## Preface

This text covers the fundamentals of thermodynamics required to understand electrical power generation systems. It then covers the application of these principles to nuclear reactor power systems. It is not a general thermodynamics text, but is a thermodynamics text aimed at explaining the fundamentals and applying them to the challenges facing actual nuclear power systems. It is written at an undergraduate level, but should also be useful to practicing engineers.

It starts with the fundamental definitions of thermodynamic variables such as temperature, pressure and specific volume. It defines the Zeroth Law of Thermodynamics. It then explains open and closed systems. The Ideal Gas law is introduced along with some of its limitations for real gases. Gas kinetic theory is then introduced to provide a background for the Ideal Gas Law and a foundation for understanding for the theory of specific heats. Then it moves on to the First Law of Thermodynamics and its realization in the internal energy and enthalpy potentials. After addressing several applications, it moves on to the Second Law of Thermodynamics and the concept of entropy. It then approaches entropy from the statistical mechanics viewpoint to validate that it truly is a measurable physical quantity. It concludes the fundamental theory portion of the book by discussing irreversibility, availability, and the Maxwell relations, touching slightly on the Third Law of Thermodynamics.

The second portion of the book is devoted to specific applications of the fundamentals to Brayton and Rankine cycles for power generation. Brayton cycle compressors, turbines, and recuperators are covered, along with the fundamentals of heat exchanger design. Rankine steam generators, turbines, condensers, and pumps are discussed. Reheaters and feed water heaters are also covered. Ultimate heat rejections by circulating water systems are also discussed.

The third part of the book covers current and projected reactor systems and how the thermodynamic principles are applied to their design, operation and safety analyses.

Detailed appendices cover metric and English system units and conversions, detailed steam and gas tables, heat transfer properties, and nuclear reactor system descriptions.

## Acknowledgments

The authors would like to acknowledge all the individuals for their help, encouragement, and support. We have decided not to name them all since some of them may not be around to see the end result of their encouragement, but we hope they can at least read this acknowledgment wherever they may be.

Last but not least, special thanks to our parents, wives, children and friends for providing constant encouragement, without which this book could not have been written. We especially appreciate their patience with our frequent absence from home and long hours in front of the computer during the preparation of this book.

## Contents

1 Definitions and Basic Principles ..... 1
1.1 Typical Pressurized Water Reactor ..... 1
1.2 Scope of Thermodynamics ..... 3
1.3 Units ..... 5
1.3.1 Fundamental Units ..... 5
1.3.2 Thermal Energy Units ..... 6
1.3.3 Unit Conversion ..... 7
1.4 Classical Thermodynamics ..... 7
1.5 Open and Closed Systems ..... 8
1.6 System Properties ..... 10
1.6.1 Density ..... 11
1.6.2 Pressure ..... 11
1.6.3 Temperature ..... 13
1.7 Properties of the Atmosphere ..... 15
1.8 The Laws of Thermodynamics ..... 16
References ..... 16
2 Properties of Pure Substances ..... 17
2.1 Introduction ..... 17
2.2 Properties of Pure Substances-Phase Changes ..... 19
2.2.1 Phases of Pure Substances ..... 21
2.2.2 Equations of State ..... 21
2.3 Ideal Gas ..... 22
2.4 Real Gases and Vapors ..... 24
2.4.1 Simple Real Gas Equations of State ..... 24
2.4.2 Determining the Adjustable Parameters ..... 25
2.4.3 Other Useful Two Parameter Equations of State ..... 28
2.4.3.1 Redlich-Kwong Equation of State ..... 28
2.4.3.2 Peng-Robinson Equation of State ..... 29
2.4.4 Common Equations of State with Additional Parameters ..... 30
2.4.4.1 Beattie-Bridgeman Equation of State ..... 30
2.4.4.2 Benedict-Webb-Rubin Equation of State ..... 31
2.4.4.3 Virial Equation of State ..... 31
2.4.4.4 Equation of State Comparison ..... 33
2.4.5 The Liquid-Vapor Region ..... 37
2.5 $T-V$ Diagram for a Simple Compressible Substance ..... 39
2.6 $P-V$ Diagram for a Simple Compressible Substance ..... 40
2.7 $P-V-T$ Diagram for a Simple Compressible Substance ..... 40
References ..... 44
3 Mixture ..... 45
3.1 Ideal Gas Mixtures ..... 45
3.1.1 Avogadro's Number ..... 45
3.1.2 Mass Fractions ..... 46
3.1.3 Mole Fractions ..... 46
3.1.4 Dalton's Law and Partial Pressures ..... 47
3.1.5 Amagat's Law and Partial Volumes ..... 48
3.2 Real Gas Mixtures ..... 49
3.2.1 Pseudo Critical States for Mixtures-Kay's Rule ..... 49
3.2.2 Real Gas Equations of State ..... 49
3.3 Liquid Mixtures ..... 50
3.3.1 Conservation of Volumes ..... 50
3.3.2 Non-Conservation of Volumes and Molecular Packing ..... 50
References ..... 51
4 Work and Heat ..... 53
4.1 Introduction of the Work and Heat ..... 53
4.2 Definition of Work ..... 53
4.3 Quasi-Static Processes ..... 56
4.4 Quasi-Equilibrium Work Due to Moving Boundary ..... 57
4.5 Definition of a Cycle in Thermodynamic ..... 61
4.6 Path Functions and Point or State Functions ..... 63
4.7 PdV Work for Quasi-Static Process ..... 65
4.8 Non-equilibrium Work ..... 67
4.9 Other Work Modes ..... 68
4.10 Reversible and Irreversible Process ..... 77
4.11 Definition of Energy (Thermal Energy or Internal Energy) ..... 79
4.12 Definition of Heat ..... 80
4.13 Comparison of Work and Heat ..... 81
References ..... 84
5 First Law of Thermodynamics ..... 85
5.1 Introduction ..... 85
5.2 System and Surroundings ..... 88
5.2.1 Internal Energy ..... 88
5.2.2 Heat Engines ..... 89
5.3 Signs for Heat and Work in Thermodynamics ..... 90
5.4 Work Done During Volume Changes ..... 90
5.5 Paths Between Thermodynamic States ..... 93
5.6 Path Independence ..... 96
5.7 Heat and Work ..... 98
5.8 Heat as Energy in Transition ..... 99
5.9 The First Law of Thermodynamics Applied to a Cycle ..... 100
5.10 Sign Convention ..... 101
5.11 Heat is a Path Function ..... 101
5.12 Energy is a Property of System ..... 103
5.13 Energy of an Isolated System is Conserved ..... 104
5.14 Internal Energy and the First Law of Thermodynamics ..... 106
5.15 Internal Energy of an Ideal Gas ..... 111
5.16 Introduction to Enthalpy ..... 112
5.17 Latent Heat ..... 114
5.18 Specific Heats ..... 115
5.19 Heat Capacities of an Ideal Gas ..... 122
5.20 Adiabatic Processes for an Ideal Gas ..... 124
5.21 Summary ..... 129
References ..... 130
6 The Kinetic Theory of Gases ..... 131
6.1 Kinetic Theory Basis for the Ideal Gas Law ..... 131
6.2 Collisions with a Moving Wall ..... 135
6.3 Real Gas Effects and Equations of State ..... 136
6.4 Principle of Corresponding States ..... 137
6.5 Kinetic Theory of Specific Heats ..... 138
6.6 Specific Heats for Solids ..... 141
6.7 Mean Free Path of Molecules in a Gas ..... 142
6.8 Distribution of Mean Free Paths ..... 144
6.9 Coefficient of Viscosity ..... 146
6.10 Thermal Conductivity ..... 150
Reference ..... 151
7 Second Law of Thermodynamics ..... 153
7.1 Introduction ..... 153
7.2 Heat Engines, Heat Pumps, and Refrigerators ..... 153
7.3 Statements of the Second Law of Thermodynamics ..... 155
7.4 Reversibility ..... 156
7.5 The Carnot Engine ..... 156
7.6 The Concept of Entropy ..... 159
7.7 The Concept of Entropy ..... 161
7.8 Entropy for an Ideal Gas with Variable Specific Heats ..... 163
7.9 Entropy for Steam, Liquids and Solids ..... 165
7.10 The Inequality of Clausius ..... 166
7.11 Entropy Change for an Irreversible Process ..... 168
7.12 The Second Law Applied to a Control Volume ..... 169
8 Reversible Work, Irreversibility, and Exergy (Availability) ..... 173
8.1 Reversible Work, and Irreversibility ..... 173
8.2 Exergy ..... 176
9 Gas Kinetic Theory of Entropy ..... 181
9.1 Some Elementary Microstate and Macrostate Models ..... 182
9.2 Stirling's Approximation for Large Values of N ..... 187
9.3 The Boltzmann Distribution Law ..... 188
9.4 Estimating the Width of the Most Probable Macrostate Distribution ..... 192
9.5 Estimating the Variation of W with the Total Energy ..... 194
9.6 Analyzing an Approach to Thermal Equilibrium ..... 196
9.7 The Physical Meaning of $\beta$ ..... 197
9.8 The Concept of Entropy ..... 198
9.9 Partition Functions ..... 199
9.10 Indistinguishable Objects ..... 200
9.11 Evaluation of Partition Functions ..... 207
9.12 Maxwell-Boltzmann Velocity Distribution ..... 211
References ..... 212
10 Thermodynamic Relations ..... 213
10.1 Thermodynamic Potentials ..... 213
10.2 Maxwell Relations ..... 216
10.3 Clapeyron Equation ..... 220
10.4 Specific Heat Relations Using the Maxwell Relations ..... 221
10.5 The Difference Between the Specific Heats for a Real Gas ..... 223
10.6 Joule-Thomson Coefficient ..... 224
References ..... 225
11 Combustion ..... 227
11.1 Introduction ..... 227
11.2 Chemical Combustion ..... 229
11.3 Combustion Equations ..... 230
11.4 Mass and Mole Fractions ..... 233
11.5 Enthalpy of Formation ..... 235
11.6 Enthalpy of Combustion ..... 239
11.7 Adiabatic Flame Temperature ..... 239
References ..... 242

## About the Authors

Dr. Bahman Zohuri is currently at the Galaxy Advanced Engineering, Inc. a consulting company that he stared himself in 1991 when he left both semiconductor and defense industries after many years working as a chief scientist. After graduating from University of Illinois in field of Physics and Applied Mathematics, he joined Westinghouse Electric Corporation where he performed thermal hydraulic analysis and natural circulation for Inherent Shutdown Heat Removal System (ISHRS) in the core of a Liquid Metal Fast Breeder Reactor (LMFBR) as a secondary fully inherent shut system for secondary loop heat exchange. All these designs were used for Nuclear Safety and Reliability Engineering for Self-Actuated Shutdown System. He designed the Mercury Heat Pipe and Electromagnetic Pumps for Large Pool Concepts of LMFBR for heat rejection purpose for this reactor around 1978 where he received a patent for it. He later on was transferred to defense division of Westinghouse where he was responsible for the dynamic analysis and method of launch and handling of MX missile out of canister. The results are applied to MX launch seal performance and muzzle blast phenomena analysis (i.e. missile vibration and hydrodynamic shock formation). He also was involved in analytical calculation and computation in the study of Nonlinear Ion Wave in Rarefying Plasma. The results are applied to the propagation of "Soliton Wave" and the resulting charge collector traces, in the rarefactions characteristic of the corona of the a laser irradiated target pellet. As part of his graduate research work at Argonne National Laboratory, he performed computation and programming of multi-exchange integral in surface physics and solid state physics. He holds different patent in areas such as diffusion processes and design of diffusion furnace while he was senior process engineer working for different semiconductor industries such as Intel, Varian, and National Semiconductor corporations. Later on, he joined Lockheed Missile and Aerospace Corporation as Senior Chief Scientist. At this position, he was responsible for Senior in R\&D and the study of vulnerability, survivability and both radiation and laser hardening of different components of payload (i.e. IR Sensor) for Defense Support Program (DSP), Boost Surveillance and Tracking Satellite (BSTS) and Space Surveillance and Tracking Satellite (SSTS) against laser or nuclear threat. While in there, he also studied and performed the analysis of characteristics of laser beam and nuclear radiation interaction with materials, Transient Radiation Effects in
xxi

Electronics (TREE), Electromagnetic Pulse (EMP), System Generated Electromagnetic Pulse (SGEMP), Single-Event Upset (SEU), Blast and, Thermo-mechanical, hardness assurance, maintenance, device technology.

He did few years of consulting under his company Galaxy Advanced Engineering with Sandia National Laboratories (SNL), where he was supporting development of operational hazard assessments for the Air Force Safety Center (AFSC) in connection with other interest parties. Intended use of the results was their eventual inclusion in Air Force Instructions (AFIs) specifically issued for Directed Energy Weapons (DEW) operational safety. He completed the first version of a comprehensive library of detailed laser tools for Airborne Laser (ABL), Advanced Tactical Laser (ATL), Tactical High Energy Laser (THEL), Mobile/Tactical High Energy Laser (M-THEL), etc.

He also was responsible on SDI computer programs involved with Battle Management C3I and artificial Intelligent, and autonomous system. He is author few publications and holds various patents such as Laser Activated Radioactive Decay and Results of Thru-Bulkhead Initiation.

Recently he has published two other books with CRC and Francis Taylor on the subject of;

1. Heat Pipe Design and Technology: A Practical Approach
2. Dimensional Analysis and Self-Similarity Methods
3. Directed Energy Weapons Technologies

Dr. Patrick McDaniel is currently adjunct and research professor at Department of Chemical and Nuclear Engineering, University of New Mexico. Patrick began his career as a pilot and maintenance officer in the USAF. After leaving the Air Force and obtaining his doctorate at Purdue University, he worked at Sandia National Laboratories in fast reactor safety, integral cross section measurements, nuclear weapons vulnerability, space nuclear power, and nuclear propulsion. He left Sandia to become the technical leader for Phillips Laboratory has (became part of Air Force Research Laboratory) Satellite Assessment Center. After 10 years at PL/AFRL, he returned to Sandia to lead and manage DARPA's Stimulated Isomer Energy Release project, a \$ 10 M per year effort. While at Sandia, he worked on the Yucca Mountain Project and DARPA's classified UER-X program. Having taught at the University of New Mexico in the Graduate Nuclear engineering program for 25 years, when he retired from Sandia in early 2009, he joined the faculty at the University of New Mexico full time. He has worked on multiple classified and unclassified projects in the application of nuclear engineering to high energy systems. Dr. McDanile hold PhD in nuclear engineering from Purde Unvivesity.

## Chapter 1 <br> Definitions and Basic Principles

Nuclear power plants currently generate better than $20 \%$ of the central station electricity produced in the United States. The United States currently has 104 operating power producing reactors, with 9 more planned. France has 58 with 1 more planned. China has 13 with 43 planned. Japan has 54 with 3 more planned. In addition, Russia has 32 with 12 more planned. Nuclear generated electricity has certainly come into its own existent and is the safest, cleanest and greenest form of electricity currently is in produced on this planet. However, many current thermodynamics texts ignore nuclear energy and use few examples of nuclear power systems. Nuclear energy presents some interesting thermodynamic challenges and it helps to introduce them at the fundamental level. Our goal here will be to introduce thermodynamics as the energy conversion science that it is and apply it to nuclear systems. Certainly, there will be many aspects of thermodynamics that are given little or no coverage. However, that is true for any textual introduction to this science; however by considering concrete systems, it is easier to give insight into the fundamental laws of the science and to provide an intuitive feeling for further study. Although brief summary of definition and basic principles of thermodynamic are touched up in this chapter for the purpose of this book, we encourage the readers to refer themselves to references [1-6] provided at the end of this chapter.

### 1.1 Typical Pressurized Water Reactor

By far the most widely built nuclear system is the Pressurized Water Reactor (PWR). There are a number of reasons for this. Steam turbines have for many decades been the dominant means of generating mechanical energy to turn electrical generators. The temperatures reached in the thermodynamic cycle of a PWR are within the range of fairly, common engineering materials. They were the first system built and operated reliably to produce electricity. A typical PWR system is described in Fig. 1.1.

Fig. 1.1 Pressurized water reactor schematic

The basic PWR consists of five major components, the reactor core, steam generator(s), steam turbine, condenser, and electrical generator and three water/ steam loops. Each loop requires a pump that is not shown to keep the diagram cleaner. The nuclear energy is converted to thermal energy in the reactor core. This thermal energy is then transported via the first loop to the steam generator where it is passed to the water in the second loop. The water in the second loop enters as a liquid and is turned to steam. The steam then passes to the turbine where the thermal energy is converted to mechanical energy to rotate the electrical generator. After the thermal energy has been converted to mechanical energy in the steam turbine, the low-pressure steam passes to the condenser to be cooled by the water in the third loop. The second law of thermodynamics tells us that we cannot simply expand the steam to a low enough energy state that it can return to the steam generator in its original liquid state. Therefore, we must extract more thermal energy from the low-pressure steam to return it to its liquid state where it can be pumped back into the steam generator. The third loop is called the circulating water system and it is open to the environment. There are multiple ways of providing this cooling water including intake and return to a river, or the ocean, intake and return to a cooling pond, or intake from a river and exhaust through a cooling tower. However, we are getting ahead of ourselves.

Consider for a minute why nuclear energy is so useful. A great deal of energy is produced by a very little mass.

Example Calculation: Calculate the U-235 consumed to produce 1 MW of thermal energy for 1 day. Note that a Megawatt is a unit of power, or energy per unit time,

$$
1 \mathrm{MW}=10^{6} \mathrm{~W}=10^{6} \text { joules } / \mathrm{s} \quad 1 \text { day }=24 \mathrm{~h}=24 * 3600 \mathrm{~s}
$$

The energy released in fission of a U-235 atom is $\sim 200 \mathrm{Mev}$
$1 \mathrm{ev}=1.6 \times 10^{-19} \mathrm{~J} \quad 1 \mathrm{Mev}=1.6 \times 10^{-13} \mathrm{~J} \quad 200 \mathrm{Mev}=32 \mathrm{pJ}$

Fissioning 1 atom of $\mathrm{U}-235$ produces $3.2 \times 10^{-11} \mathrm{~J}$
To produce $10^{6} \mathrm{~J}$ requires $106 / 3.2 \times 10^{-11}$ atoms $=3.125 \times 10^{16}$ atoms
And for a duration of $8.64 \times 10^{4} \mathrm{~s}$
The total number of atoms consumed will be $3.125 \times 8.64 \times 10^{20}$ atoms
Therefore $2.7 \times 10^{21}$ atoms will be consumed
A gram mole of $\mathrm{U}-235$ is $6.022 \times 10^{23}$ atoms
So a gram is $6.022 \times 10^{23} / 235=2.563 \times 10^{21}$ atoms $/$ gram
Therefore 1 Megawatt-Day of nuclear energy consumes 1.05 g of U-235
The fundamental thing to understand is that a PWR converts nuclear energy to electrical energy and it does this by converting the nuclear energy first to thermal energy and then converting the thermal energy to mechanical energy, which is finally converted to electrical energy. The science of thermodynamics deals with each of these conversion processes. To quantify how each of these processes takes place we must understand and apply the laws of thermodynamics.

### 1.2 Scope of Thermodynamics

Thermodynamics is the science that deals with energy production, storage, transfer and conversion. It is a very broad subject affects most fields of science including biology and microelectronics. The primary forms of energy considered in this text will be nuclear, thermal, chemical, mechanical and electrical. Each of these can be converted to a different form with widely varying efficiencies. Predominantly thermodynamics is most interested in the conversion of energy from one form to another via thermal means. However, before addressing the details of thermal energy conversion, consider a more familiar example. Newtonian mechanics defines work as force acting through a distance on an object. Performing work is a way of generating mechanical energy. Work itself is not a form of energy, but a way of transferring energy to a mass. So when one mass gains energy, another mass, or field, must lose that energy.

Consider a simple example. A $65-\mathrm{kg}$ woman decides to go over Niagara Falls in a $25-\mathrm{kg}$ wooden barrel. (The first person to go over the fall in a barrel was a woman, Annie Taylor.) Niagara Falls has a vertical drop of 50 m and has the highest flow rate of any waterfall in the world. The force acting on the woman and barrel is the force of gravity, which at the surface of the earth produces a force of 9.8 Newtons for every kilogram of matter that it acts on. So we have

$$
\begin{aligned}
& W=F \times D \quad F=(65+25) \times 9.8=882.0 \mathrm{~N} \quad D=50 \mathrm{~m} \\
& W=882.0 \times 50.0=44,100 \mathrm{~N} \mathrm{~m}=44.1 \mathrm{k} \mathrm{~J}
\end{aligned}
$$

A Newton meter is a joule and 1000 J is a kilojoule. Therefore, when the woman and barrel went over the falls, by the time they had reached the bottom, the force of gravity had performed 44.1 kilojoules (kJ) of work on them. The gravitational field had 44.1 kJ of potential energy stored in it, when the woman and the barrel were at the top of the falls. This potential energy was converted to kinetic energy by the time the barrel reached the bottom of the falls. Kinetic energy is also measured in Joules, as with all other forms of energy. However, we are usually most interested in velocities when we talk about kinetic energies, so let us extract the velocity with which she hit the waters of the inlet to Lake Ontario.

$$
\Delta K E=\Delta P E=44.1 \mathrm{~kJ}=1 / 2 m V^{2}=(90 / 2) \mathrm{kg} \times V^{2} \quad V^{2}=44.1 \mathrm{~kJ} /(90 / 2) \mathrm{kg}
$$

Now it is a matter of converting units. A Joule is a Newton-meter. 1 Newton is defined as 1 kg accelerated at the rate of $1 \mathrm{~m} /$ second $/$ second. So

$$
\begin{aligned}
44.1 \mathrm{~kJ} & =44,100 \mathrm{Nm} \\
& =44,100 \mathrm{~kg} \mathrm{~m} / \mathrm{s} / \mathrm{s} \mathrm{~m} \\
& =44,100 \mathrm{~kg}(\mathrm{~m} / \mathrm{s})^{2} \\
V^{2} & =44,100 \mathrm{~kg}(\mathrm{~m} / \mathrm{s})^{2} /(90 / 2) \mathrm{kg} \\
& =490 /(1 / 2)=980(\mathrm{~m} / \mathrm{s})^{2} \\
V & =31.3 \mathrm{~m} / \mathrm{s}(\sim 70 \mathrm{mph})
\end{aligned}
$$

Needless to say she recommended that no one ever try that again. Of course, others have, some have made it, and some have drowned.

Before leaving this example, it is worth pointing out that when we went to calculate the velocity, it was unaffected by the mass of the object that had dropped the 50 m . So one-half the velocity squared represents what we will call a specific energy, or energy per kilogram. In addition, the potential energy at the top of the falls could be expressed as a specific potential energy relative to the waters below. The potential energy per pound mass would just be the acceleration of gravity times the height of the falls. Typically, we will use lower case letters to represent specific quantities and upper case letters to represent extensive quantities. Extensive quantities are dependent upon the amount of mass present. Specific quantities are also referred to as intensive variables, though there are some intensive variables that have no extensive counterpart, such as pressure or temperature.

$$
\text { p.e. }=m g h / m=g h=9.8 \times 50=0.49 \mathrm{~kJ} / \mathrm{kg}
$$

It is also worth pointing out that Newton's law of gravity states that

$$
\begin{equation*}
F=G \frac{m_{1} M_{2}}{R^{2}} \tag{1.1}
\end{equation*}
$$

where $m_{1}$ is the smaller mass and $M_{2}$ is the mass of the Earth. We can find the specific force on an object by dividing the gravitational force by the mass of the object. For distances like 50 m on the surface of the Earth $(R=6,378,140 \mathrm{~m})$ we can treat R as constant, but if the distance the gravitational force acts through is comparable to the radius of the Earth, an integration would be required. Even on the top of Mount Everest, the gravitational potential is within $0.25 \%$ of that at Sea Level, so gravity is essentially constant for all systems operating on the face of the Earth.

### 1.3 Units

In this section, we will discuss the System International (SI) and English (E) Systems

### 1.3.1 Fundamental Units

The Before going further it will be a very good idea to discuss units for physical quantities and the conversion of units from one system to another. Unfortunately, the field of thermodynamics is beset with two popular systems of units. One is the System International (SI) system consisting of the kilogram, meter, and second. The other is the English (E) system consisting of the pound-mass, foot, and second.

Starting with the SI system, the unit of force is the Newton. The unit of work or energy is the Joule and the unit of pressure is the Pascal. We have,

$$
\begin{gathered}
1 \mathrm{~N}=1 \mathrm{~kg} \mathrm{~m} / \mathrm{s}^{2} \\
1 \mathrm{~J}=1 \mathrm{Nm} \\
1 \mathrm{~Pa}=1 \mathrm{~N} / \mathrm{m}^{2}
\end{gathered}
$$

Now the acceleration of gravity at Sea Level on Earth is $9.8066 \mathrm{~m} / \mathrm{s}^{2}$, so a 100 kg mass will weight 980.66 Newton. Also when we want avoid spelling out very large or small quantities we will usually use the standard abbreviations for powers of ten in units of 1000 . We have,

$$
\begin{aligned}
\text { kilo } & =10^{3} \\
\operatorname{meg} & =10^{6} \\
\operatorname{giga} & =10^{9}
\end{aligned}
$$

$$
\begin{aligned}
\text { deci } & =10^{-1} \\
\text { centi } & =10^{-2} \\
\text { milli } & =10^{-3} \\
\text { micro } & =10^{-6} \\
\text { nano } & =10^{-9}
\end{aligned}
$$

For the English system, we have

$$
\begin{aligned}
& \mathrm{lbm}=>1 \mathrm{lbf}(\text { at Sea Level }) \\
& 1 \mathrm{ft}-\mathrm{lbf}=1 \mathrm{lbf} \times 1 \mathrm{ft} \\
& 1 \text { British Thermal Unit }(\mathrm{BTU})=778 \mathrm{ft}-\mathrm{lbf} \\
& 1 \mathrm{psi}=1 \mathrm{lbf} / \mathrm{in}^{2}
\end{aligned}
$$

Note that the fact that $1 \mathrm{lbf}=1 \mathrm{lbm}$ at Sea Level on Earth, means that a mass of 100 lbm will weigh 100 lbf at Sea Level on Earth. The acceleration of gravity at Sea Level on Earth is $32.174 \mathrm{ft} / \mathrm{s}^{2}$. Thus we have $1 \mathrm{lbf} /\left(1 \mathrm{lbm}-\mathrm{ft} / \mathrm{s}^{2}\right)=32.174$. If we move to another planet where the acceleration of gravity is different, the statement that $1 \mathrm{lbm}=>1 \mathrm{lbf}$ doesn't hold.

Consider comparative weights on Mars. The acceleration of gravity on Mars is $38.5 \%$ of the acceleration of gravity on Earth. So in the SI system we have

$$
W=0.385 * 9.8066 \mathrm{~m} / \mathrm{s}^{2} \times 100 \mathrm{~kg}=377.7 \mathrm{~N}
$$

In the English system, we have,

$$
W=0.385 * 100 \mathrm{lbm}=38.5 \mathrm{lbf}
$$

### 1.3.2 Thermal Energy Units

The British thermal unit (Btu) is defined to be the amount of heat that must be absorbed by a 1 lb -mass to raise its temperature $1^{\circ} \mathrm{F}$. The calorie is the SI unit that is defined in a similar way. It is the amount of heat that must be absorbed by 1 g of water to raise its temperature $1^{\circ} \mathrm{C}$. This raises the question as to how a calorie compares with a joule since both appear to be measures of energy in the SI system. James Prescott Joule spent a major part of his life proving that thermal energy was simply another form of energy like mechanical kinetic or potential energy. Eventually his hypothesis was accepted and the conversion factor between the calorie and joule has been defined by,

1 calorie $=4.1868 \mathrm{~J}$
The constant 4.1868 is called the mechanical equivalent of heat.

### 1.3.3 Unit Conversion

As long as one remains in either the SI system or the English system, calculations and designs are simple. However, that is no longer possible as different organizations and different individuals usually think and work in their favorite system. In order to communicate with an audience that uses both SI and English systems it is important to be able to convert back and forth between the two systems. The basic conversion factors are,

$$
\begin{aligned}
1 \mathrm{~kg} & =2.20462 \mathrm{lbm} \\
1 \mathrm{lbm} & =0.45359 \mathrm{~kg} \\
1 \mathrm{~m} & =3.2808 \mathrm{ft} \\
1 \mathrm{ft} & =0.3048 \mathrm{~m} \\
1 \mathrm{~J} & =0.00094805 \mathrm{Btu} \\
1 \mathrm{Btu} & =1055 \mathrm{~J} \\
1 \mathrm{~atm} & =14.696 \mathrm{psi} \\
1 \mathrm{~atm} & =101325 \mathrm{~Pa} \\
1 \mathrm{psi} & =6894.7 \mathrm{~Pa} \\
1 \mathrm{bar} & =100000.0 \mathrm{~Pa} \\
1 \mathrm{bar} & =14.504 \mathrm{psi}
\end{aligned}
$$

The bar unit is simply defined by rounding off Sea Level atmospheric pressure to the nearest 100 kPa . There are many more conversion factors defined in the Appendix, but they are all derived from this basic few.

### 1.4 Classical Thermodynamics

Classical thermodynamics was developed long before the atomic theory of matter was accepted. Therefore, it treats all materials as continuous and all derivatives well defined by a limiting process. Steam power and an ability to analyze it and optimize it was one of the main drivers for the development of thermodynamic theory. The fluids involved always looked continuous. A typical example would be the definition of the density of a substance at a point. We have,

$$
\begin{equation*}
\rho=\lim _{\Delta V \rightarrow 0} \frac{\Delta m}{\Delta V} \tag{1.2}
\end{equation*}
$$

As long as $\Delta V$ does not get down to the size of an atom, this works. Since classical thermodynamics was developed, however, we have come to understand that all
gases and liquids are composed of very small atoms or molecules and a limiting process that gets down to the atomic or molecular level will eventually become discontinuous and chaotic. Nevertheless, the continuous model still works well for the macroscopic systems that will be discussed in this text and Classical Thermodynamics is based on it.

At times, we will refer to an atomistic description of materials in order to develop a method of predicting specific thermodynamic variables that classical thermodynamics cannot predict. A typical example is the derivative that is called the constant volume specific heat. This variable is defined as the rate of change of the internal energy stored in a substance as a function of changes in its temperature. Classical thermodynamics demonstrates that this variable has to exist and makes great use of it, but it has no theory for calculating it from first principles. An atomistic view will allow us to make some theoretical estimates of its value. Therefore, at times we will deviate from the classical model and adopt an atomistic view that will improve our understanding of the subject.

Classical thermodynamics is also an equilibrium science. The laws of thermodynamics apply to objects or systems in equilibrium with themselves and their surroundings. By definition, a system in equilibrium is not likely to change. However, we are generally interested in how systems change as thermal energy is converted to and from other forms of energy. This presents a bit of a dilemma in that the fundamental laws are only good for a system in equilibrium and the parameters we want to predict are a result of thermal energy changes in the system. To get around this dilemma, we define what is called a quasi-equilibrium process. A quasi-equilibrium process is one that moves from one system state to another so slowly and so incrementally, that it looks like a series of equilibrium states. This is a concept that classical thermodynamics had a great deal of difficulty clarifying and quantifying. Basically, a process was a quasi-equilibrium process if the laws of equilibrium thermodynamics could characterize it. This is sort of a circular definition, but once again, we will find that the atomistic view allows us to make some predictions and quantifications that identify a quasi-equilibrium process. Quasi-equilibrium processes can occur very rapidly on time scales typical of human observation. For example, the expansion of the hot gases out the nozzle of a rocket engine can be well described as a quasi-equilibrium process with classical thermodynamics.

### 1.5 Open and Closed Systems

In the transfer and conversion of thermal energy, we will be interested in separating the entire universe into a system and its environment. We will mainly be interested in the energy transfers and conversions that go on within the system, but in many cases, we will need to consider its interactions with the rest of the world or its environment. Systems that consist of a fixed amount of mass that is contained within fixed boundaries are called closed systems. Systems that pass the mass back and forth to the environment will be called open systems. Both open and closed systems

Fig. 1.2 A closed system
allow energy to flow across their borders, but the flow of mass determines whether they are open or closed systems. Open systems will also carry energy across their borders with the mass as it moves. Consider the simple compressed gas in the piston below as a closed system (Fig. 1.2).

In analyzing the closed system, we will be concerned about the changes in the internal energy of the compressed gas as it interacts with its environment and the transfers of mechanical and thermal energies across its boundary.

In analyzing open systems, the concept of a control volume comes into play. The control volume is the boundary for the open system where the energy changes that we are interested in takes place. The thing separates the open system from its environment. Consider the following open system where we have now allowed mass to flow in and out of the piston of our closed system above (Fig. 1.3).

Fig. 1.3 An open system

The control volume looks a lot like our system boundary from before, and it is. The only difference is that we now allow mass to flow in and out of our control volume. Thermal and mechanical energy can still flow across the boundary, or in and out of the control volume. The mass flowing in and out can also carry energy with it either way.

### 1.6 System Properties

In order to characterize a system we will have to identify its properties. Initially there are three main properties that we will be concerned with-density, pressure and temperature all of which are intensive variables. We will use intensive properties to characterize the equilibrium states of a system. Systems will be composed of pure substances and mixtures of pure substances. A pure substance is a material that consists of only one type of atom, or one type of molecule. A pure substance can exist in multiple phases. Normally the phases of concern will be gas, liquid, and solid, though for many pure substances there can be several solid phases. Water is an example of a pure substance that can readily be observed in any of its three phases.

A solid phase is typically characterized as having a fixed volume and fixed shape. A solid is rigid and incompressible. A liquid has a fixed volume but no fixed shape. It deforms to fit the shape of the container that is in it. It is not rigid but is still relatively incompressible. A gas has no fixed shape and no fixed volume. It expands to fit the container that is in it. To characterize a system composed of one or more pure components and one or more phases we will need to specify the correct number of intensive variables required to define a state. Gibbs Phase Rule named after J. Willard Gibbs who first derived it gives the correct number of intensive variables required to completely define an equilibrium state in a mixture of pure substances. It is

$$
\begin{equation*}
\mathrm{V}=\mathrm{C}-\mathrm{P}+2 \tag{1.3}
\end{equation*}
$$

$\mathrm{V}=$ Number of variables required to define an equilibrium state.
$\mathrm{C}=$ The number of pure components (substances) present.
$\mathrm{P}=$ The number of phases present.
So for pure steam at Sea Level and above $100^{\circ} \mathrm{C}$, we have one component and one phase so the number of variables required to specify an equilibrium state is 2 , typically temperature and pressure. However, temperature and density would also work. If we have a mixture of steam and liquid water in the system, we have one component and two phases, so only one variable is required to specify the state, either pressure or temperature would work. If we have a mixture like air that is composed of oxygen, nitrogen, and argon, we have three components and three phases (the gas phase for each component), we are back to requiring two variables. As we progress, we will introduce additional intensive variables that can be used to characterize the equilibrium states of a system in addition to density, pressure, and temperature.

### 1.6.1 Density

Density is defined as the mass per unit volume. The standard SI unit is kilograms per cubic meter $\left(\mathrm{kg} / \mathrm{m}^{3}\right)$. The Standard English unit is pounds mass per cubic foot $\left(\mathrm{lbm} / \mathrm{ft}^{3}\right)$. If the mass per unit volume is not constant in a system, it can be defined at a point by a suitable limiting process that converges for engineering purposes long before we get to the atomistic level. The inverse of density is specific volume. Specific volume is an intensive variable, whereas volume is an extensive variable. The standard unit for specific volume in the SI system is cubic meters per kilogram $\left(\mathrm{m}^{3} / \mathrm{kg}\right)$. The standard unit in the English system is cubic feet per pound mass (ft ${ }^{3} / \mathrm{lbm}$ ).

### 1.6.2 Pressure

Pressure is defined as force per unit area. The standard unit for pressure in the SI system is the Newton per square meter or Pascal $(\mathrm{Pa})$. This unit is fairly small for most engineering problems so pressures are more commonly expressed in kilo-Pascals ( kPa ) or mega-Pascals ( MPa ). The standard unit in the English system really does not exist. The most common unit is pounds force per square inch (psi). However, many other units exist and the appropriate conversion factors are provided in the Appendix.

Pressure as an intensive variable is constant in a closed system. It really is only relevant in liquid or gaseous systems. The force per unit area acts equally in all directions and on all surfaces for these phases. It acts normal to all surfaces that contain or exclude the fluid. (The term fluid includes both gases and liquids). The same pressure is transmitted throughout the entire volume of liquid or gas at equilibrium (Pascal's law). This allows the amplification of force by a hydraulic piston. Consider the system in the following Figure. In the Fig. 1.4, the force on the piston at B is greater than the force on the piston at A because the pressure on both is the same and the area of piston $B$ is much larger.

Fig. 1.4 A hydraulic amplifier

Fig. 1.5 Pressure in a liquid column

In a gravity field, the pressure in a gas or liquid increases with the height of a column of the fluid. For instance, in a tube containing a liquid held vertically, the weight of all of the liquid above a point in the tube is pressing down on the liquid at that point. Consider Fig. 1.5, then:

$$
\begin{align*}
d p & =\rho g d h \\
p(0) & =P(H)+\int_{0}^{H} \rho g d h \tag{1.4}
\end{align*}
$$

Thus, the pressure at the bottom of the container is equal to the pressure on the top of the fluid in the container plus the integral of the weight of the fluid per unit area in the container.

This raises an interesting concept. Often it will be important to distinguish between absolute pressure and gage pressure. The preceding equation calculates the absolute pressure. The gage pressure is simply the pressure exerted by the weight of the column without the external pressure on the top surface of the liquid. It is certainly possible to have a negative gage pressure, but not possible to have a negative absolute pressure. A vacuum pressure occurs when the absolute pressure in a system is less than the pressure in the environment surrounding the system.

Using the setup in Fig. 1.6, a very common way of measuring pressure is an instrument called a manometer. A manometer works by measuring the difference in height of a fluid in contact with two different pressures. A manometer can measure absolute pressure by filling a closed end tube with the liquid and then inverting it into a reservoir of liquid that is open to the pressure that is to be measured. Manometers can also measure a vacuum gage pressure. Consider Fig. 1.6 as below:

The tall tubes on the right in each system are open to the atmosphere. System A is operating at a small negative pressure, or vacuum, relative to the atmosphere. System $B$ is operating at a positive pressure relative to the atmosphere. The magnitude

Fig. 1.6 Pressure measurement with manometers
of the pressure in each case can be calculated by measuring the height difference between the fluids in the two sides of the U-tube and calculating its weight per unit area. This is the difference in the pressures inside the Systems A or B and the atmospheric pressure pushing down on the open columns on the right.

### 1.6.3 Temperature

The other intensive variable to be considered at this point is the temperature. Most everyone is familiar with temperature as a measure of coldness or hotness of a substance. As we continue our study of thermodynamics, we will greatly refine our concept of temperature but for now it is useful to discuss how a temperature scale is constructed. Traditionally the Fahrenheit scale was established by defining the freezing point of water at Sea Level pressure to be $32^{\circ} \mathrm{F}$ and the boiling point of water to be $212^{\circ} \mathrm{F}$ under the same conditions. A thermometer containing a fluid that expands readily as a function of temperature could be placed in contact with a system that contained ice and water vapor saturated air. The height of the fluid in the thermometer would be recorded as the $32^{\circ} \mathrm{F}$ height. Then the same thermometer would be placed in a water container that was boiling and the height of the fluid in the thermometer marked as the $212^{\circ} \mathrm{F}$ point. The difference in height between the two points would then be marked off in 180 divisions with each division representing $1^{\circ} \mathrm{F}$. The Celsius scale was defined in the same way by setting the freezing point of water at $0^{\circ} \mathrm{C}$ and the boiling point at $100^{\circ} \mathrm{C}$. Water was chosen as the reference material because it was always available in most laboratories around the world.

When it became apparent that absolute temperatures were possibly more important than simply temperatures in the normal range of human experience, absolute temperature scales were defined. The freezing point of water was defined as 273.15 K and the boiling point was defined as 373.15 K , to match up with the Celsius scale. Note that the unit on the absolute scale is Kelvins, not degrees Kelvin. It was named in honor of Lord Kelvin who had a great deal to do with the development of temperature measurement and thermodynamics. The freezing point of water was further defined as the equilibrium of pure ice and air saturated water. However, it was difficult to attain this point because as ice melts it forms a layer of pure water around itself, which prevents direct contact of pure ice, and air-saturated water. Therefore, in 1954, the two-point method was abandoned and the triple point
of water was chosen as a single standard. The triple point of water is 273.16 K , 0.01 K above the ice point for water at Sea Level pressure. A single point can be used to define the temperature scale if temperatures are measured with a constant volume, ideal gas thermometer. Basically, the ideal gas thermometer can measure the pressure exerted by a constant volume of gas in contact with the system to be measured. It can also measure the pressure exerted by the gas when in contact with a system at the triple point of water. The ratio of the two pressures gives the ratio of the measured absolute temperature to the absolute temperature of the triple point of water.

However, additional secondary standards are defined to simplify calibration over a broad range of temperatures. The International Practical Temperature Scale is defined by

| Triple point of equilibrium hydrogen | 13.81 K |
| :--- | :--- |
| Boiling point of hydrogen at 33.33 kPa | 17.042 K |
| Boiling point of hydrogen at 1 atm | 20.28 K |
| Boiling point of neon | 27.102 K |
| Triple point of oxygen | 54.361 K |
| Boiling point of oxygen | 90.188 K |
| Triple point of water | 273.16 K |
| Boiling point of water | 373.15 K |
| Freezing point of zinc | 692.73 K |
| Freezing point of silver | 1235.08 K |
| Freezing point of gold | 1337.58 K |

Once the absolute temperature scale in Kelvins was defined it became part of the SI system. An absolute scale matching the Fahrenheit scale between the freezing point of water and its boiling point has been defined for the English system. Since there are $180^{\circ}$ between the freezing and boiling points in the Fahrenheit scale and $100^{\circ}$ over the same range in the Kelvin scale, the absolute scale for the English system, where the unit of measurement is called a degree Rankine, is simply 1.8 times the number of Kelvins. So the freezing point of water on the Rankine scale is $491.67^{\circ} \mathrm{R}$ and the boiling point is $671.67^{\circ} \mathrm{R}$. Absolute zero on the Rankine scale is $-459.67^{\circ} \mathrm{F}$. To convert back and forth the following formulas apply.

$$
\begin{align*}
& T_{K}=T_{C}+273 \\
& T_{C}=T_{K}-273  \tag{1.5}\\
& T_{R}=T_{F}+460 \\
& T_{F}=T_{R}-460 \\
& T_{R}=1.8 T_{K} \\
& T_{K}=\frac{5}{9} T_{R} \\
& T_{F}=1.8 T_{C}+32 \tag{1.6}
\end{align*}
$$

### 1.7 Properties of the Atmosphere

Before going further, it will be useful to have a model for the atmosphere that can be used for calculations. This is important to realize that the atmosphere at Sea Level supports a column of air that extends upwards of 50 miles. Given the equation derived earlier for the pressure in a column of fluid, we have as always to begin at Sea Level.

$$
\begin{align*}
d p & =-\rho g d h \\
\text { Let } \rho & =p / R T \tag{1.7a}
\end{align*}
$$

Then

$$
d p=-p \frac{g}{R T} d h
$$

Or integration the last term of Eq. 1.7a, we obtain

$$
\begin{equation*}
p=p_{S L} e^{-\frac{g}{R T} h} \tag{1.7b}
\end{equation*}
$$

To perform the integration, the above temperature has been assumed constant. This is not quite true as the standard lapse rate for the Troposphere up to about $40,000 \mathrm{ft}$ is approximately $2{ }^{\circ} \mathrm{C} / 1000 \mathrm{ft}$ or $3.6^{\circ} \mathrm{F} / 1000 \mathrm{ft}$. This means that the air is denser than the exponential model predicts. However, it is approximately correct for the Troposphere particularly if only a limited range of elevations is considered and the average temperature is used. The initial values at Sea Level for the standard atmosphere are,

| Pressure: | 14.696 psi | 101.325 kPa |
| :--- | :--- | :--- |
| Temperature | $59^{\circ} \mathrm{F}\left(519^{\circ} \mathrm{R}\right)$ | $15^{\circ} \mathrm{C}(288 \mathrm{~K})$ |
| Density | $076474 \mathrm{lbm} / \mathrm{ft}^{3}$ | $1.225 \mathrm{~kg} / \mathrm{m}^{3}$ |

| Composition | Mole fraction (\%) |
| :--- | :--- |
| Nitrogen | 78.08 |
| Oxygen | 20.95 |
| Argon | 0.93 |
| Carbon dioxide | 0.03 |
| $\mathrm{Ne}, \mathrm{He}, \mathrm{CH}^{4}$ et al. | 0.01 |

A more extensive model of the atmosphere as a function of altitude is provided in the Appendix. The relative composition is essentially constant up to the top of the Troposphere.

### 1.8 The Laws of Thermodynamics

It is useful at this time to state the Laws of Thermodynamics. Later chapters will expand on them greatly, but realizing that there are four simple laws that all of the analysis is built around will provide some structure to guide the way forward.

Zeroth Law of Thermodynamics: Two bodies in thermal contact with a third body will be at the same temperature.

This provides a definition and method of defining temperatures, perhaps the most important intensive property of a system when dealing with thermal energy conversion problems.

