the nature and interaction between different courseware media the 'Groundhog Day' model (Mayes, 1995) has proved to be a strong motivating factor in the exploitation of a networked multimedia database of student discussions. In balance of the importance of such learning opportunities in traditional education media (Bransford, Franks, Vye and Sherwood, 1989; Graddol, 1989) it has been important in our work to overcome the technical, psychological and educational difficulties in providing such a resource to learners. Through our early work on promoting discourse we quickly became aware of the need to develop a set of Task Directed Discussions that would guide students in their interactions with the Primary Courseware and with each other. Having produced a corpus of such discussion tasks (some 30 hours) we implemented these as part of a structured on-line database of Tertiary courseware for other learners to exploit.

The large scale experiment conducted using the discourse database (Dissemination) has produced interesting and promising initial results. Using the information from this experiment and from continuing work in developing the multimedia database to exploit the emerging SMIL standard (Synchronised Multimedia

Integration Language) for integrated multimedia frameworks we hope to implement the full Tertiary Courseware corpus. As part of this we are currently subjecting transcripts of the discourse to a range of linguistic measures, for both content and discourse analysis (Gunawardena, Lowe and Anderson, 1998). Such an analysis will be used to further develop the logical database structure of Dissemination for exploitation by researchers interested in the form and properties of pedagogical discourse and CMC environments.

Abstract: This paper presents the results of a pedagogic verification experiment we carried out in the ARIADNE project (Forte et al. 1997a; Forte et al. 1997b; Duval 1998; Ariadne 1998). The aim of the experiment was to evaluate the use of the ARIADNE core tools in a course on algorithms and data structures, as it was delivered in 1997-1998 at the K.U.Leuven - Campus Kortrijk. The goals of the evaluation were:

- to investigate the usefulness and usability (i.e. reliability, ease of use, effectiveness and efficiency, etc.) of *the ARIADNE core tools and the ARIADNE methodology for course production and delivery* from the perspective of a *professor* who is responsible for the organization, content and teaching of a university course;
- to investigate the usefulness and usability of an ARIADNE course for *students*, by evaluating the *ARIADNE Learner Interface*. (The content provided through that interface was developed mostly with non-ARIADNE authoring tools).

With this paper, we hope to counter the general observation that formal evaluation of the actual use of technology in education and training is often neglected or even totally absent.

The Evaluation Context

The ARIADNE toolset is quite broad: it encompasses authoring tools, as well as a number of core tools for management and delivery of courses. The experiment reported upon here is concerned with the evaluation of the following core tools and their associated methodologies:

- the *Pedagogical Header Generator*: an indexing tool used to describe educational resources and to enter the descriptions (sometimes called 'metadata') and the resources themselves into the KPS (see below), so that they can be reused in many courses;
- the *Knowledge Pool System* (KPS): a distributed database of reusable multimedia educational components, with circa 10 operational sites throughout Europe at this moment (Cardinaels et al. 1998), that can be queried through the indexing tool already mentioned;
- the *ARIADNE Management Interface* (AMI): a Web interface that enables an author to define a course as a sequence of sessions with associated documents (retrieved from the KPS) and other resources (external web documents, interaction tools like discussion fora or email, etc.)
- the *ARIADNE Learner Interface* (ALI): an automatically generated Web site, based on the course definition created with the AMI (see above), that is used to deliver the educational content to the learner. It provides him with access to the educational material included in the course and guides him through the course in a way predefined by the teacher.

The first three tools were evaluated by the authors themselves, as they were responsible for the course. The latter tool was evaluated by the students who took the course. This experiment is part of a series of ARIADNE pedagogic verification experiments that were carried out by the end of the first phase of the European ARIADNE project (ARIADNE entered its second phase in June 1998).