First Law of Thermodynamics: Energy is always conserved when it is transformed from one form to another.

This is the most important law for analysis of most systems and the one that quantifies how thermal energy is transformed to other forms of energy.

Second Law of Thermodynamics: It is impossible to construct a device that operates on a cycle and whose sole effect is the transfer of heat from a cooler body to a hotter body.

Basically, this law states that it is impossible for heat to spontaneously flow from a cold body to a hot body. If heat could spontaneously flow from a cold body to a hot body, we could still conserve energy, so the First Law would hold. But every experiment that has ever been performed indicates that thermal energy always flows the other way. This law seems obvious enough but the implications are very significant, as we will see.

Third Law of Thermodynamics: It is impossible by means of any process, no matter how idealized, to reduce the temperature of a system to absolute zero in a finite number of steps.

This allows us to define a zero point for the thermal energy of a body.
To be taken under consideration and subject of this matter is beyond the scope of this book.

## Chapter 2 <br> Properties of Pure Substances

### 2.1 Introduction

A pure substance is a material with a constant chemical composition throughout its entire mass. A pure substance can exist in one or more physical phases such as a solid, liquid or vapor. Each phase will have homogeneous physical characteristics, but all three phases could be different physical forms of the same pure substance. The temperature and pressure boundaries between phases are well defined and it usually requires an input or extraction of thermal energy to change from one phase to another. Most pure substances have a well defined Triple Point where all three phases exist in equilibrium.

In general matter can be classified into two broad categories:

1. Pure-Substances.
2. Mixture.

Each of these categories can be described as.

1. Pure substance: A pure substance is defined as a substance having a constant and uniform chemical composition. Typically, it can be divided in two groups as:
2. Elements-all the same type of atom.
3. Compounds-substances made from two or more different kinds of atoms.
4. Mixture: The thermodynamic properties of a mixture of substances can be determined in the same way as for a single substance. The most common example of this is dry air, which is a mixture of oxygen, nitrogen, a small percentage of argon, and traces of other gases. The properties of air are well determined and it is often considered as a single substance. Mixtures can be categorized as two general types:
[^0]1. Homogeneous-A substance that has uniform thermodynamic properties throughout is said to be homogeneous. The characteristics of a homogeneous mixture are;
a. Mixtures, which are the same throughout with identical properties everywhere in the mixture.
b. Not easily separated.
c. This type of mixture is called a solution. A good example would be sugar dissolved in water or some type of metal alloy like the CROmiumMOLYbdenum steel used in many bike frames.
2. Heterogeneous-A heterogeneous mixture is a type of mixture in which the composition can easily be identified. Often there is two or more phases present. Each substance retains its own identifying properties (e.g., granite) and it includes.
a. Mixtures, which have different properties when sampled from different areas. An example of this would be sand mixed with water.
b. A mixture in which the individual components can be seen with the naked eye.
c. A mixture that can be easily separated.

Air is a homogeneous mixture of the gases nitrogen, oxygen, and other minor gases. Here are some other examples of homogeneous mixtures

- Salt water
- Brewed tea or coffee
- Soapy water
- A dilute solution of hydrochloric acid
- Hard alcohol
- Wine

Here are some examples of heterogeneous mixtures

- Sandy water.
- Cake mix and cookie dough.
- Salad.
- Trail mix.
- Granite.
- Sodium chloride (table salt) stirred up with iron filings.
- Sugar and salt mixed in a bowl.
- Carbonated beverage or beer (the $\mathrm{CO}_{2}$ gas is mixed with the liquid).
- Orange juice with pulp in it
- Water with ice cubes in it.
- Chicken noodle soup.

A pure substance normally requires only two independent properties to specify its state. If pressure and specific volume, for example, are fixed, then all the other properties become fixed. The equation relating pressure, volume, and temperature to each other is called an Equation of State. However, a more fundamental

## Classification of Matter

Fig. 2.1 Classification of matter. (Courtesy of NASA)
equation is required to specify all thermodynamic variables as a function of only two properties. These fundamental equations will be called Thermodynamic Potentials (Fig. 2.1).

An example of a simple equation of state which is satisfactory for most dilute gases is the Ideal Gas $\mathrm{Law}-\mathrm{pV}=\mathrm{nRT}$.

### 2.2 Properties of Pure Substances-Phase Changes

Now consider how a pure substance changes phases. the most common pure substance that is available around the world is water in its three phases-ice, liquid water and steam.

Start with a solid body like ice and add heat. At first the temperature of the body increases proportional to the amount of heat that is added. However, at some point continued addition of heat will cause the body to start to melt. Once it starts to melt the temperature stops increasing and remains constant while the solid is melting. The amount of heat that is added to complete the melting is called the Heat of Fusion and is normally expressed on per unit mass or per unit mole basis. Once the entire solid is melted the temperature increases again in proportion to the amount of heat input. Note that the increase in temperature per unit heat input for the solid and liquid are not usually equal. As the substance continues to heat up, at some point the liquid will start to vaporize. Once it starts to vaporize, the temperature remains constant until all of the liquid is vaporized. The heat input per unit mass or unit mole required to change the substance from a liquid to a vapor is called the Heat of Vaporization. Once all of the liquid is vaporized, the temperature of the substance starts to increase again propor-
tional to the heat input. This sequence of events is illustrated in Fig. 2.2 below, which is called Temperature-Specific Volume or T- $v$ Diagram.

A three dimensional view of these processes is presented in the Fig. 2.3. Note that the surface has the following regions; Solid, Liquid, Vapor, Solid-Liquid,

Fig. 2.2 The T- $v$ diagram

Fig. 2.3 The $\mathrm{P}-v-\mathrm{T}$ rendering of a substance that contract on freezing

Fig. 2.4 Illustration of phase diagram

Solid-Vapor, and Liquid-Vapor. It also has a line where all three phases can coexist called the Triple Line with an interest point that called Triple Point and depicted in Fig. 2.4 as well. At the top if the Liquid-Vapor region, a point exists called the critical point. Above the Critical Point, in either pressure or temperature, the fluid cannot be identified as either Liquid or Vapor. In the Liquid-Vapor region called the Vapor Dome, the following definition in Sect. 2.2.1 (next section) applies.

### 2.2.1 Phases of Pure Substances

A pure substance may exist in different phases, where a phase is considered to be a physically uniform form of the substance. The three principle phases are as solid, liquid and gas.

Figure 2.4 shows the typical behavior of pure substances. It is called a "phase diagram" because three lines separate all three phases from each other.

### 2.2.2 Equations of State

Consider a closed system, in a vessel so equipped that the pressure, volume, and temperature may be easily measured. If the volume is set at some arbitrary value and the temperature is maintained at a specific value, then the pressure will be fixed at a definite value. Once the $V$ and $T$ are chosen, then the value of $P$ at equilibrium
is fixed. That is, of the three thermodynamic coordinates $P, V$, and $T$, only two are independent variables. There exists an equation of equilibrium which connects the thermodynamic coordinates and which robs one of them of its independence. Such an equation, called an equation of state, is a mathematical function relating the appropriate thermodynamic coordinates of a system in equilibrium. Every thermodynamic system has its own equation of state, although in some cases the relation may be so complicated that it cannot be expressed in terms of simple mathematical functions. For a closed system, the equation of state relates the temperature to two other thermodynamic variables.

An equation of state expresses the individual peculiarities of one system as compared with another system and must, therefore, be determined either by experiment or by molecular theory. A general theory like thermodynamics, based on general laws of nature, is incapable of generating an equation of state for any substance. An equation of state is not a theoretical deduction from the theory of thermodynamics, but is an experimentally derived law of behavior for any given pure substance. It expresses the results of experiments in which the thermodynamic coordinates of a system were measured as accurately as possible, over a range of values. An equation of state is only as accurate as the experiments that led to its formulation, and holds only within the range of values measured. As soon as this range is exceeded, a different form of equation of state may be required.

Note that in any of the three homogeneous phases discussed in Sect. 2.2.1 in above, a relationship exists that gives $P=P(V, T)$. Or any of the variables can be expressed in terms of the other two. These equations are called Equations of State. In the two-phase regions, including their borders, specifying temperature alone will set the pressure and vice versa. Giving both pressure and temperature will not define the volume because we will need to know the relative proportion of the two phases present. The mass fraction of the vapor in a two-phase liquid-vapor region is called the quality.

### 2.3 Ideal Gas

Any equation that relates the pressure, temperature, and specific volume of a substance is called an equation of state. There are many equations of state, some simple and others very complex. The simplest and best-known equation of state for substances in the gas phase is the Ideal Gas equation of state. This equation predicts the $p-v-T$ behavior of a gas quite accurately for dilute or low-pressure gases. Probably the definition of a low pressure or dilute gas is that it obeys the Ideal Gas Law. It is based on the two modeling assumptions that (1) each molecule is a point mass with no volume, and (2) they only interact by billiard ball-like collision conserving energy and momentum of the colliding particles. The Ideal Gas equation of state was formulated long before the atomic hypothesis was demonstrated, but these two assumptions quickly lead to the properties of the Ideal Gas equation of state.

An Ideal Gas is one that obeys the following Equation of State.

$$
\begin{equation*}
p V=n \Re T \tag{2.1}
\end{equation*}
$$

p Absolute pressure
$V \quad$ Volume of gas
$n \quad$ Number of moles of the gas
$\mathfrak{R}$ Universal Gas Constant $=8314 \mathrm{~J} / \mathrm{kmol} / \mathrm{K}=1545 \mathrm{ft}-\mathrm{lbf} / \mathrm{lbmol} /{ }^{\circ} \mathrm{R}=1.986 \mathrm{Btu} /$ lbmol/ ${ }^{\circ}$ R
$T$ Absolute temperature in degrees Rankine or Kelvins
Note that $\mathfrak{R}$ is the Universal Gas Constant. A gas constant for a particular gas can be obtained by dividing the universal constant by the molar mass to obtain the following equation.

$$
\begin{equation*}
R=\Re / M \tag{2.2}
\end{equation*}
$$

where $M$ is molecular weight of gas. If we identify $m$ as the mass of gas in kg or $l b m$, then another form of the Ideal Gas Law can be written as:

$$
\begin{equation*}
p V=m \Re T \tag{2.3}
\end{equation*}
$$

Identifying $\rho=m / V$ as the gas density, then another form of the Ideal Gas Law is:

$$
\begin{equation*}
p=\rho \Re T \tag{2.4}
\end{equation*}
$$

Normally an Ideal Gas must be a pure substance. However, air is a mixture that obeys the Ideal Gas Equation over a broad range of values for temperature and pressure. Most gases obey the Ideal Gas Equation of State if the pressure is not too high or the temperature too low.

The Ideal Gas law gives is a simple enough equation that given any two of the thermodynamic variables, $\mathrm{p}, \mathrm{v}$, and T , the third can easily be found. Consider 2 kg moles of $\mathrm{H}_{2}$ at $1000^{\circ} \mathrm{K}$ and 0.2 MPa . Calculate the volume required to store the gas at this temperature and pressure. The required volume is,
$V=\frac{n \Re T}{p}=2.0 \mathrm{~kg}-$ moles $* 8314.47 \mathrm{~J} / \mathrm{kg}-\mathrm{mole} / \mathrm{K} * 1000^{\circ} \mathrm{K} / 200,000 \mathrm{nt} / \mathrm{m}^{2}=83.1 \mathrm{~m}^{3}$
Obviously, given temperature and density, or specific volume, the pressure could be found in a similar manner. Given pressure and density, or specific volume, the temperature is easily found from the same equation. For this reason, applying the Ideal Gas Law is usually a good first guess when trying to solve for pressure, density, or temperature.

### 2.4 Real Gases and Vapors

In this section, the behavior and properties of real gases and vapors are described and equations of state are identified.

An ideal gas is made up of particles that do not attract or repel one another. Real gases are made up of atoms or molecules that may attract one another strongly, like ammonia, water vapor, or sulfur dioxide. On the other hand, they may attract one another hardly at all, like helium.

Real gases behave like ideal gases at "ordinary" temperatures and pressures. However, if you heat them up and compress them to high pressure, then their behavior departs from ideal. If the molecules attract one another, a molecule in the center of the gas is attracted equally on all sides and its motion is not affected. For a molecule, which is very close to the wall of container, exerts lees force on the wall, due to the intermolecular attractive forces with other molecules.

### 2.4.1 Simple Real Gas Equations of State

At higher pressures or lower temperatures, the equation of state becomes more complicated. The volume taken up by the molecules of the gas must be considered and the attraction of the molecules for each other lessens the pressure they exert on their container. The first Equation of State to take these two effects into account was the Van der Waals Equation of State given by,

$$
\begin{equation*}
p=\frac{\Re T}{(v-b)}-\frac{a}{v^{2}} \tag{2.5}
\end{equation*}
$$

where $a$ and $b$ are constants appropriate to the specific gas. As far as thermodynamics is concerned, the important idea is that an equation of state exists, not whether it can be written down in a simple mathematical form. Also there exists no equation of state for the states traversed by a system that is not in mechanical and thermal equilibrium, since such states cannot be described in terms of thermodynamic coordinates referring to the system as a whole.

It is generally impossible to express the complete behavior of a substance over the whole range of measured values of $p, v$, and $T$ by means of one simple equation with two adjustable parameters (a and b). Several equations of state, such as the Ideal Gas Law and those found below can be used to characterize the gas or vapor phase. Several Equations of State that have found utility in thermodynamic analysis are listed here.
a. $p=\frac{\Re T}{(v-b)}-\frac{a}{v^{2}}$ Van der Waals equation of state
b. $p=\frac{\Re T}{v-b}-\frac{a}{T^{1 / 2} v(v+b)}$ Redlich-Kwong equation of state
c. $p=\frac{\Re T}{v-b}-\frac{\alpha a}{v^{2}+2 b v-b^{2}}$ Peng-Robinson equation of state
d. $p v=\mathfrak{R} T\left(1+B P+C P^{2}+\cdots\right)$ Virial Expansion
e. $\left(p e^{a / \Re T v}\right)(v-b)=\Re T$ Dieterici equation of state
f. $\left(p+\frac{a}{v^{2} T}\right)(v-b)=\mathfrak{R} T$ Berthelot equation of state
g. $\left(p+\frac{a}{(v+c)^{2} T}\right)(v-b)=\mathfrak{R} T$ Clausius equation of state.
h. $p v=\mathfrak{R} T\left(1+\frac{B^{\prime}}{v}+\frac{C^{\prime}}{v^{2}}+\cdots\right)$ Another type of virial expansion

### 2.4.2 Determining the Adjustable Parameters

Every equation of state must satisfy a number of conditions.

1. It must reduce to the Ideal Gas Law as the pressure approaches zero or the temperature increases without bound.
2. The critical isotherm must show a point of inflection at the critical point.
3. The isometrics on a $p-T$ diagram should approach straight lines with either decreasing density or increasing temperature. The critical isometric should be a straight line.

Since the critical point is the limiting position on a $p-v$ diagram (see Fig. 2.5 below) as the two end-points (saturated liquid and saturated vapor) on the same isotherm approach each other, it follows that the slope of the isotherm passing through the critical point (the critical isotherm) is zero, or stated mathematically as;

$$
\begin{equation*}
\left(\frac{\partial P}{\partial V}\right)_{T=T_{c}}=0 \tag{2.6a}
\end{equation*}
$$

Also, the critical point is a point of inflection on the critical isotherm, because the isotherm is concave upward at volumes less than the critical volume and concave downward at specific volumes more than the critical volume; hence

$$
\begin{equation*}
\left(\frac{\partial^{2} P}{\partial V^{2}}\right)_{T=T_{c}}=0 \tag{2.6b}
\end{equation*}
$$

Equations 2.6a and 2.6b, along with the equation of state itself, enable one to evaluate the constants in any two parameter equation of state based on the critical values $P_{C}, V_{C}$, and $T_{C}$. Consider, for example, the Van der Waals equation of state, which

## can be written:

Fig. $2.5 p-v$ diagram for pure substance showing isotherms in the region of critical point. Solid lines represent the values predicted by the Van der Waals equation of state. Points represents the experimental values

$$
\begin{equation*}
p=\frac{\Re T}{v-b}-\frac{a}{v^{2}} \tag{2.7}
\end{equation*}
$$

where $v=V / n$ is the molar volume. This equation holds fairly well in the vapor region near and above the critical point. Equations 2.6a and 2.6b for molar volume yield, respectively;

$$
\begin{equation*}
\left(\frac{\partial P}{\partial v}\right)_{T=T_{C}}=-\frac{\Re T}{(v-b)^{2}}+\frac{2 a}{v^{3}}=0 \tag{2.8a}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\frac{\partial^{2} P}{\partial v^{2}}\right)_{T=T_{C}}=\frac{2 \Re T}{(v-b)^{3}}-\frac{6 a}{v^{4}}=0 \tag{2.8b}
\end{equation*}
$$

Equations 2.8 a and 2.8 b can be rewritten as;

$$
\begin{equation*}
\frac{2 a}{v^{3}}=\frac{\Re T}{(v-b)^{2}} \tag{2.9}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{3 a}{v^{4}}=\frac{\Re T}{(v-b)^{3}} \tag{2.10}
\end{equation*}
$$

Dividing the first equation by the second to obtain the critical molar volume as;

$$
\begin{equation*}
v_{C}=3 b \tag{2.11}
\end{equation*}
$$

Substituting this value for $v$ in the first of the two equations, we obtain a relationship for the critical temperature as;

$$
\begin{equation*}
T_{C}=\frac{8 a}{27 b \mathfrak{R}} \tag{2.12}
\end{equation*}
$$

and finally, substituting these two values in the Van der Waals equation to obtain the critical pressure as

$$
\begin{equation*}
p_{C}=\frac{a}{27 b^{2}} \tag{2.13}
\end{equation*}
$$

At the critical point these equations can be written as follows;

$$
\begin{equation*}
\left(\frac{\partial P}{\partial v}\right)_{T=T_{C}}=-\frac{\Re T_{C}}{\left(v_{C}-b\right)^{2}}+\frac{2 a}{v_{C}^{3}}=0 \tag{2.14}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\frac{\partial^{2} P}{\partial v^{2}}\right)_{T=T_{C}}=\frac{2 \mathfrak{R} T_{C}}{\left(v_{C}-b\right)^{3}}-\frac{6 a}{v_{C}^{4}}=0 \tag{2.15}
\end{equation*}
$$

so that at the critical point, Van der Waals equation is given by

$$
\begin{equation*}
\left(P_{C}+\frac{a}{v_{C}^{2}}\right)\left(v_{C}-b\right)=\Re T_{C} \tag{2.16}
\end{equation*}
$$

Based on the critical point data then, we can calculate the Van der Waals constants $a$ and $b$ in terms of the critical constants. Since it is possible to experimentally measure the critical temperature and critical pressure, $a$ and $b$ can be evaluated from knowledge of $P_{C}$ and $T_{C}$ through the following relations

$$
\begin{equation*}
a=\frac{27 \Re^{2} T_{C}^{2}}{64 P_{C}} \quad \text { and } \quad b=\frac{\Re T_{C}}{8 P_{C}} \tag{2.17}
\end{equation*}
$$

Table 2.1 Calculated values of Zc

| Substance | $Z_{c}$ |
| :--- | :--- |
| Water | 0.230 |
| Ammonia | 0.242 |
| Carbon dioxide | 0.275 |
| Nitrogen | 0.287 |
| Helium | 0.291 |
| Hydrogen | 0.307 |
| Van der Waals gas | 0.375 |
| Ideal gas | 1.00 |

The values of $a$ and $b$ are provided for a number of gases in the Appendix.
It follows for the Van der Waals equation of state at the critical point,

$$
\begin{equation*}
Z_{c}=\frac{P_{C} v_{C}}{\Re T_{C}}=\frac{\frac{a}{27 b^{2}} \cdot 3 b}{\mathfrak{R} \cdot \frac{8 a}{27 b \Re}}=\frac{3}{8}=0.375 \tag{2.18}
\end{equation*}
$$

where $\boldsymbol{Z c}$ is the critical compressibility factor. If a substance behaved like an Ideal Gas at the critical point, then $Z_{c}$ would equal 1.0. If it obeys the Van der Waals equation, then this ratio should equal 0.375 , which would be a measure of the departure of the Van der Waals gas from an Ideal Gas. In Table 2.1 below, the calculated values of $\boldsymbol{Z} \boldsymbol{c}$ are listed for a number of interesting gases, and in no case is this ratio equal to 0.375 , or even close. Above the critical point, at higher pressure, the Van der Waals equation is fairly satisfactory and is useful in many cases. Other equations of state give better values of $\boldsymbol{Z c}$, but no two parameters Equation of State adequately describes all properties of pure substances near the vapor dome.

### 2.4.3 Other Useful Two Parameter Equations of State

Many equations of state have been proposed to represent $P-V-T$ data more accurately than the Ideal Gas Law for those regions where it does not apply. Most of the equations of state that have been proposed are empirical and only a few of them are in wide use in thermodynamics and related engineering and physics fields. Two other equations of state, commonly used in engineering analysis, are presented below.

### 2.4.3.1 Redlich-Kwong Equation of State

The Redlich-Kwong (RK) equation of state is an empirical equation that is widely used for engineering calculations.

$$
\begin{equation*}
P=\frac{\Re T}{v-b}-\frac{a}{T^{0.5} v(v+b)} \tag{2.19}
\end{equation*}
$$

The constants $a$ and $b$ of the Redlich-Kwong equation of state can be estimated from the critical constants by the following relations. It is generally thought to provide satisfactory results above the critical temperature for any pressure.

$$
\begin{array}{r}
a=\frac{0.42748 \Re^{2} T_{c}^{2.5}}{P_{c}} \\
b=\frac{0.0867 \Re T_{c}}{P_{c}} \tag{2.20b}
\end{array}
$$

This gives $\boldsymbol{Z}_{\boldsymbol{C}}=0.333$ which is significantly closer to the range of interest for most gases. The constants $\boldsymbol{a}$ and $\boldsymbol{b}$ are evaluated in the Appendix for a number of gases.

### 2.4.3.2 Peng-Robinson Equation of State

The Peng-Robinson equation of state gives a slightly better approximation below the critical temperature by adding another parameter, $\boldsymbol{\omega}$, the acentricity factor given by,

$$
\begin{gather*}
\omega=-1-\log _{10}\left(\frac{p^{s a t}}{p_{C}}\right)_{T / T_{C}=0.7} \kappa=0.37464+1.54226 \omega-0.26993 \omega^{2}  \tag{2.21a}\\
\alpha=\left[1+\kappa\left(1-\sqrt{T / T_{C}}\right)\right]^{2} \quad P=\frac{\Re T}{v-b}-\frac{\alpha a}{v^{2}+2 b v-b^{2}} \tag{2.21b}
\end{gather*}
$$

The Peng-Robinson constants are determined by

$$
\begin{equation*}
a=0.45723553 \frac{\mathfrak{R}^{2} T_{C}^{2}}{P_{C}} \quad b=0.07779607 \frac{\mathfrak{R} T_{C}}{P_{C}} \tag{2.21c}
\end{equation*}
$$

It gives a $Z_{C}=0.307$, closer to the range of a number of gases. The constants for the Peng-Robinson Equation of State are provided for a number of gasses in the Appendix.

### 2.4.4 Common Equations of State with Additional Parameters

Equations of state play an important role in chemical engineering design and they have assumed an expanding role in the study of the phase equilibrium of fluids and fluid mixtures. Originally, equations of state were used mainly for pure components. Many equations of state have been proposed in the literature with either an empirical, semi-empirical or a theoretical basis. Brief reviews can be found in the following sections.

### 2.4.4.1 Beattie-Bridgeman Equation of State

The Beattie-Bridgemen equation of state is given by

$$
\begin{equation*}
P v^{2}=\Re T\left(1-\frac{c}{v T^{3}}\right)\left(v-B_{0}-\frac{b B_{0}}{v}\right)-A_{0}\left(1-\frac{a}{v}\right) \tag{2.22}
\end{equation*}
$$

The constants $A_{0}, B_{0}, a, b$, and $c$ are characteristic of a gas. These constants for some substances are given in Table 2.2.

Table 2.2 Constants of Beattie-Bridgeman equation of state

| Gas | $A_{0}\left(\frac{\mathrm{Pam}^{3}}{\mathrm{~mol}^{2}}\right)$ | $B_{0} \times 10^{6}$ <br> $\left(\frac{\mathrm{~m}^{3}}{\mathrm{~mol}}\right)$ | $a \times 10^{6}$ <br> $\left(\frac{\mathrm{~m}^{3}}{\mathrm{~mol}}\right)$ | $b \times 10^{6}$ <br> $\left(\frac{\mathrm{~m}^{3}}{\mathrm{~mol}}\right)$ | $c\left(\frac{\mathrm{~m}^{3} \mathrm{~K}^{3}}{\mathrm{~mol}}\right)$ |

### 2.4.4.2 Benedict-Webb-Rubin Equation of State

The Benedict-Webb-Rubin (BWR) equation of state is given by;
$P=\frac{\Re T}{v}+\frac{1}{v^{2}}\left(\Re T\left(B_{0}+\frac{b}{v}\right)-\left(A_{0}+\frac{a}{v}+\frac{a \alpha}{v^{4}}\right)-\frac{1}{T^{2}}\left(C_{0}-\frac{c}{v}\left(1+\frac{\gamma}{v^{2}}\right) \exp \left(\frac{-\gamma}{v^{2}}\right)\right)\right)$
where $A_{0}, B_{0}, C_{0}, a, b, c, \alpha$ and $\gamma$ are constants for a given fluid. The BWR constants for a few selected gases can be found in Table 2.3 above or in Perry's Chemical Engineer's Handbook. This equation of state is quite complex and contains eight constants, and is able to predict the $p-v-T$ data with higher accuracy compared to many other equations of state.

The Equations of State used to calculate the steam properties in the Appendix was broken down into five regions. Each region required between 10 and 43 constants to adequately represent the data.

### 2.4.4.3 Virial Equation of State

The word virial comes from the Latin meaning force, thus it refers to the interaction forces between molecules. In 1901 Kamerlingh Onnes suggested the virial equation of state expressed as a power series in reciprocal volume; it is given by

$$
\begin{equation*}
\frac{p v}{\Re T}=1+\frac{B}{v}+\frac{C}{v^{2}}+\frac{D}{v^{3}} \tag{2.24a}
\end{equation*}
$$

where $B, C, D$, etc. are known as second virial coefficient, third virial coefficient etc. Virial coefficients express the deviations from the Ideal Gas Law due to intermolecular forces. These virial coefficients are functions of temperature only. The advantage of the virial equation of state is that it may be made to represent
the experimental $p-v-T$ data as accurately as required by increasing the number of constants. The values of the second virial coefficients have been determined experimentally for a number of gases. The third virial coefficients are not known for many substances and much less information is available beyond the third virial coefficient. Moreover, the virial equation of state with more than three terms is difficult to handle. The virial equation of state and the ideal gas law have a strong theoretical base. They have been derived through statistical mechanical methods. All other equations of state are empirical or semi-empirical. The virial equation of state is sometimes written as a power series in the pressure as;

$$
\begin{equation*}
\frac{p v}{\Re T}=1+B^{\prime} P+C^{\prime} P^{2}+D^{\prime} P^{3}+\ldots \tag{2.24b}
\end{equation*}
$$

where the coefficients $B^{\prime}, C^{\prime}, D^{\prime}$, etc. are functions of temperature only. The coefficients $B^{\prime}, C^{\prime}, D^{\prime}$, etc. are related to the virial coefficients $B, C, D$, etc. by the following relations:

$$
\begin{gather*}
B^{\prime}=\frac{B}{\Re T}  \tag{2.25a}\\
C^{\prime}=\frac{C-B^{2}}{(\Re T)^{2}}  \tag{2.25b}\\
D^{\prime}=\frac{D-3 B C+3 B^{3}}{(\Re T)^{3}} \tag{2.25c}
\end{gather*}
$$

It has been found that the virial Eq. 2.24a adequately represents the experimental data over a wide range of pressure, compared to the virial Eq. 2.24 b when both these equations are truncated after the third term [1]. The general form of Eq. 2.24a can be written as;

$$
\begin{equation*}
\frac{p v}{\Re T}=1+\frac{B}{v}+\frac{C}{v^{2}}+\frac{D}{v^{3}}+\ldots=\sum_{i=0}^{R} \frac{c_{i}}{v^{i}} \tag{2.26}
\end{equation*}
$$

The parameters in the equation ( $B, C, D=c_{i}$ ) are again called "virial coefficients". If $c_{i}=0$ for $i>0$, the virial equation reduces to the ideal gas equation. The accuracy required determines the number of terms that are kept - more terms makes the equation more accurate, but also more complicated to work with. Virial coefficients are different for each gas, but other than that are functions of temperature only.

Coefficients are normally obtained by making measurements of $p, v$, and $T$, and fitting the equation. These values are then published so that others may use them.

Many forms of the virial equation exist. Truncating this equation after one coefficient gives a quadratic equation in $v$. Thus, it retains some of the simplicity of the Ideal Gas law allowing quick analytic solutions for v given p and T .
要

A number of methods (correlations, etc.) are available to determine $B$. In order to improve accuracy and capture more behaviors, additional parameters are sometimes added. One example is the Benedict-Webb-Rubin (BWR) Equation of State Eq. 2.23.

This equation provides a first order correction to the Ideal Gas Law for non-polar species. It should not be attempted for polar compounds such as water that have a non-zero dipole moment [1]. The following procedure may be used to estimate $v$ or $P$ for a given $T$ for a non-polar species, one with a dipole moment close to zero, such as hydrogen or oxygen and all other symmetrical molecules.

To use the truncated virial Equation of State proceeds in the following manner.

- Look up the critical temperature and pressure $\left(T_{c}\right.$ and $\left.P_{c}\right)$ for the species of interest in Appendix. Also, look up the acentric factor, $\boldsymbol{\omega}$, a parameter that reflects the geometry and polarity of a molecule, in the constants table for the PengRobinson Equation of State in the Appendix. (A more complete list can be found in Reid et al. [2].)
- Calculate the reduced temperature $T_{r}$ using the relationship $T_{r}=T / T_{c}$.
- Calculate the following coefficients:

$$
\begin{align*}
& B_{0}=0.083-\frac{0.422}{T_{r}^{1.6}}  \tag{2.27b}\\
& B_{1}=0.139-\frac{0.172}{T_{r}^{4.2}}  \tag{2.27c}\\
& B=\frac{\Re T_{c}}{P_{c}}\left(B_{0}+\omega B_{1}\right) \tag{2.27d}
\end{align*}
$$

- Substitute into Eq. 2.27 the value of $B$ and whichever of the variables $p$ and $v$ is known and solve for the other variable. Solution for $p$ is straightforward. If $v$ is to be determined, the equation can be rearranged into a quadratic and solved using the quadratic formula.

$$
v^{2}-\frac{\Re T}{p} v-\frac{\Re T}{p} B=0
$$

- Normally one of the two solutions is reasonable and the other is not and should be discarded; if there is any doubt, estimate $v$ from the ideal gas equation of state and accept the virial equation solution that comes closest to $v_{\text {ideal }}$.

### 2.4.4.4 Equation of State Comparison

Virial equations with one coefficient cannot represent thermodynamic systems where both liquid and vapor are present. A "cubic" equation of state is needed to do this. We have identified three two-parameter equations of state above for which data
is presented in the Appendix. The most sophisticated of these is the Peng-Robinson equation because it corrects the " a " coefficient for the acentric factor.

$$
\begin{equation*}
P=\frac{\Re T}{(v-b)}-\frac{\alpha a}{v^{2}+2 b v-b^{2}} \tag{2.28a}
\end{equation*}
$$

where the constants are given by;

$$
\begin{gather*}
a=0.45723553 \frac{\mathfrak{R}^{2} T_{c}^{2}}{P_{c}}  \tag{2.28b}\\
b=0.07779607 \frac{\mathfrak{R} T_{c}}{P_{c}}  \tag{2.28c}\\
\kappa=0.37464+1.54226 \omega-0.26993 \omega^{2}  \tag{2.28d}\\
\alpha=\left(1+\kappa\left(1-\sqrt{\frac{T}{T_{c}}}\right)\right)^{2} \tag{2.28e}
\end{gather*}
$$

In this equation, the $b$ term is a volume correction, while $a$ is a molecular interaction parameter. The constants all depend on the critical temperature and pressure of the gas. These can be looked up easily in a data table.

The "acentric factor", omega $\omega$, is also easily looked up. It is related to the geometry of the gas molecule.

To use the Peng-Robinson equation:

1. Look up $T_{c}, P_{c}$, and the acentric factor for the species of interest in the Appendix.
2. Plug in and find $a, b$, and alpha $\alpha$.
3. Plug these into the Peng-Robinson equation; the result will be a cubic equation in $v$ depending on $p$ and $T$.
4. Solve for the unknown you seek.

Solving the cubic equation can be accomplished with a binary search using the computer or by analytically solving the cubic equation. The equation can be transformed to

$$
\begin{gathered}
v^{3}+\left(b-\frac{\mathfrak{R} T}{p}\right) v^{2}+\left(\frac{\alpha a}{p}-3 b^{2}-2 \frac{\Re T}{p} b\right) v+\left(b^{3}+\frac{\Re T}{p} b^{2}-\frac{\alpha a}{p} b\right)=0 \\
v^{3}+a_{1} v^{2}+a_{2} v+a_{3}=0
\end{gathered}
$$

The analytic solution is given by,

$$
\begin{gathered}
v^{3}+a_{1} v^{2}+a_{2} v+a_{3}=0 \\
\text { Transform to } \\
x^{3}+b_{1} x+b_{2}=0 \quad v=x-\frac{a_{1}}{3} \\
b_{1}=\frac{3 a_{2}-a_{1}^{2}}{3} \quad \mathrm{~b}_{2}=\frac{2 a_{1}^{3}-9 a_{1} a_{2}+27 a_{3}}{27} \\
\frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}>0,1 \text { real, } 2 \text { imaginary, } \frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}=0,3 \text { real, } 2 \text { equal, } \\
\frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}<0,3 \text { real \& distinct }
\end{gathered}
$$

For the first case

$$
\begin{aligned}
& C=\sqrt[3]{-\frac{b_{2}}{2}+\sqrt{\frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}}} \quad \mathrm{D}=\sqrt[3]{-\frac{b_{2}}{2}-\sqrt{\frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}}} \\
& x=C+D \quad x=-\frac{C+D}{2}+\frac{C-D}{2} \sqrt{-3} \quad \mathrm{x}=-\frac{C+D}{2}-\frac{C-D}{2} \sqrt{-3} \\
& v=x-\frac{a_{1}}{3}
\end{aligned}
$$

For the third case of three real unequal roots let,

$$
\begin{gathered}
\cos \phi=\frac{-a_{2} / 2}{\sqrt{-a_{1}^{3} / 27}} \\
x_{1}=2 \sqrt{-b_{1} / 3} \cos (\phi / 3) \quad x_{2}=2 \sqrt{-b_{1} / 3} \cos (\phi / 3+2 \pi / 3) \quad x_{3}=2 \sqrt{-b_{1} / 3} \cos (\phi / 3+4 \pi / 3)
\end{gathered}
$$

Example 2.1 Carbon dioxide at 500 K and 6.5 MPa flows at $100 \mathrm{~kg} / \mathrm{h}$. Use the one parameter Viral Equation of State and the Peng-Robinson Equation of State to determine the volumetric flow.

Solution The pressure and temperature are known, so look up the critical properties, the acentric factor, and the Peng-Robinson constants in the Appendix.

The critical properties are $\mathrm{T}_{\mathrm{c}}=304.2^{\circ} \mathrm{K}, \mathrm{p}_{\mathrm{c}}=7.39 \mathrm{MPa}$, and the acentric factor is 0.225 .

Evaluating the B coefficients,

$$
\begin{gathered}
\mathrm{T}_{\mathrm{r}}=500.0 / 304.2=1.64365 \quad \mathrm{~B}_{0}=0.083-0.422 / \mathrm{T}_{\mathrm{r}}^{1.6}=-0.1076 \\
\mathrm{~B}_{1}=0.139-0.422 / \mathrm{T}_{\mathrm{r}}^{4.2}=0.0867 \\
\mathrm{~B}=8314.47 * 304.2 / 7.39 \mathrm{E}+6 *(-0.1076+0.225 * 0.0867)=-0.03014 \\
v=\frac{\Re T}{2 p} \pm \sqrt{\left(\frac{\Re T}{2 p}\right)^{2}+\frac{\Re T B}{p}}=(0.31978+0.081651) / 44=0.01382 \mathrm{~m}^{3} / \mathrm{kg}
\end{gathered}
$$

The Peng-Robinson coefficients are

$$
\begin{gathered}
\mathrm{a}=0.39576 \mathrm{MPa}-\mathrm{m}^{3} / \mathrm{kgmol}^{2} \mathrm{~b}=0.02662 \mathrm{~m}^{3} / \mathrm{kgmol} \\
\kappa=0.37464+1.5422 * 0.225-0.26993 * 0.225^{2}=0.70797 \\
\alpha=\left(1.0+0.70797\left\{1-\sqrt{\mathrm{T} / \mathrm{T}_{\mathrm{c}}}\right\}\right)^{2}=0.6357 \\
p=\frac{\Re T}{v-b}-\frac{\alpha a}{v^{2}+2 b v-b^{2}} \\
v^{3}+\left(b-\frac{\Re T}{p}\right) v^{2}+\left(\frac{\alpha a}{p}-3 b^{2}-2 \frac{\Re T}{p} b\right) v+b^{3}+\frac{\Re T}{p} b^{2}-\frac{\alpha a}{p} b=0
\end{gathered}
$$

Applying the cubic formula gives
$a_{1}=-0.61295, a_{2}=0.002526, a_{3}=-0.00055844, b_{1}=-0.12271, b_{2}=-0.017101$

$$
\begin{gathered}
\frac{b_{2}^{2}}{4}+\frac{b_{1}^{3}}{27}>0,1 \text { real, } 2 \text { imaginary } \\
\mathrm{C}=0.22044 \quad \mathrm{D}=0.18555 \\
v=0.5^{*}(0.22044+0.18555) / 44.0=0.01387 \mathrm{~m}^{3} / \mathrm{kg}
\end{gathered}
$$

It is worth noting that the Ideal Gas solution is
$v=\frac{\Re T}{p A M}=\frac{8314.47 * 500}{6500000.0 * 44}=0.01454 \mathrm{~m}^{3} / \mathrm{kg}$ and the tables give $0.01389 \mathrm{~m}^{3} / \mathrm{kg}$

Fig. 2.6 The $P-V, T-V$, and $P-T$ diagrams

So the Ideal Gas solution is high by $4.65 \%$. The virial solution is low by $0.54 \%$, and the Peng-Robinson solution is low by $0.14 \%$.

The volumetric flow rate with the viral solution will be $100 * 0.01382=1.382 \mathrm{~m}^{3} / \mathrm{h}$
The volumetric flow rate with the Peng-Robinson solution would be $100 * 0.01387=1.387 \mathrm{~m}^{3} / \mathrm{h}$

### 2.4.5 The Liquid-Vapor Region

Appling Fig. 2.6 shows that at any given $(T, v)$ between saturated points $\mathbf{1}$ and $\mathbf{2}$, liquid and vapor exist as a mixture in equilibrium. Let $v_{f}$ and $v_{g}$ to represent the specific volumes of the saturated liquid and the saturated vapor, respectively, while $m$ is the total mass of the system that is shown in Fig. 2.6 and $m_{f}$ the mass amount of mass in the liquid phase, and $m_{g}$ the amount of mass in the vapor phase, then for a state of the system represented by $(T, v)$ the total volume of the mixture is the same of the volume occupied by the liquid and the occupied by the vapor as [3]:

$$
\begin{gather*}
m v=m_{f} v_{f}+m_{g} v_{g}  \tag{2.29}\\
m=m_{f}+m_{g} \tag{2.30}
\end{gather*}
$$

or dividing both side of Eq. 2.29 by $m$, then utilizing Eq. 2.30 , we have;

Fig. 2.7 The $T-V$ diagram showing the saturated liquid and saturated vapor points

The ratio $x=\frac{m_{g}}{m}$ is called quality because steam that has a larger proportion of vapor is considered "higher quality" than steam with a lesser mass of vapor. $v_{f g}=v_{g}-v_{f}$ is the heat of vaporization. If we take a slice through the 3-D plot to form the $P-T$ plane and include the Critical Point we will obtain the plot that is shown in Fig. 2.4.

Note that the percentage liquid by mass in a mixture is $1000(1-x)$ and the percentage vapor is $100 x$. See Fig. 2.7.

For most substances, the relationships among thermodynamic properties are too complex to be expressed by simple equations. Therefore, properties are frequently presented in the form of tables. Some thermodynamic properties can be measured easily and those that can't are calculated by using the thermodynamic relations that they must satisfy and the measurable properties.

Fig. 2.8 Illustration of $T-v$ process steps and its diagram

The working fluid of most interest to engineer's and by far the fluid most studied is water. Its properties have been tabulated for years in what are called Steam Tables. A set of Steam Tables are provided in the back of the book, within the Appendix. The Tables are Appendix 14.1-14.7.

## 2.5 $T$-V Diagram for a Simple Compressible Substance

Consider an experiment in which a substance starts as a solid and is heated up at constant pressure until it becomes a gas. The process is depicted in Fig. 2.8.

As heat is applied to the solid, the temperature increases and the volume increases slightly. When the melt temperature is reached, the temperature remains constant but the volume continues to increase as the solid is converted to a liquid. Once all of the material has been converted to a liquid, the temperature begins to increase again as more heat is added. When the vaporization temperature is reached, the liquid begins to be converted to a vapor and the temperature remains constant as more heat is added. Once all of the liquid has been converted to vapor, adding more heat will once again cause the temperature to rise.[3-7].

Fig. 2.9 Illustration of $P-V$ diagram

## 2.6 $\boldsymbol{P}-V$ Diagram for a Simple Compressible Substance

The general shape of a $p-V$ diagram for a pure substance is very similar to that of a $T-V$ diagram and its representation by the vapor dome as discussed before. Figure 2.9 is a presentation of a $p-V$ diagram.

On this diagram the subscript $f$ denotes a saturated liquid (fluid) and $g$ denotes a saturated vapor (gas).

## 2.7 $\boldsymbol{P}$ - $V$ - $T$ Diagram for a Simple Compressible Substance

All the data that are represented on both the $p-v$ and $p-T$ diagrams can be shown one diagram if the three coordinates $p, v$, and $T$ are plotted along orthogonal axes. The result is called the $p-v-T$ surface and two such surfaces are shown in Figs. 2.10 and 2.11, the first for a kilogram of an unusual substance like water that contracts upon melting, and the second for a kilogram of a typical substance like carbon dioxide that expands upon melting.

Where the critical point is denoted by the letter $C$ and the triple point by $T P$. The critical isotherm is marked $T_{C}$. Every point on the $P-V-T$ surface represents a state of equilibrium for the substance. If the $p-v-T$ surface is projected on the $p-v$ plane, then the usual $p-v$ diagram is seen and upon projecting the $p-v-T$ surface onto the $p-T$ plane, the entire solid-vapor region projects into the sublimation curve, the entire liquid-vapor region projects into the vaporization curve, the entire solid-liquid region projects into the fusion curve, and, finally, the Triple-Point Line projects into the triple point on the phase diagram [4].

Fig. 2.10 $P-V-T$ surface for $\mathrm{H}_{2} \mathrm{O}$, which contracts while melting

Fig. 2.11 $P-V-T$ surface for $\mathrm{CO}_{2}$, which expands while Melting

The $P-V-T$ surfaces present a great deal of information at once, but in typical thermodynamic analysis it is more convenient to work with two-dimensional diagrams, such as the $p-v$ and $T-v$ diagrams (Fig. 2.12).

Example 2.2 Determine the volume change when 1 kg of saturated water is completely vaporized at a pressure of (a) 1 kPa , (b) 100 kPa , and (c) 10000 kPa .

Solution Appendix A14.2 provides the necessary values. The quantity being sought is $v_{f g}=v_{g}-v_{f}$. Note that $\boldsymbol{p}$ is given in MPa

Fig. 2.12 Illustration of $P-V-T$ diagram for two cases
a. 1 kPa . Thus, $v_{f g}=129.183-0.001=129.182 \mathrm{~m}^{3} / \mathrm{kg}$.
b. 100 kPa MPa. Again $v=1.673-0.001=1.672 \mathrm{~m}^{3} / \mathrm{kg}$.
c. $10,000 \mathrm{kPa}=10 \mathrm{MPa}$. Finally, $v_{f g}=0.018034-0.001453=0.016581 \mathrm{~m}^{3} / \mathrm{kg}$.

Example 2.3 Four kg of water is placed in an enclosed volume of $1 \mathrm{~m}^{3}$. Heat is added until the temperature is $420^{\circ} \mathrm{K}$. Find (a) the pressure, (b) the mass of vapor, and (c) the volume of the vapor.

Solution Appendix A14.1 is used. The volume of 4 kg of saturated vapor at $420^{\circ} \mathrm{K}$ is $(0.425255)(4)=1.701 \mathrm{~m}^{3}$. Since the given volume is less than this, we assume the state to be in the quality region.
a. In the quality region the pressure is given as $\boldsymbol{p}=437.24 \mathrm{kPa}$.
b. To find the mass of the vapor we must determine the quality. It is found from Eq. 2.3, using the actual $\boldsymbol{v}=1 / 4 \mathrm{~m}^{3} / \mathrm{kg}$, as;

$$
0.25=0.001087+(0.425255-0.001087)
$$

thus $x=0.2489 / 0.425255=0.5853$. Using the relationship of $x=\frac{m_{g}}{m}$, the vapor mass is

$$
m_{g}=m x=(4)(0.5853)=2.341 \mathrm{~kg}
$$

Finally, the volume of the vapor is found from

$$
V_{g}=v_{g} m_{g}=(0.4253)(2.341)=0.9956 \mathrm{~m}^{3}
$$

Note that in a mixture where the quality is not very close to zero, the vapor phase occupies most of the volume. In this example, with a quality of $58.53 \%$ it occupies $99.56 \%$ of the volume.

Example 2.4 Four kg of water is heated at a pressure of 220 kPa to produce a mixture with quality $x=0.8$. Determine the final volume occupied by the mixture.

Solution Using Appendix A14.2 to determine the appropriate number at 220 kPa we linearly interpolate between 0.2 and 0.3 MPa . This provides, at 220 kPa .

$$
v_{g}=\left(\frac{220-200}{250-200}\right)(0.718697-0.885735)+0.885735=0.8189 \mathrm{~m}^{3} / \mathrm{kg}
$$

Note that no interpolation is necessary for $v_{f}$, since for both pressures $v_{f}$ is the same to four decimal places. Using Eq. 2.6, we now find

$$
v=v_{f}+x\left(v_{g}-v_{f}\right)=0.0011+(0.8)(0.8189-0.001)=0.6554 \mathrm{~m}^{3} / \mathrm{kg}
$$

The total volume occupied by 4 kg is $V=m v=(4 \mathrm{~kg})\left(0.6640 \mathrm{~m}^{3} / \mathrm{kg}\right)=2.621 \mathrm{~m}^{3}$.
Example 2.5 Two lb of water is contained in a constant-pressure container held at 540 psia . Heat is added until the temperature reaches $1100^{\circ}$ R. Determine the final volume of the container.

Solution: Use Appendix 14.7. Since 540 psia lies between the table entry values, the specific volume is simply

$$
v=1.2223+(0.4)(1.0017-1.2223)=1.1341 \mathrm{ft}^{3} / \mathrm{lbm}
$$

The final volume is then $V=m v=(2)(1.2115)=2.2681 \mathrm{ft}^{3}$
Example 2-6 Calculate the pressure of steam at a temperature of $500^{\circ} \mathrm{C}$ and a density of $24 \mathrm{~kg} / \mathrm{m}^{3}$ using (a) the ideal-gas equation, (b) the van der Waals equation, (c) the Redlich-Kwong equation, (d) the Peng-Robinson equation, and (e) the steam table.

## Solution

a. Using the ideal-gas equation, $P=\rho R T=(24 / 18)(8.31447)(773)=8569.4 \mathrm{kpa}$.
b. Using values for $a$ and $b$ from the Appendix for the Van der Waals equation provides;

$$
P=\frac{R T}{v-b}-\frac{a}{v^{2}}=\frac{8.31447(773)}{\frac{18}{24}-0.03084}-\frac{553.04}{\left(\frac{18}{24}\right)^{2}}=7954 \mathrm{kpa}
$$

c. Using values for $a$ and $b$ from the Appendix for the Redlich-Kwong equation gives;
$P=\frac{R T}{v-b}-\frac{a}{v(v+b) \sqrt{T}}=\frac{(8.31447)(773)}{\frac{18}{24}-0.02110}-\frac{14258.5}{\left(\frac{18}{24}\right)\left(\frac{18}{24}+0.02110\right) \sqrt{773}}=7931 \mathrm{kpa}$
d. For the Peng-Robinson equation the acentric factor for water is 0.3437 .

$$
\begin{gathered}
\kappa=0.37464+1.54226 \omega-0.26993 \omega^{2} \\
\alpha=\left(1+\kappa\left(1-\sqrt{\frac{T}{T_{c}}}\right)\right)^{2} \\
\alpha=0.8447: \\
p=\frac{8.31447 * 773}{0.75-0.01895}-\frac{0.8447 * 599.4}{\left(0.75^{2}+2 * 0.01895 * 0.75-0.01895^{2}\right)}=7934.24 \mathrm{kPa}
\end{gathered}
$$

e. The steam table provides the most precise value for the pressure. Using $T=500^{\circ} \mathrm{C}$ and $v=1 / 24=0.04166 \mathrm{~m}^{3} / \mathrm{kg}$, we find $P=8141 \mathrm{kPa}$. Note that the ideal-gas law has an error of $5.3 \%$, and the errors of each of the other three equations are Van der Waals $=-2.29 \%$, Redlich Kwong $=-2.58 \%$, Peng-Robinson $=-2.54 \%$

## Chapter 3 Mixture

Not all thermodynamic systems contain only pure substances. Many systems of interest are composed of mixtures of pure substances. It is important to be able to analyze these systems as well as those containing only pure substances. Therefore, an understanding of mixtures is essential to the study of thermodynamics.

### 3.1 Ideal Gas Mixtures

In the following section we will be studying gas mixtures and introduce certain conceptual framework and properties of substances that are mixed. Rederas can also refer to references at the end of this chapter for further information on the subject of mixture.[1-3].

### 3.1.1 Avogadro's Number

In order to provide a conceptual framework for understanding mixtures it is easiest to start with Ideal Gas Mixtures and address the fundamentals. Then real gas effects and liquid effects can be added in. The Ideal Gas is composed of point molecules that have no volume and only interact with billiard ball-like collisions. This description does not distinguish between one type of molecule or another. So the only thing that matters when combining two or more ideal gases is how many molecules of each gas are present. To get the number of molecules of a gas present it is a simple matter to divide the mass of the gas by the molecular weight of the gas and multiply by a constant known as Avogadro's Number. A kilogram-mole of any pure substance contains $\mathbf{6 . 0 2 2} \times \mathbf{1 0}^{\mathbf{2 6}}$ molecules or atoms. Avogadro's number gives the number of molecules in a mole of a pure substance. To get the number of
kilogram-moles in a given mass, the mass of the substance is divided by the molecular mass in kilograms. For instance,

$$
\begin{aligned}
5 \text { kilograms of } \mathrm{He} & =5 \mathrm{~kg} / 4 \mathrm{~kg} \text { per kg-mole } \\
& =1.25 \mathrm{~kg} \text {-moles } \mathrm{He}=7.528 \times 10^{26} \text { atoms } \mathrm{He} \\
5 \text { kilograms of } \mathrm{N}_{2} & =5 \mathrm{~kg} / 28 \mathrm{~kg} \text { per kg-mole } \\
& =0.1786 \mathrm{~kg} \text {-moles } \mathrm{N}_{2}=1.075 \times 10^{26} \text { molecules } \mathrm{N}_{2}
\end{aligned}
$$

It is generally not important to know the number of atoms or molecules present, but in most cases, it is important to know the number of moles present. So it is useful to remember that when quantities are measured in moles, it is the same as if they were measured in atoms or molecules. Classical thermodynamics was developed long before the atomic hypothesis was demonstrated but the concept of a mole of material superseded classical thermodynamics.

### 3.1.2 Mass Fractions

When pure substances are mixed, they are typically quantified by the amount of mass of each substance present. The mass fraction for a component of a mixture is the mass of that component divided the total mass of the mixture. Knowing the mass fractions for a mixture is useful if one wants to know the recipe for putting the mixture together, but they are generally not usually useful for predicting the thermodynamic characteristics of the mixture. Consider a mixture of $5 \mathrm{~kg} \mathrm{~N}_{2}$ an 15 kg of $\mathrm{CO}_{2}$.

$$
\begin{aligned}
& \text { Total Mass }=5 \mathrm{~kg}+15 \mathrm{~kg}=20 \mathrm{~kg} \\
& \text { Mass fraction } \mathrm{N} 2=5 / 20=0.25 \\
& \text { Mass Fraction } \mathrm{CO} 2=15 / 20=0.75
\end{aligned}
$$

Unfortunately, the mass fractions tell very little about the thermodynamic characteristics of the mixture other than the recipe for putting it together.

### 3.1.3 Mole Fractions

A more useful characterization of the mixture is the mole fraction of the components. In order to calculate mole fractions, the moles of each component present must be calculated first. To get the moles of a component present the components mass must be divided by its molecular weight. For instance
$5 \mathrm{~kg} \mathrm{~N}_{2}=5 \mathrm{~kg} / 28 \mathrm{~kg}$ per kg-mole $=0.1786 \mathrm{~kg}-\mathrm{moles}$ of $\mathrm{N}_{2}$
$15 \mathrm{~kg} \mathrm{CO}_{2}=15 \mathrm{~kg} / 44 \mathrm{~kg}$ per kg-mole $=0.3409 \mathrm{~kg}-$ moles of $\mathrm{CO}_{2}$

$$
\begin{aligned}
& \text { Total kg-moles }=0.1786+0.3409=0.5195 \mathrm{~kg} \text {-moles } \\
& \text { Mole Fraction } \mathrm{N}_{2}=0.1786 / 0.5195=0.3438 \\
& \text { Mole Fraction } \mathrm{CO}_{2}=0.3409 / 0.5195=0.6562
\end{aligned}
$$

Now that we have the mole fractions present, we have the relative numbers of molecules of each gas present. These fractions will be far more useful for determining the properties of the gas mixture than the relative masses.

Example 3.1 Consider a mixture of $\mathrm{O}_{2}$ and $\mathrm{H}_{2}$ that is $5 \mathrm{wt} \% \mathrm{H}_{2}$. If it is burned, which component will be consumed entirely, and which component will be left over.

Solution To solve this problem we must find the mole fractions of the two gases and consider that 1 mol of $\mathrm{O}_{2}$ combines with 2 moles of $\mathrm{H}_{2}$ to form water.
$n_{H_{2}}=0.1 / 2=0.05$
$n_{o_{2}}=0.9 / 32=0.0281$
$n_{\text {total }}=0.0781$
$n_{f, H_{2}}=0.05 / 0.0781=0.64$
$n_{f, O_{2}}=0.0281 / 0.0781=0.36$
0.32 moles of $\mathrm{O}_{2}$ will combine with 0.64 moles of $\mathrm{H}_{2}$ leaving 0.04 moles of excess $\mathrm{O}_{2}$ The final mixture will contain 0.32 moles of $\mathrm{H}_{2} \mathrm{O}$ and 0.04 moles of $\mathrm{O}_{2}$
$n_{f, \mathrm{H}_{2} \mathrm{O}}=\frac{0.32}{0.32+0.04}=0.889 \quad n_{f, \mathrm{O}_{2}}=\frac{0.04}{0.32+0.04}=0.111$

### 3.1.4 Dalton's Law and Partial Pressures

Ideal gases when combined to form a mixture can be modeled fairly easily. Basically each if the gases expand to fill the volume of the mixture. Each gas exerts a pressure proportional to the number of atoms or molecules present. So each gas behaves as it is an Ideal Gas ignoring the other gases present. Dalton' s Law states that the total pressure exerted by a mixture is simply the sum of the partial pressures of the gases in the mixture.

$$
\begin{aligned}
p_{\text {Total }} & =\sum_{i} p_{i}=\sum_{i} \frac{n_{i} \Re T}{V} \\
\frac{p_{i}}{p_{\text {Total }}} & =\frac{n_{i}}{\sum_{i} n_{i}}=n_{f, i}
\end{aligned}
$$

Thus, the partial pressure of an Ideal Gas is equal to the mole fraction of the gas in the mixture.

### 3.1.5 Amagat's Law and Partial Volumes

Amagat's law is similar in that it states that the partial volumes occupied by a mixture add up to the total volume of the mixture at the system pressure.

$$
\begin{aligned}
V_{i} & =\frac{n_{i} \Re T}{p} \\
\frac{V_{i}}{V} & =\frac{n_{i}}{\sum_{i} n_{i}}=n_{f, i}
\end{aligned}
$$

It is a little harder to measure partial volumes but the concept has utility in some cases.

Example 3.2 A rigid tank contains 2 kg of $\mathrm{N}^{2}$ and 4 kg of $\mathrm{CO}^{2}$ at a temperature of $25^{\circ} \mathrm{C}$ and 2 MPa . Find the partial pressures of the two gases and the gas constant of the mixture.

Solution To find the partial pressures we need the mole fractions. The moles of $\mathrm{N}_{2}$ and $\mathrm{CO}_{2}$ are, respectively as follows;

$$
\left.\begin{array}{l}
N_{1}=\frac{m_{1}}{M_{1}}=\frac{2}{28}=0.0714 \mathrm{~mol} \\
N_{2}=\frac{m_{2}}{M_{2}}=\frac{4}{44}=0.0909 \mathrm{~mol}
\end{array}\right\}
$$

Therefore

$$
N_{m}=N_{1}+N_{2}=0.1623 \mathrm{~mol}
$$

The mole fractions are

$$
\left.\begin{array}{l}
n_{f, 1}=\frac{N_{1}}{N_{m}}=\frac{0.0714 \mathrm{~mol}}{0.1623 \mathrm{~mol}}=0.440 \\
n_{f, 2}=\frac{N_{2}}{N_{m}}=\frac{0.0909 \mathrm{~mol}}{0.1623 \mathrm{~mol}}=0.560
\end{array}\right\}
$$

The partial pressures are then;
$P_{1}=n_{f, 1} P=(0.44)(2)=0.88 \mathrm{MPa} \quad$ and $\quad P_{2}=n_{f, 2} P=(0.56)(2)=0.1 .12 \mathrm{MPa}$

The molecular weight is $M_{m}=M_{1} n_{f, 1}+M_{2} n_{f, 2}=(28)(0.44)+(44)(0.56)=36.96$ $\mathrm{kg} / \mathrm{kmol}$. The gas constant of the mixture is then given by;

$$
R_{m}=\frac{R_{u}}{M_{m}}=\frac{8.314}{36.96}=0.225 \mathrm{~kJ} / \mathrm{kg} . \mathrm{K}
$$

### 3.2 Real Gas Mixtures

Real gas mixtures are more complicated than Ideal Gas Mixtures because the molecules have volume and they are attracted to each other in different ways. The best that can be done is to develop a real gas model based on equivalent critical temperatures and pressures.

### 3.2.1 Pseudo Critical States for Mixtures-Kay's Rule

Kay's rule states that mixtures of real gases can be approximately modeled by calculating a psuedo-critical state for the mixture based on a mole fraction weighted critical temperature and mole fraction weighted critical pressure. We have,

$$
\begin{aligned}
& T_{c, \text { equiv }}=\sum_{i} n_{f, i} T_{c, i} \\
& p_{c, e q u i v}=\sum_{i} n_{f, i} p_{c, i}
\end{aligned}
$$

This will not work very well if the conditions of interest are too close to the highest critical temperature of one of the components.

### 3.2.2 Real Gas Equations of State

Once the pseudo-critical temperature and pressure have been determined, either the Van der Waals or Redlich-Kwong equation of state can be used to estimate properties. The virial and Peng-Robinson equations present the added difficulty of trying to estimate the acentric factor, which adds an additional source of uncertainty.

Example 3.3 Estimate the pressure exerted on a $3 \mathrm{~m}^{3}$ tank used to store 100 kg of air at 200 K . The mole fractions for air are $0.78 \mathrm{~N}_{2}, 0.21 \mathrm{O}_{2}$, and 0.01 Ar .

Solution First calculate the pseudo-critical state for the mixture.

$$
\begin{aligned}
& T_{c, \text { equiv }}=0.78 * 126.2+0.21 * 154.8+0.01 * 151.0=132.45 \mathrm{~K} \\
& p_{c, \text { equiv }}=0.78 * 3.39+0.21 * 5.08+0.01 * 4.86=3.76 \mathrm{MPa} \\
& M W=0.78 * 28+0.21 * 32+0.01 * 39.95=28.96
\end{aligned}
$$

Choose to model the air with the Redlich-Kwong model. Note,

$$
v=0.03 \mathrm{~m}^{3} / \mathrm{kg}=0.03 * 28.96=0.8687 \mathrm{~m}^{3} / \mathrm{kgmol}
$$

The Redlich-Kwong constants become

$$
\begin{aligned}
& a=\frac{0.42748 * \mathfrak{R}^{2} T_{c}^{2.5}}{p_{c}}=\frac{0.42748 * 8314.47^{2} 132.45^{2.5}}{3760000}=1.5868 \times 10^{6} \\
& b=\frac{0.0867 * \mathfrak{R} * T_{c}}{p_{c}}=\frac{0.0867 * 8314.47 * 132.45}{3760000}=0.02539
\end{aligned}
$$

Then calculating the required pressure,

$$
\begin{aligned}
p & =\frac{\Re T}{v-b}-\frac{a}{T^{0.5} v(v-b)} \\
& =\frac{8314.47 * 200}{0.8687-0.02539}-\frac{1.5868 \times 10^{6}}{200^{0.5}(0.8687)(0.8687-0.02539)} \\
& =1.819 \mathrm{MPa}
\end{aligned}
$$

For the Ideal Gas model the pressure would have been 1.914 MPa or about $5.2 \%$ more.

### 3.3 Liquid Mixtures

Liquid mixtures can be very simple or quite complicated.

### 3.3.1 Conservation of Volumes

Typically gases are assumed to have an indefinite shape and an indefinite volume, whereas liquids are assumed to have an indefinite shape but a definite volume, and solids have a definite shape and definite volume. When this simple model works, combining two volumes of different liquids will produce a volume that is simply the sum of the volumes of the components. If the volumes of the molecules of the two liquids are similar, this is a good approximation.

### 3.3.2 Non-Conservation of Volumes and Molecular Packing

However, if one of the components of the mixture has a large molecular structure and the other component is a fairly small molecule like $\mathrm{H}_{2} \mathrm{O}$, it is possible for the smaller molecules to take up space between the large molecules and the net volume of the mixture to be significantly smaller than the simple sum of the volumes of the two components. Quantifying this effect is beyond the level of this text.

## Chapter 4 <br> Work and Heat

This chapter deals with two quantities that affect the thermal energy stored in a system. Work and heat represent the transfer of energy to or from a system, but they are not in any way stored in the system. They represent energy in transition and must carefully defined to quantify their effect on the thermal energy stored in a system. Once they are quantified, they can be related to the conservation of energy principle known as the First Law of Thermodynamics.

### 4.1 Introduction of the Work and Heat

A closed system can interact with its surroundings in two ways, either by;
a. Work Transfer.
b. Heat Transfer.

These may be called energy transfer or energy interactions and they bring about changes in the properties of the system. Positive work occurs when the system transfers energy to its surroundings by some mechanical or electrical process. Positive heat transfer occurs when the surroundings transfer thermal energy to the system. Normally a temperature difference is the driving potential that moves thermal energy into or out of a system.

### 4.2 Definition of Work

The formal definition of work is "a force acting through a distance". When a system undergoes a displacement due to the action of a force, work is taking place and the amount of work is equal to the product of the force and the displacement in the direction of the force. The term work is so common with many meanings in the English language that it is important to be very specific in its thermodynamic definition.

Fig. 4.1 Work being done by expanding gases in a cylinder

Work is done by a force as it acts upon a body moving in the direction of the force.

If the force acts, but no movement takes place, no work is done. Work is performed by the expanding exhaust gases after combustion occurs in a cylinder of an automobile engine as shown in Fig. 4.1. In this case the energy produced by the combustion process can be transferred to the crankshaft by means of the connecting rod, in the form of work. Therefore, the work can be thought of as energy being transferred across the boundary of a system, the system being the gases in the cylinder.

A similar concept is the work done in the turbine to generate electricity in a nuclear power plant. The gas pressure rotates the turbine blades producing a torque that turns generator. Thermal energy is transferred from the reactor core to the steam generator in the first loop. The second loop then uses this steam to drive the turbine. See Fig. 4.2 for the basic configuration of the loops.

Work is done by a system, if the sole external effect on the surroundings would be the raising of a weight [1]. The work done, however, by one part of a system on another part is called internal work. Internal work is not discussed in macroscopic thermodynamics. Only the work that involves an interaction between a system and its surroundings can be analyzed. When a system does external work, the changes that take place can be described by means of macroscopic quantities referring to the system as a whole, in which case the change may be imagined as the raising or lowering of a suspended weight, the winding or unwinding of a spring, or more generally the alteration of the position or configuration of some external mechanical device.

The magnitude of the work is the product of the weight and the distance that the weight is lifted. Figures 4.3 a , b shows that the battery cell is connected to an external circuit through which charge flows. The current may be imagined to produce rotation of the armature of a motor, thereby lifting a weight or winding a spring. For an electrochemical cell to do work, it must be connected to an external circuit. Figure 4.3 b is the interaction for Fig. 4.3a that qualifies as work in the thermodynamic sense.

## HOW Nuclear Plants WORK

 steps involved in producing energy from a nuclear power plant.

Fig. 4.2 Basic schematic of nuclear power plants and steam loops

Fig. 4.3 Work being done by electrical means

The thermodynamic convention defines positive work as that done by the system on its surroundings. Negative work is defined as work is done on the system. Figure 4.4 is a simple presentation of positive and negative work $W$ for interactions between a system and its surroundings.

The units of work in the SI system are Newton-meters. A Newton-meter is also defined as a Joule. In the English system, the basic unit is foot-pound force. There is no other name. A new quantity defined as power can be introduced as the rate of doing work $W$. In the SI system, the unit for power is Joules per second ( $\mathrm{J} / \mathrm{s}$ ) or Watts (W), while in English system the unit is ft-lbf/sec. An additional English system unit is the horsepower (hp) which is defined as $550 \mathrm{ft}-\mathrm{lbf} / \mathrm{sec}$. Note that $1 \mathrm{hp}=746 \mathrm{~W}$.

Fig. 4.4 Work interaction between a system and its surroundings

The work associated with a unit mass will be designated as $w$ or specific work. It should not be confused with specific weight as is given by:

$$
\begin{equation*}
w=\frac{W}{m} \tag{4.1}
\end{equation*}
$$

### 4.3 Quasi-Static Processes

Before going further, it is important to note that thermodynamics can only be used to describe equilibrium states. A system in thermodynamic equilibrium will satisfy the following requirements:

1. Mechanical equilibrium: There are no unbalanced forces or torques acting on any part of the system or on the system as a whole.
2. Thermal equilibrium: There are no temperature differences between parts of the system or between the system and its surroundings.
3. Chemical equilibrium: There are no chemical reactions within the system and no motion of any chemical constituent from one part of a system to another part.

A system in thermodynamic equilibrium with its surroundings will have no motion take place and as result, no work will be done, since there is no displacement of any kind.

If the sum of the external forces is changed so that there is a finite unbalanced force acting on the system, then the condition for mechanical equilibrium is no longer satisfied and the following situations will arise:

1. Unbalanced forces or torques will be created within the system; resulting in turbulence, waves, etc.. The system as a whole may execute some sort of accelerated motion.
2. As a result of this turbulence, acceleration, etc., a non-uniform temperature distribution may be brought about, as well as a finite difference of temperature between the system and its surroundings. The sudden change in the forces and in the temperature may produce a chemical reaction or the motion of a chemical constituent.

The above finite unbalanced force may cause the system to pass through non-equilibrium states. If it is desired, during a process, to describe every state of a system by means of system-wide thermodynamic coordinate, then the process must not be performed using a finite unbalanced force or torque. Under these circumstances, the external forces acting on a system are varied only slightly so that the unbalanced force is infinitesimal, and the process proceeds infinitesimally slowly. A process performed in this mode is said to be quasi-static.

If all of the states through which the system passes can be described by means of thermodynamic coordinates referring to the system as a whole, and an equation of state for all these states is valid, the process is called quasi-static. A quasi-static process is an idealization that is applicable to any thermodynamic system, including electric and magnetic ones. The conditions for such a process can never be achieved in the real world, but can often be approached with almost any degree of accuracy.

Classical thermodynamics does not quantify how infinitesimally slowly a process must take place to be considered quasi-static. Molecular gas kinetics requires only that the process proceed slowly compared to the speed of the molecules in the gas. This allows system properties to be equilibrated across the system faster than the system configuration changes. Examples of processes that seem rapid, but can be treated as quasi-static are the expansion of combustion products in a gasoline engine, or the expansion of the exhaust gases of a chemical rocket.

The reason for the introduction of a quasi-static process is to allow calculations without addressing the complications of friction within the system. This approach is no different from that of Newtonian's mechanics with its mass-less springs and ideal pulleys, or that of circuit theory with wires with no resistance, or batteries with constant voltage. Later reversible processes will be considered that are synonymous quasi-static processes because dissipative processes are ignored.

### 4.4 Quasi-Equilibrium Work Due to Moving Boundary

Consider the piston-cylinder arrangement with the included gas in it as shown in Fig. 4.5. The expanding gas can be treated as instantaneously in equilibrium at a given pressure $p$ and volume $V$. Initially the system is characterized by the pressure $p_{1}$ and volume $V_{1}$. If we let the piston move out to the new equilibrium state at position 2 that is specified by pressure $p_{2}$ and volume $V_{2}$ via a quasi-static process, all intermediate points in the travel path of the piston can be characterized by the pressure $p$ and the volume $V$ at those points. This is required because the macroscopic properties $p$ and $V$ are significant only for equilibrium states.

If $A$ is the area of the piston and the piston moves an infinitesimal distance $d l$, the force $F$ acting on the piston is $F=p A$. The infinitesimal amount of work done by the gas on the piston is:

$$
\begin{equation*}
\delta W=F \cdot d l=p A d l \tag{4.2}
\end{equation*}
$$

Fig. $4.5 p d V$ work

where $d V=A d l=$ infinitesimal displacement volume. The small delta $(\delta)$ sign in $\delta W$ represents an inexact differential. When the piston moves out from position $\mathbf{1}$ to position 2 with the volume changing from $V_{1}$ to $V_{2}$, the amount of work $W$ done by the system will be (Fig. 4.6);

$$
\begin{equation*}
W_{1-2}=\int_{V_{1}}^{V_{2}} p d V \tag{4.3}
\end{equation*}
$$

In Fig. 3.6, the magnitude of the work done is given by the area under path $1-2$. Since $p$ is at all times a thermodynamic coordinate, all the states passed through by the system as the volume changes from $V_{1}$ to $V_{2}$ must be equilibrium states, and

Fig. 4.6 Quasi-state $p d V$ work
the path 1-2 must be quasi-static. The piston moves infinitely slowly so that every state passed through is an equilibrium state.

The integration $\int p d V$ can be performed only on a quasi-state path.
The significant key in Eq. 4.3 is that we assume the pressure is known for each position as the piston moves from volume $V_{1}$ to volume $V_{2}$ and typical pressurevolume ( $P-V$ ) diagrams are shown in Fig. 4.7 below. The work $W_{1-2}$ is the crosshatched area under the $P$ - V Curve from the definition of the integration process. The integration process highlights two very important features.

First, as work is performed from state 1 to state 2 by the moving piston of Fig. 4.7, pressure and volume changes of a gas during expansion may be indicated by the area under the curve of Fig. 4.8a. However, the expansion of the gas could be represented by the area under curve of Fig. 4.8b. The area under curve of Fig. 4.8b work is significantly larger than the work under the curve of Fig. 4.8a.

The end states 1 and 2 are identical, yet the areas under the $P-V$ curves are very different. In addition to being dependent on the end points, work depends on the actual path that connects the two end points.

Thus, work is a path function, as contrasted with a point, or state, function, which is dependent only on the end-points. The differential of a path function is called an

Fig. 4.7 Work due to a moving boundary

Fig. 4.8 Work depends on the path between two states
inexact differential, whereas the differential of a point or state, function is an exact differential. An inexact differential will be denoted with the symbol $\delta$ and the integral of $\delta W$ is $W_{1-2}$ as shown in Eq. 4.2 in above, where the subscript emphasizes that the work is associated with the path as the process passes from state 1 to state 2 , however the subscript may be omitted when the work done is written simply as $W$. In this case, we would never write $W_{1}$ or $W_{2}$, since work is not associated with a state but with a process. Work is not a property.

The integral of an exact differential, for example, $d T$, would be

$$
\begin{equation*}
\int_{T_{1}}^{T_{2}} d T=T_{2}-T_{1} \tag{4.4}
\end{equation*}
$$

where $T_{1}$ is the temperature at state 1 and $T_{2}$ is the temperature at state 2 .
The second observation to be made from Eq. 4.3 is that the pressure is assumed to be constant throughout the volume at each intermediate position. The system passes through each equilibrium state shown in the $P$ - $V$ diagrams of Fig. 4.8a and b. An equilibrium state can usually be assumed even though the variables may appear to be changing quite rapidly. Combustion is a very rapid process that cannot be modeled as a quasi-static process. The other processes in the internal combustion engine (expansion, exhaust, intake, and compression) can be assumed to be quasistatic processes, as they occur at a slow rate, thermodynamically.

As a final comment regarding work we may now discuss what is meant by a simple system. For a system free of surface, magnetic, and electrical effects, the only work mode is that due to pressure acting on a moving boundary. Such simple systems require only two independent variables to establish an equilibrium state of the system composed of a homogeneous substance. If other work modes were present, such as an electric field, additional independent variables would be necessary, such as the electric field intensity.

On the P-V Diagram depicted in Fig. 4.9, an initial equilibrium state characterized by the coordinates $P_{i}, V_{i}$, and $T_{i}$, as well as a final equilibrium state coordinates by $P_{f}, V_{f}$ and $T_{f}$ of a hydrostatic system are represented by two the points $i$ and $f$, respectively.

There are many ways in which the system may expand from $i$ to $f$. For example, using Fig. 4.9 the pressure may be kept constant from $i$ to $a$ (isobaric process) and then the volume kept constant from $a$ to $f$ (isochoric processes), in which case the work done is equal to the area under the line $i a, \mathrm{~W}=2 P_{0} V_{0}$ and positive, because work is being done by the system. Another possibility is the path $i b f$, in which case the work is the area under the line $b f$, or $P_{0} V_{0}$. The straight line from $i$ to $f$ represents another path, where the work is $\frac{3}{2} P_{0} V_{0}$. The most work is done by system traversing path iaf, which does more work than traversing path if, which does more work than traversing path ibf. We can see, that the work done by a system depends not only on the initial and final states but also on the intermediate

Fig. 4.9 Work depends on the path of integration from initial equilibrium state $i$ to the final equilibrium state $f$
states, namely, on the path of integration. This basically another way of saying that, for a quasi-static process, the expression

$$
\begin{equation*}
W=\int_{V_{i}}^{V_{f}} P d V \tag{4.5}
\end{equation*}
$$

cannot be integrated until $P$ is specified as a function of $V$ using an appropriate equation of state.

The expression $P d V$ is an infinitesimal amount of work and is represented by the symbol of $\delta W$. There is, however, an important distinction between an infinitesimal amount of work and the other infinitesimals, such as $d P$ or $d V$. An infinitesimal amount of hydrostatic work is an inexact differential, that is, $\delta W$ is not the differential of an actual function of the thermodynamic coordinates. To indicate that an infinitesimal amount of work is not a mathematical differential of a function $W$ and to emphasize at all times that it is an inexact differential, it gets denoted by $\delta W$.

### 4.5 Definition of a Cycle in Thermodynamic

Any process or series of processes whose end states are identical is termed a cycle. The processes through which the system has passed can be shown on a state diagram, but a complete description of the path also requires a statement of the heat and work crossing the boundary of the system. Consider Fig. 4.10. It shows such a cycle in which a system starts at state ' 1 ' and changes pressure and volume through a path $1-2-3$ to return to its initial state ' 1 '.

Fig. 4.10 Cycle of operations

With this definition of a cycle, consider the following p-V diagrams. For curve I in Fig. 4.11a an expansion, the volume increases, $d V$ is positive, and the integral Eq. 4.3 is positive. For curve II in Fig. 4.11 b, where the gas is being compressed, the volume decreases, so the same integral is negative. According to the sign convention for work, work is done by the system in the process represented by curve I, and work is done on the system in the process represented by curve II. In Fig. 4.11c, curve I and II are drawn together so that they constitute two processes that bring the gas back to its initial state. The net work for the cycle is positive as represented by the area enclosed between the two curves.

Such a series of two or more processes, represented by a closed figure is called a cycle. The area within the closed figure in Fig. 4.11c is obviously the difference between the areas curves I and II and, therefore, represents the net work done in the cycle. Notice that the cycle is traversed in a direction such that the net work is positive, and the net work is done by the system. If the direction of the cycle were reversed, then the net work would be negative as the net work is done on the system [2].

Fig. 4.11 P-V diagram of a gas with shaded area to show work done by the system or work done on the system. a curve I, expansion; b curve II, compression; c curves I and II together constitute a cycle

### 4.6 Path Functions and Point or State Functions

Further interpretation of Eq. 4.3 and with reference to Fig. 4.12, it is possible to take a system from state 1 to state 2 along many quasi-static paths as mentioned in above, such as $A, B$ or $C$. Since the area under each curve represents the work for each process, the amount of work involved in each case is not a function of the states of the process, and it depends on the path the system follows in going from state 1 to state 2 . For this reason, work is called a path function, and $\delta W$ is an inexact or imperfect differential.

Thermodynamic properties are point or state functions, since for a given state; there is a definite value for each property. The change in a thermodynamic property of a system when changing states is independent of the path the system follows during the change of state, and depends only on the initial and final states of the system. The differentials of point, or state, functions are exact or perfect differentials, and the integration is simply

$$
\begin{equation*}
\int_{V_{1}}^{V_{2}} d V=V_{2}-V_{1} \tag{4.6}
\end{equation*}
$$

The change in volume thus depends only the end states of the system irrespective of the path the system of follows. On the other hand, work done in a quasi-static process between two given states depends on the path followed and will be expressed as;

$$
\begin{equation*}
\int_{1}^{2} \delta W \neq W_{2}-W_{11} \tag{4.7a}
\end{equation*}
$$

Or a more simple form will be written as

$$
\begin{equation*}
\int_{1}^{2} \delta W \neq W_{1-2}={ }_{1} W_{2} \tag{4.7b}
\end{equation*}
$$

Path Functions and Point or State Functions can be expressed as:

Fig. 4.12 Work-a path function

- Path functions: Magnitudes depend on the path followed during a process as well as the end states. Work $(W)$, heat $(Q)$ are considered as path functions. Work and heat are examples of path functions. Heat and work are inexact differentials. Their change cannot be written as difference between their end states. Thus;

In the case of Work,

$$
\begin{equation*}
\int_{1}^{2} \delta W \neq W_{2}-W_{1} \quad \text { abbreviated as } W_{1-2} \text { or }_{1} W_{2} \tag{4.8a}
\end{equation*}
$$

In case of Heat we will have;

$$
\begin{equation*}
\int_{1}^{2} \delta Q \neq Q_{2}-Q_{1} \quad \text { abbreviated as } Q_{1-2} \text { or }{ }_{1} Q_{2} \tag{4.8b}
\end{equation*}
$$

- Point or State Functions: Depend on the state only, and not on how a system reaches that state. Properties are point functions, (i.e. pressure, volume, temperature, etc) and they are exact differentials. For example Temperature and Volume can be expressed as,

$$
\begin{align*}
& \int_{T_{1}}^{T_{2}} d T=T_{2}-T_{1}  \tag{4.9a}\\
& \int_{V_{1}}^{V_{2}} d V=V_{2}-V_{1} \tag{4.9b}
\end{align*}
$$

In addition, to distinguish an inexact differential $\delta W$ from an exact differential $d V$ or $d P$ as we explained in Sect. 4.4 of this chapter the $\delta$ symbol is used.

From Eq. 4.2b, we can write the following expression.

$$
\begin{equation*}
d V=\frac{1}{p} \delta W \tag{4.10}
\end{equation*}
$$

Here, $1 / p$ is called the integration factor. Therefore, an inexact differential $\delta W$ when multiplied by an integrating factor $1 / p$ becomes an exact differential $d V$.

For a cyclic process, the initial and final states of the system are the same, and hence, the change in any property is zero, i.e.

$$
\begin{equation*}
\oint d V=0 \cdot \oint d \varphi=0 \cdot \oint d T=0 \tag{4.11}
\end{equation*}
$$

where the symbol $\oint$ denotes the cyclic integral around a closed path. Therefore, the cyclic integral of a property is always zero.

### 4.7 PdV Work for Quasi-Static Process

It must be emphasized that the area on a $P$-V diagram represents the work for a qua-si-static process only. For non-equilibrium processes the work cannot be calculated using $\int P d V$. Either $p$ must be given as a function of $V$ or it must be determined by some other means. Consider the following examples in which integration of $\int P d V$ can be carried out, because the path of integration is provided by an equation of state or a state function.

1. Constant pressure expansion presented by Fig. 3.13 process $1-2$, which is depicts an isobaric process (Fig. 4.13).

$$
\begin{equation*}
W_{1-2}=\int_{V_{1}}^{V_{2}} P d V=P\left(V_{2}-V_{1}\right) \tag{4.12}
\end{equation*}
$$

2. Constant volume process represented in Fig. 4.14 as the process $1-2$, depicting an isochoric process.

$$
\begin{equation*}
W_{1-2}=\int_{V_{1}}^{V_{2}} P d V=0 \tag{4.13}
\end{equation*}
$$

Fig. 4.13 Constant pressure process

Fig. 4.14 Constant volume process

Fig. 4.15 Process in which $P V$ is constant

3. A process in which $P V=$ Constant as shown in Fig. 4.15. $W_{1-2}=\int_{V_{1}}^{V_{2}} P d V, P V=P_{1} V_{1}=C$, where $C$ is a constant presentation.

$$
P=\frac{\left(P_{1} V_{1}\right)}{V}
$$

Substitution gives;

$$
\begin{align*}
W_{1-2} & =P_{1} V_{1} \int_{V_{1}}^{V_{2}} \frac{d V}{V}=P_{1} V_{1} \ln \frac{V_{2}}{V_{1}} \\
& =P_{1} V_{1} \ln \frac{P_{1}}{P_{2}} \tag{4.14}
\end{align*}
$$

4. A process in which $P V^{n}=C$ as shown in Fig. 4.16, where both $n$ and $C$ are constant.

Fig. 4.16 Process in which $P V^{n}$ is constant

$$
\begin{gather*}
P V^{n}=P_{1} V_{1}^{n}=P_{2} V_{2}^{n}=C \\
P=\frac{P_{1} V_{1}^{n}}{V^{n}} \\
W_{1-2}=\int_{V_{1}}^{V_{2}} P d V=\int_{V_{1}}^{V_{2}} \frac{P_{1} V_{1}^{n}}{V^{n}} \cdot d V=\left(P_{1} V_{1}^{n}\right)\left[\frac{V^{-n+1}}{-n+}\right]_{V_{1}}^{V_{2}} \\
=\frac{P_{1} V_{1}^{n}}{1-n}\left(V_{2}^{1-n}-V_{1}^{1-n}\right)=\frac{P_{2} V_{2}^{n} \times V_{2}^{1-n}-P_{1} V_{1}^{n} \times V_{1}^{1-n}}{1-n}  \tag{4.15}\\
=\frac{P_{1} V_{1}-P_{2} V_{2}}{n-1}=\frac{P_{1} V_{1}}{n-1}\left[1-\left(\frac{P_{2}}{P}\right)^{n-1 / n}\right]
\end{gather*}
$$

For each of these processes the inexact differential can be converted to an exact differential so that the integration can easily be performed. The states that the quasi-static process passes through are defined by the function that performs this conversion

### 4.8 Non-equilibrium Work

In order to have a concept for a non-equilibrium work process, we consider a system to be formed by the gas in Fig. 4.17. In part (a) work is crossing the boundary of the system by means of the rotating shaft and the volume doesn't change. We calculate the work input, neglecting any friction in the pulley system, by multiplying the distance the weight drops by its weight. This action does not mean the work is equal to $W=\int P d V$, which is zero. The paddle wheel provides a non-equilibrium work mode.

Suppose the membrane in Fig. 4.17b ruptures, allowing the gas to be expanded and fill the evacuated volume. There is no resistance to the expansion of the gas at

Fig. 4.17 A system with rotating shaft paddle and weight attached to a pulley

Fig. 4.18 Illustration of example 4.1

the moving boundary as the gas fills the volume; hence, there is no work done. Yet there is a change in volume by the gas's expansion to fill the entire container. The sudden expansion is a non-equilibrium process, and again the $W=\int P d V$ relationship cannot be used to calculate the work.
Example 4.1 A $100-\mathrm{kg}$ mass drops 3 m , resulting in an increased volume in the cylinder of 0.002 of Fig. 4.18. The piston maintains a constant gage pressure of 200 kPa . Determine the net work done by the gas on the surroundings.
Solution Assessing the problem and considering Fig. 3.18, we see that, the paddle wheel does work on the system, the gas, due to the 100 kg mass dropping 3 m , consequently the work done is negative.

$$
W=-(F)(d)=-(m g)(d)=-(100)(9.8)(3)=-2940 \text { Joules }
$$

The work done by the system on this frictionless piston is positive since the system is doing the work. It is

$$
W=(P A)(h)=(P)(A h)=P V=(200000)(0.002)=400 \text { Joules }
$$

Therefore, the net work done is;

$$
W_{\text {net }}=-2940+400=-2540 \text { Joules }
$$

### 4.9 Other Work Modes

There are many other forms of work than $W=\int P d V$ or simple displacement work on a straight line. Some additional types of work are,
a. Electrical Work: When a current flows through a resistor that is shown in Fig. 4.19, taken as a system, there is work transfer into the system. This is because the current can drive a motor, the motor can drive a pulley and the pulley can raise a weight.

Fig. 4.19 Electrical work illustration

Work and Heat Transfer

The current flow is $I=\frac{d C}{d \tau}$, and $C$ is the charge in coulombs and $\tau$ is the time in seconds. Thus $d C$ is the charge crossing a boundary during time $d \tau$. If $E$ is the voltage potential, the work is given by:

$$
\begin{aligned}
\delta W & =E \cdot d C \\
& =E I d \tau
\end{aligned}
$$

Therefore

$$
\begin{equation*}
W=\int_{1}^{2} E I d \tau \tag{4.16}
\end{equation*}
$$

The electrical power will be;

$$
\begin{equation*}
\dot{W}=\lim _{d \tau \rightarrow \infty} \frac{d W}{d \tau}=E I \tag{4.17}
\end{equation*}
$$

Work is transferred at this rate.
b. Shaft Work: When a shaft, taken as the system according to Fig. 4.10, is rotated by a motor, there is work transfer into the system. This is because the shaft can rotate a pulley which can raise a weight. If $T$ is the torque applied to the shaft and $d \theta$ is the angular displacement of the shaft, the shaft work is then given by:

$$
\begin{equation*}
W=\int_{1}^{2} T d \theta \tag{4.18}
\end{equation*}
$$

and the shaft power is

$$
\begin{equation*}
\dot{W}=\int_{1}^{2} T \frac{d \theta}{d \tau}=T \omega \tag{4.19}
\end{equation*}
$$

where $\omega$ is the angular velocity and $T$ is applied torque (Fig. 4.20).
c. Paddle-Wheel Work or Stirring Work: As the weight is lowered, and the paddle wheel turns as shown in Fig. 4.21, there is work transfer into the fluid system which gets stirred. Since the volume of the system remains constant, $\int P d V=0$.