The Course

The course 'Informatie- en Programma-Structuren' ("Information and Programming Structures") is delivered to 2nd year informatics ('2de Kandidatuur informatica') students at the 'K.U.Leuven Afdeling Kortrijk' (KULAK for short), a *distant campus* of K.U.Leuven, at circa 130 kilometers of Leuven. Professor Erik Duval comes to Kortrijk once a week, where a local assistant is actually based full-time. KULAK students typically take the first two years of their four year program in Kortrijk. Afterwards, they can take the second part of their program in Leuven itself, or in another university.

The *organization* of the course was not so much an ARIADNE related task, but required substantial work during the pre-experiment and the actual experiment phase, because this course was very substantially reorganized, based on the findings of a study committee at our Computer Science Department. Eventually, the course consisted of:

- 23 lecturing sessions of 2 hours each
- 9 guided exercise sessions of 2.5 hours each
- 2 practicals of 20 hours and 50 hours individual student work respectively
- an 0.5 hour oral examination with 2.5 hour preparation time.

The actual *course material* was developed in very close collaboration with prof. Eric Steegmans at K.U.Leuven who was teaching the same course to K.U.Leuven students. In concrete terms, the course content consisted primarily of:

- slides in Microsoft Powerpoint;
- text in Microsoft Word;
- text in LaTex, translated into HTML (manually and/or automatically);
- active existing documents (applets and the like), developed by our team or located with Web search engines, to
- illustrate particularly challenging concepts and algorithms that benefit greatly from visual animations and the like.

This material is structured in an ARIADNE 'curriculum' that defines sessions and the appropriate documents for these sessions. The table below shows a small excerpt of the curriculum for this course. Note that the evolution of the course in time is defined (through the date and duration of the different sessions), so that students can always be guided to the appropriate material at a particular moment in time. An assignment is defined as a so-called 'fuzzy session' that has a start and end date, in between which students must complete the assignment.

...
Session 1: Inleiding
Date: 2/10/97 11:00
Duration: 2:00
Description: Deze sessie handelt over het verloop en de inhoud van de cursus. Tevens wordt kort ingegaan op Java als programmeertaal. Deze sessie komt overeen met p.1-13 in de cursus.
Documents (2):
1.VERLOOP VAN DE CURSUS INFORMATIE- EN PROGRAMMASTRUCTUREN
2.DE PROGRAMMEERTAAL JAVA
...
Assignment: Practicum 2
Start: 12/2/98 15:30 - End: 5/3/98 11:00
Duration: 5:00
Description: Dit is het tweede deel van het practicum.
Documents (1):
1.OPGAVE PRACTICUM 2 INFORMATIE- EN PROGRAMMASTRUCTUREN 1997-98 (KULAK)
...
Session 26: Oefenzitting 8
Date: 19/2/98 15:30
Duration: 2:30
Description: Dit is de tweede oefenzitting rond correctheidsbewijzen.
If-then-else opdrachten
Oproep van procedures, functies, mutatoren en inspectoren
Bewijs van eindigheid
Bewijs van data- en klasse-invarianten
We behandelen ook een uitgebreider voorbeeld: 'het eerste langste plateau'.
Documents (5):

1.If-then-else opdrachten
2.Oproep
3.Bewijs van eindigheid
4.Bewijs van data- en klasse-invarianten
5.Eerste langste plateau

Sample from the ARIADNE curriculum for this course

The Evaluation: Professor Perspective

For the evaluation of the *usefulness and usability of the ARIADNE core tools* from the perspective of a *professor and his team*, the following statements summarize the main findings. These are based on personal experience by the authors as recorded in an interim report:

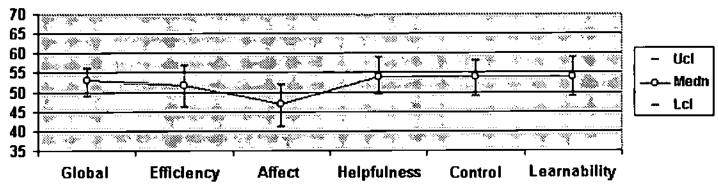
- There is a lot of work involved in organizing a *new* course (or rather: a heavily restructured existing course). This is probably true in general, but the situation was not alleviated through the use of ARIADNE technology. In other words: the *workload of course preparation and elaboration certainly didn't seem to diminish* because of the use of ARIADNE tools
- An important concern was to present and treat the content (algorithms and data structures) in a more *object-oriented* way, with a focus on structured and carefully planned development of solutions, using Java as a programming language. *Few really good examples* exist that treat the content of the course in this way. Even books that promised to offer what we were looking for often used an object-oriented language like Java for the notation, but not the associated object-oriented programming techniques. This resulted in the need for more original work than anticipated, which was only possible through close collaboration with the team that teached the same course in Leuven, as this team has extensive experience in teaching on related topics. *This problem was completely unrelated to the use of ARIADNE tools.*
- Using an ARIADNE *curriculum* to document the actual progress of the course as it takes place actually helps to keep track of the *administration* of the course.
- The ARIADNE Management Interface was *not always robust and easy to use*: updating a course extensively and then not being able to upload the new version is a major source of frustration. (Current developments in the ARIADNE project are tackling this problem.)
- *Adding value* with the ARIADNE approach to a course whose main mode of operation is traditional (face-to-face lecturing with regular practical sessions) *is far from trivial*, the more so in this case where the situation is relatively luxurious in that the students constitute only a relatively small group of 10 where real interactivity with the whole group can actually be achieved.

The Evaluation: Student Perspective

Because of the rather informal nature of the course, with the interactive sessions involving a group of 10 students in a relatively small room, and the very regular contacts between the students and the teaching assistant at Kortrijk, we opted for a *continuous evaluation* through discussions during coffee breaks, email messages, short class discussion during the actual lectures and regular updates with the teaching assistant. Close to the end of the course, a *standardized questionnaire* was handed to the students, with a request to return the filled in questionnaire before the final examination. Five out of ten students did indeed return the questionnaire. Using a commercially available software tool (SUMI), the answers from the students were analyzed statistically, through the kind assistance of SCET, one of the ARIADNE project partners.

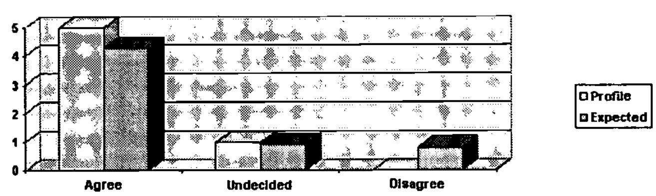
The students were generally quite receptive to the whole idea, although some questioned whether the use of technology didn't make life too easy for the professor, as he no longer had to 'teach' directly, and too hard for the students, as the amount of content could be increased substantially without any immediately apparent organizational problems. It was agreed that the electronic material would be supportive only and that all content would be discussed during the interactive sessions as well.

The figure below represents the overall 'Profile Analysis Graph'. In this graph, the *Global scale and five Usability Subscales* are shown for the ARIADNE Learner Interface, as evaluated by the students. For each scale, the median value is shown circled in the middle of the line; the 95% upper and lower confidence limits are shown by the opening and closing points. These limits indicate the range within which we can be 95% certain that the true scale median for the software can be found. The scales are so arranged that the standard for state of the art software is 50. Software above 50 is ahead of state of the art for quality of use; software below 50 is behind state of the art. Each sub-scale is on a numeric scale from 11 (low usability) to 71 (high usability), with a mean of 50 and a standard deviation of 10.

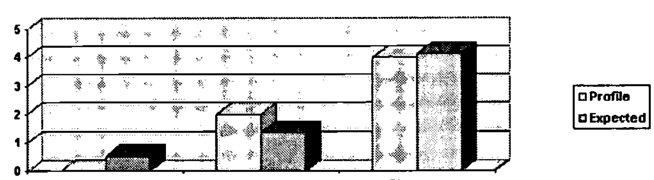


Essentially, the graph above means that students rated the usability of the ARIADNE Learner Interface slightly above 'state of the art'. The main findings of a more detailed analysis of the evaluation results are:

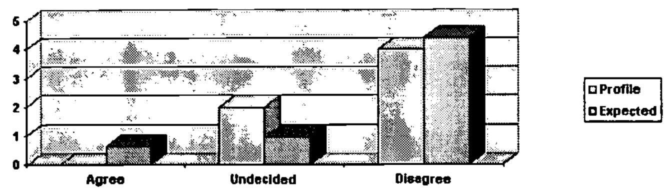
- The overall ARIADNE infrastructure does work *well in field experiments with real students in a real course.* The students do not seem to get the impression that they are treated as guinea pigs for immature technologies.
- The overall ARIADNE *methodology* for course material distribution, based on content in a Knowledge Pool System with structure defined in a separate curriculum and a student web site generated automatically from the combination of these two, is very compatible with a *develop-while-you-deliver* approach to course material production. It should be noted that the latter approach arose from practical requirements and limitations, rather than from an a priori intent. However, this approach is certainly very common and thus the above mentioned compatibility seems quite important for acceptance of the ARIADNE toolset.
- The relatively structured approach to learning, which is typical to ARIADNE, seems to lead, as expected, to purposeful behavior on the students part, as illustrated in the graph below with the reactions to the statement "It is relatively easy to move from one part of a task to another",



and by the graph below with the reactions to "This software seems to disrupt the way I normally like to arrange my work".



- From the standardized questionnaires filled in by the students, one can safely conclude that the ARIADNE Learner Interface is easy to understand and learn working with. Most of the students are by now probably quite accustomed to a World-Wide Web interface with a navigation panel on the left and a content panel that takes up most of the remainder of screen estate. This is illustrated by the graph below, which represents the reactions to the statement "It takes too long to learn the software commands".



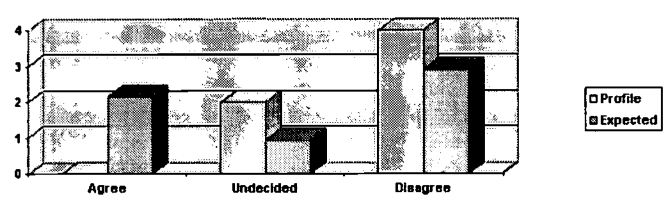
Conclusions

Being responsible for this course, we certainly felt that the ARIADNE toolset and methods helped us to structure the development of this course.

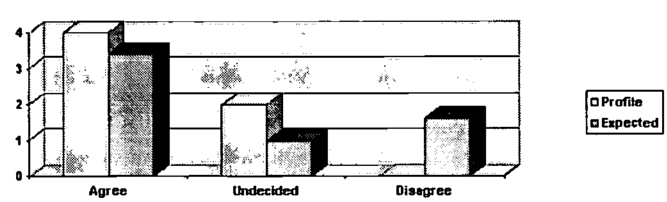
The most crucial remaining problem in our opinion is that it is unclear to see how exactly ARIADNE tools and methodologies can *add value* to a relatively *comfortable traditional situation*, where a small group of students meet almost weekly for 2 hours to discuss the course content, meet every two or three weeks for a 2.5 hours guided practical session and submit the results of their individual work two or three times a year, on which they receive relatively detailed feedback. Of course, this situation is becoming more and more the *exception* and therefor in more general terms the usefulness of the ARIADNE approach seems much more obvious. Remains the question whether developments like ARIADNE do not actually encourage administrations and political responsibles to continue to make the teaching situation more problematic ...

Regarding the evaluation by the students, it should be noted that:

- These were 2nd year students in informatics. One could therefor expect that these students would be somewhat positively prejudiced with respect to the use of telematics for education. This is illustrated by the graph below that lists reactions to the statement "There have been times in using this software when I have felt quite tense".



- The students were explicitly instructed to evaluate the ARIADNE Learner Interface, not the actual content (i.e. the pedagogical documents) provided to them through this interface. It is not clear whether they really were able to make this difference.
- The students were typically working in a LAN environment, with relatively high bandwidth connections on a local ethernet network, as illustrated by the graph below with the answers to the statement "The speed of this software is fast enough".