Fig. 4.20 Shaft work illustration

If $m$ is the mass of the weight lowered through a distance $d z$ and $T$ is the torque transmitted by the shaft in rotating through an angle $d \theta$, the differential work transfer to the fluid is given by;

$$
d W=m g d z=T d \theta
$$

Fig. 4.21 Paddle-wheel work illustration
and the total work transfer is presented by.

$$
\begin{equation*}
W=\int_{1}^{2} m g d z=\int_{1}^{2} T d \theta \tag{4.20}
\end{equation*}
$$

d. Flow Work: The flow work, significant only in a flow process or an open system, represents the energy transferred across the system boundary because of the energy imparted to the fluid by a pump, blower or compressor to make the fluid flow across the control volume. Flow work is analogous to displacement work. Let $P$ be the fluid pressure in the plane of the imaginary piston, which acts in a direction normal to it as it can be seen in Fig. 4.22. The work done on this imaginary piston by the external pressure as the piston moves forward is given by:

$$
\begin{equation*}
\delta W_{\text {flow }}=p d V \tag{4.21}
\end{equation*}
$$

Fig. 4.22 Flow work illustration

where $d V$ is the volume of fluid element about to enter the system.

$$
\begin{equation*}
\delta W_{\text {flow }}=p v d m \tag{4.22}
\end{equation*}
$$

where $d V=v d m$. Therefore, flow work at inlet Fig 4.22 is given by:

$$
\begin{equation*}
\left(\delta W_{\text {flow }}\right)_{\text {in }}=p_{1} v_{1} d m_{1} \tag{4.23}
\end{equation*}
$$

Equation 4.23 can also be derived in a slightly different manner. If the normal pressure $p_{1}$ is exerted against the area $A_{1}$, giving a total force $\left(p_{1} A_{1}\right)$ against the piston, in time $d \tau$, this force moves a distance a distance $V_{1} d \tau$, where $V_{1}$ is the velocity of flow (piston). The work in time $d \tau$ is $p_{1} A_{1} V_{1} d \tau$, or the work per unit time is $p_{1} A_{1} V_{1}$. Since the flow rate

$$
\begin{equation*}
w_{1}=\frac{A_{1} V_{1}}{v_{1}}=\frac{d m_{1}}{d \tau} \tag{4.24}
\end{equation*}
$$

The work done in time $d \tau$ becomes;

$$
\begin{equation*}
\left(\delta W_{\text {flow }}\right)_{\text {in }}=p_{1} v_{1} d m_{1} \tag{4.25}
\end{equation*}
$$

Similarly, flow work of the fluid element leaving the system is;

$$
\begin{equation*}
\left(\delta W_{\text {flow }}\right)_{\text {out }}=p_{2} v_{2} d m_{2} \tag{4.26}
\end{equation*}
$$

The flow work per unit mass is thus

$$
\begin{equation*}
W_{\text {flow }}=p v \tag{4.27}
\end{equation*}
$$

It is the displacement work done by mass moving across the system boundary.
e. Work Done in Stretching a Wire: Let us consider a wire as the system. If the length of the wire is changed from $L$ to $L+d L$ by the tension $f_{T}$ the infinitesimal amount of work done is equal to,

$$
\delta W=-f_{T} d L
$$

The minus sign is used because a positive value of $d L$ means an expansion of the wire, for which work must be done on the wire, i.e., negative work. For a finite change of length,

$$
\begin{equation*}
W=-\int_{1}^{2} f_{T} d L \tag{4.28}
\end{equation*}
$$

If the stretching is kept within the elastic limit, where $E$ is the modulus of elasticity, $s$ is the stress, $\varepsilon$ is the strain, and $A$ is the cross-sectional area, then;

$$
\begin{gathered}
f_{T}=s A=E \varepsilon A \quad \text { since } \frac{s}{\varepsilon}=E \\
d \varepsilon=\frac{d L}{L} \\
\delta W=-f_{T} d L=-E \varepsilon A L d \varepsilon
\end{gathered}
$$

Therefore;

$$
\begin{equation*}
W=-A \varepsilon L \int_{1}^{2} \varepsilon d \varepsilon=-\frac{A E L}{2}\left(\varepsilon_{2}^{2}-\varepsilon_{1}^{2}\right) \tag{4.29}
\end{equation*}
$$

f. Work Done in Changing the Area of a Surface Film: A film on the surface of a liquid has a surface tension, which is a property of the liquid and the surroundings. The surface tension acts to make the surface area of the liquid a minimum. It has units of force per unit length. The work done on a homogeneous liquid film in changing its surface area by an infinitesimal amount $d A$ is;

$$
\delta W=-\sigma d A
$$

where $\sigma$ is the surface tension $(\mathrm{N} / \mathrm{m})$. Therefore.

$$
\begin{equation*}
W=-\int_{1}^{2} \sigma d A \tag{4.30}
\end{equation*}
$$

g. Magnetization of a Paramagnetic Solid: The work done per unit volume on a magnetic material through which the magnetic and magnetization fields are uniform is;

$$
\delta W=-H d I
$$

and

$$
\begin{equation*}
W_{1}-W_{2}=-\int_{I_{1}}^{I_{2}} H d I \tag{4.31}
\end{equation*}
$$

where $H$ is the field strength, and $I$ is the component of the magnetization field in the direction of the field. The minus sign provides that an increase in magnetization (positive $d I$ ) involves negative work.
The following equations summarize the different forms of work transfer:
Displacement Work:
Compressible Fluid $W=\int_{1}^{2} p d V$

Electrical Work $W=\int_{1}^{2} E d C=\int_{1}^{2} E I d \tau$
Shaft Work $W=\int_{1}^{2} T d \theta$
Surface Film $W=\int_{1}^{2} \sigma d A$
Stretched Wire $W=\int_{1}^{2} f_{T} d L$
Magnetized Solid $W=-\int_{1}^{2} H d I$
It may be noted in the above expressions that the work is equal to the integral of the product of an intensive property and the change in its related extensive property. These expressions are valid only for quasi-static processes.

There are some other forms of work, which can be identified in processes that are not quasi-static, for example, the work done by shearing forces in a process involving friction in a viscous fluid.

Example 4.2 One kg of steam with a quality of $20 \%$ is heated at a constant pressure of 200 kPa until the temperature reaches 700 K . Calculate the work done by the steam.

Solution The work is given by;

$$
W=\int P d V=P\left(V_{2}-V_{1}\right)=m P\left(v_{2}-v_{1}\right)
$$

To evaluate the work we must determine $v_{1}$ and $v_{2}$. Using Steam Tables, we find

$$
v_{f}+x\left(v_{g}-v_{f}\right)=0.001061+(0.2)(0.8857-0.001061)=0.1780 \mathrm{~m}^{3} / \mathrm{kg}
$$

From the superheat table we locate state 2 at $T_{2}=400{ }^{\circ} \mathrm{C}$ and $P_{2}=0.2 \mathrm{MPa}$ as:

$$
v_{2}=1.61172 \mathrm{~m}^{3} / \mathrm{kg}
$$

The work is then

$$
W=(1)(200)(1.61172-0.1780)=286.7 \mathrm{~kJ}
$$

Note: With the pressure having units of kPa , the result is in kJ
Example 4.3 A $110-\mathrm{mm}$-diameter cylinder contains $100 \mathrm{~cm}^{3}$ of water at 330 K . A $50-\mathrm{kg}$ piston sits on top of the water. If heat is added until the temperature is 500 K , find the work done.

Solution The pressure in the cylinder is due to the weight of the piston and remains constant. Assuming a frictionless seal (this is always done unless information is given to the contrary), a force balance provides

$$
m g=p A-p_{\text {atm }} A \quad p \frac{\pi(0.110)^{2}}{4}=(50)(9.81)+101325.0 \frac{\pi(0.110)^{2}}{4}
$$

The atmospheric pressure is included so that absolute pressure results. The volume at the initial state 1 is given as

$$
V_{1}=100 \times 10^{-6}=10^{-4} \mathrm{~m}^{3}
$$

Using $v_{1}$ at 330 K , the mass is calculated to be

$$
m=\frac{V_{1}}{v_{1}}=\frac{10^{-4}}{0.001015}=0.09852 \mathrm{~kg}
$$

At state 2 the temperature is 500 K and the pressure is 0.1516 MPa . Interpolating to find the specific volume gives,

$$
\begin{gathered}
v_{2}=3.18482+\frac{(1.61172-3.18482)}{(0.2-0.101325)}(0.152938 .6-0.101325)=2.362 \mathrm{~m}^{3} / \mathrm{kg} \\
V_{2}=m v_{2}=(0.09852)(2.362)=0.2327 \mathrm{~m}^{3}
\end{gathered}
$$

Finally, the work is calculated to be

$$
W=P\left(V_{2}-V_{1}\right)=152938.6^{*}(0.2327-0.0001)=35573.5 \mathrm{~J} \text { or } 35.6 \mathrm{~kJ}
$$

Example 4.4 Energy is added to a piston-cylinder arrangement, and the piston is withdrawn in such a way that the quantity $P V$ remains constant. The initial pressure and volume are 200 kPa and $2 \mathrm{~m}^{3}$, respectively. If the final pressure is 100 kPa , calculate the work done by the gas on the piston.

Solution The work is found from Eq. 3.3 to be

$$
W_{1-2}=\int_{2}^{V_{2}} P d V=\int_{2}^{V_{2}} \frac{C}{V} d V
$$

Where we have used $P V=C$. To calculate the work we must find $C$ and $V_{2}$. The constant $C$ is found from

$$
C=P_{1} V_{1}=(200)(2)=400 \mathrm{~kJ}
$$

To find $V_{2}$ we use $P_{1} V_{1}=P_{2} V_{2}$, which is, of course, the equation that would result from an isothermal process (constant temperature) involving an ideal gas. This can be written as

$$
\frac{P_{1} V_{1}}{P_{2}}=\frac{(200)(2)}{100}=4 \mathrm{~m}^{3}
$$

Finally,

This is positive, since work is done during the expansion process by the system (the gas contained in the cylinder).

Example 4.5 Determine the horsepower required to overcome the wind drag on a modern car traveling $90 \mathrm{~km} / \mathrm{h}$ if the drag coefficient $C_{D}$.is 0.2 . The drag force is given by $F_{D}=\frac{1}{2} \rho V^{2} A C_{D}$, where $A$ is the projected area of the car and $V$ is the velocity. The density $\rho$ of air is $1.23 \mathrm{~kg} / \mathrm{m}^{3}$. Use $A=2.3 \mathrm{~m}^{2}$.

Solution To find the drag force on a car we must express the velocity in $\mathrm{m} / \mathrm{s}$ :
$V=(90)(1000 / 3600)=25 \mathrm{~m} / \mathrm{s}$. The drag force is then
The drag force is then

$$
F_{D}=\frac{1}{2} \rho V^{2} A C_{D}=\left(\frac{1}{2}\right)(1.23)\left(25^{2}\right)(2.3)(0.2)=177 \mathrm{~N}
$$

To move this drag force at $25 \mathrm{~m} / \mathrm{s}$ the engine must do work at the rate

$$
W=F_{D} V=(177)(25)=4425 \mathrm{~W}
$$

The horsepower is then

$$
H_{P}=\frac{4425 \mathrm{~W}}{746 \mathrm{~W} / \mathrm{hp}}=5.93 \mathrm{hp}
$$

Example 4.6 The drive shaft in an automobile delivers $100 \mathrm{~N}-\mathrm{m}$ of torque as it rotates at 3000 rpm . Calculate the horsepower delivered.
Solution The power is found by using $\dot{W}=T \omega$. This requires $\omega$ to be expressed in $\mathrm{rad} / s$.

$$
\omega=(3000)(2 \pi)\left(\frac{1}{60}\right)=314.2 \mathrm{rad} / \mathrm{s}
$$

Hence $\dot{W}=(100)(314.2)=31420$ Watt or $H_{p}=\frac{31420}{746}=42.1 \mathrm{hp}$

Example 4.7 The air in a circular cylinder of Fig. 4.23 is heated until the spring is compressed 50 mm . Find the work done by the air on the frictionless piston. The spring is initially unstretched, as shown in the figure.

Solution The pressure in the cylinder is initially found from a force balance:

$$
P_{1} A_{1}=P_{\mathrm{atm}} A+W \quad P_{1} \frac{\pi(0.1)^{2}}{4}=(101325) \frac{\pi(0.1)^{2}}{4}+(50)(9.81) \quad \therefore p_{1}=163777 \mathrm{~Pa}
$$

Fig. 4.23 For example 4.7

To raise the piston a distance of 50 mm , without the spring, the pressure would be constant required would be force times distance:

$$
W=P A \times d=(163777) \frac{\pi(0.1)^{2}}{4}(0.05)=64.32 \text { Joules }
$$

For the additional work performed to compress the spring, with spring constant $K$ and the compression from a length $x_{1}$ to $x_{2}$ the force doing the work given by $F=K x$.This becomes,

$$
W=\int_{x_{1}}^{x_{2}} F d x=\int_{x_{1}}^{x_{2}} K x d x=\frac{1}{2} K\left(x_{2}^{2}-x_{1}^{2}\right)=\left(\frac{1}{2}\right)(2500)(0.05)^{2}=3.125 \text { Joules }
$$

The total work is then, found by summing the above two values:

$$
W_{\text {Total }}=64.32+3.125=67.45 \text { Joules }
$$

### 4.10 Reversible and Irreversible Process

Reversible Process: A reversible process (also sometimes called a quasi-static process) is one that can be stopped at any stage and reversed so that the system and surroundings are exactly restored to their initial stage. See Fig. 4.24

This Process has the following characteristics:

1. It must pass through the same states on the reversed path as were initially visited on the forward path.
2. This process when undone will leave no history of events in the surroundings. 3. It must pass through a continuous series of equilibrium states.

Fig. 4.24 Reversible process

No real process is truly reversible but some processes may approach reversibility, to a close approximation.

Example Some examples of nearly reversible processes are:

1. Frictionless relative motion
2. Expansion and compression of a spring
3. Frictionless adiabatic expansion or compression of a fluid
4. Polytropic expansion or compression of a fluid
5. Isothermal expansion or compression of a fluid
6. Electrolysis

Irreversible Process An irreversible process is one in which there are frictionslike losses, usually involving heat transfer, such that it cannot be reversed. See Fig. 4.25.

An irreversible process is usually represented by a dotted (or discontinuous) line joining the end states to indicate that the intermediate states are indeterminate. Irreversibilities are of two types:

Fig. 4.25 Irreversible process

1. External Irreversibilities: These are associated with dissipating effects outside the working fluids. An example is mechanical friction occurring during due to some external movement.
2. Internal Irreversibilities: These are associated with dissipating effects within the working fluid. An example is unrestricted expansion of a gas.

Example: Some examples of irreversible processes are:

1. Relative motion with friction
2. Combustion
3. Diffusion
4. Free expansion
5. Throttling
6. Electricity flow through a resistance
7. Heat Transfer
8. Plastic deformation

### 4.11 Definition of Energy (Thermal Energy or Internal Energy)

Energy is generally defined as the potential to do work. Mechanical energy is classically divided into kinetic and potential energy. Kinetic mechanical energy is related to the velocity that a mass possesses. Potential mechanical energy is related to the distance a mass is above some neutral reference plane. Tension in a spring or surface film tension are other forms of potential mechanical energy. There are many other forms of energy including electrical, chemical, and nuclear. Thermodynamics deals with another type of energy called "thermal energy" or "internal energy". If energy were not such a broad term, it might simply be possible to call the internal energy stored in a fluid simply "energy". But to distinguish the thermal energy stored in a fluid as a result of the temperature of the fluid, from other forms of energy the normal thermodynamic term is Internal Energy. Internal Energy, or thermal energy, is generally represented by a capital $\mathbf{U}$ (sometimes and E). Normally the two ways that the Internal Energy of a system is changed is by Work or Heat Transfer. Both Work and Heat Transfer affect the Internal Energy of a system. When a system does Work on its environment, it gives up Internal Energy. When Heat is transferred to a system, its Internal Energy increases. Heat Transfer, like Work, is a path dependent process. Both Heat transfer and Work represent energy in transition. These are the only forms in which energy can cross the boundaries of a system. Neither heat nor work can exist as stored energy.

### 4.12 Definition of Heat

Detailed analysis of heat and heat transfer will be addressed in Chapter twelve of the text, but it will be discussed conceptually at this time to relate it to changes in Internal Energy of systems. In the preceding section, several work modes by which energy is transferred macroscopically to or from a system were addressed. Energy can also be transferred microscopically to or from a system by means of interactions between the molecules that form the surface of the system and those that form the surface of the surroundings. If the molecules of the system boundary are more active than those of the surrounding boundary, they will transfer energy from the system to the surroundings, with the faster molecules transferring energy to the slower molecules. On this microscopic scale the energy is transferred by a work mode: collisions between particles. A force occurs over an extremely short time span, with work transferring energy from the faster molecules to the slower ones. The problem is that this microscopic transfer of energy is not observable macroscopically as any of the work modes addressed so far and a means must be developed to account for it.

System temperature is a property, which increases with increased molecular activity. Thus, it is not surprising that microscopic energy transfer can be related to the macroscopic property temperature. This macroscopic transfer of energy that we cannot account for by any of the classic macroscopic work modes will be called heat. Heat is energy transferred across the boundary of a system due to a difference in temperature between the system and its surroundings. A system does not contain heat, it contains energy, and heat is energy in transit.

Heat, like work, is something that crosses a boundary. Because a system does not contain heat, heat is not a property. Thus, its differential is inexact and is written as $\delta Q$ where $Q$ is the heat transfer. For a particular process between state 1 and state 2 the heat transfer could be written as $Q_{1-2}$ (or ${ }_{1} Q_{2}$ ), but it will generally be denoted by $Q$. The rate of heat transfer will be denoted by $\dot{Q}$.

By convention, if heat is transferred to a system it is considered positive. If it is transferred from a system, it is negative. This is opposite from the convention chosen for work; if a system performs work on the surroundings it is positive. Positive heat transfer adds energy to a system, whereas positive work subtracts energy from a system. A process in which there is zero heat transfer is called an adiabatic process. Such a process is approximated experimentally by insulating the system so that negligible heat is transferred.

Heat denoted by the symbol of $Q$, and it may be defined in an analogous way to work as follows:
"Heat is something which appears at the boundary when a system changes its state due to a difference in temperature between the system and its surroundings".

Heat, like work, is a transient quantity, which only appears at the boundary while a change is taking place within the system.

It is apparent that neither $\delta W$ or $\delta Q$ are exact differentials and therefore any integration of the elemental quantities of work or heat which appear during a change from state 1 to state 2 must be written as;

$$
\text { -), } \int_{1}^{2} \delta W=W_{1}-W_{2}=W_{1-2}=W_{1} W_{2} \text { or simply } W
$$

and

$$
\begin{equation*}
\int_{1}^{2} \delta Q=Q_{1}-Q_{2}=Q_{1-2}=1 Q_{2} \tag{4.32b}
\end{equation*}
$$

Sign Convention If the heat flows into a system from the surroundings, the quantity is said to be positive and, conversely, if heat flows from the system to the surroundings it is said to be negative. In other words, we can say:

- Heat received by the system $=+Q$
- Heat rejected or given up by the system $=-Q$

### 4.13 Comparison of Work and Heat

There certain Similarities and Dissimilarities between Work and Heat,

## 1. Similarities:

1. Both are path functions and inexact differentials.
2. Both are boundary phenomenon i.e., both are recognized at the boundaries of the system as they cross them.
3. Both are associated with a process, not a state. Unlike properties, work or heat has no meaning at a state.
4. Systems possess energy, but not work.

## 2. Dissimilarities:

1. In heat transfer temperature difference is required.
2. In a stable system there cannot be work transfer, however, there is no restriction for the transfer of heat.
3. The sole effect external to the system from work could be reduced to rise of a weight but in the case of a heat transfer other effects are also observed.

In case of heat and heat transfer process, it is sometimes convenient to refer to heat transfer per unit mass. Heat transfer per unit mass will be designated by letter $q$ and defined by the following expression as;

$$
\begin{equation*}
q=\frac{Q}{m} \tag{4.33}
\end{equation*}
$$

There are three modes of heat transfer,

1. Conduction
2. Convection
3. Radiation

Briefly, each of these modes can be explained as follows,

## 1. Conduction

This results from the collision of neighboring molecules in which the kinetic energy of vibration of one molecule is transferred to its nearest neighbor. Thermal energy is thus spread by conduction even if the molecules themselves do not move their location appreciably. The mathematical expression of this process is given by Fourier's Law of heat transfer, which for a one-dimensional plane wall takes the form

$$
\begin{equation*}
\dot{Q}=-k A \frac{\Delta T}{\Delta L} \tag{4.34}
\end{equation*}
$$

where $k$ is the thermal conductivity with units of $\mathrm{W} / \mathrm{m} . \mathrm{K}$ ( $\mathrm{Btu} / \mathrm{sec}-\mathrm{ft}-{ }^{-} \mathrm{R}$ ), $\Delta L$ is the thickness of the wall, $\Delta T$ is the temperature difference, and $A$ is the wall area. Often, the heat transfer is related to the common $R$-factor, resistivity, given by $R_{\text {mat }}=\Delta L / k$. Note that heat flows in the opposite direction of the temperature gradient.

## 2. Convection

In addition to conduction, when a vibrating molecule moves from one region to another, it takes its thermal energy with it. This type of movement of thermal energy is called convection. Convection is expressed in terms of the temperature difference between the bulk temperature of a fluid $T_{\infty}$ and the temperature of the surface $T_{s}$. Newton's law of cooling expresses this as;

$$
\begin{equation*}
\dot{Q}=h_{c} A\left(T_{s}-T_{\infty}\right) \tag{4.35}
\end{equation*}
$$

where $h_{c}$ is the convective heat transfer coefficient, with units of $\mathrm{W} / \mathrm{m}^{2} \mathrm{~K}$ ( $\mathrm{Btu} / \mathrm{sec}$ -$\mathrm{ft}^{2-0} \mathrm{R}$ ), and depends on the properties of the fluid including its velocity and the wall geometry. Free convection occurs due to the temperature difference only, whereas forced convection results from the fluid being forced, as with a fan. Convection is once again in the direction opposite the temperature difference. Heat must move from high to low temperature.

## 3. Radiation

Radiation is energy that is transmitted by electromagnetic radiation. All bodies emit electromagnetic radiation as a result of electron transitions within their atoms. The electrons are moved to excited states via collisions with other atoms. When they return to their normal state, they emit radiation. At absolute zero, temperature there is no atomic motion, so there is no exciting of the electrons and bodies do not radiate. Radiation heat transfer is calculated using the Stefan-Boltzmann law and accounts for the energy emitted and the energy absorbed from the surroundings.

$$
\begin{equation*}
\dot{Q}=\varepsilon \sigma A\left(T^{4}-T_{\text {surr }}^{4}\right) \tag{4.36}
\end{equation*}
$$

where $\sigma$ is the Stefan-Boltzmann constant $\left(\sigma=5.67 \times 1^{-8} \mathrm{~W} / \mathrm{m}^{2} . \mathrm{K}^{4}\right), \varepsilon$ is the emissivity which is a number within the interval of $0<\varepsilon<1$ where $\varepsilon=1$ is for a blackbody, a body that emits the maximum amount of radiation, and $T_{\text {surr }}$ is the uniform temperature of the surroundings. The temperatures must be absolute tem-
peratures and the area A must be the area over which the systems in question face each other.

Example: 4.8 A paddle wheel adds work to a rigid container by dropping a 50 kg weight a distance of 2 m from a pulley. How much heat must be transferred to result in an equivalent effect?

Solution For this non-equilibrium process the work is given by;

$$
W=(m g)(d)=(50)(9.8)(2)=980 \text { Joules }
$$

The heat $Q$ that must be transferred equals the work, 980 J .
Example: 4.9 A $10-\mathrm{m}$ long by 3-m high wall is composed of an insulation layer with $R=2 \mathrm{~m}^{2} \mathrm{~K} / \mathrm{W}$ and a wood layer with $R=0.5 \mathrm{~m}^{2} \mathrm{~K} / \mathrm{W}$. Estimate the heat transfer rate through the wall if the temperature difference is $40^{\circ} \mathrm{C}$.

Solution The total resistance to heat flow through the wall is

$$
R_{\text {Total }}=R_{\text {Insulation }}+R_{\text {Wood }}=2+0.5=2.5 \mathrm{~m}^{2} \cdot \mathrm{~K} / \mathrm{W}
$$

The heat transfer rate is then;

$$
\dot{Q}=\frac{A}{R_{\text {Total }}} \Delta T=\frac{10 \times 3}{2.5} \times 40=480 \mathrm{~W}
$$

Note that $\Delta T$ measured in ${ }^{\circ} \mathrm{C}$ is the same as $\Delta T$ measured in Kelvin
Example: 4.10 The heat transfer from a 2-m-diameter sphere to a $25^{\circ} \mathrm{C}$ air stream over a time interval of 1 h is 3000 kJ . Estimate the surface temperature of the sphere if the heat transfer coefficient is $10 \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}$. Note that the surface area of a sphere is $4 \pi r^{2}$.

Solution The heat transfer is

$$
Q=h_{c} A\left(T_{s}-T_{\infty}\right) \text { or } 3 \times 10^{6}=10 \times 4 \pi \times 1^{2}\left(T_{s}-25\right) \times 3600
$$

The surface temperature is calculated to be

$$
T_{s}=31.6^{\circ} \mathrm{C}
$$

Example: 4.11 Estimate the rate of heat transfer from $200^{\circ} \mathrm{C}$ sphere which has an emissivity of 0.8 if it is suspended in a cold room maintained at $-20^{\circ} \mathrm{C}$. The sphere has a diameter of 20 cm .

Solution The rate of heat transfer is given by;

$$
\dot{Q}=\varepsilon \sigma A\left(T^{4}-T_{\text {surr }}^{4}\right)=0.8 \times 5.67 \times 10^{-8} \times 4 \pi \times 0.1^{2}\left(473^{3}-253^{4}\right)=262 \mathrm{~J} / \mathrm{s}
$$

## Chapter 5 First Law of Thermodynamics

The first law of thermodynamics states that the total energy of a system remains constant, even if it is converted from one form to another.

### 5.1 Introduction

The first law of thermodynamics is generally thought to be the least demanding to grasp, for it is an extension of the law of conservation of energy, meaning that energy can be neither created nor destroyed. However much energy there was at the start of the universe, there will be that amount at the end. However, thermodynamics is a subtle subject, and the first law is much more interesting than this remark might suggest. Moreover, like the zeroth law, which provided an impetus for the introduction of the property 'temperature' and its clarification, the first law motivates the introduction and helps to clarify the meaning of the elusive concept of 'energy'.

Energy balance, based on the First Law of Thermodynamics, is developed to better understand any process, to facilitate design and control, to point at the needs for process improvement, and to enable eventual optimization. The degree of perfection in the energy utilization of the process, or its particular parts, allows comparison with the degree of perfection, and the related process parameters, to those in other similar processes. Comparison with the currently achievable values in the most efficient systems is especially important. Priorities for the required optimization attempts for a system, or its components, can be established. Such priorities can be carried out based either on the excessive energy consumption, or on the particularly low degree of perfection.

However, the energy approach has some deficiencies. Generally, energy exchange is not sensitive to the assumed direction of the process, e.g., energy analysis allows heat to be transferred spontaneously in the direction of the increasing temperature. Energy also does not distinguish its quality, e.g., 1 Watt of heat equals 1 Watt of work or electricity.

The first law of thermodynamics states that the total energy of a system remains constant, even if it is converted from one form to another. For example, kinetic
energy-the energy that an object possesses when it moves-is converted to heat energy when a driver presses the brakes on the car to slow it down. The first law of thermodynamics relates the various forms of kinetic and potential energy in a system to the work, which a system can perform, and to the transfer of heat. This law is sometimes taken as the definition of internal energy, and also introduces an additional state variable, enthalpy. The first law of thermodynamics allows for many possible states of a system to exist. However, experience indicates that only certain states occur. This eventually leads to the second law of thermodynamics and the definition of another state variable called entropy.

Work is motion against an opposing force. Raising a weight against the opposing force of gravity requires work. The magnitude of the work depends on the mass of the object, the strength of the gravitational pull on it, and the height through which it is raised. Work is the primary foundation of thermodynamics and in particular of the first law. Any system has the capacity to do work. For instance, a compressed or extended spring can do work such as that can be used to bring about the raising of a weight. An electric battery has the capacity to do work, for it can be connected to an electric motor, which in turn can be used to raise a weight. It is not an entirely obvious point, but when an electric current passes through a heater, it is doing work on the heater, for the same current could be used to raise a weight by passing it through an electric motor rather than the heater. Then why a heater is called a 'heater' and not a 'worker' is obvious from the concept of heat that was defined in Chap. 4.

The first law of thermodynamics is commonly called the conservation of energy. In elementary physics courses, the study of the conservation of energy emphasizes changes in mechanical kinetic and potential energy and their relationship to work. A more general form of conservation of energy includes the effects of heat transfer and internal energy changes. This more general form is usually called the first law of thermodynamics. Other forms of energy may also be included, such as electrostatic, magnetic, strain, and surface energy.

To understand and have better concept of work from thermodynamics point of view, a term is needed to denote the capacity of a system to do work. That term is energy. A fully stretched spring has a greater capacity to do work than the same spring only slightly stretched. A liter of hot water has a greater energy than a liter of cold water. Therefore concept of energy is just a measure of the capacity of a system to do work.

The First Law of Thermodynamics states that energy can neither be created nor destroyed only altered in form. For any system, energy transfer is associated with mass crossing the control boundary, external work, or heat transfer across the boundary. These produce a change of stored energy within the control volume. The mass flow of a fluid is associated with the kinetic, potential, internal, and "flow" energies that affect the overall energy balance of the system. The exchanges of external work and heat complete the energy balance. That is why The First law of Thermodynamics is referred to as the Conservation of Energy principle, meaning that energy can neither be created nor destroyed, but rather transformed into various forms as the fluid within the control volume changes. A system is a region in
space (control volume) through which a working fluid may or may not pass. The various energies associated with the fluid are then observed as they cross the boundaries of the system and the balance is made. As discussed in Chap. 1, a system may be one of three types:

## 1. Isolated System

## 2. Closed System

3. Open System

The open system, the most general of the three, allows mass, heat, and external work to cross the control boundary. The balance is expressed in work, as all energies into the system are equal to all energies leaving the system plus the change in storage of energies within the system.

The system might be a mechanical device, a biological organism, or a specified quantity of material such as the refrigerant in an air conditioner, or the steam expanding in a turbine. A thermodynamic system is a system that can interact (and exchange energy) with its surroundings, or environment, in at least two ways, one of which is heat transfer. A familiar example is a quantity of popcorn kernels in a pot with a lid. When the pot is placed on a stove, energy is added to the popcorn by conduction of heat; as the popcorn pops and expands, it does work as it exerts an upward force on the lid and displaces it (Fig. 5.1).

The state of the popcorn changes in this process, since the volume, temperature, and pressure of the popcorn all change as it pops. A process such as this one, in which there are changes in the state of a thermodynamic system, is called a thermodynamic process. With thermodynamic systems, it is essential to define clearly at the start exactly what is and is not included in the system. Only then can the energy transfers be unambiguously described. For instance, in the popcorn example, the system was defined to include the popcorn, but not the pot, lid, or stove.

Fig. 5.1 The popcorn in the pot is a thermodynamic system. In the thermodynamic process shown here, heat is added to the system, and the system does work on its surroundings to lift the lid of the pot

### 5.2 System and Surroundings

The First Law of Thermodynamics tells us that energy is neither created nor destroyed, thus the energy of the universe is a constant. However, energy can certainly be transferred from one part of the universe to another. To work out thermodynamic problems we will need to isolate a certain portion of the universe (the system) from the remainder of the universe (the surroundings).

For example, consider the pendulum example given in the last section. In real life, there is friction and the pendulum will gradually slow down until it comes to rest. We can define the pendulum as the system and everything else as the surroundings. Due to friction there is a small but steady transfer of heat energy from the system (pendulum) to the surroundings (the air and the bearing upon which the pendulum swings). Due to the first law of thermodynamics the energy of the system must decrease to compensate for the energy lost as heat until the pendulum comes to rest. [Remember though the total energy of the universe remains constant as required by the First Law.]

When it comes time to work homework, quiz and exam problems not to mention to design a power plant the first Law of Thermodynamics will be much more useful if we can express it as an equation.

$$
\Delta E=Q+W \text { (First Law of Thermodynamicsa chemical reaction the energy })
$$

- $\Delta E=$ The change internal energy of the system.
- $Q=$ The heat Transferred into/out of the system.
- $W=$ The work done by/on the system.

This reformulation of the First Law tells us that once we define a system (remember we can define the system in any way that is convenient) the energy of the system will remain constant unless there heat added or taken away from the system, or some work takes place.

### 5.2.1 Internal Energy

We have already discussed work and heat extensively, but a few comments are in order regarding internal energy. The internal energy encompasses many different things, including:

- The kinetic energy associated with the motions of the atoms,
- The potential energy stored in the chemical bonds of the molecules,
- The gravitational energy of the system.

It is nearly impossible to sum all of these contributions up to determine the absolute energy of the system. That is why we only worry about $\Delta E$, the change in the energy of the system. This saves all of us a lot of work, for example:

- If the temperature doesn't change we can ignore the kinetic energy of the atoms,
- If no bonds are broken or destroyed we can ignore the chemical energy of the system,
- If the height of the system does not change then we can ignore gravitational potential energy of the system.

Our convention for $\Delta E$ is to subtract the initial energy of the system from the final energy of the system.

$$
\Delta E=E(\text { final })-E(\text { initial })=Q+W
$$

In a chemical reaction the energy of the reactants is $E$ (initial) and the heat of the products is $E$ (final). Now if we ask the question whether the nuclear power plant follow the first law of thermodynamics, we can positive say yes to the question and the reason behind is that because a Nuclear Power plant does not create or destroy energy, and they convert energy, and the amount of energy in the system and the surroundings remains constant.

### 5.2.2 Heat Engines

The work-producing device that best fits into the definition of a heat engine is the steam power plant, which is an external-combustion engine. That is, the combustion process takes place outside the engine, and the thermal energy released during this process is transferred to the steam as heat.

Heat engines, technically speaking, are continuously operating thermodynamic systems at the boundary of where there are heat and work interactions. Simply, a heat engine converts heat to work energy or vice versa (Fig. 5.2).

An example of a common heat engine is a power plant. It consists of four main elements, a boiler, turbine, condenser, and feed pump, and the main circulating heat transfer entity is water. If we consider the power plant to be a closed system with its boundary enclosing the operating components, we can apply the First Law of Thermodynamics. The boiler burns a fuel source, causing a transfer of $\mathbf{Q}_{\text {combustion }}$ heat to water inside, vaporizing it. The high-pressure vapor enters the turbine, resulting in a work output of $\mathbf{W}_{\text {turbine }}$, and then leaves still as steam but at lower pressure and temperature. The vapor moves through the condenser where it condenses back into water, losing $\mathbf{Q}_{\text {condensation }}$ heat to the surroundings. The water is pumped back into the boiler, requiring $\mathbf{W}_{\text {pump }}$ work.

Since $\Delta \mathbf{E}=\mathbf{Q}+\mathbf{W}$, and assuming a steady state of operation $(\Delta E=0)$,

$$
\left(Q_{\text {combustion }}-Q_{\text {condensation }}\right)+\left(W_{\text {pump }}-W_{\text {turbine }}\right)=0
$$

or

$$
Q_{\text {combustion }}-Q_{\text {condensation }}=W_{\text {turbine }}-W_{\text {pump }}
$$

Generally, $\mathbf{W}_{\text {pump }}$ is significantly less than the $\mathbf{W}_{\text {turbine }}$ attained. However, $\mathbf{Q}_{\text {condensation }}$ may be even more than two-thirds the magnitude of $\mathbf{Q}_{\text {combustion }}$, meaning that the total useful work obtained from the combustion of fuel is less than one third of

Fig. 5.2 Diagram of steam power plant
the total work theoretically possible from a complete conversion of $\mathbf{Q}_{\text {combustion }}$. The second law of thermodynamics embodies the fact that no engine can be constructed that is $100 \%$ efficient.

### 5.3 Signs for Heat and Work in Thermodynamics

As noted in Chap. 4 energy transfers in any thermodynamic process are measured in terms of the quantity of heat $Q$ added to the system and the work W done by the system. Both $Q$ and W may be positive, negative, or zero (Fig. 5.3).

A positive value of $Q$ represents heat flow into the system, with a corresponding input of energy to the system. A negative value of $Q$ represents heat flow out of the system. A positive value of $W$ represents work done by the system against its surroundings, such as work done by an expanding gas, and hence corresponds to energy leaving the system. Negative $W$, such as work done during compression of a gas by its surroundings, represents energy entering the system.

### 5.4 Work Done During Volume Changes

A gas in a cylinder with a movable piston is a simple example of a thermodynamic system. Internal-combustion engines, steam engines, and compressors in refrigerators and air conditioners all use some version of such a system.

Fig. 5.3 A thermodynamic system may exchange energy with its surroundings (environment) by means of heat and work. a When heat is added to the system, $Q$ is positive. $\mathbf{b}$ When heat is transferred out of the system, $Q$ is negative. $\mathbf{c}$ When work is done by the system, W is positive. $\mathbf{d}$ When work is done on the system, W is negative. Energy transfer by both heat and work can occur simultaneously; in $\mathbf{e}$ heat is added to the system and work is done by the system, and in $\mathbf{f}$ heat is transferred out of the system and work is done on the system ([1])

Consider a microscopic viewpoint, based on the kinetic and potential energies of individual molecules in a material, to develop intuition about thermodynamic quantities. (It is important to understand that the central principles of thermodynamics can be treated in a completely macroscopic way, without reference to microscopic models. Indeed, part of the great power and generality of thermodynamics is that it does not depend on details of the structure of matter.) First, consider the work done by the system during a volume change. When a gas expands, it pushes outward on its boundary surface as it moves outward. Hence an expanding gas always does positive work. The same thing is true of any solid or fluid material that expands under pressure, such as the popcorn in Fig. 4.1.

The work done by a gas in a volume change can be understood by considering the molecules that make up the gas. When one such molecule collides with a stationary surface, it exerts a momentary force on the wall but does no work because the wall does not move. However, if the surface is moving, such as a piston in a
gasoline engine, the molecule does work on the surface during the collision. If the piston in Fig. 5.4a moves to the right, so that the volume of the gas increases, the molecules that strike the piston exert a force through a distance and do positive work on the piston. If the piston moves toward the left as in Fig. 5.4b, so the volume of the gas decreases, then positive work is done on the molecule during the collision. Hence the gas molecules do negative work on the piston.

Figure 5.5 shows a fluid in a cylinder with a movable piston. Suppose that the cylinder has a cross-sectional area $A$ and that the pressure exerted by the system at the piston face is $p$. The total force $F$ exerted by the system on the piston is $F=p A$. When the piston moves out a small distance $\Delta x$, the work $\Delta W$ done by this force is

$$
\begin{equation*}
\Delta W=F \Delta x=p A \Delta x \tag{5.1}
\end{equation*}
$$

where $\Delta V$ is the infinitesimal change of volume of the system. Thus, we can express the work done by the system in this infinitesimal volume change as

$$
\begin{equation*}
\Delta W=p \Delta V \tag{5.2}
\end{equation*}
$$

In a finite change of volume from $V_{1}$ to $V_{2}$

$$
\begin{equation*}
W=\sum p \Delta V \tag{5.3}
\end{equation*}
$$

Fig. 5.4 a When a molecule strikes a wall moving away from it, the molecule does work on the wall-the molecule's speed and kinetic energy decrease. The gas does positive work on the piston. $\mathbf{b}$ When a molecule strikes a wall moving toward it, the wall does work on the molecule-the molecule's speed and kinetic energy increase. The gas does negative work on the piston ([1])

Fig. 5.5 The infinitesimal work done by the system during the small expansion $\Delta x$ is $\Delta W=p A \Delta x$

Fig. 5.6 The work done equals the area under the curve on a $p V$-diagram. a In this change from state 1 to state 2 the volume increases and the work and area are positive. $\mathbf{b}$ In this change from state 1 to state 2 the volume decreases; the area is taken to be negative to agrees with the sign of $W$. The two states are reversed from part (a). c The area of the rectangle gives the work done for a constant-pressure process. In this case, volume increases and $W>0$

This equation says the total work is equal to the sum of all the infinitesimally small volume changes time the pressure at that volume.

In general the pressure of the system may vary during the volume change. To evaluate Eq. 5.3, we have to know how the pressure varies as a function of volume. We can represent this relationship as a graph of $p$ as a function of $V$ (called a $p V-$ diagram). Figure 5.5a shows a simple example. In the figure, Eq. 5.3 is represented graphically as the area under the curve of $p$ versus $V$ between the limits $V_{1}$ and $V_{2}$.

According to the rule we stated for the sign of work, work is positive when a system expands. In an expansion from state 1 to state 2 in Fig. 5.6a the area under the curve and the work are positive. A compression from 1 to 2 in Fig. 5.6b gives a negative area; when a system is compressed, its volume decreases and it does negative work on its surroundings.

If the pressure $p$ remains constant while the volume changes from $V_{1}$ to $V_{2}$ (Fig. 5.5c), the work done by the system is

$$
\begin{equation*}
W=p\left(V_{2}-V_{1}\right) \tag{5.4}
\end{equation*}
$$

In any process in which the volume is constant, the system does no work because there is no displacement.

### 5.5 Paths Between Thermodynamic States

We have seen that if a thermodynamic process involves a change in volume, the system undergoing the process does work (either positive or negative) on its surroundings. Heat also flows into or out of the system during the process, if there is a temperature difference between the system and its surroundings. Consider

Fig. 5.7 a Three different paths between state 1 and state 2 . b-d. The work done by the system during a transition between two states depends on the path chosen [1]
now how the work done by, and the heat added to, the system during a thermodynamic process depend on the details of how the process takes place.

When a thermodynamic system changes from an initial state to a final state, it passes through a series of intermediate states. We call this series of states a path. There are always infinitely many different possibilities for these intermediate states. When they are all equilibrium states, (a quasi-static process) the path can be plotted on a $p V$-diagram (Fig. 5.7a). Point 1 represents an initial state with pressure $p_{1}$ and volume $V_{1}$. Point 2 represents a final state with pressure $p_{2}$ and volume $V_{2}$. To pass from state 1 to state 2 , we could keep the pressure constant at $p_{1}$ while the system expands to volume $V_{2}$ (point 3 in Fig. 5.7b.), then reduce the pressure to $p_{1}$ (probably by decreasing the temperature) while keeping the volume constant at $V_{2}$ (to point 2 on the diagram). The work done by the system during this process is the area under the line $1 \rightarrow 3$; no work is done during the constant-volume process $3 \rightarrow$ 2. Or the system might traverse the path $1 \rightarrow 4 \rightarrow 2$ (Fig. 5.7c); in that case the work is the area under the line $4 \rightarrow 2$, since no work is done during the constant-volume process $1 \rightarrow 4$. The smooth curve from 1 to 2 is another possibility (Fig. 5.7d), and the work for this path is different from that for either of the other paths.

The work done by the system depends not only on the initial and final states, but also on the intermediate states, that is, on the path. Furthermore, the system can move through a series of states forming a closed loop, such as $1 \rightarrow 3 \rightarrow 2 \rightarrow 4 \rightarrow$ 1. In this case, the final state is the same as the initial state, but the total work done by the system is not zero. (In fact, it is represented on the graph by the area enclosed by the loop). It follows that it does not make sense to talk about the amount of work contained in a system. In a particular state, a system may have definite values of the state coordinates $p, V$, and $T$, but it wouldn't make sense to say that it has a definite value of $W$.

Example 5.1 A gas is taken through the cycle illustrated below. During one cycle, how much work is done by an engine operating on this cycle? (Fig. 5.8)

Solution Start in the lower left hand corner of the rectangle and work clockwise. Call the lower left corner point 1, the upper left corner point 2, the upper right corner point 3 and the lower right corner point 4 .

$$
W=W_{1 \rightarrow 2}+W_{2 \rightarrow 3}+W_{3 \rightarrow 4}+W_{4 \rightarrow 1}
$$

Fig. 5.8 Sketch of a full cycle in Example 5.1

a
Fig. 5.9 a Slow, controlled isothermal expansion of a gas from an initial state 1 to a final state 2 with the same temperature but lower pressure. b Rapid, uncontrolled expansion of the same has starting at the same state 1 and ending at the same state 2

$$
W=(p \Delta V)_{1 \rightarrow 2}+(p \Delta V)_{2 \rightarrow 3}+(p \Delta V)_{3 \rightarrow 4}+(p \Delta V)_{4 \rightarrow 1}
$$

From 1 to 2, $\Delta V=0$, so $(p \Delta V)_{1 \rightarrow 2}=0$. From 2 to $3,(p \Delta V)_{2 \rightarrow 3}=2 P \times 3 V=6 P V$. From 3 to $4,(p \Delta V)_{3 \rightarrow 4}=0$, and from 4 to $1,(p \Delta V)_{4 \rightarrow 1}=-P \times 3 V=-3 P V$. Adding these up gives

$$
W=0+6 P V+0-3 P V=3 P V
$$

Therefore, the work done by an engine operating on this cycle is a positive $3 P V$ on each cycle.

Like work, the heat added to a thermodynamic system when it undergoes a change of state depends on the path from the initial state to the final state. Here is an example. Consider changing the volume of a certain quantity of an ideal gas from 2.0 to 5.0 L while keeping the temperature constant at $T=300 \mathrm{~K}$. Figure 5.9 shows two different ways to do this. In Fig. 5.9a the gas is contained in a cylinder with a
piston, with an initial volume of 2.0 L . The gas expands slowly, supplying heat from the electric heater to keep the temperature at 300 K . After expanding in this slow, controlled, isothermal manner, the gas reaches its final volume of 5.0 L; it absorbs a definite amount of heat in the process.

Figure 5.9 b shows a different process leading to the same final state. The container is surrounded by insulating walls and is divided by a thin, breakable partition into two compartments. The lower part has volume 2.0 L , and the upper part has volume 3.0 L. In the lower compartment, place the same amount of the same gas as in Fig. 5.9a, again at $T=300 \mathrm{~K}$. The initial state is the same as before. Now break the partition. The gas undergoes a rapid, uncontrolled expansion, with no heat passing through the insulating walls. The final volume is 5.0 L , the same as in Fig. 5.9a. The gas does not do any work during this expansion because it does not push against anything that moves. The uncontrolled expansion of a gas into vacuum is called a

## free expansion.

Experiments have shown that when an ideal gas undergoes a free expansion, there is no temperature change. Therefore the final state of the gas is the same as in Fig. 5.9a. The intermediate states (pressures and volumes) during the transition from state 1 to state 2 are entirely different in the two cases; Fig. 5.9 a and b represent two different paths connecting the same states 1 and 2. For the path in Fig. 5.9b, no heat is transferred into the system and the system does not do any work. Like work, heat depends not only on the initial and final states but also on the path.

Because of this path dependence, it would not make sense to say that a system "contains" a certain quantity of heat. To see this, suppose that an arbitrary value is assigned to "the heat in a body" in some reference state. Then presumably the "heat in the body" in some other state would equal the "heat in the body" in the reference state and the heat added when the body goes to the second state. However, that is ambiguous. The heat added depends on the path taken from the reference state to the second state. The obvious conclusion is that there is no consistent way to define "heat in a body". It is not a useful concept.