All in all, it seems that the students were more positive about the usability of the ARIADNE Learner Interface than we had anticipated. It is of course possible that they wanted to 'please' the professor that took their examinations...

Conclusion

In the current academic year, we are reusing much of the content for a new run of this course. This is of course absolutely in line with the 'share and reuse' philosophy that drives the ARIADNE project. We will focus our developments this year on the elaboration of new and the reuse of existing (ARIADNE and non-ARIADNE alike) active components that can really add value to the more conventional course delivery: these components will include simulations, visualizations, self-tests, etc.

More generally, our team is also using the ARIADNE toolset for new courses on computer science topics (first-year programming, Java language, hardware, productivity tools, etc.). Beyond that, the same infrastructure is being adopted by a most active user community that already includes about 40 universities, a number of industrial companies and some consortia of such users. We constantly try to monitor, evaluate and analyze the actual use of the ARIADNE tools in these very diverse circumstances.

Introduction

At Europe's premier distance learning institution, the Open University (OU), we have made computer conferencing central to our flagship computing course, M206 "Computing: An Object-oriented Approach" which began with over 5,000 students in Western Europe in 1998 and which this year is also being studied by 600 students at the Singapore Institute of Management. The course will also become available in North America by the end of the year. The course is primarily concerned with introducing software development and does not recognize the distinction between "computer science" and "software engineering" (see Woodman et al. 1999). It was designed to address the needs of industry and has been given a prestigious IT Award by the British Computer Society. Computer conferencing is central to the course and is used to encourage our students to 'talk' informally about their new discipline, as portrayed in our teaching materials, and also formally to participate in group working projects for which they are graded. At present we are using the FirstClass™ conferencing system[1] for all conference based work – both for the informal talk and the formal group working. FirstClass was chosen because the university has a great deal of experience of it and could commit to supporting our extremely high usage.

The Case for Group Working

People skills are hugely important to the software industry. In contrast to the early decades of software development, its cost and efficiency are now dominated by people issues. Software developers (programmers, designers, analysts) exhibit the normal human characteristics of fallibility and miscommunication. Analysts fail to understand customer requirements or fail to communicate constraints to designers; designers misinterpret specifications or fail to understand technological issues; programmers ignore architectures or skip unit testing. Developing communication skills in students is vital if they are to be useful and, indeed, fulfilled practitioners. Of course, because the language of their discourse is a complex technical one, and an inconsistent one at that, the acquisition and use of vocabulary is itself non-trivial. Another of the problems that neophyte programmers face is that at any stage of their learning their knowledge is incomplete and their skills deficient. From time to time many of them believe that their lack of competence is a permanent state and they fail to realize that what distinguishes professional practitioners is that they have sufficient knowledge and skills to be able to deal with such problems. As well as helping students formulate and organize their knowledge, conferencing encourages students to be reflective, a necessary attribute for collaborative working. The benefits of collaborative working are well established and the practice of it in software development is more or less universal. We summarize the benefits to students of the group working part of their study thus:

- it allows the sharing of information and experience, which allows software development problems to be resolved;
- students can learn from one another;
- group members give support to one another;
- group members often provide motivation to sustain interest and involvement.

[1] FirstClass is a proprietary conferencing system from SoftArc Inc. See http://www.softarc.com

Organization, Problems and Solutions

Students on M206 are assessed by seven assignments that must be submitted by published deadlines coupled with a final exam. The group working element of M206 is composed of four conference-based projects which are associated with questions on three of these assignments. These projects are concerned with concepts students have studied several weeks earlier (the elapsed time for the course is 33 weeks as it represents one sixth of a degree). Hence students should not be overly taxed by the technical content of a project, although in some projects the content is intended to reinforce and extend ideas previously met. Grades for group working are awarded primarily for participation in collective work but there is no dependence on the abilities of other group members for an individual student's grades. That is, there are no collective marks divided among group members, only individual marks. These principles are the core of this part of our pedagogy.