While it does not make sense to talk about "work in a body" or "heat in a body," it does make sense to speak of the amount of internal energy in a body.

### 5.6 Path Independence

Consider a system enclosed in adiabatic (thermally non-conducting) walls. In practice, 'adiabatic' means a thermally insulated container, like a well-insulated vacuum flask. The temperature of the contents of the flask can be monitored using a thermometer, a concept introduced by the zeroth law. Now do some experiments.

First, churn the contents of the flask (that is, the system) with paddles driven by a falling weight, and note the change in temperature this churning brings about. J. P. Joule (1818-1889), one of the fathers of thermodynamics, performed exactly this type of experiment in the years following 1843. The work accomplished can be calculated based on heaviness of the weight and the distance through which it

Fig. 5.10 The observation that different ways of doing work on a system and thereby changing its state between fixed endpoints required the same amount of work is analogous to different paths on a mountain resulting in the same change of altitude leads to the recognition of the existence of a property called the internal energy

fell. Then remove the insulation and let the system return to its original state. After replacing the insulation, put a heater into the system and pass an electric current through it for a time that result in the same work being done by the heater as was done by the falling weight. The conclusion arrived at in this pair of experiments and in a multitude of others of a similar kind is that the same amount of work, however it is performed, brings about the same change of state of the system.

This is analogous to climbing a mountain by a variety of different paths, each path corresponding to a different method of doing work (see Fig. 5.10). Provided we start at the same base camp and arrive at the same destination, we shall have climbed through the same height regardless of the path we took between them. That is, we can attach a number (the 'altitude') to every point on the mountain, and calculate the height we have climbed, regardless of the path, by taking the difference of the initial and final altitudes for our climb. Exactly the same process, applies to our system. The fact that the change of state is path-independent means that we can associate a number, which we shall call the internal energy (symbol $U$ ) with each state of the system. Then we can calculate the work needed to travel between any two states by taking the difference of the initial and final values of the internal energy, and using Fig. 5.9, then we can write;

$$
\begin{equation*}
\text { Work required }(W)=U_{f}(\text { final })-U_{i}(\text { initial }) \tag{5.5}
\end{equation*}
$$

The observation of the path-independence of the work required to go between two specified states in an adiabatic system (remember, at this stage the system is adiabatic) has motivated the recognition that there is a property of the system that is a measure of its capacity to do work. In thermodynamics, a property that depends only on the current state of the system and is independent of how that state was prepared (like altitude in geography) is called a state function. The state function for the energy stored in a closed system is called internal energy. It has a definite parallel with the state function called temperature that was defined by the Zeroth Law of Thermodynamics.

### 5.7 Heat and Work

Internal energy can change by an agency other than by doing work. One way of regarding this additional change in internal energy is to interpret it as arising from the transfer of energy from the system into the surroundings due to the difference in temperature caused by the work that has been done. This transfer of energy because of a temperature difference is called heat.

A simple model gives "work as the transfer of energy that makes use of the uniform motion of atoms in the surroundings" as depicted in Fig. 5.11. Moreover, "heat is the transfer of energy that makes use of the random motion of atoms in the surroundings".

In more pictorial terms, using Fig. 5.11 and noting that temperature is a property that tells us the relative numbers of atoms in the allowed energy states, with the higher energy states progressively more populated as the temperature is increases. A block of iron at high temperature consists of atoms that are oscillating vigorously around their average positions. At low temperatures, the atoms continue to oscillate, but with less vigor. If a hot block of iron is put in contact with a cooler block, the vigorously oscillating atoms at the edge of the hot block jostle the less vigorously oscillating atoms at the edge of the cool block into more vigorous motion, and they pass on their energy by jostling their neighbors. There is no net motion of either block, but energy is transferred from the hotter to the cooler block by this random jostling where the two blocks are in contact. That is why the above statement that was made, and is repeated here again, is a valid statement. That is, "heat is the transfer of energy that makes use of the random motion of atoms in the surroundings" [2].

Fig. 5.11 The molecular distinction between the transfer of energy as work (left) and heat (right). Doing work results in the uniform motion of atoms in the surroundings; heating stimulates their disorderly motion

### 5.8 Heat as Energy in Transition

The amount of energy that is transferred as heat into or out of the system can be measured very simply: we measure the work required to bring about a given change in an adiabatic system, and then the work required to bring about the same change of state in a non-adiabatic system (the one with thermal insulation removed), and take the difference of the two values.

That difference is the energy transferred as heat. A point to note is that this type of the measurement of the rather elusive concept of 'heat' has been put on a purely mechanical foundation as the difference in the heights through which a weight falls to bring about a given change of state under two different conditions (See Fig. 5.12 below).

Once the energy is inside the system, either by making use of the uniform motion of atoms in the surroundings (a falling weight) or of randomly oscillating atoms (a hotter object, such as a flame), there is no memory of how it was transferred. Once inside, the energy is stored as the kinetic energy (the energy due to motion) and the potential energy (the energy due to position) of the constituent atoms and that energy can be withdrawn either as heat or as work. The distinction between work and heat is made in the surroundings: the system has no memory of the mode of transfer nor is it concerned about how its store of energy will be used.

Consider a closed system and use it to do some work or allow a release of energy as heat. Its internal energy falls. Then leave the system isolated from its surroundings for an indefinite amount of time. Return to it and measure its capacity to do work. Invariably it's capacity to do work - its internal energy - is the same as when it was first isolated. In other words,

Fig. 5.12 When a system is adiabatic (left), a given change of state is brought about by doing a certain amount of work. When the same system undergoes the same change of state in a non-adiabatic container (right), more work has to be done. The difference is equal to the energy lost as heat

## The internal energy of an isolated system is constant.

That is the first law of thermodynamics, or at least one statement of it, for the law comes in many equivalent forms.

### 5.9 The First Law of Thermodynamics Applied to a Cycle

Having discussed the concepts of work and heat completely in Chap. 3 and briefly in Sect. 5.7 of this chapter again, we are now ready to present the first law of thermodynamics. Recall that a law is not derived or proved from basic principles but is simply a statement that we write based on our observations of many experiments. If an experiment shows a law to be violated, either the law must be revised or additional conditions must be placed on the applicability of the law. Historically, the first law of thermodynamics was stated for a cycle and the net heat transfer is equal to the net work done for a system undergoing a cycle. This is expressed in equation form by Eq. 5.6 as follow;

$$
\begin{equation*}
\sum W=\sum Q \tag{5.6}
\end{equation*}
$$

or

$$
\begin{equation*}
\oint \delta W=\oint \delta Q \tag{5.7}
\end{equation*}
$$

where the symbol $\oint$ implies an integration around a complete cycle. Therefore, the first law of thermodynamics can be stated as: whenever a system undergoes a cyclic change, however complex the cycle may be, the algebraic sum of the work transfer is equal to the algebraic sum of energy transfer as heat. Another way of interpreting the first law of thermodynamics is the conclusion that Joule made from his experiment which is depicted in Fig. 5.9a, b and that is, the net work done on the system is always proportional to the net energy removed from the system as heat, irrespective of the type of work interaction, the rate at which work was done on the system, and the method employed for transferring the energy in the form of work into thermal energy and it can be shown as the following equation

$$
\begin{equation*}
\oint d Q_{(\text {from system })}=\oint d W_{(\text {onsystem })} \tag{5.8}
\end{equation*}
$$

The first law can be illustrated by considering the following experiment. Let a weight be attached to a pulley/paddle-wheel setup, such as that shown in Fig. 5.9a. Let the weight fall certain distance thereby doing work on the system, contained in the insulated (adiabatic) tank shown, equal to the multiplied by the distance dropped. The temperature of the system (the fluid in the tank) will rise an amount of $\Delta T$. Now, the system is returned to its initial state (the completion of the cycle) by transferring heat to the surrounding, as implied by the $Q$ in Fig. 5.9b. This reduces the temperature of the system to its initial temperature. The first law states that this heat transfer will be exactly equal to the work, which was done by the falling weight [3].

### 5.10 Sign Convention

To avoid confusion as to whether the work is being done on the system by the surrounding, or by the system on the surroundings and whether energy is transferred as heat from the system, or to the system, the following sign convention is defined with reference to Fig. 5.13. The work done by a system on its surroundings is treated as a positive quantity. Similarly, the energy transfer as heat to a system from its surroundings is also treated as a positive quantity. With this convention, Eq. 5.8 becomes,

$$
\begin{equation*}
-\oint d Q-\oint(-d W)=\oint d Q-\oint(d W)=0 \tag{5.9}
\end{equation*}
$$

or

$$
\begin{equation*}
\oint(d Q-d W)=0 \tag{5.10}
\end{equation*}
$$

It should be noted that there is no restriction on the type of process the system has undergone. Therefore, the first law of thermodynamics is applicable to reversible as well as irreversible processes.

The first law of thermodynamics, as stated above, has a number of important consequences.

### 5.11 Heat is a Path Function

Suppose a system is taken from an initial state 1 to state 2 by the path 1 a 2 and it is restored to the initial state through the 2 b 1 according to Fig. 5.14. Then, the system has undergone a cyclic change. If the system is restored to the initial state by following path 1a2c1 it has experienced a different cycle. Apply the first law of thermodynamics to the two cycles 1 a 2 b 1 and 1 a 2 c 1 .

$$
\begin{align*}
& \int_{1 a 2} d Q+\int_{2 b 1} d Q-\int_{1 a 2} d W-\int_{2 b 1} d W=0  \tag{5.11}\\
& \int_{1 a 2} d Q+\int_{2 c 1} d Q-\int_{1 a 2} d W-\int_{2 c 1} d W=0 \tag{5.12}
\end{align*}
$$

Fig. 5.13 Sign convention for heat and work interactions

Fig. 5.14 Reversible cycles on $P-V$ diagram

Subtracting Eq. 5.12 from 5.11, gives,

$$
\begin{equation*}
\int_{2 b 1} d Q-\int_{2 c 1} d Q-\left(\int_{2 b 1} d W-\int_{2 c 1} d W\right)=0 \tag{5.13}
\end{equation*}
$$

Since work depends on the path, we have

$$
\begin{equation*}
\int_{2 b 1} d W-\int_{2 c 1} d W \neq 0 \tag{5.14}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\int_{2 b 1} d Q \neq \int_{2 c l} d Q \tag{5.15}
\end{equation*}
$$

That is, energy transfer as heat is not a point function, neither is it a property of the system. Therefore, heat interaction is a path function and its differential is not exact.

Example 5.2 A spring is stretched a distance of 0.8 m and attached to a paddle using the figure below. The paddle wheel then rotates until the spring is unstretched. Calculate the heat transfer necessary to return the system to its initial state (Fig. 5.15).

Solution The work done by spring on the system is given by;

$$
W_{1-2}=\int_{0}^{0.8} F d x=\int_{0}^{0.8} 100 x d x=(100)\left[\frac{(0.8)^{2}}{2}\right]=32 \mathrm{~N}
$$

Fig. 5.15 Example 5.2

Since the heat transfer returns the system to its initial state, a cycle results. The first law then states that $Q_{1-2}=W_{1-2}=32 \mathrm{~J}$.

### 5.12 Energy is a Property of System

Quite often changes in the state of a system when it undergoes a process are important, rather than when it passes through a cycle. Evaluating the energy changes of the system while it interacts with its surrounding for a specific process is necessary. Rearranging Eq. 5.13 gives;

$$
\begin{equation*}
\int_{2 b 1}(d Q-d W)=\int_{2 c 1}(d Q-d W) \tag{5.16}
\end{equation*}
$$

This shows that while $\int d Q$ and $\int d W$ depend on the path followed by the system, the quantity $\int(d Q-d W)$ is the same for both the processes $2 b 1$ and $2 c 1$, connecting states 2 and 1 . By considering several other cycles, it can be observed that $\int(d Q-d W)$ is the same for all the processes connecting states 1 and 2 . Therefore $\int(d Q-d W)$ does not depend on the path followed by the system, but depends only on the initial and final states of the system. Hence, the quantity $\int(d Q-d W)$ is an exact differential. Therefore it is the differential of a property of the system. This property is the energy of the system and is represented by $E$. The differential change in the energy of the system is given by,

$$
\begin{equation*}
d E=d Q-d W \tag{5.17}
\end{equation*}
$$

The energy of a system is the sum of the macroscopic and microscopic modes of energy, i.e.

$$
\begin{equation*}
E=K E+P E+U \tag{5.18}
\end{equation*}
$$

and

$$
\begin{equation*}
d E=d(K E)+d(P E)+d U=d Q-d W \tag{5.19}
\end{equation*}
$$

Therefore, whenever a system undergoes a change of state, energy may cross the boundary as either heat or as work, and the change in the energy of the system is equal to the total energy that crosses the boundary. The energy of the system may change from one form to the other. For example, kinetic energy may change into either potential energy or internal energy. Equation 5.19 simply accounts for the energy when the system interacts with the surroundings. The quantity $[d(K E)+d(P E)+d U]$ represents the net change in the energy of the system while $d Q$ and $d W$ represent the energy transfer across the boundary of the system in the form of heat and work, respectively. The net change in the energy of the system is exactly equal to the net energy transfer across the boundary of the system.

### 5.13 Energy of an Isolated System is Conserved

A system, which does not exchange energy with the surroundings, in the form of either heat or work, is called an isolated system. During any process in such a system $d Q=0$ and $d W=0$. The first law of thermodynamics then reduces to

$$
\begin{equation*}
d E=0 \text { or } E_{2}=E_{1} \tag{5.20}
\end{equation*}
$$

for a reversible or an irreversible process. Therefore, the energy of an isolated system remains constant.
Example 5.3 A radiator of a heating system with a volume of $0.1 \mathrm{~m}^{3}$ contains saturated steam at 0.2 MPa . The inlet and outlet valve of the radiator are closed. Due to the energy transfer as heat to the surroundings, the pressure drops to 0.15 MPa . Determine the amount of steam and water at the final pressure.

Solution Steam contained in the radiator.
The process followed by the system is shown on a $P-v$ diagram in Fig. 5.14 below (Fig. 5.16).

Specific volume of the saturated steam at $0.2 \mathrm{MPa}, v_{1}=0.885 \mathrm{~m}^{3} / \mathrm{kg}$.
Volume of the radiator, $V=0.1 \mathrm{~m}^{3}$
Total mass of the steam, $m=\frac{V}{v_{1}}=\frac{0.1}{0.8854}=0.113 \mathrm{~kg}$.
Since the quantity of steam and the volume of the radiator are constant, the steam undergoes a constant volume process. Therefore, $v=$ constant; or $v_{1}=v_{2}$
At $P_{2}=0.15 \mathrm{MPa} v_{f}=0.001053 \mathrm{~m}^{3} / \mathrm{kg} v_{g}=1.159 \mathrm{~m}^{3} / \mathrm{kg} T=111.37^{\circ} \mathrm{C}$

Fig. 5.16 Sketch for Example 5.3 on a $P-v$ diagram

Since $v_{f}<v<v_{g}$, the final state is wet steam of quality $X_{2}$.

$$
v_{2}=X_{2} v_{g}+\left(1-X_{2}\right) v_{f} 0.8854=X_{2}(1.159)+\left(1-X_{2}\right)(0.001053)
$$

Or $X_{2}=0.7637$
The saturation temperature at $P_{2}=0.15 \mathrm{MPa}, T_{2}=111.37^{\circ} \mathrm{C}$. Quality of the steam in the final state, $X_{2}=0.7637$. Mass of vapor $=0.7637(0.1138)=0.86 \mathrm{~kg}$ and mass of liquid $=0.027 \mathrm{~kg}$.

Example 5.4 An insulated and rigid container of $1 \mathrm{~m}^{3}$ volume contains helium at $20^{\circ} \mathrm{C}$ and 100 kPa pressure. A paddle wheel is rotated inside the container raising the temperature of helium to $60^{\circ} \mathrm{C}$. Assume that helium obeys the relation $P V=N R T$ and $d u=C_{v} d T$ with $C_{v}=12.4717 \mathrm{~kJ} / \mathrm{kmol} \mathrm{K}$. Determine the work done on helium and the final pressure of helium.

## Solution

$$
\begin{gathered}
N=\frac{P_{1} V_{1}}{R T_{1}}=\frac{100 \times 10^{3} \times 1}{8.314 \times 10^{3} \times 293.15}=0.041 \mathrm{kmol} \\
\Delta u=C_{v} \Delta T
\end{gathered}
$$

or

$$
\Delta U=N C_{v} \Delta T=0.041 \times 12.4717(40)=20.4685 \mathrm{~kJ}
$$

$$
\begin{gathered}
\Delta U=-W \text { or } W=-20.4685 \mathrm{~kJ} \\
\frac{P_{2}}{P_{1}}=\frac{T_{2}}{T_{1}} \quad \text { or } \quad P_{2}=\frac{P_{1} T_{2}}{T_{1}}=\frac{100 \times 10^{3} \times 313.15}{293.15}=106.82 \mathrm{kPa}
\end{gathered}
$$

### 5.14 Internal Energy and the First Law of Thermodynamics

Internal energy is one of the most important concepts in thermodynamics. What is internal energy? It can be approached in various ways. Start with one based on the ideas of mechanics. Matter consists of atoms and molecules, and these are made up of particles having kinetic and potential energies. Tentatively define the internal energy of a system as the sum of the kinetic energies of all its constituent particles, plus the sum of all the potential energies of interaction among these particles.

Note that internal energy does not include potential energy arising from the interaction between the system and its surroundings. If the system is a glass of water, placing it on a high shelf increases the gravitational potential energy arising from the interaction between the glass and the earth. But this has no effect on the interaction between the molecules of the water, and so the internal energy of the water does not change.

The symbol $U$ represents internal energy. During a change of state of the system the internal energy may change from an initial value $U_{1}$ to a final value $U_{2}$. Denote the change in internal energy as $\Delta U=U_{2}-U_{1}$.

Heat transfer is energy transfer. Adding a quantity of heat $Q$ to a system, without doing any work during the process, will increase the internal energy by an amount equal to $Q$. That is, $\Delta U=Q$. When a system does work $W$ by expanding against its surroundings and no heat is added during the process, energy leaves the system and the internal energy decreases. That is, when $W$ is positive, $\Delta U$ is negative, and conversely. So $\Delta U=-W$. When both heat transfer and work occur, the total change in internal energy is

$$
\begin{equation*}
U_{2}-U_{1}=\Delta U=Q-W \quad \text { (First law of thermodynamics) } \tag{5.21}
\end{equation*}
$$

This can be rearranged to

$$
\begin{equation*}
Q=\Delta U+W \tag{5.22}
\end{equation*}
$$

The message of Eq. 5.5 .22 is that in general when heat $Q$ is added to a system, some of this added energy remains within the system, changing its internal energy by an amount $\Delta U$. The remainder leaves the system again as the system does work $W$ against its surroundings. Because $W$ and $Q$ may be positive, negative, or zero, $U$ can be positive, negative, or zero for different processes (Fig. 5.17).

Fig. 5.17 In a thermodynamic process, the internal energy of a system may increase, decrease, or stay the same. a If more heat is added to the system than the system does work, $\Delta U$ is positive and the internal energy increases. b If more heat flows out of the system than work is done on the system, $\Delta U$ is negative and the internal energy decreases. c If the heat added to the system equals the work done by the system, $\Delta U=0$ and the internal energy is unchanged

Equations (5.21) or (5.22) is The First Law of Thermodynamics. It is a generalization of the principle of conservation of energy to include energy transfer through heat as well as mechanical work. This principle can be extended to ever-broader classes of phenomena by identifying additional forms of energy and energy transfer. In every situation in which it seems that the total energy in all known forms is not conserved, it has been possible to identify a new form of energy such that the total energy, including the new form, is conserved. There is energy associated with electric fields, with magnetic fields, and, according to the theory of relativity, even with mass itself.

At the beginning of this discussion, internal energy was tentatively defined in terms of microscopic kinetic and potential energies. This has drawbacks, however. Actually calculating internal energy in this way for any real system would be hopelessly complicated. Furthermore, this definition isn't an operational one because it doesn't describe how to determine internal energy from physical quantities that can be measured directly.

So look at internal energy in another way. Starting over, define the change in internal energy $\Delta U$ during any change of a system as the quantity given by Eq. 5.21, $\Delta U=Q-W$. This is an operational definition, because $Q$ and $W$ can be measured. It does not define $U$ itself, only $\Delta U$. This is not a shortcoming, because the value of the internal energy of a system can be defined to have a specified value in some reference state, and then use Eq. 5.21 to define the internal energy in any other state.

This new definition trades one difficulty for another. If $U$ is defined by Eq. 5.21, then when the system goes from state 1 to state 2 by two different paths, is $\Delta U$ the same for both paths? $Q$ and W are, in general, not the same for different paths. If $\Delta U$, which equals $Q-W$, is also path-dependent, then $\Delta U$ is ambiguous. If so, the concept of internal energy of a system is subject to the same criticism as the erroneous concept of quantity of heat in a system, as discussed earlier in the chapter.

The only way to answer this question is through experiment. For various materials and processes, $Q$ and $W$ have been measured for various changes of state and various paths to learn whether $\Delta U$ is, or is, not path-dependent. The results of many such investigations are clear and unambiguous: While $Q$ and $W$ depend on the path, $\Delta U=Q-W$ is independent of path. The change in internal energy of a system during any thermodynamic process depends only on the initial and final states, not on the path leading from one to the other.

Experiment, then, is the ultimate justification for believing that a thermodynamic system in a specific state has a unique internal energy that depends only on that state. An equivalent statement is that the internal energy $U$ of a system is a function of the state coordinates $p, V$, and $T$ (actually, any two of these, since the three variables are related by the equation of state).

To say that the first law of thermodynamics, given by Eqs. 5.21 or 5.22 , represents conservation of energy for a thermodynamic process is correct, as far as it goes. However, an important additional aspect of the first law is the fact that internal energy depends only on the state of a system. In changes of state, the change in internal energy is path-independent.

All this may seem a little abstract if one wants to think of internal energy as microscopic mechanical energy. But remember classical thermodynamics and the concept of internal energy were developed long before atoms and molecules were proven to exist. There's nothing wrong with the microscopic view. But in the interest of precise operational definitions, internal energy, like heat, can and must be defined in a way that is independent of the detailed microscopic structure of the material.

Two special cases of the first law of thermodynamics are worth mentioning. A process that eventually returns a system to its initial state is called a cyclic process. For such a process, the final state is the same as the initial state, and so the total internal energy change must be zero. Then;

$$
\begin{equation*}
U_{2}=U_{1} \quad \text { and } \quad Q=W \tag{5.23}
\end{equation*}
$$

If a net quantity of work W is done by the system during this process, an equal amount of energy must have flowed into the system as heat $Q$. But there is no reason why either $Q$ or $W$ individually has to be zero.

Another special case occurs in an isolated system, one that does not do any work on its surroundings and has no heat flow to or from its surroundings. For any process taking place in an isolated system,

$$
\begin{equation*}
W=Q=0 \tag{5.24}
\end{equation*}
$$

and therefore

$$
\begin{equation*}
U_{2}-U_{1}=\Delta U=0 \tag{5.25}
\end{equation*}
$$

In other words, the internal energy of an isolated system is constant.
Example 5.5 You propose to eat a 900 Calorie hot fudge sundae (with whipped cream) and then run up several flights of stairs to work off the energy you have taken in. How high do you have to climb? Assume that your mass is 60 kg .

Solution The system consists of you and the earth. Remember that one food-value calorie is $1 \mathrm{kcal}=1000 \mathrm{cal}=4190 \mathrm{~J}$. The energy intake is;

$$
Q=900 \mathrm{kcal}(4190 \mathrm{~J} / \mathrm{kcal})=3.77 \times 10^{6} \mathrm{~J}
$$

The potential energy output required to climb a height $h$ is;

$$
W=m g h=(60 \mathrm{~kg})\left(9.8 \mathrm{~m} / \sec ^{2}\right) h=(588 \mathrm{~N}) h
$$

If the final state of the system is the same as the initial state (that is, no fatter, no leaner), these two energy quantities must be equal: $Q=W$. Then

$$
\left.h=\frac{Q}{m g}=\frac{3.77 \times 10^{6} \mathrm{~J}}{588 \mathrm{~N}}=6410 \mathrm{~m} \text { about } 21,000 \mathrm{ft}\right) \text { Good luck! }
$$

Example 5.6 Figure 5.18 below shows a $P V$-diagram for a cyclic process, one in which the initial and final states are the same. It starts at point $a$ and proceeds counterclockwise in the $P V$-diagram to point $b$, then back to $a$, and the total work is $W=-500 \mathrm{~J}$. (a) Why is the work negative? (b) Find the change in internal energy and the heat added during this process.

## Solution

a. The work done equals the area under the curve, with the area taken as positive for increasing volume and negative for decreasing volume. The area under the lower curve from $a$ to $b$ is positive, but it is smaller than the absolute value of the negative area under the upper curve from $b$ back to $a$. Therefore, the net area (the area enclosed by the path, shown with red stripes) and the work are negative. In other words, 500 more joules of work are done on the system than by the system.
b. For this and any other cyclic process (in which the beginning and end points are the same), $\Delta U=0$, so $W=Q=-500 \mathrm{~J}$. That is, 500 J of heat must come out of the system.

Fig. 5.18 The net work done by the system in the process $a b a$ is -500 J . Would it have been if the process had proceeded clockwise in this $P V$-diagram?

Example 5.7 A rigid volume tank contains $6 \mathrm{ft}^{3}$ of steam originally at a pressure of 400 psia and a temperature of $1300^{\circ} \mathrm{R}$. Estimate the final temperature if 800 Btu of heat is added.

Solution The first law of thermodynamics, with $\triangle K E=\triangle P E=0$, is $Q-W=\Delta U$. For a rigid container the work is zero. Thus

$$
Q=\Delta U=m\left(u_{2}-u_{1}\right)
$$

From Steam tables on page A-80 first column and second row group, we read $u_{1}=1302 \mathrm{Btu} / \mathrm{lbm}$ and $v_{1}=1.8871 \mathrm{ft}^{3} / \mathrm{lbm}$ for a temperature of $1300^{\circ} \mathrm{R}$. The mass is then;

$$
m_{1}=\frac{V_{1}}{v_{1}}=\frac{6\left[\mathrm{ft}^{3}\right]}{1.8871\left[\mathrm{ft}^{3} / \mathrm{lbm}\right]}=3.1791 \mathrm{bm}
$$

Then using the First Law for the energy transferred to the volume by heat is given, thus we + have

$$
800=3.179\left(u_{2}-1302\right) \quad \therefore u_{2}=1553.7 \mathrm{Btu} / \mathrm{lbm}
$$

So the state is specified by $\mathrm{v}_{2}=1.8871 \mathrm{ft}^{3} / \mathrm{lbm}$ and $\mathrm{u}_{2}=1553.7 \mathrm{Btu} / \mathrm{lbm}$. $u$ and v are two thermodynamic parameters which are enough to define a state. However no tables exist for temperature as a function of $u$ and $v$. So a double linear interpolation is required. First four pressure-temperature combinations must be identified that bound both the desired $u$ and v. For this case these combinations are (from Table A14.7. pages A-86 and A-87)

$$
\begin{aligned}
& \mathrm{P}=550 \mathrm{psiT}=1800 \mathrm{Rv}=1.9358 \mathrm{ft}^{3} / \mathrm{lbmu}=1513.8 \mathrm{Btu} / \mathrm{lbm} \\
& \mathrm{P}=600 \mathrm{psiT}=1800 \mathrm{Rv}=1.7729 \mathrm{ft}^{3} / \mathrm{lbmu}=1513.1 \mathrm{Btu} / \mathrm{lbm} \\
& \mathrm{P}=550 \mathrm{psiT}=1900 \mathrm{Rv}=2.0479 \mathrm{ft}^{3} / \mathrm{lbmu}=1558.8 \mathrm{Btu} / \mathrm{lbm} \\
& \mathrm{P}=600 \mathrm{psiT}=1900 \mathrm{Rv}=1.8760 \mathrm{ft}^{3} / \mathrm{lbmu}=1558.3 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

A double linear interpolation is required. The first interpolation can be done in pressure or temperature, but then the second one must be performed in the other variable. Consider interpolating in pressure first. At 1800 R this gives

$$
\begin{aligned}
& \mathrm{U}_{1800}=1513.8+(1.9358-1.8871) /(1.9358-1.7729) *(1513.1-1513.8) \\
& U_{1800}=1513.8+0.298 *(-0.7)=1513.6 \text { Btu } / \mathrm{lbm}
\end{aligned}
$$

$$
\begin{aligned}
\mathrm{U}_{1900} & =1558.8+(2.0479-1.8871) /(2.0479-1.8760) *(1558.3-1558.8) \\
\mathrm{U}_{1900} & =1558.8+0.936 *(-0.5)=1558.33 \\
\mathrm{~T}(1553.7) & =1800+(1553.7-1513.6) /(1558.33-1513.6) * 100 \\
\mathrm{~T}(1553.7) & =1800+0.896 * 100=1889.6 R
\end{aligned}
$$

Example 5.8 A frictionless piston is used to provide a constant pressure of 400 kPa in a cylinder containing steam originally at 500 K with a volume of $2 \mathrm{~m}^{3}$. Calculate the final temperature if 3500 kJ of heat is added.

Solution The first law of thermodynamics gives $\Delta U=Q-W$. The work done is $W=p\left(V_{2}-V_{1}\right)$. The mass remains unchanged $m_{1}=m_{2}$.

$$
m_{1}=\frac{V_{1}}{v_{1}}=\frac{2}{0.56722}=3.526 \mathrm{~kg}
$$

Then the First Law gives

$$
3500=400 *\left(3.526 v_{2}-2\right)+3.526 *\left(u_{2}-2690\right)
$$

This requires iteration on $v_{2}$ and $u_{2}$ to find the final temperature. After some effort this gives,

$$
\mathrm{T}_{\mathrm{f}}=965 \mathrm{~K}
$$

### 5.15 Internal Energy of an Ideal Gas

For an ideal gas, the internal energy $U$ depends only on temperature, not on pressure or volume. Consider again the free-expansion experiment described earlier. A thermally insulated container with rigid walls is divided into two compartments by a partition (Fig. 5.19). One compartment has a quantity of an ideal gas, and the other is evacuated.

When the partition is removed or broken, the gas expands to fill both parts of the container. The gas does not do any work on its surroundings because the walls of the container don't move, and there is no heat flow through the insulation. So both $Q$ and $W$ are zero, and the internal energy $U$ is constant. This is true of any substance, whether it is an ideal gas or not.

Does the temperature change during a free expansion?. Suppose it does change, while the internal energy stays the same. In that case we have to conclude that the internal energy depends on both the temperature and the volume or on both the temperature and the pressure, but certainly not on the temperature alone. But if $T$ is

Fig. 5.19 The partition is broken (or removed) to start the free expansion of gas into the vacuum region

constant during a free expansion, for which we know that $U$ is constant even though both $P$ and $V$ change, then we have to conclude that $U$ depends only on $T$, not on $P$ or $V$.

Many experiments have shown that when a low-density gas undergoes a free expansion, its temperature does not change. Such a gas is essentially an ideal gas. The conclusion is: The internal energy of an ideal gas depends only on its temperature, not on its pressure or volume. This property, in addition to the ideal-gas equation of state, is part of the ideal-gas model. Both properties will be used frequently in later systems calculations.

### 5.16 Introduction to Enthalpy

In the solution of problems involving systems, certain products or sums of properties occur with regularity. One such combination of properties can be demonstrated by considering the addition of heat to the constant-pressure situation shown in Fig. 5.20. Heat is added slowly to the system (the gas in the cylinder), which is maintained at constant pressure by assuming a frictionless seal between the piston and the cylinder. If the kinetic energy changes and potential energy changes of the system are neglected and all other work modes are absent, the first law of thermodynamics requires that Eq. 5.21 apply,

$$
\begin{equation*}
Q-W=U_{2}-U_{1} \tag{5.26}
\end{equation*}
$$

The work done using the weight for the constant pressure process is given by;

$$
\begin{equation*}
W=P\left(V_{2}-V_{1}\right) \tag{5.27}
\end{equation*}
$$

The first law can then be written as;

$$
\begin{equation*}
Q=(U+P V)_{2}-(U+P V)_{1} \tag{5.28}
\end{equation*}
$$

Fig. 5.20 Constant pressure heat addition

The quantity in parentheses $U+p V$ is a combination of properties, and it is thus a property itself. It is called the enthalpy $H$ of the system,

$$
\begin{equation*}
H=U+P V \tag{5.29}
\end{equation*}
$$

The specific enthalpy $h$ is found by dividing by the mass.

$$
\begin{equation*}
h=u+P v \tag{5.30}
\end{equation*}
$$

Enthalpy is a property of a system. It is so useful that it is tabulated in the steam tables along with specific volume and specific internal energy. The energy equation can now be written for a constant pressure process as

$$
\begin{equation*}
Q_{1-2}=H_{2}-H_{1} \tag{5.31}
\end{equation*}
$$

The enthalpy has been defined assuming a constant-pressure system with difference in enthalpies between two states being the heat transfer. For a variable-pressure process, the difference in enthalpy is not quite as obvious. However, enthalpy is still of use in many engineering problems and it remains a property as defined by Eq. 5.29. In a non-equilibrium constant-pressure process $\Delta H$ would not equal the heat transfer.

Because only changes in the enthalpy or the internal energy are important, the datum for each can be chosen arbitrarily. Normally the saturated liquid at $0^{\circ} \mathrm{C}$ is chosen as the datum point for water.

Example 5.9 A frictionless piston is used to provide a constant pressure of 400 kPa in a cylinder containing steam originally at 500 K with a volume of $2 \mathrm{~m}^{3}$. Calculate the final temperature if 3500 kJ of heat is added.

Solution This is the same problem as Example 5.8. However using the concept of enthalpy the solution is simpler, $Q=H_{2}-H_{l}$. Then

$$
\begin{aligned}
3500 & =\left(h_{2}-2916.2\right) * 3.526 \\
h_{2} & =\frac{3500+2916.2 * 3.526}{3.526}=3908.8 \\
T_{f} & =964.8 \mathrm{~K}
\end{aligned}
$$

### 5.17 Latent Heat

When a substance changes phase from either a solid to a liquid or a liquid to a gas, it requires an input of energy to do so. The potential energy stored in the inter-atomic forces between molecules needs to be overcome by the kinetic energy of the motion of the particles before the substance can change phase.

Starting with a substance that is initially solid, as it is heated, its temperature will rise as depicted in the graph of Fig. 5.21.

Starting a point $\mathbf{A}$, the substance is in its solid phase, heating it brings the temperature up to its melting point but the material is still a solid at point $\mathbf{B}$. As it is heated further under constant pressure, the energy from the heat source goes into breaking the bonds holding the atoms in place. This takes place from $\mathbf{B}$ to $\mathbf{C}$. At point C all of the solid phase has been transformed into the liquid phase. Once again, as energy is added the energy goes into the kinetic energy of the particles raising the temperature, $(\mathbf{C}$ to $\mathbf{D})$. At point $\mathbf{D}$ the temperature has reached its boiling point but it is still in the liquid phase. From points, $\mathbf{D}$ to $\mathbf{E}$ thermal energy overcomes the bonds holding the particles in the liquid state and the particles have enough kinetic energy to escape to the vapor state. Then substance enters the gas phase and its temperature continues to rise with added heat inputs. Beyond $\mathbf{E}$, further heating under pressure can raise the temperature still further.

Fig. 5.21 Temperature change with time. Phase changes are indicated by flat regions where heat energy used to overcome attractive forces between molecules

Table 5.1 Latent heat of fusion and vaporization for certain substances

| Substance | Specific latent heat of <br> fusion $\mathrm{kJ} / \mathrm{kg}^{-1}$ | ${ }^{\circ} \mathrm{C}$ | Specific latent heat of <br> vaporization $\mathrm{kJ} / \mathrm{kg}^{-1}$ | ${ }^{\circ} \mathrm{C}$ |
| :--- | :--- | ---: | :--- | ---: |
| Water | 334 | 0 | 2258 | 100 |
| Ethanol | 109 | -114 | 838 | 78 |
| Ethanoic acid | 192 | 17 | 395 | 118 |
| Chloroform | 74 | -64 | 254 | 62 |
| Mercury | 11 | -39 | 294 | 357 |
| Sulphur | 54 | 115 | 1406 | 445 |
| Hydrogen | 60 | -259 | 449 | -253 |
| Oxygen | 14 | -219 | 213 | -183 |
| Nitrogen | 25 | -210 | 199 | -196 |

The Latent Heats of Fusion and Vaporization are the heat inputs required to produce the phase changes. The word latent means hidden, when the phase change is from solid to liquid it is the latent heat of fusion, and when the phase change is from liquid to a gas, it is the latent heat of vaporization.

The energy required is $Q=m L$, where $m$ is the mass of the substance and $L$ is the specific latent heat of fusion or vaporization required to produced the phase change.

Table 5.1 lists the Latent Heat of Fusion and Vaporization for certain substances.
The amount of energy that must be transferred in the form of heat to a substance held at constant pressure in order that phase changes occur is called the latent heat. It is the change in enthalpy of the substance at the saturated conditions of the two phases. The heat that is necessary to melt (or freeze) a unit mass at the substance at constant pressure is the heat of fusion and is equal to $h_{i f}=h_{f}-h_{i}$, where $h_{i}$ is the enthalpy of saturated solid and $h_{f}$ is the enthalpy of saturated liquid. The heat of vaporization is the heat required to completely vaporize a unit of saturated liquid (or condense a unit mass of saturated vapor) and it equal to $h_{f g}=h_{g}-h_{f}$. When a solid changes phases directly to a gas, sublimation occurs and the heat of sublimation is equal to $h_{i g}=h_{g}-h_{i}$.

The heat of fusion and the heat of sublimation are relatively insensitive to pressure or temperature changes. For ice the heat of fusion is approximately $320 \mathrm{~kJ} / \mathrm{kg}$ ( $140 \mathrm{Btu} / \mathrm{lbm}$ ) and the heat of sublimation is about $2040 \mathrm{~kJ} / \mathrm{kg}(880 \mathrm{Btu} / \mathrm{lbm})$. The heat of vaporization of water is identified as $h_{f g}$ in Appendices 14.1, 14.2, 14.5 and 14.6 .

### 5.18 Specific Heats

For a simple system, only two independent variables are necessary to establish the state of the system as specified by Gibbs Phase Rule. This means that properties like specific internal energy $u$ can be tabulated as a function of two variables, In the case of $u$, it is particularly useful to choose $T$ and $v$. Or,

$$
\begin{equation*}
u=u(T, v) \tag{5.32}
\end{equation*}
$$

Using the calculus chain rule, we express the differential in terms of the partial derivative as follow using the function $u$ and its independent variables $T$ and $v$ in Eq. 5.32;

$$
\begin{equation*}
d u=\left.\frac{\partial u}{\partial T}\right|_{v} d T+\left.\frac{\partial u}{\partial v}\right|_{T} d v \tag{5.33}
\end{equation*}
$$

## The Chain Rule for Functions of Two Variables

The Chain Rule
If $x=x(t)$ and $y=y(t)$ are differentiable at $t$ and $z=f(x, y)=f(x(t), y(t))$ is differentiable at $(x(t), y(t))$, then $z=f(x(t), y(t))$ is differentiable at $t$ and is written as;

$$
\frac{d z}{d t}=\frac{\partial z}{\partial x} \frac{d x}{d t}+\frac{\partial z}{\partial y} \frac{d y}{d t}=\left.\frac{\partial z}{\partial x}\right|_{y} d x+\left.\frac{\partial z}{\partial y}\right|_{x} d y
$$

This can be proved directly from the definitions of $z$ being differentiable at $(x(t), y(t))$ and $x(t)$ and $y(t)$ being differentiable at $t$.

## Example of Chain Rule

In physics and chemistry, the pressure $P$ of a gas is related to the volume $V$, the number of moles of gas $n$, and temperature $T$ of the gas by the following equation:

$$
P=\frac{n R T}{V}
$$

where $R$ is a constant of proportionality. We can easily find how the pressure changes with volume and temperature by finding the partial derivatives of $P$ with respect to $V$ and $P$, respectively. But, now suppose volume and temperature are functions of variable time $t$ (with $n$ constant): $V=V(t)$ and $T=T(t)$. We wish to know how the pressure $P$ is changing with time. To do this we need a chain rule for functions of more than one variable. We will find that the chain rule is an essential part of the solution of any related rate problem, then we can write $d P / d t$ as;

$$
\frac{d P}{d t}=\frac{\partial P}{\partial T} \frac{d T}{d t}+\frac{\partial P}{\partial V} \frac{d V}{d t}=\frac{n R}{V} \frac{d T}{d t}-\frac{n R T}{V^{2}} \frac{d V}{d t}
$$

Since $u, v$, and $T$ are all properties, the partial derivative is also a property and is called the constant volume specific heat, $C_{v}$ and that is

$$
\begin{equation*}
C_{v}=\left.\frac{\partial u}{\partial T}\right|_{v} \tag{5.34}
\end{equation*}
$$

Since many experiments have shown that when a low-density gas undergoes a free expansion, its temperature does not change. Such a gas is by definition an Ideal Gas. The conclusion is that, the internal energy of an Ideal Gas depends only on its temperature, not on its pressure or volume. This property, in addition to the Ideal Gas equation of state, is part of the Ideal Gas model. Because there is no change in temperature, there is no net heat transfer to the substance under experiment. Obviously since no work is involved, the first law requires that the internal energy of an ideal gas does not depend on volume. Thus the second term in Eq. 5.33 is zero.

$$
\begin{equation*}
\left.\frac{\partial u}{\partial v}\right|_{T}=0 \tag{5.35}
\end{equation*}
$$

Combining Eqs. 5.33, 5.34 and 5.35 we have;

$$
\begin{equation*}
d u=C_{v} d T \tag{5.36}
\end{equation*}
$$

This can be integrated to give;

$$
\begin{equation*}
u_{2}-u_{1}=\int_{T_{1}}^{T_{2}} C_{v} d T \tag{5.37}
\end{equation*}
$$

For a known $C_{v}(T)$ the Eq. 5.37 can be integrated to find the change in internal energy over any temperature interval for an ideal gas. By a similar argument, considering specific enthalpy to be dependent on the two variables temperature $T$ and pressure $P$, we have;

$$
\begin{equation*}
d h=\left.\frac{\partial h}{\partial T}\right|_{P} d T+\left.\frac{\partial h}{\partial P}\right|_{T} d P \tag{5.38}
\end{equation*}
$$

The constant-pressure specific heat $C_{p}$ is defined as the partial,

$$
\begin{equation*}
C_{p}=\left.\frac{\partial h}{\partial T}\right|_{P} \tag{5.39}
\end{equation*}
$$

For an Ideal Gas and the definition of enthalpy,

$$
\begin{equation*}
h=u+P v=u+R T \tag{5.40}
\end{equation*}
$$

Where we have used the ideal-gas equation of state. Since $u$ is only a function of $T$ per Eq. 5.5.32, $h$ also is only a function of $T$ for an ideal gas. Hence, for an ideal gas;

$$
\begin{equation*}
\left.\frac{\partial h}{\partial P}\right|_{T}=0 \tag{5.41}
\end{equation*}
$$

Then from Eq. 5.38, we have;

$$
\begin{equation*}
d h=C_{p} d T \tag{5.42}
\end{equation*}
$$

and integrating 5.5.5.42 over the temperature range $T_{1}$ to $T_{2}$ will give the following result.

$$
\begin{equation*}
h_{2}-h_{1}=\int_{T_{1}}^{T_{2}} C_{p} d T \tag{5.43}
\end{equation*}
$$

Often it is convenient to denote the specific heat on a per-mole rather than a per kilogram basis and the specific heats can be written as:

$$
\begin{equation*}
\bar{C}_{v}=\bar{M} C_{v} \quad \text { and } \quad \bar{C}_{P}=\bar{M} C_{P} 3 \tag{5.44a}
\end{equation*}
$$

where $M$ is the molar mass. The value of $\bar{C}_{v}$ and $\bar{C}_{P}$ have been fit very accurately with a five parameter fit whose coefficients are given in Appendix A11 for a number of gases and combustion products. $C_{v}$ and $C_{P}$ can be derived from the specific heats per mole by dividing by the Molar mass $\bar{M}$ defined as

$$
\begin{equation*}
\bar{M}=\frac{m}{n} \tag{5.44b}
\end{equation*}
$$

where $m$ is the mass and $n$ is the number of moles of the substance. The normal units used for $m$ and $n$ are kg and kgmol . Therefore the normal unit for $\bar{M}$ is $\mathrm{kg} / \mathrm{kgmol}$.

The enthalpy Eqs. 5.30 or 5.40 for an ideal gas can written as,

$$
\begin{equation*}
d h=d u+d(P v) \tag{5.45}
\end{equation*}
$$

Introducing the specific heat relations and the ideal-gas equation, gives,

$$
\begin{equation*}
C_{p} d T=C_{v} d T+R d T \tag{5.46}
\end{equation*}
$$

Dividing both sides by $d T$ results in the following relation for an Ideal Gas:

$$
\begin{equation*}
C_{p}=C_{v}+R \tag{5.47}
\end{equation*}
$$

The same relation holds for the molar specific heats and the universal gas constant $\bar{C}_{p}=\bar{C}_{v}+\bar{R}$. Note that the difference between $C_{p}$ and $C_{v}$ for an ideal gas is al-
ways a constant, even though both are functions of temperature. Defining the ratio of specific heats $\gamma$, we can see this ratio is also property of interest and is written as,

$$
\begin{equation*}
\gamma=\frac{C_{p}}{C_{v}} \tag{5.48}
\end{equation*}
$$

Substitution of Eq. 5.48 into Eq. 5.47 , results in the following useful relationships.

$$
\begin{equation*}
C_{p}=\left(\frac{\gamma}{\gamma-1}\right) R \tag{5.49a}
\end{equation*}
$$

or

$$
\begin{equation*}
C_{v}=\left(\frac{1}{\gamma-1}\right) R \tag{5.49b}
\end{equation*}
$$

Since $R$ for an ideal gas is constant, the specific heat ratio $\gamma$ just depends on temperature $T$.

For gases, the specific heat slowly increases with increasing temperature. Since they do not vary significantly over fairly large temperature differences, it is often acceptable to treat $C_{p}$ and $C_{v}$ as constants. In this case, the integration is simple and the internal energy and enthalpy can be expressed as,

$$
\begin{align*}
& u_{2}-u_{1}=C_{v}\left(T_{2}-T_{1}\right)  \tag{5.50}\\
& h_{2}-h_{1}=C_{p}\left(T_{2}-T_{1}\right) \tag{5.51}
\end{align*}
$$

Example 5.10 The specific heat of superheated steam at 200 kPa can be determined by the equation

$$
C_{p}=2.0+\frac{T-700}{2500} \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{K}
$$

a. What is the enthalpy change between 500 and 1000 K for 5 kg of steam? Compare with the steam tables.
b. What is the average Cp between 500 and $1000^{\circ} \mathrm{K}$ based on the equation and based on the tabulated data?

## Solution

a. The enthalpy change is found to be

$$
\Delta H=m \int_{T_{1}}^{T_{2}} C_{p} d T=5 \int_{500}^{1000}\left(2.0+\frac{T-700}{2500}\right) d T=5323 \mathrm{~kJ}
$$

From Table 14.3 at page A-53 and A-59 we find, using $P=200 \mathrm{kpa}$

$$
\Delta H=m(3990.1-2924.8)=5(1065.3)=5326.5 \mathrm{~kJ}
$$

b. The average value $C_{P, \text { Avg }}$, is found by using the relation

$$
m C_{P, \mathrm{Avg}} \Delta T=m \int_{T_{1}}^{T_{2}} C_{p} d T
$$

or

$$
(5)(1000-500) C_{P, \text { Avg }}=5 \int_{500}^{1000}\left(2.0+\frac{T-700}{2500}\right) d T
$$

The integral on right-hand side of above relation was evaluated in part (a) of the problem; hence, we have

$$
\left\{\begin{array}{l}
(5)(500) C_{P, \mathrm{Avg}}=5323 \\
C_{P, \mathrm{Avg}}=\frac{5323}{2500}=2.1292=2.13 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{K}
\end{array}\right.
$$

Using the values from the steam table, we have

$$
C_{P, \mathrm{Avg}} \simeq \frac{\Delta h}{\Delta T}=\frac{(3990.1-2924.8)}{500}=\frac{1065.3}{500}=2.1306 \approx 2.13 \mathrm{~kJ} / \mathrm{kg} \cdot{ }^{\circ} \mathrm{K}
$$

Because the steam tables give the same values as the linear equation of this example, we can safely assume that the $C_{P}(T)$ relationship for steam over this temperature range is closely approximated by a linear relation. This linear relation would change, however, for each pressure chosen; hence, the steam tables are essential.
Example 5.11 Determine the value of $C_{p}$ for steam at $T=1500{ }^{0} \mathrm{R}$ and $P=800$ psia (See Appendix 14.6 page A-87).

Solution To determine $C_{P}$ we use a finite-difference approximation to Eq. 5.39. We use the entries at $T=1600{ }^{\circ} \mathrm{R}$ and $T=1400{ }^{\circ} \mathrm{R}$ are used (a forward difference), $C_{P}$ is too low. If values at $T=1500{ }^{0} \mathrm{R}$ and $T=1300{ }^{0} \mathrm{R}$ are used (a backward
difference), $C_{P}$ is too high. Thus, both a forward and a backward value (a central difference) should be used resulting in a more accurate of the slope.

Example 5.12 Calculate the change in enthalpy between 300 and 1200 K for nitrogen gas three ways:

1. Look up the change in the enthalpy given in the tables in Appendix A13.7.
2. Calculate the constant pressure specific heat at 300 K based on the fitted coefficients in Appendix A11. Multiply this specific heat value times the temperature difference to get the change in enthalpy over this temperature range.
3. Integrate the fitted expansion from 300 to 1200 K to get the enthalpy change.

## Solution

## 1. From Appendix A13.7

$$
\begin{aligned}
h(300 \mathrm{~K}) & =7754.4 \mathrm{kj} / \mathrm{kgmol} h(1200 \mathrm{~K})=35806.4 \mathrm{~kJ} / \mathrm{kgmol} \\
\Delta h & =35806.4-7754.4=28,052 \mathrm{~kJ} / \mathrm{kgmol}
\end{aligned}
$$

2. From Appendix A11

$$
\begin{aligned}
\theta & =\frac{T}{100} C_{p}=c_{0}\left\{\frac{\theta^{2}}{\theta^{2}+\tau}\right\}+c_{1} \theta^{1 q_{2}}+c_{2} \theta+c_{3} \theta^{3} \mathrm{q}_{2}+c_{4} \theta^{2} \\
\theta & =3 C_{p}=12.2568(1)-7.0276 * 3^{1} \mathrm{q}_{2}+3.1766 * 3-0.5465 * 3^{3} \mathrm{q}_{2}+0.0328 * 3^{2} \\
C_{p} & =12.2568-12.1722+9.5298-2.8396+0.2952=7.070 \frac{\mathrm{kcal}}{\mathrm{kgmol}-\mathrm{K}} \\
C_{p} & =7.07 * 4.1868=29.60 \mathrm{~kJ} / \mathrm{kgmol} \\
\Delta h & =29.6 *(1200-300)=26,640 \mathrm{~kJ} / \mathrm{kgmol}(-5 \%)
\end{aligned}
$$

3. The following steps is used to calculate the step 3 of this problem

$$
\begin{aligned}
& \theta_{1}=\frac{300}{100}=3 \quad \theta_{2}=\frac{1200}{100}=12 \\
& \Delta h=\int_{T_{1}}^{T_{2}} C_{p} d T=100 \int_{\theta^{1}}^{\theta_{2}} C_{p} d \theta=100 \int_{\theta_{1}}^{\theta_{2}}\left(c_{0}+c_{1} \theta^{1 / 2}+c_{2} \theta+c_{3} \theta^{3 / 2}+c_{4} \theta^{2}\right) d \theta \\
& \Delta h=100 *\left\{\begin{array}{l}
12.2568 *(12-3)-7.0276 * \frac{\left(12^{3 / 2}-3^{3 / 2}\right)}{3 / 2} \\
+3.1766 * \frac{\left(12^{2}-3^{2}\right)}{2}-0.5465 * \frac{\left(12^{5 / 2}-3^{5 / 2}\right)}{5 / 2}+0.0328 * \frac{\left(12^{3}-3^{3}\right)}{3}
\end{array}\right\} \\
& \Delta h=6728.15 \mathrm{kcal} / \mathrm{kgmol}=28,169.4 \mathrm{~kJ} / \mathrm{kgmol}(+0.4 \%)
\end{aligned}
$$

### 5.19 Heat Capacities of an Ideal Gas

It is usually easiest to measure the heat capacity of a gas in a closed container under constant-volume conditions. The corresponding heat capacity is called the specific heat at constant volume and is designated $C_{v}$. Heat capacity measurements for solids and liquids are usually carried out in the atmosphere under constant atmospheric pressure, and we call the corresponding heat capacity the specific heat at constant pressure, designated $C_{p}$. If neither $p$ nor $V$ is constant, we have an infinite number of possible heat capacities.

Consider $C_{v}$ and $C_{p}$ for an ideal gas. To measure $C_{v}$, an ideal gas is heated in a rigid container at constant volume. To measure $C_{p}$, the gas is allowed expand just enough to keep the pressure constant as the temperature rises.

Why should these two molar heat capacities be different? The answer lies in the first law of thermodynamics. In a constant-volume temperature increase, the system does not do any work, and the change in internal energy $\Delta U$ equals the heat added $Q$. In a constant-pressure temperature increase, on the other hand, the volume must increase; otherwise, the pressure (given by the ideal-gas equation of state) could not remain constant. As the material expands, it does an amount of work $W$. According to the first law,

$$
\begin{equation*}
Q=\Delta U+W \tag{5.52}
\end{equation*}
$$

For a given temperature increase, the internal energy change $U$ of an ideal gas has the same value no matter what the process (remember that the internal energy of an ideal gas depends only on temperature, not pressure or volume). Equation 5.52 then shows that the heat input for a constant-pressure process must be greater than that for a constant-volume process because additional energy must be supplied to account for the work done during the expansion. So $C_{p}$ is greater than $C_{v}$ for an ideal gas. The $p V$-diagram in Fig. 5.22 shows this relationship. For air, $C_{p}$ is $40 \%$ greater than $C_{v}$ at temperatures near room temperature.

The ratio of specific heats then is a dimensionless parameter that will be useful for predicting many Ideal Gas processes. It is denoted by, denoted by the Greek letter gamma,

$$
\begin{equation*}
\gamma=\frac{C_{p}}{C_{v}} \tag{5.53}
\end{equation*}
$$

For gases, $C_{p}$ is always greater than $C_{v}$ and $\gamma$ is always greater than unity. This quantity plays an important role in adiabatic presses for an ideal gas. Below is a table with specific heats and ratios of specific heats for various temperatures for air. Note that in most gas dynamics text books $\gamma$ also is known as Adiabatic Index (Table 5.2).

Here's a final reminder: For an Ideal Gas the internal energy change in any process is given by $\Delta U=n C_{v} \Delta T$, whether the volume is constant or not.

Fig. 5.22 Raising the temperature of an ideal gas from $T_{1}$ to $T_{2}$ by a constant-volume or a constant-pressure process. For an ideal gas, $U$ depends only on $T$, so $\Delta U$ is the same for both processes. In the constant-volume process, no work is done, so $Q=\Delta U$. But for the constant-pressure process, $Q$ is greater, since it must include both $\Delta U$ and $W=p_{1}\left(V_{2}-V_{1}\right)$. Thus $C_{p}>C_{v}$

Table 5.2 Table of ratio of specific heat for air

| Temperature <br> K | $C_{p}$ <br> $\mathrm{~kJ} / \mathrm{kg} \mathrm{K}$ | $C_{v}$ <br> $\mathrm{~kJ} / \mathrm{kg} \mathrm{K}$ | $\gamma$ |
| :--- | :--- | :--- | :--- |
| 200 | 1.002 | 0.715 | 1.401 |
| 300 | 1.005 | 0.718 | 1.400 |
| 500 | 1.029 | 0.742 | 1.387 |
| 1000 | 1.140 | 0.853 | 1.336 |
| 2000 | 1.249 | 0.962 | 1.298 |

Example 4.13 Cooling a Dorm Room.
A typical dorm room or bedroom is about $8 \mathrm{~m} \times 4 \mathrm{~m} \times 2.5 \mathrm{~m}$. The density of air on a typical day is about $1.225 \mathrm{~kg} / \mathrm{m}^{-3}$. First find the mass of the air in the room. Then find the change in the internal energy of this much air when it is cooled from 23.9 to $11.6^{\circ} \mathrm{C}$ at an constant pressure of 1.00 atm . Treat the air as an ideal gas.

Solution This is a constant pressure process. One way to do this is to find $Q$ from $Q=n C_{p} \Delta T$, then find the volume change. After finding the volume change, then find the work done by the gas from $W=p \Delta V$. Finally, use the first law to find $\Delta U$. This would be perfectly correct, but there's a much easier way. For an ideal gas the internal-energy change is $\Delta U=n C_{v} \Delta T$ for every process, whether the volume is constant or not. So all that is needed is $C_{v}$. The average of $23.9^{\circ} \mathrm{C}$ and $11.6^{\circ} \mathrm{C}$ is about $18^{\circ} \mathrm{C}$ or about 291 K . We'll use the value for $C_{v}$ from the table at 300 K which is $0.718 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$. We also need the mass of the air.

$$
\text { mass }=\rho \times V=1.225 \mathrm{~kg} / \mathrm{m}^{-3 \times} 8 \times 4 \times 2.5 \mathrm{~m}=98 \mathrm{~kg}
$$

Then

$$
\begin{aligned}
& \Delta U=98 \mathrm{~kg} \times 0.718 \mathrm{~kJ} / \mathrm{kg} \mathrm{~K} \times\left(11.6^{\circ} \mathrm{C}-23.9^{\circ} \mathrm{C}\right) \\
& \Delta U=-865 \mathrm{~kJ}=-8.65 \times 10^{5} \mathrm{~J}
\end{aligned}
$$

A room air conditioner must extract this much internal energy from the air in the room and transfer it to the air outside.

### 5.20 Adiabatic Processes for an Ideal Gas

An adiabatic process is a process in which no heat transfer takes place between a system and its surroundings. Zero heat transfer is an idealization, but a process is approximately adiabatic if the system is well insulated or if the process takes place so quickly that, there is not enough time for appreciable heat flow to occur.

In an adiabatic process, $Q=0$, so from the first law, $\Delta U=-W$. An adiabatic process for an ideal gas is shown in the $p V$-diagram in Fig. 5.23 below.

As the gas expands from volume $V_{a}$ to $V_{b}$, it does positive work, so its internal energy decreases and its temperature drops. If point $a$, representing the initial state, lies on an isotherm at temperature $T+\Delta T$, then point $b$ for the final state is on a different isotherm at a lower temperature $T$. For an ideal gas, an adiabatic curve at any point is always steeper than the isotherm passing through the same point. For an adiabatic compression from $V_{b}$ to $V_{a}$, the situation is reversed and the temperature rises accordingly.

Fig. 5.23 A $p V$-diagram of an adiabatic process for an ideal gas. As the gas expands from $V_{a}$ to $V_{b}$, its temperature drops from $T+\Delta T$ to $T$, corresponding to the decrease in internal energy due to the work $W$ done by the gas (indicated by the shaded area). For an ideal gas, when an isotherm and an adiabatic pass through the same point on a $p V$-diagram, the adiabatic is always steeper

The air in the output pipes of air compressors used in gasoline stations and in paint-spraying equipment is always warmer than the air entering the compressor; this is because the compression is rapid and hence approximately adiabatic. Adiabatic cooling occurs when you open a bottle of your favorite carbonated beverage. The gas just above the beverage surface expands rapidly in a nearly adiabatic process; the temperature of the gas drops so much that water vapor in the gas condenses, forming a miniature cloud.

Caution Keep in mind that "adiabatic heating" and "adiabatic cooling," really mean "raising the temperature" and "lowering the temperature," in an adiabatic process respectively. In an adiabatic process, the temperature change is due to work done by, or on the system; there is no heat flow at all.

A relation can be derived between volume and temperature changes for an infinitesimal adiabatic process in an ideal gas. Equation 5.55 gives the internal energy change $\Delta U$ for any process for an ideal gas, adiabatic or not, so we have $\Delta U=n C_{v} \Delta T$. Also, the work done by the gas during the process is given by $F$. Then, since $\Delta U=-\Delta W$ for an adiabatic process, we have

$$
\begin{equation*}
n C_{v} \Delta T=-p \Delta V \tag{5.54}
\end{equation*}
$$

To obtain a relation containing only the volume $V$ and temperature $T$, eliminate $p$ using the ideal-gas equation in the form $p=\rho R T$. Since $m=\rho V$, write the ideal gas equation as $p=(n / V) \cdot R T$. Substituting this into Eq. 4.63, gives

$$
n C_{v} \Delta T=-\frac{n}{V} R T \Delta V
$$

Rearranging, gives

$$
\frac{\Delta T}{T}+\frac{R}{C_{v}} \frac{\Delta V}{V}=0
$$

The coefficient $R / C_{v}$ can be expressed in terms of $\gamma=C_{p} / C_{v}$. We have

$$
\begin{gather*}
\frac{R}{C_{v}}=\frac{C_{p}-C_{v}}{C_{v}}=\frac{C_{p}}{C_{v}}-1=\gamma-1 \\
\frac{\Delta T}{T}+(\gamma-1) \frac{\Delta V}{V}=0 \tag{5.55}
\end{gather*}
$$

Because $\gamma$ is always greater than unity for a gas, $(\gamma-1)$ is always positive. This means that in Eq. $5.55, \Delta V$ and $\Delta T$ always have opposite signs. An adiabatic expansion of an ideal gas $(\Delta V>0)$ always occurs with a drop in temperature $(\Delta T<0)$, and an adiabatic compression $(\Delta V<0)$ always occurs with a rise in temperature ( $\Delta T>0$ ); this confirms the earlier prediction.

Equation 5.5.55 does not help much in its current form for solving problems. To get it to a form that will help requires a little calculus. Taking differentials and integrating gives,

$$
\begin{gather*}
\ln T+(\gamma-1) \ln V=\text { constant } \\
\ln \left(T V^{\gamma-1}\right)=\text { constant } \tag{5.56}
\end{gather*}
$$

Thus, for an initial state $\left(T_{1}, V_{l}\right)$ and a final state $\left(T_{2}, V_{2}\right)$,

$$
\begin{equation*}
T_{1} V_{1}^{\gamma-1}=T_{2} V_{2}^{\gamma-1} \text { (Adiabatic process, ideal gas) } \tag{5.57}
\end{equation*}
$$

The $T$ 's must always be absolute (Kelvin) temperatures.
Equation 5.56 can be converted into a relation between pressure and volume by eliminating $T$, using the ideal-gas equation in the form $T=p / R \rho=p V / n R$. Substituting this into Eq. 5.56 , gives

$$
\frac{p V}{n R} V^{\gamma-1}=\mathrm{constant}
$$

or because $n$ and $R$ are constant

$$
\begin{equation*}
p V^{\gamma}=\text { constant } \tag{5.58}
\end{equation*}
$$

For an initial state $\left(p_{1}, V_{1}\right)$ and a final state $\left(p_{2}, V_{2}\right)$, Eq. 5.58 becomes

$$
\begin{equation*}
p_{1} V_{1}^{\gamma}=p_{2} V^{\gamma} \text { (Adiabatic process, ideal gas) } \tag{5.59}
\end{equation*}
$$

$V_{1}$ and $V_{2}$ can be eliminated between Eqs. 5.58 and 5.59 to obtain

$$
\begin{equation*}
\frac{p_{1}}{p_{2}}=\left(\frac{T_{1}}{T_{2}}\right)^{\frac{\gamma}{\gamma-1}} \tag{5.60}
\end{equation*}
$$

It is also possible to calculate the work done by an ideal gas during an adiabatic process. In this case $Q=0$ and $W=-\Delta U$ which holds true for any adiabatic process. For an ideal gas, $\Delta U=n C_{v}\left(T_{2}-T_{1}\right)$. If the mass $n$ and the initial and final temperatures $T_{1}$ and $T_{2}$ are known, then

$$
\begin{equation*}
W=n C_{v}\left(T_{1}-T_{2}\right) \tag{5.61}
\end{equation*}
$$

Using the Ideal Gas law $p=\rho R T=(m / V) \cdot R T$ in this equation to obtain

$$
\begin{equation*}
W=\frac{C_{v}}{R}\left(p_{1} V_{1}-p_{2} V_{2}\right)=\frac{1}{\gamma-1}\left(p_{1} V_{1}-p_{2} V_{2}\right) \tag{5.62}
\end{equation*}
$$

[^1]Fig. 5.24 Hot steam pressure cooker

where $C_{v}=R /(\gamma-1)$. If the process is an expansion, the temperature drops. $T_{1}$ is greater than $T_{2} \cdot p_{1} V_{1}$ is greater than $p_{2} V_{2}$, and the work is positive, as expected. If the process is a compression, the work is negative.

Throughout this analysis of adiabatic processes assumed the Ideal Gas equation of state, which is valid only for equilibrium states. Strictly speaking, these results are valid only for processes that are fast enough to prevent appreciable heat exchange with the surroundings (so that $Q=0$ and the process is adiabatic), yet slow enough that the system does not depart very much from thermal and mechanical equilibrium. Even when these conditions are not strictly satisfied, though, Eq. 5.59 through 5.61 gives useful approximate results.

Hot steam escapes from the top of this pressure cooker at high speed. Hence, it has no time to exchange heat with its surroundings, and its expansion is nearly adiabatic. As the steam's volume increases, its temperature drops so much (See Eq. 5.59) that it feels cool on this chef's hand (See Fig. 5.24 above).

Example 5.14 Adiabatic Compression in a Diesel Engine
The compression ratio of a diesel engine is 15 to 1 ; this means that air in the cylinders is compressed to $1 / 15$ of its initial value (Fig. 5.25). If the initial pressure is $1.10 \times 10^{5} \mathrm{~Pa}$ and the initial temperature is $27^{\circ} \mathrm{C}(300 \mathrm{~K})$, find the final pressure and the temperature after compression. Air is mostly a mixture of diatomic oxygen and nitrogen; treat it as an ideal gas with $\gamma=1.4$.

Solution We have $p_{1}=1.10 \times 105 \mathrm{~Pa}, T_{1}=300 \mathrm{~K}$, and $V_{1} / V_{2}=15$. From Eq. 5.57,

$$
T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1}=(300 \mathrm{~K})(15)^{0.4}=886 \mathrm{~K}=613^{\circ} \mathrm{C}
$$

From Eq. 5.59,

$$
\begin{aligned}
p_{2} & =p_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma}=\left(1.01 \times 10^{5} p a\right)(15)^{1.4} \\
& =44.8 \times 10^{5} p a=44 \mathrm{~atm}
\end{aligned}
$$

Fig. 5.25 Adiabatic compression of air in a cylinder of a diesel engine

If the compression had been isothermal, the final pressure would have been 15 atm , but because the temperature also increases during an adiabatic compression, the final pressure is much greater.

When fuel is injected into the cylinders near the end of the compression stroke, the high temperature of the air attained during compression causes the fuel to ignite spontaneously without the need for spark plugs.

Example 5.15 Work done in an adiabatic process
In Example 5.12, how much work does the gas do during the compression if the initial volume of the cylinder is $1.00 \mathrm{~L}=1.00 \times 10^{-3} \mathrm{~m}^{3}$ ? Assume that $C_{v}$ for air is $0.718 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$ and $\gamma=14$.

Solution Determine the mass using the Ideal Gas equation of state

$$
\begin{gathered}
p=\rho R T=(\mathrm{m} / \mathrm{V}) R T . \\
m=\frac{p_{1} V_{1}}{R T_{1}}=\frac{\left(1.01 \times 10^{5} \mathrm{~Pa}\right)\left(1.00 \times 10^{-3} \mathrm{~m}^{3}\right)}{\left(287.05^{N m} \mathrm{q} \mathrm{kgK}\right)(300 \mathrm{~K})} \\
\mathrm{m}=1.173 \times 10^{-3} \mathrm{~kg}
\end{gathered}
$$

and Eq. 5.26 gives

$$
\begin{gathered}
W=n C_{v}\left(T_{1}-T_{2}\right) \\
=1.173 \times 10^{-3} \mathrm{~kg}(0.718 \mathrm{~kJ} / \mathrm{kg} \mathrm{~K})(300 \mathrm{~K}-886 \mathrm{~K})
\end{gathered}
$$

$$
W=-0.494 \mathrm{~kJ}=-494 \mathrm{~J}
$$

With the second method,

$$
\begin{gathered}
W=\frac{1}{\gamma-1}\left(P_{1} V_{1}-P_{2} V_{2}\right) \\
W=\frac{1}{1.40-1}\left[\left(1.01 \times 10^{5} \mathrm{~Pa}\right)\left(1.00 \times 10^{-3} \mathrm{~m}^{3}\right)-\left(44.8 \times 10^{5} \mathrm{~Pa}\right)\left(\frac{1.00 \times 10^{-3} \mathrm{~m}^{3}}{15}\right)\right] \\
W=-494 \mathrm{~kJ}=-494 \mathrm{~J}
\end{gathered}
$$

The work is negative because the gas is compressed.

### 5.21 Summary

This has been a long Chapter but its fundamentals can be summarized with the following main points and equations.

- A thermodynamic system can exchange energy with its surroundings by heat transfer or by mechanical work and in some cases by other mechanisms. When a system at pressure $p$ expands from volume $V_{1}$ to $V_{2}$, it does an amount of work $W$ given by

$$
\begin{equation*}
W=\sum p \Delta V \tag{5.63}
\end{equation*}
$$

If the pressure is constant during the expansion

$$
\begin{equation*}
W=p\left(V_{2}-V_{1}\right) \tag{5.64}
\end{equation*}
$$

- In any thermodynamic process, the heat added to the system and the work done by the system depends not only on the initial and final states, but also on the path (the series of intermediate states through which the system passes).
- The first law of thermodynamics states that when heat $Q$ is added to a system while it does work W , the internal energy $U$ changes by an amount

$$
\begin{equation*}
U_{2}-U_{1}=\Delta U=Q-W \text { (First Law of Thermodynamics) } \tag{5.65}
\end{equation*}
$$

- The internal energy of any thermodynamic system depends only on its state. The change in internal energy during a process depends only on the initial and final states, not on the path. The internal energy of an isolated system is constant.
- An adiabatic process requires no heat transfer into or out of a system, $Q=0$.
- An isochoric process implies constant volume, $\Delta V=0, \Rightarrow W=0$.
- An isobaric process implies constant pressure, $\Delta p=0 \Rightarrow W=p\left(V_{2}-V_{1}\right)$.
- An isothermal process implies constant temperature.
- The heat capacities $C_{v}$ and $C_{p}$ of an ideal gas are related by

$$
\begin{equation*}
C_{p}=C_{v}+R \tag{5.67}
\end{equation*}
$$

The ratio of heat capacities, $C_{p} / C_{v}$, is denoted by $\gamma$

$$
\begin{equation*}
\gamma=\frac{C_{p}}{C_{v}} \tag{5.68}
\end{equation*}
$$

- For an adiabatic process for an ideal gas the quantities $T V^{\gamma-1}$ and $p V^{\gamma}$ are constant. For an initial state $\left(p_{1}, V_{1}, T_{1}\right)$ and a final state $\left(p_{2}, V_{2}, T_{2}\right)$,

$$
\begin{align*}
T_{1} V_{1}^{\gamma-1} & =T_{2} V_{2}^{\gamma-1}  \tag{5.67}\\
p_{1} V_{1}^{\gamma} & =p_{2} V^{\gamma} \tag{5.68}
\end{align*}
$$

Or eliminating $V_{l}$ and $V_{2}$ between these equations gives,

$$
\begin{equation*}
\frac{p_{1}}{p_{2}}=\left(\frac{T_{1}}{T_{2}}\right)^{\frac{\gamma}{\gamma-1}} \tag{5.69}
\end{equation*}
$$

The work done by an ideal gas during an adiabatic expansion is

$$
\begin{equation*}
W=n C_{v}\left(T_{1}-T_{2}\right)=\frac{C_{v}}{R}\left(p_{1} V_{1}-p_{2} V_{2}\right)=\frac{1}{\gamma-1}\left(p_{1} V_{1}-p_{2} V_{2}\right) \tag{5.70}
\end{equation*}
$$

## Chapter 6 <br> The Kinetic Theory of Gases

As stated previously Classical Thermodynamics is very much a mathematical discipline. Given that the defining equations are known, the theory is developed around multi-variable calculus. The theory is actually quite elegant, but it does not predict how to estimate or calculate the fundamental quantities or the properties that characterize them. For this, a transition to Statistical Thermodynamics is required. Statistical Thermodynamics starts with the kinetic theory of gases and treats fluids as made up of large assemblages of atoms or molecules. It can be a very detailed and extensive theory that extends well beyond the subjects of interest to this text. However, a smattering of Statistical Thermodynamics, including the kinetic theory of gases, will be useful for understanding a number of Classical Thermodynamics phenomena. A brief sojourn into the kinetic theory of gases is useful.

### 6.1 Kinetic Theory Basis for the Ideal Gas Law

Classical thermodynamics is based on treating all fluids (gases and liquids) as a continuum. This means there is no macroscopic structure to the fluid. However, liquids and gases in particular are made up of individual atoms or molecules. To extend Classical Thermodynamics to be able to predict some of the parameters that show up in the classical equations, molecular structure must be considered. Begin by considering the size of some molecules of interest. Though there is some internal structure to each of these molecules, they can be approximated as spheres to first order (Table 6.1).

Generally of more interest to the analysis are the number of molecules per cubic millimeter and the fraction of available volume they take up. For the above molecules, this data is presented in Table 6.2.

Example 6.1 Estimate the molecules per cubic millimeter for $\mathrm{CO}_{2}$ and the fraction of volume it occupies at STP. The average radius for the $\mathrm{CO}_{2}$ molecule is 0.226 nm .

Table 6.1 Effective molecular radii and volumes per molecule

| Gas | Effective atom/ <br> molecule radius <br> $(\mathrm{nm})$ | Volume per <br> atom/molecule <br> (cubic mm) |
| :--- | :--- | :--- |
| Helium | 0.152 | $1.46 \mathrm{E}-20$ |
| Argon | 0.181 | $2.50 \mathrm{E}-20$ |
| Nitrogen | 0.175 | $2.23 \mathrm{E}-20$ |
| Oxygen | 0.161 | $1.76 \mathrm{E}-20$ |
| Hydrogen | 0.155 | $1.57 \mathrm{E}-20$ |
| Water | 0.157 | $1.62 \mathrm{E}-20$ |

Table 6.2 Volume fraction occupied at STP

| Gas | Fraction of volume at STP |
| :--- | :--- |
| Helium | $3.93 \mathrm{E}-5$ |
| Argon | $6.71 \mathrm{E}-5$ |
| Nitrogen | $5.99 \mathrm{E}-5$ |
| Oxygen | $4.73 \mathrm{E}-5$ |
| Hydrogen | $4.21 \mathrm{E}-5$ |
| Water | $4.34 \mathrm{E}-5$ |
| STP standard temperature and pressure, 273.15 K and 1 atmo- <br> sphere pressure $(101.3 \mathrm{k} \mathrm{Pa})$ |  |

Solution The effective volume of the $\mathrm{CO}_{2}$ molecule is

$$
V=\frac{4 \pi}{3} r^{3}=\frac{4 \pi}{3}\left(0.226 \times 10^{-9}\right)^{3}=4.835 \times 10^{-20} \mathrm{~nm}^{3}
$$

And the number of molecules per cubic meter for any gas at STP is given by
$N=N_{a} \frac{\rho}{M}=\frac{N_{a} p / R T}{M}=\frac{N_{a} p}{M \frac{\mathfrak{R}}{M} T}=\frac{N_{a} p}{\mathfrak{R} T}=\frac{6.022 \times 10^{26} * 101325}{8314.47 * 273.15}=2.687 \times 10^{25} \frac{\text { molecules }}{\mathrm{m}^{3}}$
$N_{a}=$ Avogadro's Number
Then the volume per cubic millimeter occupied by the molecules is,

$$
V_{\text {molecules }}=V^{*} N=4.835 \times 10^{-20} * 2.687 \times 10^{25} / 1.0 \times 10^{9}=1.299 \times 10^{-3} \mathrm{~mm}^{3}
$$

It is clear that in a volume as small as a cubic millimeter there are a huge number of molecules and they fill only a very small fraction of the volume.

Fig. 6.1 Column volume for molecules impacting the wall

Now consider these molecules as they hit a stationary wall that confines them. Assume that they are moving equally in all directions and have a distribution of speeds. Thus at each speed the number that pass through a small area on the surface of a sphere that is characterized by the polar and azimuthal angles $\theta$ and $\phi$ is given by

$$
\begin{equation*}
d n_{v \theta \phi}=d n_{v} \frac{\sin \theta d \theta d \phi}{4 \pi} \tag{6.1}
\end{equation*}
$$

Consider a cylinder that ends on the surface of the wall and intercepts a small area $\boldsymbol{d} \boldsymbol{A}$ on the wall. The cylinder is of length $\boldsymbol{v} \boldsymbol{d t}$. (Only consider molecules close enough to the wall that they do not collide with each other before they hit the wall.) (Fig. 6.1).

Then the molecules with a given speed that will intercept the surface during $d t$ are those that are contained in the volume $\boldsymbol{d} \boldsymbol{V}$ given by,

$$
\begin{equation*}
d V=d A(v d t \cos \theta) \tag{6.2}
\end{equation*}
$$

The number that are headed in the right direction and can intercept the surface in the time $d t$ are given by,

$$
\begin{equation*}
d n_{\text {colliding }}=d n_{v \theta \phi} d V=d A d t d n_{v} \frac{v \sin \theta \cos \theta d \theta d \phi}{4 \pi} \tag{6.3}
\end{equation*}
$$

So the number colliding per $\boldsymbol{d} \boldsymbol{A d t}$ is given by,

$$
\begin{equation*}
\frac{d n_{\text {colliding }}}{d A d t}=v d n_{v} \frac{\sin \theta \cos \theta d \theta d \phi}{4 \pi} \tag{6.4}
\end{equation*}
$$

Now for every collision in which the molecule is scattered elastically, each molecule has a change in momentum corresponding to twice its momentum perpendicular to the fixed surface.

$$
\begin{equation*}
\Delta m v=m v \cos \theta-(-m v \cos \theta)=2 m v \cos \theta \tag{6.5}
\end{equation*}
$$

The total momentum change for those colliding in $\boldsymbol{d A d t}$ is

$$
\begin{equation*}
\Delta m v d n_{\text {colliding }}=m v^{2} d n_{v} \frac{\sin \theta \cos ^{2} \theta d \theta d \phi}{2 \pi} d A d t \tag{6.6}
\end{equation*}
$$

Integrating over $\theta$ from 0 to $\pi / 2$ and $\phi$ from 0 to $2 \pi$ gives,

$$
\begin{equation*}
\Delta m v d n_{\text {colliding }}=\frac{1}{3} m v^{2} d n_{v} d A d t \tag{6.7}
\end{equation*}
$$

for the total momentum change due to molecules at velocity $\boldsymbol{v}$. Integrating over all velocities to get the total momentum change and setting that equal to the total impulse gives,

$$
\begin{equation*}
d F d t=\frac{1}{3} m \int_{0}^{\infty} v^{2} d n_{v} d A d t \tag{6.8}
\end{equation*}
$$

or

$$
\begin{equation*}
\frac{d F d t}{d A d t}=\frac{1}{3} m\left[\int_{0}^{\infty} v^{2} d n_{v}\right]=\frac{d F}{d A}=p \tag{6.9}
\end{equation*}
$$

Then defining

$$
\begin{equation*}
n\left\langle v^{2}\right\rangle=\int_{0}^{\infty} v^{2} d n_{v} \tag{6.10}
\end{equation*}
$$

Thus

$$
\begin{equation*}
p=\frac{1}{3} n m\left\langle v^{2}\right\rangle \tag{6.11}
\end{equation*}
$$

Remembering that $\boldsymbol{n}=\boldsymbol{N} / \boldsymbol{V}$, gives,

$$
\begin{equation*}
p V=\frac{1}{3} N m\left\langle v^{2}\right\rangle \tag{6.12}
\end{equation*}
$$

This looks like the Ideal Gas law,

$$
\begin{equation*}
p V=n \boldsymbol{R} T \tag{6.13}
\end{equation*}
$$

Note that $n=N / N_{a}$ where $N_{a}$ is Avogadro's number $6.022 \mathrm{E}+26$ molecules per kilo-gram-mole. So the Ideal Gas law is

$$
p V=N\left(R / N_{a}\right) T=N k T
$$

$$
k=R / N a=8314.47 \mathrm{~J} / \mathrm{kmol} / \mathrm{K} / 6.022 E+26 \mathrm{molecules} / \mathrm{kmol}
$$

$k=1.381 E-23 \mathrm{~J} /$ molecule/ $K-$ Boltzmanns constant
and,

$$
\begin{equation*}
p V=N k T=\frac{1}{3} N m\left\langle v^{2}\right\rangle \quad\left\langle v^{2}\right\rangle=\frac{3 k T}{m} \quad v_{r m s}=\sqrt{\left\langle v^{2}\right\rangle}=\sqrt{\frac{3 k T}{m}} \tag{6.14}
\end{equation*}
$$

Example 6.2 Estimate $V_{r m s}$ for a nitrogen molecule in a gas at 300 K . Compare this with the speed of sound in nitrogen at this temperature given by $V_{\text {sound }}=\sqrt{\gamma R T}$.
Solution So estimating the Vrms for nitrogen at 300 K gives

$$
V_{r m s}=\sqrt{\frac{3 k T}{m}}=\sqrt{\frac{3 * 1.381 \times 10^{-23} \frac{n t-m}{K} * 300 K}{28 * 1.661 \times 10^{-27} \mathrm{~kg}}}=516.9 \mathrm{~m} / \mathrm{sec}
$$

The speed of sound in nitrogen is

$$
V_{\text {sound }}=\sqrt{\gamma R T}=\sqrt{1.4 * 8314.47 / 28 * 300}=353.2 \mathrm{~m} / \mathrm{s}
$$

So the molecules, on average, are traveling significantly faster than the speed of sound. Thus if the gas is pushing a piston at speeds below 0.1 the speed of sound, the gas molecules hardly know the piston is moving and the process of moving the piston looks like a quasi-static one.

Perhaps more important is the following relationship.

$$
\begin{equation*}
E_{K E}=\frac{1}{2} m\left\langle v^{2}\right\rangle=\frac{3}{2} k T \tag{6.15}
\end{equation*}
$$

which relates the average kinetic energy of a gas molecule to the absolute temperature.

### 6.2 Collisions with a Moving Wall

Now using the same type of analysis to evaluate collisions with a moving wall, consider a wall moving relatively slowly compared to the RMS velocity of the molecules in the gas. The change in kinetic energy of a molecule striking a wall moving away from it is given by,

$$
\begin{align*}
& \Delta K E_{A, v, \theta, \phi}=\frac{1}{2} m\left[(v \cos \theta)^{2}-(v \cos \theta-2 u)^{2}\right] \\
& \Delta K E_{A, v, \theta, \phi}=\frac{1}{2} m\left[v^{2} \cos ^{2} \theta-v^{2} \cos ^{2} \theta+4 u v \cos \theta-4 u^{2}\right] \\
& \Delta K E_{A, v, \theta, \phi}=2 m u v \cos \theta \tag{6.16}
\end{align*}
$$

Multiplying this by the number of molecules striking the wall with velocity $\boldsymbol{v}$ gives,

$$
\begin{align*}
& \Delta K E_{A, v}=2 m v u \int_{0}^{\frac{\pi}{2}} \cos \theta v d n_{v} \frac{\sin \theta \cos \theta d \theta \int_{0}^{2 \pi} d \phi}{4 \pi} \\
& \Delta K E_{A, v}=m u v^{2} d n_{v} \int_{0}^{\frac{\pi}{2}} \sin \theta \cos ^{2} \theta d \theta \\
& \Delta K E_{A, v}=\frac{1}{3} m u v^{2} d n_{v} \tag{6.17}
\end{align*}
$$

Then integrating over velocity gives,

$$
\begin{equation*}
\Delta K E_{A}=\frac{1}{3} n m u\left\langle v^{2}\right\rangle=p u \tag{6.18}
\end{equation*}
$$

Multiplying by the area of the moving wall gives

$$
\begin{align*}
& p A u=p A \frac{d x}{d t}=p \frac{d V}{d t}=\frac{\Delta K E_{g a s}}{d t} \\
& p d V=\Delta K E_{g a s} \tag{6.19}
\end{align*}
$$

### 6.3 Real Gas Effects and Equations of State

The Ideal Gas assumes that the molecules are small spherical masses of negligible volume that only interact with each other by bouncing off each other elastically. This is not true because as the temperature goes down and the pressure increases, eventually each gas will condense into a liquid. So as a minimum, there are two corrections that must be made to the Ideal Gas law as an Ideal Gas becomes a 'real gas' or vapor. The first correction is for the volume that the molecules take up as they get in the way of each other. Rudolf Clausius proposed that the actual volume $V$ could be corrected to a volume $V^{\prime}$ such that $V^{\prime}=V-b$. He estimated that the excluded volume should be four times the volume of each molecule. So he calculated b' as $\frac{16}{3} N \pi r^{2}$ where $r$ is the molecular radius. Van der Waals in 1873 included a second correction factor to take into account the forces of attraction that molecules exert on each other. These forces typically fall off very rapidly with distance between molecules $\sim 1 / \mathrm{r}^{6}$, so they are appreciable only between one molecule and its nearest neighbor. Since the molecules are attracted to each other one would expect that the actual pressure would be reduced from the pressure calculated by the Ideal Gas Law. If p' is the pressure based only on instantaneous collisions, the actual pressure would be given by,

$$
\begin{equation*}
p=p^{\prime}-a^{\prime}\left(\frac{N}{V}\right)^{2} \tag{6.20}
\end{equation*}
$$

Combining this effect with the Clausius correction gives the Van der Waals equation of state.

$$
\begin{equation*}
\left[p+a^{\prime}\left(\frac{N}{V}\right)^{2}\right]\left(V-b^{\prime}\right)=m \Re T \tag{6.21}
\end{equation*}
$$

Redefining

$$
\begin{equation*}
a=a^{\prime} N a^{2} \quad b=b^{\prime} N a / N \tag{6.22}
\end{equation*}
$$

gives Van der Waal's equation of state,

$$
\begin{equation*}
\left(p+a / v^{2}\right)(v--b)=R T \quad(\text { Van der Waals }) \tag{6.23}
\end{equation*}
$$

### 6.4 Principle of Corresponding States

Van der Waals also noticed that if the actual temperature and pressure for a gas are normalized by the pressure and temperature at the critical point (the top of the vapor dome) to produce a reduced temperature and pressure. The compressibility factor, $\boldsymbol{Z}=\boldsymbol{p} \boldsymbol{v} / \boldsymbol{R T}$, for most gases could then be plotted on a small number of charts with the value of $\mathrm{Z}_{\mathrm{C}}$ being the distinguishing factor among the charts. A typical generalized compressibility chart is given below for $Z_{C}=0.27$ (Fig. 6.2).

Fig. 6.2 Generalized compressibility chart for $Z$

As shown previously the Van der Waals coefficients $a$ and $b$ are found in terms of the critical state values. The coefficients are given by

$$
\begin{equation*}
a=\frac{27 \Re^{2} T_{c r}^{2}}{64 p_{c r}} \quad b=\frac{\Re T_{c r}}{8 p_{c r}} \tag{6.24}
\end{equation*}
$$

when these values are substituted into the Van der Waals equation, it can be expressed in terms of the reduced pressure, temperature and specific volume.

$$
\begin{equation*}
\left(P_{r}+\frac{3}{v_{r}^{2}}\right)\left(3 v_{r}-1\right)=8 T_{r} \quad P_{r}=\frac{P}{P_{C}}, \quad T_{r}=\frac{T}{T_{C}}, \quad v_{r}=\frac{v}{v_{C}} \tag{6.25}
\end{equation*}
$$

For the Redlich-Kwong model this becomes,

$$
\begin{equation*}
P_{r}=\frac{T_{r}}{v_{r}-0.0867}-\frac{0.42748}{T_{r}^{1 / 2} v_{r}\left(v_{r}+0.0867\right)} \tag{6.26}
\end{equation*}
$$

and for the Peng-Robinson model; this becomes

$$
\begin{equation*}
P_{r}=\frac{T_{r}}{v_{r}-0.077796}-\frac{0.45724 \alpha}{v_{r}^{2}+0.1556 v_{r}-0.00605} \tag{6.27}
\end{equation*}
$$

Note that based on the corresponding states theory, the Ideal Gas Constant does not show up and units depend only on what is used for critical state values.

### 6.5 Kinetic Theory of Specific Heats

The relationship for point molecules was derived above

$$
\begin{equation*}
\frac{1}{2} m\left\langle v^{2}\right\rangle=\frac{3}{2} k T \tag{6.28}
\end{equation*}
$$

where the average kinetic energy of a point molecule is equal to $3 / 2 k T$. Had the same derivation been made for point molecules in a plane, the average kinetic energy would equal to $\boldsymbol{k} \boldsymbol{T}$, and if the molecules were confined to a line, the average kinetic energy would be equal to $\mathbf{1 / 2 k T}$. Since the molecules are bouncing around in three dimensions, they essentially have three degrees of freedom. The Equi-Partition of Energy theorem states that each degree of freedom contributes $\mathbf{1 / 2 \boldsymbol { k } \boldsymbol { T }}$ to
the thermal energy of the gas. Admittedly at this point this is somewhat of a hand waving argument, but it will be proven more rigorously later on.

Now when dealing with diatomic and polyatomic molecules, they can store energy in two additional modes. Since they have a non-spherical shape, they can store energy as a rotation about their center of mass. In addition, since they are not rigidly connected, they can store energy because of vibration between the atoms.

For any three-dimensional structure, there are potentially three different axes about which energy can be stored in the rotation of the structure. However, for a diatomic molecule there are really only two degrees of freedom associated with the rotation of the molecule. Rotation about the axis joining the two atoms stores an insignificant amount of energy and its contribution to stored energy is negligible. Therefore, for a diatomic molecule, gas rotation can contribute only $\boldsymbol{k} \boldsymbol{T}$ to the stored energy per molecule. Of course, for polyatomic molecules, the full three degrees of freedom associated with rotation are possible and rotation can potentially contribute $\mathbf{3 / 2 k} \boldsymbol{T}$ to the stored energy per molecule.

A diatomic molecule stores the energy of vibration as the kinetic energy of separation and the potential energy of separation. Therefore, vibration contributes two degrees of freedom to the energy storage in a diatomic molecule. The relationship for polyatomic molecules depends on the vibration modes available and excited, but certainly more than two degrees of freedom are possible.

Based on this model a diatomic gas should store internal energy in the following manner.

$$
\begin{align*}
& U=U_{\text {trans }}+U_{\text {rot }}+U_{v i b} \\
& U=\frac{3}{2} N k T+N k T+N k T \tag{6.29}
\end{align*}
$$

Or factoring out the number of molecules,

$$
\begin{align*}
& U=N\left(\frac{3}{2} k T+k T+k T\right) \\
& U=n\left(\frac{3}{2} \Re T+\Re T+\Re T\right) \tag{6.30}
\end{align*}
$$

Then to calculate the specific heat we have

$$
\begin{align*}
& u=\frac{U}{n}=\left(\frac{3}{2} \mathfrak{\Re} T+\mathfrak{R} T+\mathfrak{R} T\right) \\
& C_{v}=\left.\frac{d u}{d T}\right|_{v}=\frac{3}{2} \mathfrak{R}+\mathfrak{R}+\mathfrak{R}=\frac{7}{2} \mathfrak{R}  \tag{6.31}\\
& C_{p}=C_{v}+\mathfrak{R}=\frac{9}{2} \mathfrak{R}
\end{align*}
$$

This implies that for a monatomic Ideal Gas we should have,

$$
\begin{align*}
C_{v} & =\frac{3}{2} \Re=1.5 * 8.3143 \mathrm{kj} /(\mathrm{kgmole}-\mathrm{K})=12.47 \mathrm{kj} /(\mathrm{kgmole}-\mathrm{K}) \\
C_{p} & =\frac{5}{2} \Re=20.79 \mathrm{kj} /(\mathrm{kgmole}-\mathrm{K})  \tag{6.32}\\
k & =5 / 3=1.667
\end{align*}
$$

All of which are in excellent agreement with experiment. However, for a diatomic gas like hydrogen this implies that

$$
\begin{align*}
C_{v} & =\frac{7}{2} \Re=3.5 * 8.3143 \mathrm{kj} /(\mathrm{kgmole}-K)=29.1 \mathrm{kj} /(\mathrm{kgmole}-K) \\
C_{p} & =\frac{9}{2} \mathfrak{R}=37.4 \mathrm{kj} /(\mathrm{kgmole}-\mathrm{K})  \tag{6.33}\\
k & =9 / 7=1.286
\end{align*}
$$

which is not in good agreement with experiments. These are over estimates of the specific heats for diatomic gases at normal temperatures below the onset of disassociation.

Consider the following chart for hydrogen. Basically at low temperatures, $\mathrm{C}_{\mathrm{p}}$ takes the value of a monatomic gas. As the temperature increases, the specific heat increases in what appears to be two steps when plotted against the temperature on a logarithmic scale. The first step corresponds to the activation of rotational degrees of freedom. The second step corresponds to the activation of the vibration degrees of freedom (Fig. 6.3).

The transitions between the levels are functions of characteristic temperatures for rotation and vibration. For hydrogen these temperatures are $T_{\text {rot }}=87.5 \mathrm{~K}$ and $T_{\text {vib }}=6382 \mathrm{~K}$. For other diatomic gases the transition temperatures are listed in Table 6.3.

Perhaps the most useful thing to observe from this table is that for temperatures of interest with air as the working fluid, both oxygen and nitrogen are in the region where the rotational degrees of freedom have been activated and the vibration degrees of freedom are still dormant. Thus for both gases $\mathbf{C}_{v}$ should be $\mathbf{5 / 2} \mathbf{R}$ and $\mathbf{C}_{p}$ should be $7 / 2 \mathrm{R}$. This gives a value for $\mathbf{k}$ of $\mathbf{7 / 5}$ or $\mathbf{1 . 4}$ which matches the experimental value quite well near room temperature.

## Constant Pressure Specific Heat for Hydrogen

Fig. 6.3 Constant pressure specific heat for $\mathrm{H}_{2}$ vs. temperature

Table 6.3 Characteristic rotation \& vibration temperatures for diatomic molecules (Reference: [1])

| Gas | Characteristic rota- <br> tion temp (K) | Characteristic <br> vibration temp (K) |
| :--- | :--- | :--- |
| $\mathrm{H}_{2}$ | 87.5 | 6382 |
| OH | 27.2 | 5411 |
| HCl | 15.2 | 4331 |
| CH | 20.8 | 4145 |
| $\mathrm{~N}_{2}$ | 2.88 | 3416 |
| HBr | 12.2 | 3839 |
| CO | 2.78 | 3143 |
| NO | 2.45 | 2758 |
| $\mathrm{O}_{2}$ | 2.08 | 2289 |
| Cl 2 | 0.346 | 813 |
| $\mathrm{Br}_{2}$ | 0.116 | 468 |
| $\mathrm{Na}_{2}$ | 0.223 | 231 |
| $\mathrm{~K}_{2}$ | 0.081134 |  |

### 6.6 Specific Heats for Solids

Based on the simple models above, its worth commenting on the specific heat of a solid. The atoms vibrating in a solid at room temperature store energy in two modes-the kinetic energy of movement about the neutral position, and the potential energy of the field trying to restore the atoms to the neutral position. So for

Table 6.4 Debye temperatures for selected materials

| Substance | Debye temperature (K) |
| :--- | :--- |
| Lead | 88 |
| Mercury | 97 |
| Iodine | 106 |
| Sodium | 172 |
| Silver | 215 |
| Calcium | 226 |
| Zinc | 235 |
| Copper | 315 |
| Aluminum | 398 |
| Iron | 453 |
| Diamond | 1860 |

each possible direction of motion, there is kT energy stored. (A solid is essentially a constant volume phase so the constant pressure and constant volume specific heats are equal.) This gives

$$
\begin{equation*}
\mathrm{U}=3 \mathrm{NkT}=3 \mathrm{RT} \mathrm{C}_{\mathrm{v}}=3 \mathrm{R} \tag{6.34}
\end{equation*}
$$

This is known as the law of Dulong and Petit. It is only valid if the temperature of the solid is well above the Debye temperature for the solid. Below the Debye temperature of a solid the constant volume specific heat is given by

$$
\begin{equation*}
C_{v}=3 \Re\left[\frac{12}{x_{o}^{3}} \int_{0}^{x_{o}} \frac{x^{3} d x}{e^{x}-1}-\frac{3 x_{o}}{e^{x_{o}}-1}\right], x_{o}=\frac{\Theta_{D}}{T}, \Theta_{D}=\text { DebyeTemperature } \tag{6.35}
\end{equation*}
$$

Some typical values of Debye temperatures are given in Table 6.4.
This end the excursion to solids. Unfortunately, liquids are a bit more complicated and cannot easily be addressed here.

### 6.7 Mean Free Path of Molecules in a Gas

So far, the collisions between gas molecules have been neglected, which is the equivalent of treating the molecules as point masses. Collisions actually do not affect the velocities of the molecules if the gas is in an equilibrium state. When two molecules collide their energies change, but because the gas is in equilibrium, for every molecule whose energy increases another's energy must decrease. Now consider some properties that can apply to non-equilibrium states. In order to do this, collisions and the size of the molecules must be taken into account.

Fig. 6.4 A track of a molecule in a gas

The first thing that must be considered is how far molecules travel between collisions. Begin by assuming that one molecule of interest is moving and all of the other molecules are frozen in place. The moving molecule moves from place to place colliding with the other molecules as it travels with a track like that described in Fig. 6.4.

Treating the molecules as hard spheres, when the moving molecule approaches another molecule, the closest its center can come to the other molecule's center is two times their radii. Now in many cases the two molecules will not meet with a collision velocity vector aligned with their centers. Often there will be skimming collisions. So the area that a stationary molecule presents to the moving molecule looks like a circular target with a radius twice that of one of the molecules. The area presented to the moving molecule that will produce a collision will be called its cross section and will be symbolized by $\sigma$. Thus,

$$
\begin{equation*}
\sigma=\pi(2 r)^{2}=4 \pi r^{2} \tag{6.36}
\end{equation*}
$$

Now if the molecule is moving with velocity $v$ along this zigzag path, in a time $t$, it will sweep out a volume given by

$$
V=v t \sigma
$$

The number of non-moving molecules per unit volume can be represented by $N$, measured in molecules per $\mathrm{cm}^{3}$.

$$
\begin{align*}
N & =N_{a} \frac{\rho}{M} \\
\rho & =\text { density in kilograms } / m^{3} \\
M & =\text { molecular mass }  \tag{6.37}\\
N_{a} & =\text { Avogadro's Number }
\end{align*}
$$

Then the number of collisions occurring in the volume swept out by the moving molecules path will be

$$
\begin{align*}
& C=N \sigma v t \\
& \frac{C}{t}=N \sigma v \tag{6.38}
\end{align*}
$$

The collisions per unit time will depend on the number of atoms per unit volume, the collision cross section, and the speed of the colliding molecule. The average distance between collisions will be the distance traveled divided by the number of collisions.

$$
\begin{equation*}
\lambda=\frac{v t}{N \sigma v t}=\frac{1}{N \sigma} \tag{6.39}
\end{equation*}
$$

The average distance between collisions is called the Mean Free Path and is usually identified with the symbol $\lambda$.

Example 6.3 Calculate the scattering cross section for $\mathrm{CO}_{2}$ and the mean free path at STP.

Solution The effective molecular radius for $\mathrm{CO}_{2}$ is 0.226 nm so,

$$
\sigma=4 \pi r^{2}=4 * 3.1415926 *\left(0.226 \times 10^{-9}\right)^{2}=6.41 \times 10^{-19} \mathrm{~m}^{2}
$$

Then the mean free path is

$$
\lambda=\frac{1}{2.687 \times 10^{25} * 6.41 \times 10^{-19}}=5.8 \times 10^{-8} \mathrm{~m}=58 \mathrm{~nm}
$$

Therefore, a $\mathrm{CO}_{2}$ molecule will normally average traveling about 128 diameters before having a collision at STP.

When the assumption that only one molecule is moving and all of the others are stationary is relaxed the equation for the mean free path must be modified slightly. If all of the molecules are assumed to have the same speed, the equation for the mean free path is given by,

$$
\begin{equation*}
\lambda=\frac{0.75}{N \sigma} \tag{6.40}
\end{equation*}
$$

If the molecules have a distribution of speeds typical of a gas at temperature, (Max-well-Boltzmann distribution) the mean free path is modified to,

$$
\begin{equation*}
\lambda=\frac{0.707}{N \sigma} \tag{6.41}
\end{equation*}
$$

### 6.8 Distribution of Mean Free Paths

Not all collisions occur after a molecule travels one mean free path. Some travel farther and some travel less than a mean free path. Consider starting with a group of molecules $n_{0}$. In traveling a distance dx , some of them $d n$ will collide with atoms in the gas. There will be $n_{0}-d n$ left. In the next distance $d x$, some more will collide,
but the number that collide will be proportional to the number that are traveling, so a balance equation can be written as,

$$
\begin{equation*}
d n=-p_{c} n d x \tag{6.42}
\end{equation*}
$$

where $p_{c}$ is simply the probability of a collision. The number of collisions per unit distance is simply the number of collisions per unit time divided by the velocity of the molecules. Therefore, from Eq. 6.38 the collisions per unit distance are given by,

$$
\begin{equation*}
\frac{C}{v t}=N \sigma \tag{6.43}
\end{equation*}
$$

The inverse of collisions per unit distance is simply distance per collision, which is the probability of a collision in a unit distance. Thus

$$
\begin{equation*}
p_{c}=N \sigma \tag{6.44}
\end{equation*}
$$

Then separating variables and integrating Eq. 6.42 gives,

$$
\begin{align*}
\frac{d n}{n} & =-N \sigma d x \\
\ln (n) & =-N \sigma x+\mathrm{constant}  \tag{6.45}\\
n & =n_{0} e^{-N \sigma x}
\end{align*}
$$

Given this distribution of free paths, now calculate the average path, or mean free path.

$$
\begin{equation*}
\lambda=\frac{\int_{0}^{\infty} x d n}{n_{0}}=\frac{\int_{0}^{\infty} x p_{c} n_{0} e^{-p_{c} x} d x}{n_{0}}=\frac{1}{p_{c}} \int_{0}^{\infty}\left(p_{c} x\right) e^{-p_{c} x} d\left(p_{c} x\right)=\frac{1}{p_{c}}=\frac{1}{N \sigma} \tag{6.46}
\end{equation*}
$$

as expected. So Eq. 6.45 can be written as

$$
\begin{equation*}
n=n_{0} e^{-x / \lambda} \tag{6.47}
\end{equation*}
$$

Fig. 6.5 A gas between a moving and a stationary plate y Moving Plate

### 6.9 Coefficient of Viscosity

Consider Fig. 6.5. It represents two plates that are moving relative to each other with a gas in between. The lower plate is stationary and the upper plate is moving to the right. To keep the upper plate moving a force is required to overcome the friction of the gas between the two plates. The friction force is defined by

$$
\begin{align*}
& F=\mu A \frac{d v}{d y}  \tag{6.48}\\
& \mu=\text { coefficient of viscosity }
\end{align*}
$$

The coefficient of viscosity establishes the relationship between the friction force and the velocity gradient in the fluid. The gas must have zero velocity in the $x$ direction at the bottom plate and it must have the velocity of the upper plate at the point in meets the upper plate.

The dashed line represents a surface with in the gas at an arbitrary distance from the bottom plate. The macroscopic velocity of the gas, $v$, is much less than the rms velocity of the gas molecules due to thermal excitation, so the results for an equilibrium gas can be used. The gas molecules above the dashed line possess a greater momentum than the gas molecules below the dashed line. As a result when the molecules cross the dashed line there is a net rate of transport of momentum and by Newton's second law there must be a force to sustain this momentum transport.

A macroscopic analogy would be two pickup trucks passing each other on the road with one going faster than the other does. If a rider in the bed of the faster pickup truck tosses a bale of hay to the slower pickup truck at right angles to the trucks, the slower truck will feel a jump in momentum because the bale of hay is traveling at a faster speed when it arrives. In the reverse situation, if a rider in the back of the slower pickup truck tosses a bale of hay to the faster truck, the faster truck will feel a loss of momentum because the hay is traveling at a slower speed when it lands in the faster truck.

Fig. 6.6 Demonstration of small volume at distance $r$

Now consider Fig. 6.6. Compute the average height above the dashed line plane that a molecule has its last collision (or change in momentum) prior to crossing the plane.

In Fig. $6.6 d V$ is a small volume at a distance $r$ from the differential $d A$ in the crossing plane. The vector $r$ makes an angle with the normal to the plane of $\theta$ and $d A$ fills a solid angle $d \omega$ with respect to $d V$. Now if $C_{f}$ is the collision frequency in $d V$, and the total number of molecules in $d V$ is $N d V$ the the total number of collisions in $d V$ in time $d t$ will be,

$$
\begin{equation*}
n_{c}=\frac{1}{2} C_{f} N d V d t \tag{6.49}
\end{equation*}
$$

The factor $1 / 2$ appears so as to not count collisions twice. At each collision, two new free paths originate and they start off uniformly in all directions. The number headed toward dA is given by,

$$
\begin{equation*}
d n_{f p}=\frac{d \omega}{4 \pi} C_{f} N d V d t \quad d \omega=\frac{d A \cos \theta}{r^{2}} \tag{6.50}
\end{equation*}
$$

The fraction that reach dA is given by Eq. 6.43 and writing dV in spherical coordinates as $d V=r^{2} \sin \theta d \theta d \phi d r$ gives

$$
\begin{equation*}
d n_{f p}=\frac{1}{4 \pi} C_{f} N d A d t \sin \theta \cos \theta e^{-\frac{r}{\lambda}} d \theta d \phi d r \tag{6.51}
\end{equation*}
$$

Then

$$
\begin{equation*}
n_{f p}=\frac{1}{4 \pi} C_{f} N \int_{0}^{\pi / 2} \int_{0}^{2 \pi} \int_{0}^{\infty} d A d t \sin \theta \cos \theta e^{-\frac{r}{\lambda}} d \theta d \phi d r=\frac{1}{4} C_{f} N \lambda d A d t \tag{6.52}
\end{equation*}
$$

And since

$$
\begin{equation*}
C_{f}=\frac{\bar{v}}{\lambda} \mathrm{n}_{f p}=\frac{1}{4} N \bar{v} d A d t \bar{v}=\text { averagemoleculespeed } \tag{6.53}
\end{equation*}
$$

Now to get the average height of the last collision before crossing the plane, multiply by the height $r \cos \theta$ and integrate over $r, \theta$, and $\phi$. This gives,

$$
\begin{equation*}
n_{y}=\frac{1}{4 \pi} C_{f} d A d t \int_{0}^{\pi / 2} \sin \theta \cos ^{2} \theta d \theta \int_{0}^{2 \pi} d \phi \int_{0}^{\infty} r e^{-\frac{r}{\lambda}} d r=\frac{C_{f}}{6} N \lambda^{2} d A d t \tag{6.54}
\end{equation*}
$$

And dividing by the total collision rate in $d V$ gives

$$
\begin{equation*}
y_{\text {ave }}=\frac{\frac{1}{6} C_{f} N \lambda^{2} d A d t}{\frac{1}{4} C_{f} N \lambda d A d t}=\frac{2}{3} \lambda \tag{6.55}
\end{equation*}
$$

Now at a height above the plane the flow velocity is

$$
\begin{equation*}
v=v_{\text {plane }}+\frac{2}{3} \lambda \frac{d v}{d y} \tag{6.56}
\end{equation*}
$$

And the momentum carried by a single molecule is

$$
\begin{equation*}
p=m\left(v+\frac{2}{3} \lambda \frac{d v}{d y}\right) \tag{6.57}
\end{equation*}
$$

So the total net momentum carried across the plane by molecules crossing from above is given by,

$$
P_{u p p e r}=\frac{1}{4} N \bar{v} m\left(v+\frac{2}{3} \lambda \frac{d v}{d y}\right)
$$

And the total net momentum by those crossing from below is

$$
P_{\text {lower }}=\frac{1}{4} N \bar{v} m\left(v-\frac{2}{3} \lambda \frac{d v}{d y}\right)
$$

The net rate then is the difference of these two quantities, or,

$$
\begin{equation*}
P_{n e t}=\frac{1}{3} N m \bar{v} \lambda \frac{d v}{d y} \tag{6.58}
\end{equation*}
$$

From Newton's second law this is equal to the viscous force per unit area. Therefore, the coefficient of viscosity is given by

$$
\begin{equation*}
\mu=\frac{1}{3} N m \bar{v} \lambda \text { or } \mu=\frac{1}{3} \frac{m \bar{v}}{\sigma} \tag{6.59}
\end{equation*}
$$

The substituting for the mean velocity, $\bar{v}$

$$
\begin{equation*}
\mu=\frac{2}{3 \sigma}\left(\frac{2 m k T}{\pi}\right)^{1 / 2} \tag{6.60}
\end{equation*}
$$

Once again, more advanced analysis taking into account the motion of all of the molecules in the gas will give

$$
\begin{equation*}
\mu=\frac{5 \pi}{16 \sqrt{2} \sigma}\left(\frac{2 m k T}{\pi}\right)^{1 / 2} \tag{6.61}
\end{equation*}
$$

Note that these two equations only differ by $3 \%$. An unexpected conclusion of this equation is that the viscosity of the gas only depends on the temperature and is independent of the pressure or density. Experiment bears this out except at very low pressures where the mean free path becomes of the order of the distance between the two plates. In addition, this relation was can be used to determine the size of molecules. Consider

$$
\mu=\frac{5 \pi}{16 \sqrt{2} \sigma}\left(\frac{2 m k T}{\pi}\right)^{1 / 2}=\frac{C}{4 \pi r^{2}}
$$

and for the liquid state

$$
\frac{V}{m}=\frac{N_{a} V_{\text {molecule }}}{M}=\frac{N_{a}^{4 \pi} /{ }_{3} r^{3}}{M}=\frac{1}{\rho}=\frac{4 \pi N_{a}}{3 M} r^{3}=B r^{3}
$$

Combining

$$
\begin{equation*}
r^{3}=\frac{1}{B \rho} \quad r^{2}=\frac{C}{4 \pi \mu} \quad r=\frac{4 \pi \mu}{C B \rho} \tag{6.62}
\end{equation*}
$$

This was one of the earliest methods developed for determining the size of molecules.

### 6.10 Thermal Conductivity

The analysis for thermal conductivity proceeds in the same fashion as viscosity where the velocity gradient in Eq. 6.48 is replaced by the temperature gradient and both planes are stationary. This gives,

$$
\begin{equation*}
Q=k_{T} A \frac{d T}{d y} \quad q=\frac{Q}{A}=k_{T} \frac{d T}{d y} \tag{6.63}
\end{equation*}
$$

The mean energy of a molecule at a temperature $T$ is $\frac{f}{2} k_{T} T$, where $f$ is the number of degrees of freedom that are active. The energy carried across the arbitrary plane per unit area per unit time from a volume above the plane is

$$
q_{u p p e r}=\frac{1}{4} N \bar{v} \frac{f}{2} k_{B}\left(T+\frac{2}{3} \lambda \frac{d T}{d y}\right)
$$

and the energy carried across the plane from a volume below the plane is

$$
q_{\text {lower }}=\frac{1}{4} N \bar{v} \frac{f}{2} k_{B}\left(T-\frac{2}{3} \lambda \frac{d T}{d y}\right)
$$

Differencing these two gives

$$
\begin{equation*}
q_{n e t}=\frac{1}{6} N \bar{v} f k_{B} \lambda \frac{d T}{d y} \tag{6.64}
\end{equation*}
$$

Comparing Eq. 6.65 with Eq. 6.64 the thermal conductivity must be given by

$$
\begin{equation*}
k_{T}=\frac{1}{6} N \bar{v} f k_{B} \lambda=\frac{1}{6} \frac{\bar{v} f k_{B}}{\sigma}=\frac{1}{3} \frac{f k_{B}}{\sigma}\left(\frac{2 k_{B} T}{\pi m}\right)^{1 / 2} \tag{6.65}
\end{equation*}
$$

Once again more exact theories give

$$
\begin{equation*}
k_{T}=\frac{25 \pi}{64 \sqrt{2}} \frac{f k_{B}}{\sigma}\left(\frac{2 k_{B} T}{\pi m}\right)^{1 / 2} \tag{6.66}
\end{equation*}
$$

Thus, the thermal conductivity should only depend on temperature. This is in good agreement with experiment down to pressures where the mean free path becomes comparable to the separation between the plates.

Now the ratio of the viscosity to the thermal conductivity from Eqs. 6.57 and 6.62 is

Table 6.5 Comparison of reduced viscosity-thermal conductivity ratio for several gases

| Gas (273 K) | $\frac{\alpha c_{v}}{M k_{\text {thermal }}}$ |
| :--- | :--- |
| Argon | 0.405 |
| Hydrogen | 0.504 |
| Oxygen | 0.511 |
| Nitrogen | 0.512 |
| Carbon dioxide | 0.590 |

But

$$
c_{v}=\frac{f}{2} \Re, \quad k_{B}=\frac{\Re}{N_{a}}, \quad m=\frac{M}{N_{a}}
$$

This gives

$$
\begin{equation*}
\frac{\mu c_{v}}{M k_{\text {thermal }}}=\frac{2}{5} \tag{6.67}
\end{equation*}
$$

Consider Table 6.5 for some common gases.
The ratio is pretty accurate for Argon but the multi-atom molecules overshoot due to internal degrees of freedom for energy storage. The velocity does not carry all of the energy that is transported.

## Chapter 7 <br> Second Law of Thermodynamics

The second law stipulates that the total entropy of a system plus its environment cannot decrease; it can remain constant for a reversible process but must always increase for an irreversible process.

### 7.1 Introduction

The First Law of Thermodynamics has been validated experimentally many times in many places. It is truly a law of physics. It always allows the conversion of energy from one form to another, but never allows energy to be produced or destroyed in the conversion process. But it is not a complete description of thermal energy conversion processes. The First Law would allow heat to be transferred from a cold body to a hot body as long as the amount of heat transferred decreased the internal energy of the cold body by the amount it increased the internal energy of the hot body. However, this never happens. Heat can only be transferred from a hot body to a cold body. Therefore, there is a requirement for a Law that explicitly states the direction of thermal energy transfer in addition to the conservation of energy expressed by the First Law. This is the Second Law of Thermodynamics. A simple statement of the Second Law would be that "heat can't be spontaneously transferred from a cold body to a hot body." More statements that are elegant will be provided shortly.

### 7.2 Heat Engines, Heat Pumps, and Refrigerators

Consider Fig. 7.1. Heat is transferred from a heat reservoir to an ideal heat engine to produce work.

Unfortunately, it is virtually to transfer heat to a heat engine without using some kind of a working fluid. Therefore, if the working fluid is passed to the heat engine

Fig. 7.1 Ideal heat engine

Fig. 7.2 Real heat engine

and all of its contained heat is converted to work, it will have to be released to the environment with no heat or at zero absolute temperature. This is virtually impossible to do, so any realistic heat engine will need to operate between two heat reservoirs, one to provide the heat and another to absorb the working fluid after the work has been extracted from it. Therefore, a simple concept of a heat engine would have to look like Fig. 7.2. There must be a high temperature reservoir to provide heat and a low temperature reservoir to accept heat after the work has been performed. Then

$$
W=Q_{H}-Q_{L}
$$

Now there are basically three devices that operate in a cycle that can be represented by this model of a heat engine. These are a True Heat Engine, a Heat Pump, and a Refrigerator.

For the True Heat Engine, the objective is to produce work, so its efficiency is given by,

$$
\begin{equation*}
\eta=\frac{W}{Q_{H}} \tag{7.1}
\end{equation*}
$$

Note that $Q_{H}=W+Q_{L}$ and h could be optimized by minimizing $Q_{L}$, The heat pump absorbs work and produces heat to the upper reservoir. Its Coefficient of Performance is given by,

$$
\begin{equation*}
C O P_{H P}=\frac{Q_{H}}{W} \tag{7.2}
\end{equation*}
$$

Once again $Q_{H}=W+Q_{L}$, but COP could be maximized by minimizing $W$. The refrigerator absorbs work and removes heat from the low temperature reservoir. Its Coefficient of Performance is given by,

$$
\begin{equation*}
C O P_{R}=\frac{Q_{L}}{W} \tag{7.3}
\end{equation*}
$$

In this case COP could be maximized by minimizing $W$ also.

### 7.3 Statements of the Second Law of Thermodynamics

The Second Law must apply to each of these devices, so consider two more elegant statements of the Second Law.

Clausius Statement "It is impossible to construct a device which operates on a cycle and whose sole effect is the transfer of heat from a cooler body to a hotter body".

Kelvin-Plank Statement "It is impossible to construct a device which operates on a cycle and produces no other effect than the production of work and the transfer of heat from a single body".

The two statements are equivalent. See Figs. 7.3a and b as follow;
Note that both statements are negations. They cannot be proven theoretically from some higher first principle argument, but have simply been determined to be correct by experiments similar to the First Law. They also rule out any heat engine that can be $100 \%$ efficient.

Fig. 7.3 a Not allowed by Kelvin-Plank statement. b Not allowed by Clausius statement

### 7.4 Reversibility

Now in order to find the most efficient engine possible given two heat reservoirs, the concept of reversibility must be quantified. Reversibility was touched on in the First Law chapter when quasi-static processes were discussed. A reversible process is simply one that once it has taken place it can be reversed back to the original state. It is the thermodynamic equivalent of a frictionless surface in mechanics or a resistance-less wire in an electrical circuit. No process is reversible, but a process can reversed if the energy losses are so small as to be negligible. The energy losses that have to be considered are

1. Friction losses
2. Heat transfer across a finite temperature difference
3. Unrestrained expansion of a gas
4. Mixing of simple substances
5. Chemical or nuclear reactions

Friction losses mean that energy is lost when two bodies slide across each other. When the sliding is reversed, additional friction losses occur so a process involving friction cannot be reversed. Heat transfers across a finite temperature drop mean that when the process is reversed, the heat must transfer from a colder body to a hotter body. This is impossible. Unrestrained expansion of a gas means that the volume increased without work or heat being applied. A gas cannot be compressed without doing work. When substances are mixed, it requires work to separate them so this type of process cannot be reversed. Finally, once a chemical or nuclear reaction has occurred, the products cannot be converted back to the ingredients without the input of energy. Now if these processes are eliminated and only reversible processes considered, it is possible to talk about the Carnot engine.

### 7.5 The Carnot Engine

The heat engine that operates most efficiently between a given high temperature reservoir and a given low temperature reservoir is a Carnot engine named after Sadi Carnot who first proposed it. It uses reversible processes to complete a thermodynamic cycle and produce the most useful work possible. It also establishes a standard to which other heat engines can be compared to determine how well they use the thermal energy available in a high temperature reservoir. If their efficiency is significantly less than the Carnot efficiency, there may be improvements possible to boost their efficiency. The simplest model for a Carnot Engine is one based on an Ideal Gas cycle. The cycle consists of four processes and is described in Fig. 7.4, which the figure is the plot of the cycle in a $T-v$ diagram.

Assume a piston cylinder arrangement that can alternately be placed in contact with hot and cold reservoirs and during the transition can be treated as adiabatic.

Fig. 7.4 T-v diagram for Carnot cycle

T

v

Process 1-2 is an isothermal expansion from point 1 to point 2. Heat is added reversibly at the high temperature reservoir and the volume contained by the piston expands.

$$
\begin{equation*}
Q_{H 1-2}=W_{1-2}=\int p d V=m R T_{H} \ln \left(V_{2} / V_{1}\right) \tag{7.4}
\end{equation*}
$$

Process 2-3 is an adiabatic expansion form point 2 to point 3 . The volume continues to expand adiabatically.

$$
\begin{equation*}
Q=0 \quad \frac{V_{2}}{V_{3}}=\left(\frac{T_{L}}{T_{H}}\right)^{1 / \gamma-1} \tag{7.5}
\end{equation*}
$$

Process 3-4 is an isothermal compression from point 3 to point 4 . The piston cylinder arrangement is placed in contact with the cold reservoir and the gas is compressed isothermally.

$$
\begin{equation*}
Q_{L, 3-4}=W_{3-4}=\int p d V=m R T_{L} \ln \left(\frac{V_{4}}{V_{3}}\right) \tag{7.6}
\end{equation*}
$$

Process $4-1$ is an adiabatic compression from point 4 to point 1 . The gas continues its compression back to its initial conditions.

$$
\begin{equation*}
Q=0 \quad\left(\frac{T_{L}}{T_{H}}\right)^{1 / \gamma-1}=\frac{V_{1}}{V_{2}} \tag{7.7}
\end{equation*}
$$

Then the efficiency for the cycle is given by
and for the adiabatic processes,

$$
\begin{equation*}
\frac{V_{3}}{V_{2}}=\frac{V_{4}}{V_{1}} \quad V_{3} V_{1}=V_{2} V_{4} \quad \frac{V_{1}}{V_{2}}=\frac{V_{4}}{V_{3}} \quad \ln \left(V_{4} / V_{3}\right)=\ln \left(V_{1} / V_{2}\right) \tag{7.9}
\end{equation*}
$$

Therefore

$$
\begin{equation*}
\eta=1-\frac{T_{L}}{T_{H}} \tag{7.10}
\end{equation*}
$$

which is the fundamental relationship for the Carnot efficiency of a reversible heat engine.

When the cycle is operated in reverse, the heat engine becomes a heat pump and this gives,

$$
\begin{equation*}
C O P_{H P}=\frac{Q_{h}}{W_{n e t}}=\frac{Q_{H}}{Q_{H}-Q_{L}}=\frac{1}{1-\frac{Q_{L} / Q_{H}}{1-T_{L} / T_{H}}}=\frac{1}{1} \tag{7.11}
\end{equation*}
$$

This is the fundamental relationship for a Carnot heat pump.
By the same analysis the COP for a Carnot refrigerator is given by

$$
\begin{equation*}
C O P_{R}=\frac{Q_{L}}{W_{\text {net }}}=\frac{Q_{L}}{Q_{H}-Q_{L}}=\frac{1}{Q_{H} / Q_{L}-1}=\frac{1}{T_{H} / T_{L}-1} \tag{7.12}
\end{equation*}
$$

and this is the fundamental relationship for a Carnot refrigerator.
Example 7.1: A Carnot Engine operates between two temperature reservoirs maintained at $240^{\circ} \mathrm{F}$ and $40^{\circ} \mathrm{F}$. If the desired output from the heat engine is 15 hp what is the heat transfer from the high temperature reservoir and the heat transfer to the low temperature reservoir?

Solution: The efficiency of the Carnot Engine is given by

$$
\begin{aligned}
& \eta=1-\frac{T_{L}}{T_{H}}=1-\frac{40+460}{240+460}=1-\frac{500}{700}=\frac{2}{7}=0.286 \\
& 0.286=\frac{Q_{H}}{W} \quad Q_{H}=\frac{W}{0.286}=\frac{15^{*} 2545}{0.286}=1.33 \times 10^{5} \mathrm{Btu} / \mathrm{hr} \\
& Q_{L}=Q_{H}-W=1.33 \times 10^{5}-15 * 2545=(1.33-0.38) \times 10^{5}=9.5 \times 10^{4} \mathrm{Btu} / \mathrm{hr}
\end{aligned}
$$

Example 7.2: A Carnot engine operates with air on the following cycle.
Process 1-2 Constant temperature expansion at $327^{\circ} \mathrm{C}$

Process 2-3 Adiabatic expansion to $8 \mathrm{~m}^{3} / \mathrm{kg}$
Process 3-4 Constant temperature compression at $77^{\circ} \mathrm{C}$
Process 4-1 Adiabatic compression starting at 80 kPa back to $327^{\circ} \mathrm{C}$
Determine the thermal efficiency and the work output per cycle per kg.
Solution: The thermal efficiency is

$$
\eta=1-\frac{T_{L}}{T_{H}}=1-\frac{77+273}{327+273}=1-\frac{350}{600}=0.417
$$

At 4 the specific volume can be found from the Ideal Gas equation
$v_{4}=\frac{R T_{4}}{p_{4}}=\frac{8314.47 / 28.9669^{* 350}}{8.0 \times 10^{4}}=1.256 \mathrm{~m}^{3} / \mathrm{kg}$
Then for an adiabatic compression from 4 to 1 ,
$v_{1}=v_{4}\left(\frac{T_{4}}{T_{1}}\right)^{\frac{1}{\gamma-1}}=1.256\left(\frac{350}{600}\right)^{2.5}=0.3264$
Also for the adiabatic exp ansion from 2 to 3 ,
$v_{2}=v_{3}\left(\frac{T_{3}}{T_{2}}\right)^{\frac{1}{\gamma-1}}=8\left(\frac{350}{600}\right)^{2.5}=2.079$
Then the work for the isothermal exp ansion from 1 to 2 ,
$q_{H}=R T_{H} \ln \left(v_{2} / v_{1}\right)=287 * 600 * \ln (2.079 / 0.3264)=3.189 \times 10^{5}$ Joules
$q_{L}=R T_{L} \ln \left(v_{4} / v_{3}\right)=287 * 350 * \ln (1.256 / 8)=-1.860 \times 10^{5}$ Joules
$w_{\text {per cycle }}=q_{H}-q_{L}=(3.189-1.860) \times 10^{5}$ Joules $=1.329 \times 10^{5}$ Joules
Or
$\eta=\frac{w}{q_{H}}=0.417=\frac{w}{3.189 \times 10^{5}} \quad w=0.417 * 3.189 \times 10^{5}=1.329 \times 10^{5}$ Joules

### 7.6 The Concept of Entropy

When the fundamental concepts of Classical Thermodynamics were being formulated the scientific community investigated a number of concepts that would formalize the Second Law analytically. The concept that was finally settled on was $\delta Q / T$. If a cyclic integral of this quantity is taken for the Carnot engine cycle it gives,

$$
\begin{equation*}
\oint \frac{\delta Q}{T}=\frac{Q_{H}}{T_{H}}-\frac{Q_{L}}{T_{L}} \tag{7.13}
\end{equation*}
$$

and for the Carnot cycle

$$
\begin{equation*}
\frac{Q_{L}}{Q_{H}}=\frac{T_{L}}{T_{H}} \quad \text { or } \quad \frac{Q_{H}}{T_{H}}=\frac{Q_{L}}{T_{L}} \tag{7.14}
\end{equation*}
$$

This then leads to the conclusion that

$$
\begin{equation*}
\oint \frac{\delta Q}{T}=0 \tag{7.15}
\end{equation*}
$$

As a result $\delta Q / T$ is a perfect differential and it can define a new property of a thermodynamic system. This property is called entropy and given the symbol $S$. Its differential is given by,

$$
\begin{equation*}
d S=\left.\frac{\delta Q}{T}\right|_{\text {reversible }} \tag{7.16}
\end{equation*}
$$

$1 / T$ serves as an integrating factor for $d Q$. It can be integrated for a process to give,

$$
\begin{equation*}
\Delta S=\int_{1}^{2} \frac{\delta Q}{T} \tag{7.17}
\end{equation*}
$$

Note that $S$ is an extensive property and it can be converted to a specific entropy by dividing by the mass, $s=S / m$. In addition, an adiabatic-reversible process implies $\Delta S=0$, the Carnot cycle can be plotted on a T-s diagram rather than a $T-v$ diagram. Figure 7.5 is such a plot.

Then,

Fig. 7.5 Temperatureentropy plot for a Carnot cycle

$$
\begin{align*}
& \Delta S_{1-2}=S_{2}-S_{1}=\int_{1}^{2} \frac{\delta Q}{T}=\frac{Q_{H, 1-2}}{T_{H}} \\
& \Delta S_{2-3}=S_{3}-S_{2}=\int_{2}^{3} \frac{\delta Q}{T}=0  \tag{7.18}\\
& \Delta S_{3-4}=S_{4}-S_{3}=\int_{3}^{4} \frac{\delta Q}{T}=-\frac{Q_{L, 3-4}}{T_{L}} \\
& \Delta S_{4-1}=S_{1}-S_{4}=\int_{4}^{1} \frac{\delta Q}{T}=0
\end{align*}
$$

For a reversible process the heat transfer can be written as $d Q=T d S$. This allows the First Law for closed systems to be written as

$$
\begin{equation*}
d U=\delta Q-\delta W=T d S-p d V \tag{7.19}
\end{equation*}
$$

Or on a per unit mass basis it can be written,

$$
\begin{equation*}
d u=T d s-p d v \tag{7.20}
\end{equation*}
$$

The First Law for a flow system using the enthalpy gives,

$$
\begin{align*}
& h=u+p v \\
& d h=d u+p d v+v d p  \tag{7.21}\\
& d h=T d s+v d p
\end{align*}
$$

### 7.7 The Concept of Entropy

Now consider an Ideal Gas with constant specific heats. Dividing Eq. 7.20 by $T$ and using the Ideal Gas law gives

$$
\begin{equation*}
d s=\frac{d u}{T}+\frac{p d v}{T}=C_{v} \frac{d T}{T}+R \frac{d v}{v} \tag{7.22}
\end{equation*}
$$

This can be integrated to give,

$$
\begin{equation*}
s_{2}-s_{1}=C_{v} \ln \left(\frac{T_{2}}{T_{1}}\right)+R \ln \left(\frac{v_{2}}{v_{1}}\right) \tag{7.23}
\end{equation*}
$$

Equation 7.23 can also be evaluated as,

$$
\begin{align*}
& d s=C_{p} \frac{d T}{T}-\frac{v}{T} d p=C_{p} \frac{d T}{T}-R \frac{d p}{p}  \tag{7.24}\\
& s_{2}-s_{1}=C_{p} \ln \left(\frac{T_{2}}{T_{1}}\right)-R \ln \left(\frac{p_{2}}{p_{1}}\right)
\end{align*}
$$

Of course, these equations only apply to reversible processes. However since they relate changes in entropy to other thermodynamic properties at the two end states, the can be used for reversible and irreversible processes.

If the entropy change is zero, called an isentropic process, then Eq. 7.23 becomes

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{\gamma-1} \quad \frac{T_{2}}{T_{1}}=\left(\frac{p_{2}}{p_{1}}\right)^{\gamma-1 / \gamma} \Rightarrow \frac{p_{2}}{p_{1}}=\left(\frac{v_{1}}{v_{2}}\right)^{\gamma} \tag{7.25}
\end{equation*}
$$

Of course, these equations are exactly the ones obtained earlier for a quasi-static adiabatic process.

Example 7.3: Nitrogen is contained in a rigid volume at $27^{\circ} \mathrm{C}$ and 100 kPa . A paddle wheel does 900 kJ of work on the nitrogen. If the volume is $3 \mathrm{~m}^{3}$, calculate the entropy increase assuming constant specific heats.
Solution: Treating the process as adiabatic

$$
-W=\Delta U=m C_{v} \Delta T
$$

Calculating the mass based on the Ideal Gas law

$$
\begin{gathered}
m=\frac{p V}{R T}=\frac{1.0 \times 10^{5} * 3}{8314.47 / 28 * 300}=3.367 \mathrm{~kg} \\
C_{v}=\frac{R}{\gamma-1}=\frac{8314.47 / 28}{1.4-1}=742.4 \mathrm{~J} / \mathrm{kg} / \mathrm{K} \\
9.0 \times 10^{5}=3.367 * 742.4 *\left(T_{2}-300\right) \\
T_{2}=300+\frac{9.0 \times 10^{5}}{3.367 * 742.4}=300+360=660 \mathrm{~K} \\
\Delta S=m * C_{v} * \ln \left(T_{2} / T_{1}\right)=3.367 * 742.4 * \ln (660 / 300)=1.97 \mathrm{~kJ} / \mathrm{K}
\end{gathered}
$$

Example 7.4: Nitrogen is heated to $327^{\circ} \mathrm{C}$ and a pressure of 1.5 MPa . It is then expanded to 200 kPa with a reversible adiabatic process. Calculate the work done by the nitrogen assuming it to be calorically perfect.

Solution: The first law gives

$$
\begin{align*}
& -W=m C_{v}\left(T_{2}-T_{1}\right) \\
& T_{2}=T_{1}\left(\frac{p_{2}}{p_{1}}\right)^{\gamma-1 / \gamma}=600 *(0.2 / 1.5)^{0.286}=337 \mathrm{~K}  \tag{7.26}\\
& -w=742.4 *(337-600)=-195 \mathrm{~kJ} / \mathrm{kg}
\end{align*}
$$

### 7.8 Entropy for an Ideal Gas with Variable Specific Heats

If the Ideal Gas does not have constant specific heats over the temperature range of interest, the entropy change equations are very useful. Consider the constant pressure specific heat equation,

$$
\begin{aligned}
& d s=\frac{d h}{T}-\frac{v d p}{T}=C_{p} \frac{d T}{T}-R \frac{d p}{p} \\
& s_{2}-s_{1}=\int_{T_{1}}^{T_{2}} C_{p} \frac{d T}{T}-R \ln \left(\frac{p_{2}}{p_{1}}\right)
\end{aligned}
$$

Now define

$$
\begin{equation*}
s_{2}^{0}-s_{1}^{0}=\int_{T_{1}}^{T_{2}} \frac{C_{p}}{T} d T \tag{7.27}
\end{equation*}
$$

and

$$
\begin{equation*}
s_{2}-s_{1}=s_{2}^{0}-s_{1}^{0}-R \ln \left(\frac{p_{2}}{p_{1}}\right) \tag{7.28}
\end{equation*}
$$

This can be rearranged as,

$$
\begin{equation*}
\frac{p_{2}}{p_{1}}=e^{\frac{s_{2}^{0}-s_{1}^{0}}{R}}=\frac{e^{s_{2}^{0} / R}}{e^{s_{1}^{0} / R}}=\frac{f\left(T_{2}\right)}{f\left(T_{1}\right)} \tag{7.29}
\end{equation*}
$$

This allows the definition of a relative pressure, $p_{r}$, as,

$$
\begin{equation*}
p_{r}=e^{s^{0} / R} \tag{7.30}
\end{equation*}
$$

Thus for an isentropic process,

$$
\begin{equation*}
\frac{p_{2}}{p_{1}}=\frac{p_{r 2}}{p_{r 1}} \tag{7.31}
\end{equation*}
$$

The volume ratio can be found by applying the Ideal Gas law to get

$$
\begin{equation*}
\frac{v_{2}}{v_{1}}=\frac{R T_{2} / p_{2}}{R T_{1} / p_{1}}=\frac{p_{1}}{p_{2}} \frac{T_{2}}{T_{1}}=\frac{T_{2} / p_{2}}{T_{1} / p_{1}} \tag{7.32}
\end{equation*}
$$

Therefore a relative volume can be defined as, $v_{r}$, with

$$
\begin{equation*}
\frac{v_{2}}{v_{1}}=\frac{v_{r 2}}{v_{r 1}} \tag{7.33}
\end{equation*}
$$

Both $p_{r}$ and $v_{r}$ are tabulated as a function of temperature for several gases in Appendix 13.
Example 7.5: Rework Example 7.3 assuming variable specific heats.
Solution: As before $\mathrm{m}=3.367 \mathrm{~kg}$
First law $-w=u_{2}-u_{1}$

$$
\begin{aligned}
& u_{2}=-W / m+u_{1}=-\frac{(-900)}{3.367}+5551.2 / 28=465.56 \mathrm{~kJ} / \mathrm{kg}=13035.6 \mathrm{~kJ} / \mathrm{kmol} \\
& T(13035.6)=650+\frac{13035.6-13010.8}{13566.4-13010.8} * 25=650+0.0446 * 25=651.1 \mathrm{~K} \\
& s_{1}^{0}=186.3310 \\
& s_{2}^{0}=209.411+0.0446 *(210.2928-209.1411)=209.193
\end{aligned}
$$

The Ideal Gas law gives the pressure at state 2

$$
\begin{aligned}
& p_{2}=p_{1}\left(\frac{T_{2}}{T_{1}}\right)=100 *\left(\frac{651.1}{300}\right)=217 \mathrm{kPa} \\
& \Delta S=m\left[\left(s_{2}^{0}-s_{1}^{0}\right)-R \ln \left(p_{2} / p_{1}\right)\right] \\
& =3.367 *[209.193-186.3310-8.31447 * \ln (217 / 100)] / 28 \\
& =1.97 \mathrm{~kJ} / \mathrm{K}
\end{aligned}
$$

Example 7.6: Rework Example 7.4 assuming variable specific heats.
Solution: Assume isentropic process,
At $T=600 \mathrm{~K}, P_{r l}=16.13$

$$
\begin{aligned}
& p_{r 2}=p_{r 1}\left(\frac{p_{2}}{p_{1}}\right)=16.13 *\left(\frac{0.2}{1.5}\right)=2.15 \\
& T(2.15)=325+\frac{2.15-1.84}{2.38-1.84} * 25=325+0.574 * 25=339.4 \mathrm{~K} \\
& -w=u_{2}-u_{1} \\
& u_{1}=11911.4 / 28=425.4 \\
& u_{2}=\frac{6073.4+0.574 *(6595.7-6073.4)}{28}=227.6 \\
& w=425.4-227.6=197.7 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

### 7.9 Entropy for Steam, Liquids and Solids

For pure substances like steam the specific entropy is included in the steam tables similar to specific volume, specific internal energy and specific enthalpy. In the mixed phase region, the specific entropy is calculated based on the steam quality similar to the other properties.

$$
\begin{equation*}
s=s_{f}+x s_{f g} \tag{7.34}
\end{equation*}
$$

For a compressed liquid or solid, the specific heat can be assumed constant and both assumed incompressible $(d v=0)$, so,

$$
\begin{align*}
& T d s=d u=C d T \\
& d s=C \frac{d T}{T}  \tag{7.35}\\
& \Delta s_{1-2}=C \ln \left(\frac{T_{2}}{T_{1}}\right)
\end{align*}
$$

Certainly if the specific heat is known as a function of temperature, the functional dependence can be substituted in the above equations and the integration performed. Specific heats for liquids and metals are listed in Appendix B and Appendix 9 (Bahman).

Example 7.7: Steam is contained in a rigid container at 600 K and 0.8 MPa . The pressure is reduced to 60 kPa . Calculate the entropy change and heat transfer.

Solution: The specific volume must remain the same. The initial specific volume is taken from the superheated steam tables

$$
v_{1}=0.34046 \mathrm{~m}^{3} / \mathrm{kg} \quad u_{1}=2841.1 \mathrm{~kJ} / \mathrm{kg} \quad s_{1}=7.33094 \mathrm{k} / \mathrm{kg} / \mathrm{K}
$$

Then at 60 kPa the fluid must be in the mixed liquid-vapor region, so from Ta ble 14.2 of Appendix 14, the specific volumes are

$$
v_{f}=0.001033 \mathrm{~m}^{3} / \mathrm{kg} \quad v_{g}=2.73183 \mathrm{~m}^{3} / \mathrm{kg}
$$

$$
0.34046=0.001033+x * 2.73183 x=(0.34046-0.001033) / 2.73183=0.124
$$

So the final internal energy is

$$
u_{f}=359.8+0.124 * 2129.2=623.8 \mathrm{~kJ} / \mathrm{kg}
$$

and

$$
\begin{aligned}
s_{f}=1.14524+0.124 * 6.38586 & =1.93709 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K} \\
\Delta u=2841.1-623.8 & =2217.3 \mathrm{~kJ} / \mathrm{kg} \\
\Delta s=7.330904-1.93709 & =5.38385 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}
\end{aligned}
$$

### 7.10 The Inequality of Clausius

The Carnot cycle is a reversible cycle operating between two reservoirs. If an irreversible cycle operates between the same two reservoirs, the available work from the irreversible cycle will have to be less than the available work from the reversible cycle. That is

$$
W_{i r r}<W_{r e v}
$$

If the First Law is applied to a cycle and equal amounts of heat QH are transferred from the high temperature reservoir, more heat will be transferred to the low temperature reservoir for the irreversible cycle.

$$
\begin{aligned}
& Q_{H}=W_{r e v}+Q_{L, r e v} \\
& Q_{H}=W_{i r r}+Q_{L, i r r}
\end{aligned}
$$

So when performing the cyclic integral for dS.

$$
\begin{equation*}
\oint\left(\frac{\delta Q}{T}\right)_{i r r}<0 \tag{7.36}
\end{equation*}
$$

For a reversible process the above integral is 0 , of course. If an irreversible refrigerator is being considered more work will be required that for a reversible refrigerator, the heat transferred at the high temperature reservoir will be greater so the cyclic integral will still be less than zero for an irreversible process. So the fundamental result can be written for any cycle,

Fig. 7.6 Power plant cycle

$$
\begin{equation*}
\oint\left(\frac{\delta Q}{T}\right)_{i r r} \leq 0 \tag{7.37}
\end{equation*}
$$

This is known as the inequality of Clausius. It is a consequence of the Second Law of Thermodynamics.

Example 7.6: A steam power plant operates on the cycle shown in the Fig. 7.6 below
Process 1-2: Adiabatic compression in the pump
Process 2-3: Isothermal heat transfer in the boiler
Process 3-4: Adiabatic expansion in the turbine
Process 4-1: Isothermal heat transfer in the condenser
The quality at point 4 after expansion through the turbine is $88 \%$. The quality leaving the condenser and entering the pump at point 1 is $18 \%$. Does this cycle the inequality of Clausius?

Solution: To check the inequality of Clausius the following integral must be evaluated.

$$
\oint \frac{\delta Q}{T}=\frac{Q_{2-3}}{T_{2-3}}-\frac{Q_{4-1}}{T_{4-1}}
$$

From the steam tables Appendix 14.2, the two temperatures are

$$
T_{2-3}=453.0 \mathrm{~K} \quad T_{4-1}=333.2 \mathrm{~K}
$$

The heat transfer in the boiler is $u_{2-3}=1821.2 \mathrm{~kJ} / \mathrm{kg}$
The heat transfer in the condenser is $u_{4-1}=(0.88-0.18) * 2204.6=1543.2 \mathrm{~kJ} / \mathrm{kg}$
Then

$$
\oint \frac{\delta Q}{T}=\frac{1821.2}{453.0}-\frac{1543.2}{333.2}=4.02031-4.63145=-0.61114
$$

Therefore, the inequality of Clausius is satisfied.

### 7.11 Entropy Change for an Irreversible Process

Now consider a cycle composed of two reversible processes as shown in Fig. 7.7.
Process $1_{\text {rev }}$ goes from state $A$ to state $B$ as a reversible process. Process $2_{\text {rev }}$ returns from state $B$ to state $A$ as a reversible process. Process $3_{\text {irr }}$ also returns from state B to state A, but it is an irreversible process. The reversible processes give,

$$
\begin{equation*}
\left.\left.\int_{A}^{B} \frac{\delta Q}{T}\right)_{\text {along } 1}+\int_{B}^{A} \frac{\delta Q}{T}\right)_{\text {along } 2}=0 \tag{7.38}
\end{equation*}
$$

But for the cycle A-1-B-3-A,

$$
\begin{equation*}
\left.\left.\int_{A}^{B} \frac{\delta Q}{T}\right)_{\text {along } 1}+\int_{B}^{A} \frac{\delta Q}{T}\right)_{\text {along } 3}<0 \tag{7.39}
\end{equation*}
$$

Subtracting Eq. 7.38 from Eq. 7.39 gives

$$
\begin{equation*}
\left.\left.\int_{B}^{A} \frac{\delta Q}{T}\right)_{\text {along } 2}>\int_{B}^{A} \frac{\delta Q}{T}\right)_{\text {along } 3} \tag{7.40}
\end{equation*}
$$

But along path 2,

$$
\left.\Delta S=\int_{B}^{A} \frac{\delta Q}{T}\right)_{\text {Along 2 }}
$$

Thus for any path representing any process,

$$
\begin{equation*}
\Delta S \geq \int \frac{\delta Q}{T} \quad \text { or } \quad \mathrm{dS} \geq \frac{\delta Q}{T} \tag{7.41}
\end{equation*}
$$

The relationship expressed by Eq. 7.41 leads to a fundamental statement. Consider an infinitesimal heat transfer to a system at an absolute temperature T , if the process

Fig. 7.7 A cycle with an irreversible process T

Fig. 7.8 Insulated tank

is reversible, the change in entropy is $\Delta Q / T$. If the process is irreversible the change in entropy is greater than $\Delta Q / T$. The effect of irreversibility, e.g. friction, is to increase the entropy of the system.

So to check to see if a process is possible, simply see if it satisfies Eq. 7.41. If it does not then the process is impossible. Entropy plays the same roll for the Second Law, as does energy for the First Law.

Now consider an isolated system. It exchanges no work or heat with its surroundings. The First Law requires that for any process $U_{2}=U_{1}$. For this case Eq. 7.41 becomes $\Delta S \geq 0$. Therefore, the entropy of the isolated system must remain constant or increase. For any real process that must be irreversible to some extent, the entropy of the system increases.

It is possible to consider the universe as an isolated system and break it down to a subsystem and its environment. This would then give,

$$
\begin{equation*}
\Delta S_{\text {universe }}=\Delta S_{\text {sub-system }}+\Delta S_{\text {environment }} \geq 0 \tag{7.42}
\end{equation*}
$$

Once again the equality applies to a reversible process and the inequality applies to any real (irreversible) process. This is sometimes, referred to the mathematical statement of the Second Law.

Example 7.9: Helium is contained in one-half of an insulated tank as shown below, confined by a membrane. The membrane is ruptured and the helium expands to fill the tank. Calculate the specific entropy change for this system. See Fig. 7.8 below
Solution: There is no heat transfer so the final temperature is equal to the initial temperature. Using Eq. 7.23 for the entropy change gives,

$$
\Delta s=R * \ln \left(v_{2} / v_{l}\right)=8.31447 / 4 * \ln 2=1.44 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}
$$

### 7.12 The Second Law Applied to a Control Volume

The Second Law can be applied to a control volume in the same way that the First Law was. It simply requires a balance equation that conserves, or increases, entropy. This can be written,

$$
\begin{equation*}
\Delta S_{\text {In Control Volume }}+\Delta S_{\text {exiting }}-\Delta S_{\text {entering }}+\Delta S_{\text {surroundings }} \geq 0 \tag{7.43}
\end{equation*}
$$

This can be refined to

$$
\Delta S_{c v}+m_{2} s_{2}-m_{1} S_{1}+\frac{\delta Q_{s u r r}}{T_{s u r r}} \geq 0
$$

Then considering changes as a function of time and using the dot notation to signify a rate this becomes,

$$
\begin{equation*}
\dot{S}_{c v}+\dot{m}_{2} s_{2}-\dot{m}_{1} s_{1}+\frac{\dot{Q}}{T} \geq 0 \tag{7.44}
\end{equation*}
$$

For a steady flow process, the entropy in the control volume does not change and the mass entering is equal to the mass exiting so this becomes,

$$
\begin{equation*}
\dot{m}\left(s_{2}-s_{1}\right)+\frac{\delta \dot{Q}_{\text {surr }}}{T_{\text {surr }}} \geq 0 \tag{7.45}
\end{equation*}
$$

In all cases the equal sign applies to reversible processes and the greater than sign applies to all real (irreversible) processes. If a process is adiabatic and reversible, $\Delta S=m \Delta s=0$ and the process is called isentropic.

Finally, for devices like turbines and compressors, an isentropic process defines the ideal process and the adiabatic efficiency of a device can be defined as,

$$
\begin{equation*}
\eta_{\text {turbine }}=\frac{W_{\text {actual }}}{W_{\text {isentropic }}} \quad \eta_{\text {compressor }}=\frac{W_{\text {isentropic }}}{W_{\text {actual }}} \tag{7.46}
\end{equation*}
$$

Note that since a turbine does work on its environment, the actual work is less than the isentropic work, so the efficiency requires the actual to be divided by the theoretically maximum possible, the isentropic work. On the other hand, for a compressor, the environment is doing work on the working fluid, so the work required will be greater that the theoretical minimum work, the isentropic work. The relationship is reversed.

Example 7.10: Superheated steam enters a turbine at 900 K and 1 MPa and exits at 10 kPa . If the mass flow is $2 \mathrm{~kg} / \mathrm{sec}$, determine the power output if the process is assumed to be isentropic.

Solution: The enthalpy for the high temperature steam is $3758.5 \mathrm{~kJ} / \mathrm{kg}$ and the entropy is $8.09857 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$. For an isentropic expansion the entropy at 10 kPa must be the same. At 10 kPa the saturation entropies are $\mathrm{s}_{\mathrm{f}}=0.64922 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$ and $\mathrm{s}_{\mathrm{g}}=8.14889 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$, so

$$
8.09857=0.64922+x * 7.49968 x=(8.09857-0.64933) / 7.49968=0.9933
$$

Therefore, the final enthalpy is

$$
\begin{gathered}
h=191.8+0.9933 * 2392.1=2567.8 \mathrm{~kJ} / \mathrm{kg} \\
\Delta h=3758.5-2567.8=1190.7 \mathrm{~kJ} / \mathrm{kg} \\
P=2 * 1190.7=2381.4 \mathrm{~kW}
\end{gathered}
$$

Example 7.11: Assume that the turbine in Example 7.10 is $80 \%$ efficient. Determine the entropy and temperature of the final state.
Solution: For $80 \%$ efficiency, the change in enthalpy must be $80 \%$ of the isentropic change in enthalpy.

$$
\begin{gathered}
h_{a c t}=0.8 * 1190.7=952.6 \mathrm{~kJ} / \mathrm{kg} \\
h_{f}=3758.5-952.6=2805.9 \mathrm{~kJ} / \mathrm{kg}
\end{gathered}
$$

At $10 \mathrm{kPa}, \mathrm{h}=2805.9 \mathrm{~kJ} / \mathrm{kg}$ gives a vapor in the super heated region between 400 K and 450 K .

$$
\begin{aligned}
& T_{f}=400+(2805.9-2738.7) /(2834.7-2738.7) * 50=400+0.7 * 50=435 \mathrm{~K} \\
& s_{f}=8.58137+0.7 *(8.80763-8.58137)=8.73975 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}
\end{aligned}
$$

## Chapter 8 <br> Reversible Work, Irreversibility, and Exergy (Availability)

From thermodynamic point of view, work is considered a macroscopic event, such as raising or lowering a weight or winding or unwinding of a spring. In this, chapter we talk about, which work can be reversible or irreversible and what do we mean by either of these processes.

### 8.1 Reversible Work, and Irreversibility

Second law efficiency is defined as the actual work divided by the reversible work.

$$
\begin{equation*}
\eta_{I I}=\frac{W_{\text {actual }}}{W_{\text {Reversible }}} \tag{8.1}
\end{equation*}
$$

It is easiest to explain in terms of a heat engine cycle. Let us consider two heat engines that operate between hot and cold temperature reservoirs. The first engine operates between 600 and 300 K . The second operates between 1200 and 300 K . Both have a thermal efficiency of $30 \%$.

$$
\eta_{T}=0.30=\frac{W}{Q_{H}}
$$

Now the Carnot efficiency for a reversible engine is given by,
or

$$
\eta_{C}=1.0-\frac{T_{L}}{T_{H}}
$$

$$
\eta_{C}=1.0-\frac{300}{600}=50 \% \text { for the first }
$$

[^2]and
$$
\eta_{C}=1.0-\frac{300}{1200}=75 \% \text { for the second. }
$$

Since they are both operating at a thermal efficiency of $30 \%$, the first is operating at a second law efficiency

$$
\eta_{I I, 1}=\frac{0.3}{0.5}=0.6 \text { or } 60 \%
$$

and the second is operating at a second law efficiency

$$
\eta_{I I, 2}=\frac{0.3}{0.75}=0.4 \text { or } 40 \%
$$

Therefore, the first is making better use of its heat source than the second is. This is the fundamental concept of a second law efficiency. It should be possible to improve the thermal efficiency of the second engine more than the first.

For individual processes, the concept becomes a little more difficult to define.
For a turbine or engine the second law efficiency is given by

$$
\begin{equation*}
\eta_{I I, t}=\frac{W_{\text {Actual }}}{W_{\text {Reversible }}} \tag{8.2}
\end{equation*}
$$

but for a compressor or pump the second law efficiency is given by

$$
\begin{equation*}
\eta_{I I, c}=\frac{W_{\text {Reversible }}}{W_{\text {Actual }}} \tag{8.3}
\end{equation*}
$$

For an open system control volume the first law can be written as

$$
\begin{equation*}
\dot{Q}-\dot{W}_{S}=\dot{m}_{2} h_{2}-\dot{m}_{1} h_{1}+\dot{U}_{c v} \tag{8.4}
\end{equation*}
$$

The second law for a control volume is

$$
\begin{equation*}
\dot{S}_{c v}+\dot{m}_{2} s_{2}-\dot{m}_{1} s_{1}-\frac{\dot{Q}}{T_{o}}-\dot{S}_{p r o d}=0 \tag{8.5}
\end{equation*}
$$

Eliminating $\dot{Q}$ between the two equations gives

$$
\begin{equation*}
\dot{W}_{S}=-\dot{U}_{c v}+T_{o} \dot{S}_{c v}-\dot{m}_{2}\left(h_{2}-T_{o} s_{2}\right)+\dot{m}_{1}\left(h_{1}-T_{o} s_{1}\right)-T_{o} \dot{S}_{p r o d} \tag{8.6}
\end{equation*}
$$

$\dot{S}_{\text {prod }}$ represents the irreversibility. So setting it to zero gives the reversible shaft work. Then integrating over time gives,

$$
\begin{equation*}
W_{s, r e v}=m_{i}\left(u_{i}-T_{o} s_{i}\right)-m_{f}\left(u_{f}-T_{o} s_{f}\right)+m_{1}\left(h_{1}-T_{o} s_{1}\right)-m_{2}\left(h_{2}-T_{o} s_{2}\right) \tag{8.7}
\end{equation*}
$$

The actual work can be measured or determined from a First Law analysis

$$
\begin{equation*}
W_{s, a c t}=m_{i} u_{i}-m_{f} u_{f}+m_{1} h_{1}-m_{2} h_{2}+Q \tag{8.8}
\end{equation*}
$$

The second law efficiency then is simply the ratio of the two. The irreversibility is given by

$$
\begin{equation*}
I=W_{s, r e v}-W_{s, a c t}=T_{o}\left(m_{f} s_{f}-m_{i} s_{i}+m_{2} s_{2}-m_{1} s_{1}\right)-Q \tag{8.9}
\end{equation*}
$$

For a steady flow process

$$
\begin{gather*}
\dot{W}_{s, \text { rev }}=\dot{m}\left[h_{1}-h_{2}+T_{o}\left(s_{2}-s_{1}\right)\right]  \tag{8.10}\\
\dot{W}_{s, a c t}=\dot{m}\left(h_{1}-h_{2}\right)+Q  \tag{8.11}\\
\dot{I}=\dot{m} T_{o}\left(s_{2}-s_{1}\right)-\dot{Q} \tag{8.12}
\end{gather*}
$$

Example 8.1 An ideal steam turbine is supplied with steam at 14 MPa and 1100 K , and exhausts at 60 kPa . (a) Determine the reversible work and irreversibility. (b) If the turbine has an adiabatic efficiency of 0.88 , what is the reversible work, irreversibility and second law efficiency?

## Solution

a. From the steamtables at $14 \mathrm{MPa} \& 1100 \mathrm{~K}, h_{1}=4170 \mathrm{~kJ} / \mathrm{kg}$ and $s_{1}=7.37798 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$. From the saturated pressure table at $60 \mathrm{kPa}, s_{g}=7.53110 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$ which is greater than $\mathrm{s}_{1}$, so the final steam is in the quality region.
$s_{f}=1.14524 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K} . \quad s_{f g}=6.38586 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$
$h_{f}=359.8 \mathrm{~kJ} / \mathrm{kg} \quad h_{f g}=2293.0 \mathrm{~kJ} / \mathrm{kg}$
$x=\frac{7.37798-1.14524}{6.38586}=0.976$
$h_{2}=359.8+0.976 * 2293.0=2597.8 \mathrm{~kJ} / \mathrm{kg}$
$\Delta h=4170-2597.8=1572.2 \mathrm{~kJ} / \mathrm{kg}$
$w_{\text {rev }}=1572.2 \mathrm{~kJ} / \mathrm{kg} \quad I=0$
b. For an adiabatic efficiency of $0.88, w_{\text {act }}=0.88^{*} w_{\text {rev }}=1383.5 \mathrm{~kJ} / \mathrm{kg}$
$h_{2}=h_{1}-1383.5=4170-1383.5=2786.5 \mathrm{~kJ} / \mathrm{kg}$
Interpolating in the superheated steam tables at $60 \mathrm{kPa}, \mathrm{T}_{2}=426.8$,
$\mathrm{s}_{2}=7.86890 \mathrm{~kJ} / \mathrm{kg} / \mathrm{K}$
Assuming $T_{0}=298 \mathrm{~K}$,

$$
\begin{aligned}
& w_{r e v}=h_{1}-h_{2}-T_{0}\left(s_{1}-s_{2}\right)=1383.5-298 *(7.37798-7.8689)=1529.8 \mathrm{~kJ} / \mathrm{kg} \\
& w_{\text {act }}=h_{1}-h_{2}=1383.5 \mathrm{~kJ} / \mathrm{kg} \eta_{I I}=1383.5 / 1529.8=0.904 I=T_{o}\left(s_{2}-s_{1}\right)
\end{aligned}
$$

Example 8.2 Measurements are made on an adiabatic compressor with its supply air at 100 kPa and $300^{\circ} \mathrm{K}$. The exhaust air is measured at 600 kPa and $525^{\circ} \mathrm{K}$. Can these measurements be correct?

Solution At $300^{\circ} \mathrm{K}, p_{r 1}=1.39$ so $p_{r 2}=1.39^{*} 600 / 100=8.34$. This gives $T_{2, r e v}=498.2^{\circ} \mathrm{K}$ so since the reversible temperature is less than $525^{\circ} \mathrm{K}$, the process is possible. The adiabatic efficiency can be calculated as $\eta=\Delta \mathrm{h}_{\mathrm{rev}} / \Delta \mathrm{h}_{\text {act }}=5826.3 / 6627.0=0.879$.

### 8.2 Exergy

It is often important to know the maximum work available from a heat source or thermal body that must reject heat to the local atmosphere or environment. For energy production systems like geothermal or ocean gradients, the peak reservoir temperatures are specified. For combustion systems, the peak temperature of the working fluid is determined by the heating value of the fuel and its complete combustion in air. For nuclear systems and solar thermal systems, the peak temperature is essentially infinite. However, all systems are limited by the material that must contain them, so the peak temperature for combustion systems often does not reach that possible by complete combustion of all of the air available. Nuclear and solar thermal systems are even more limited by material properties because they must use a thermal gradient to transfer heat to the working fluid rather than heating it directly as in combustion systems. Therefore, one of the concepts useful for comparing thermal systems is a concept called exergy. It is defined as,

$$
\begin{equation*}
X=\left(W_{\text {Reversible }}\right)_{M a x} \tag{8.13}
\end{equation*}
$$

The maximum reversible work can be obtained from an energy source that must reject heat to the local environment. On the other hand, one can express that Exergy (also called Availability or Work Potential): the maximum useful work that can be obtained from a system at a given state in a given environment; in other words, the most work you can get out of a system. It is also sometimes called Availability and sometimes the symbol $\Psi$ or $\Phi$ is used.

The local environment is called the "dead state" and symbolize it with a $\boldsymbol{o}$ because an energy source that is at the temperature and pressure of the local environment does not have a heat sink to which it can reject heat. To estimate the exergy available both the temperature and pressure of the local environment must be considered.

The work that can be done in expanding from the initial pressure of the fixed mass to the environmental pressure is,

$$
\begin{equation*}
W=p d V=\left(p-p_{o}\right) d V+p_{o} d V=\delta W_{\text {useful }}+p_{o} d V \tag{8.14}
\end{equation*}
$$

For a reversible process, the only way that heat can be transferred is through a Carnot cycle. And since the energy will be removed from the mass with the excess energy above the dead state, the heat transfer will be negative. The work available from the heat engine is given by,

$$
\begin{equation*}
\delta W_{H E}=\left(1-\frac{T_{o}}{T}\right) \delta Q=\delta Q-\frac{T_{o}}{T} \delta Q=\delta Q-T_{o} \frac{\delta Q}{T} \tag{8.15}
\end{equation*}
$$

In this case the $\frac{\delta Q}{T}=d S$ is negative because heat is being transferred from the
system, so system, so

$$
\begin{array}{ll}
\delta W_{H E} & =\delta Q-\left(-T_{o} d S\right)=\delta Q+T_{o} d S \\
\delta Q & =\delta W_{H E}-T_{o} d S \tag{8.16}
\end{array}
$$

The First Law gives for a negative heat transfer

$$
\begin{equation*}
d U=-\delta Q-\delta W=-\delta W_{H E}+T_{o} d S-\delta W_{\text {useful }}-p_{o} d V \tag{8.17}
\end{equation*}
$$

So,

$$
\begin{equation*}
\delta W_{\text {TotalUseful }}=\delta W_{H E}+\delta W_{\text {Useffl }}=-d U-p_{o} d V+T_{o} d S \tag{8.18}
\end{equation*}
$$

Performing the integration from the initial state to the dead state gives,

$$
\begin{equation*}
W_{\text {TotalUseful }}=X=\left(U-U_{o}\right)+p_{o}\left(V-V_{o}\right)-T_{o}\left(S-S_{o}\right) \tag{8.19}
\end{equation*}
$$

which gives the exergy for a closed system.
Now for an open system or control volume the First Law is,

$$
\begin{equation*}
\dot{Q}-\dot{W}_{S}=h_{2} \dot{m}_{2}-h_{1} \dot{m}_{1}+\dot{U}_{C V} \tag{8.20}
\end{equation*}
$$

and for the Second Law,

$$
\begin{equation*}
\dot{S}_{\text {prod }}=s_{2} \dot{m}_{2}-s_{1} \dot{m}_{1}+\dot{S}_{C V}-\frac{\dot{Q}}{T_{o}} \tag{8.21}
\end{equation*}
$$

Eliminating $\dot{Q}$ between the First and Second Law equations gives,

$$
\begin{equation*}
\dot{W}_{s}=-\dot{U}_{C V}+T_{o} \dot{S}_{C V}-\left(h_{2}-T_{o} s_{2}\right) \dot{m}_{2}+\left(h_{1}-T_{o} s_{1}\right) \dot{m}_{1}-T_{o} \dot{S}_{\text {Prod }} \tag{8.22}
\end{equation*}
$$

Now integrating over time and noting that $\mathrm{S}_{\text {Prod }}$ is due to irreversibilities, we have,

$$
\begin{equation*}
W_{\operatorname{Re} v}=\left(u_{i}-T_{o} s_{i}\right) m_{i}-\left(u_{f}-T_{o} s_{f}\right) m_{f}+\left(h_{1}-T_{o} s_{1}\right) m_{1}-\left(h_{2}-T_{o} s_{2}\right) m_{2} \tag{8.23}
\end{equation*}
$$

The actual work can be determined from a First Law analysis as before,

$$
\begin{equation*}
W_{\text {Actual }}=m_{i} u_{i}-m_{f} u_{f}+m_{1} h_{1}-m_{2} h_{2}+Q \tag{8.24}
\end{equation*}
$$

Then the irreversibility is given by,

$$
\begin{equation*}
I=T_{o}\left(s_{f} m_{f}-s_{i} m_{i}+s_{2} m_{2}-s_{1} m_{1}\right)-Q \tag{8.25}
\end{equation*}
$$

For steady flow,

$$
\begin{equation*}
\dot{W}_{\operatorname{Re} v}=\left(h_{1}-h_{2}\right) \dot{m}+T_{o}\left(s_{2}-s_{1}\right) \text { and } \dot{I}=\dot{m} T_{o}\left(s_{2}-s_{1}\right)-\dot{Q} \tag{8.26}
\end{equation*}
$$

Note that the reversible work is not necessarily the same as the isentropic work. If the entropy changes during the process, the reversible work does not equal to isentropic work. So a process must be both adiabatic and reversible to be isentropic.

In all of the above, the changes in kinetic or potential energy have been neglected. If the changes in kinetic or potential energy are significant, they can be included by noting that they will have zero values in the "dead state" so these energies are essentially completely recoverable in a reversible process.

If we include the kinetic and potential energies, we can define a state variable exergy by,

$$
\begin{equation*}
x=h+\frac{v^{2}}{2}+g z-T_{o} s \tag{8.27}
\end{equation*}
$$

However, it is important to remember that $\boldsymbol{x}$ has a zero value at the appropriate "dead state" of interest for the particular process or engine.

The concept of second law efficiency can be generalized to that of second law effectiveness given by,

$$
\begin{equation*}
\varepsilon_{I I}=\frac{(\text { exergy produced })+(\text { work produced })+(\text { adjusted heat produced })}{(\text { exergy supplied })+(\text { work used })+(\text { adjusted heat used })} \tag{8.28}
\end{equation*}
$$

Remember that the adjusted heat produced or used by a device is based on the heat reservoir that interacts with the device and it must do so through a Carnot cycle, or the process would not be reversible.

$$
\begin{equation*}
Q_{\text {adjusted }}=\left(1-\frac{T_{o}}{T_{h r}}\right) Q \tag{8.29}
\end{equation*}
$$

Example 8.3 Which system can do more useful work, 1.0 kg of $\mathrm{H}_{2} \mathrm{O}$ at 1000 K and 500 kPa or 1.0 kg of Air at 1000 K and 500 kPa .

Solution Assume a dead state of 300 K and 101.325 kPa .
Then the exergy for the $\mathrm{H}_{2} \mathrm{O}$ is given by

$$
\begin{aligned}
& X=m\left[h-h_{o}-T_{o}\left(s_{1}^{0}-s_{2}^{0}-R \ln \left(\frac{p}{p_{o}}\right)\right)\right] \\
& X=\frac{1}{18}\left[34790.1-8853.5-300\left(182.830-226.5235-8.31447 \ln \left(\frac{500}{101.325}\right)\right)\right] \\
& X=2390.35 \mathrm{~kJ}
\end{aligned}
$$

And the exergy for the air is given by
$X=m\left[h-h_{o}-T_{o}\left(s_{1}^{0}-s_{2}^{0}-R \ln \left(\frac{p}{p_{o}}\right)\right)\right]$
$X=\frac{1}{28.9669}\left[29016.1-7414.4-300\left(55.7943-92.4604-8.31447 \ln \left(\frac{500}{101.325}\right)\right)\right]$
$X=1262.93 \mathrm{~kJ}$

Therefore, for the same conditions, the kilogram of water has almost twice the exergy.

Example 8.4 How much useful work is wasted in the condenser of a power plant that takes in steam with a quality of 0.85 and 1 psi and delivers saturated liquid at the same pressure?

Solution Choose the dead state as $537^{\circ} \mathrm{R}$ and 1 psi . Note the atmosphere is not the reference here.

The exergy at the inlet is $x_{1}=h_{1}-h_{o}-T_{o}\left(s_{1}-s_{o}\right)$
The exergy at the outlet is $x_{2}=h_{2}-h_{o}-T_{o}\left(s_{2}-s_{o}\right)$
The difference in exergy is the useful work wasted, so

$$
\begin{aligned}
& W_{\text {wasted }}=x_{1}-x_{2}=h_{1}-h_{2}-T_{o}\left(s_{1}-s_{2}\right) \\
& W_{\text {wasted }}=69.9+0.85 * 1037.9-537(0.13292+0.85 * 1.84897-0.13292) \\
& W_{\text {wasted }}=0.85 * 1037.9-537 * 0.85 * 1.84897=38.3 \text { Btu } / \mathrm{lbm}
\end{aligned}
$$

Example 8.5 Calculate the exergy of steam at $1000^{\circ} \mathrm{R}$ and 500 psia. The surroundings are at $520^{\circ} \mathrm{R}$ and atmospheric pressure.

## Solution

$$
\begin{aligned}
& x=h-h_{o}-T_{o}\left(s-s_{o}\right) \quad \text { by definition } h_{o}=s_{o}=0 \\
& x=h-T_{o} s=1263.2-520 * 1.5253=470.0 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

Example 8.6 Determine the second law efficiency for an ideal isentropic nozzle. Hydrogen enters the nozzle at 3000 K and 7.0 MPa with negligible kinetic energy and exits to a pressure of 0.1 MPa . Assume the dead state is 300 K and 0.1 MPa .

Solution Since the process is isentropic, use the gas tables for hydrogen

$$
\begin{aligned}
& s_{2}^{0}=s_{1}^{0}-R \ln \frac{p_{1}}{p_{2}}=197.898-8.31447 * \ln \frac{7}{0.1}=162.574 \mathrm{~kJ} / \mathrm{kmol} \\
& T_{2}=1045.4 K \quad h_{1}=96,299.9 \mathrm{~kJ} / \mathrm{kmol} \quad h_{2}=29,631.1 \mathrm{~kJ} / \mathrm{kmol} \\
& h_{1}=h_{2}+\frac{M V^{2}}{2} \quad \mathrm{~V}=\sqrt{\frac{2 *\left(h_{1}-h_{2}\right)}{M}}=\sqrt{\frac{2 *(96,299.9-29,631.1) * 1000}{2}}=8,165.1 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

The exergies are

$$
\begin{aligned}
x_{1} & =\left[h_{1}-h_{o}-T_{o}\left(s_{1}^{0}-s_{o}^{0}-R \ln \frac{p_{1}}{p_{o}}\right)\right] / M \\
& =\left[96,299.9-7,628.8-300\left(197.898-125.873-8.31447 * \ln \frac{7}{0.1}\right)\right] / 2=38,830.4 \mathrm{~kJ} / \mathrm{kg} \\
x_{2} & =\left[h_{2}-h_{0}+\frac{V^{2}}{2}-T_{o}\left(s_{2}^{0}-s_{o}^{0}-R \ln \frac{p_{2}}{p_{o}}\right)\right] / M \\
& =\left(36,259.5-7,628.8+\frac{2 * 8165.1^{2}}{2 * 1000}-300(168.337-125.873)\right] / 2=38,830.4 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

And the second law effectiveness is

$$
\varepsilon_{I I}=\frac{x_{2}}{x_{1}}=\frac{38,830.4}{38,830.4}=1.0
$$

which is to be expected since it is an isentropic process.

## Chapter 9 <br> Gas Kinetic Theory of Entropy

This chapter will attempt to provide a physical understanding of the concept of entropy based on the kinetic theory of gases. Entropy in classical thermodynamics is a mathematical concept that is derived from a closed cycle on a reversible Carnot heat engine. For many students it lacks physical meaning. Most students have a physical understanding of variables like volume, temperature, and pressure. Internal energy and enthalpy are easy to understand, if not intuitive. However, entropy is a bit more difficult. The discussion that follows is an attempt to provide physical insight into the concept of entropy at the introductory level. Prof. Leonard K. Nash, Dover Edition, 2006, bases this discussion on the excellent text, "Elements of Statistical Thermodynamics" [1-4].

In basic mechanics, the student learns that all two-body problems are solvable analytically, and some three-body problems are also solvable. However, beyond that, many-body problems are very complicated. However, they can theoretically be solved numerically for any given set of conditions that specify the initial position and momentum for all of the bodies involved, the problems become extraordinarily difficult for more than a handful of bodies. If we consider only the simplest of interactions, the collisions of hard spheres, for the molecules in a cubic millimeter of gas at standard temperature and pressure there is no hope of producing deterministic solutions for the $\sim 1020$ molecules that could have any engineering meaning. However, we know that the behavior of a gas under these conditions is predictable and we need only measure a few parameters with relatively crude instruments to describe its condition. The analytic technique that allows us to explain how this is possible is statistical mechanics. We can characterize the hard sphere interactions of many molecules in a statistical manner and derive macroscopic properties, or relations between properties that allow us to predict gas behavior.

### 9.1 Some Elementary Microstate and Macrostate Models

In order to develop this capability, let us start by analyzing some very simple experiments. The simplest experiment is the flipping of a fair coin multiple times. Consider the outcomes of flipping two coins. There are four possible outcomes. We have

| First coin | H | H | T | T |
| :--- | :--- | :--- | :--- | :--- |
| Second coin | H | T | H | T |

Now consider the total number of heads observed. One-fourth of the time, two heads will be observed. One-half of the time one head will be observed. In addition, one-fourth of the time no heads will be observed. Each tossing sequence is "independent and equally probable", but the "observation of one head" is most likely. Consider what happens when we toss four coins.

| First coin | H | H | H | H | T | T | T | T | H | H | H | H | T | T | T | T |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Second coin | H | H | H | H | T | T | T | T | T | T | T | T | H | H | H | H |
| Third coin | H | T | H | T | H | T | H | T | H | T | H | T | H | T | H | T |
| Fourth coin | H | H | T | T | H | H | T | T | H | H | T | T | H | H | T | T |
| Number of heads | 4 | 3 | 3 | 2 | 2 | 1 | 1 | 0 | 3 | 2 | 2 | 1 | 3 | 2 | 2 | 1 |

Note that the distribution is,
One observation with zero heads,
Four observations with one head,
Six observations with two heads,
Four observations with three heads, and
One observation with four heads.
The number of observations W , with H heads, and T tails, out of N tosses, can be predicted by the formula

$$
\begin{equation*}
W=\frac{N!}{H!T!} \tag{9.1}
\end{equation*}
$$

Zero Heads $\quad W=\frac{4!}{0!4!}=1$
One Head $\quad W=\frac{4!}{1!3!}=4$
Two Heads $\quad W=\frac{4!}{2!2!}=\frac{4 * 3}{1 * 2}=6$
Three Heads $W=\frac{4!}{3!1!}=4$
Four Heads $W=\frac{4!}{4!0!}=$

Now consider what happens with eight coins. We have
Zero Heads $\quad W=\frac{8!}{0!8!}=1$
One Head $\quad W=\frac{8!}{1!7!}=8$
Two Heads $\quad W=\frac{8!}{2!6!}=28$
Three Heads $W=\frac{8!}{3!5!}=56$
Four Heads $\quad W=\frac{8!}{4!4!}=70$
Five Heads $\quad W=\frac{8!}{5!3!}=56$
Six Heads $\quad W=\frac{8!}{6!2!}=28$
Seven Heads $W=\frac{8!}{7!1!}=8$
Eight Heads $W=\frac{8!}{8!0!}=1$
Note that the peak number of observations always occurs for the distribution that gives half heads and half tails, exactly as we would expect.

Now it will be useful to identify each of the possible outcomes of flipping the coins a "microstate" for our system. Each of these microstates is assumed to be equally likely. With the two coins there are four such microstates. With the four coins, there are 16 such microstates. When we go to eight coins, there are 256 such microstates. Now the observed results of the coin flips will be called a "macrostate" for the system. For the two coins, there are three macrostates (1, 2 , or 3 heads) that can be distinguished. For the four coins, there are five macrostates that can be distinguished. And for the eight coins there are nine macrostates that can be distinguished. The probability of observing a macrostate will depend upon what fraction of the microstates possible that will produce an outcome that is observed as that macrostate.

In order to compare these distributions with distributions for larger numbers of coins it is useful to normalize them by dividing the number of observations for each number of heads by the number of observations for the most likely number of heads. When we do this, we get the following normalized values for the observation of the number of heads in each case.

| Two coins |  |  | Four coins |  | Eight coins |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0 Heads | 0.5000 | 0 Heads | 0.1667 | 0 Heads | 0.0143 |
|  |  |  |  | 1 Head | 0.1143 |

| Two coins |  |  | Four coins |  | Eight coins |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :---: |
|  |  |  |  | 3 Heads | 0.8000 |  |
| 1 Head | 1.0000 | 2 Heads | 1.0000 | 4 Heads | 1.0000 |  |
|  |  |  |  | 5 Heads | 0.8000 |  |
|  |  | 3 Heads | 0.6667 | 6 Heads | 0.4000 |  |
|  |  |  |  | 7 Heads | 0.1143 |  |
| 2 Heads | 0.5000 | 4 Heads | 0.1667 | 8 Heads | 0.0143 |  |

A plot of the normalized data is presented in the Fig. 9.1 along with the data for 16 and 32 coins.

Note that the curve for the frequency of the number of observed heads peaks at the $50 \%$ point and the curve get narrower as the number of coins increases. So we can say that the most likely observation is that half of the coins are heads, and as we increase the number of coins, it is more and more likely that we get closer to the $50 \%$ heads observation. In fact by the time we have flipped 14,000 coins, a $1 \%$ deviation from the expected observation of 7000 heads will occur less than $50 \%$ of the time. By the time, we have flipped 46,000 coins a $1 \%$ deviation from the expected 23,000 heads will occur less than $10 \%$ of the time. By the time we have flipped 92,000 coins, a $1 \%$ deviation from the expected 46,000 heads will occur less than $1 \%$ of the time. As the number of coins increases, the probability of observing a macrostate deviation from the expected $50 \%$ heads that is measurable continues to shrink until it is "impossible". Certainly if we flipped $10^{20}$ "fair" coins the probability of measuring a number of heads that deviated from the $5 \times 10^{19}$ heads estimate by more than a hundredth of a percent would be negligible.

Now consider an example closer to a system of interest in thermodynamics. In a solid, the atoms vibrate about their equilibrium positions at all temperatures above absolute zero, or the zero internal energy level. Quantum mechanics tells us that the frequency of vibration is quantitized and that only certain frequencies are allowed.

Frequency of Number of Heads

Fig. 9.1 Normalized frequency of number of heads observed

This leads to the following equation for the allowed energy levels for a vibrating atom.

$$
\begin{equation*}
\varepsilon_{n}=\left(n+\frac{1}{2}\right) h v \tag{9.2}
\end{equation*}
$$

Where $v$ is the fundamental vibration frequency and $h$ is Plank's constant-required to convert a frequency to energy units. The ground state for the atom corresponds to $n=0$ and each increasing integral value of $\boldsymbol{n}$ corresponds to the atom acquiring another quantum of energy. This model establishes a uniform energy grid with units of energy being passed from one atom to the next as a single phonon.

Now let us consider three distinguishable atoms and distribute three quanta or units of energy among them. This can be done ten possible ways.

| Configuration | Atom 1 | Atom 2 | Atom 3 |
| :--- | :--- | :--- | :--- |
| 1 | 3 | 0 | 0 |
| 2 | 0 | 3 | 0 |
| 3 | 0 | 0 | 3 |
| 4 | 2 | 1 | 0 |
| 5 | 0 | 2 | 1 |
| 6 | 1 | 0 | 2 |
| 7 | 2 | 0 | 1 |
| 8 | 1 | 2 | 0 |
| 9 | 0 | 1 | 2 |
| 10 | 1 | 1 | 1 |

Therefore, there are ten microstates for this problem, but only three macrostates. We can observe in the first macrostate that one atom of the three has all three units of energy. In the second macrostate, one atom has two units of energy and another has one unit of energy. Finally, each of the atoms could have a single unit of energy. Three microstates contribute to the first macrostate, six microstates to the second, and one microstate to the third. If each microstate is equally likely, then the macrostates should be observed in the ratio of $3: 6: 1$. Note that the seemingly best-ordered macrostate, one unit of energy in each atom, is the least likely.

As we increase the number of microstates, it will become important to have a generic formula to predict the number of microstates that contribute to a particular macrostate. Let us start with the second macrostate. To achieve this macrostate there are three ways that we can assign the first two quanta of energy. Once this has been done, there are two atoms left that we can assign the remaining quanta. Then we can assign zero quanta to the last atom. Therefore, there are 3 times 2 times 1 ways this macrostate can be achieved. So we will have $3 \times 2 \times 1$ or 3 ! Microstates. Now consider the first macrostate. There are three choices for assigning all three quanta of energy. Once that is done we can assign zero quanta to either of the remaining two atoms and then assign another zero quanta to the last atom. However, these two choices are indistinguishable. So once again, we have 3! Choices, but 2 or 2 ! of them are indistinguishable. Finally consider the third macrostate. We can assign the
first quanta to any of the three atoms, the second quanta to either of the two remaining, and the last quanta to the last atom. There are once again 3! Ways of assigning the quanta, but 3! of them are indistinguishable. So we have

Macrostate 1: $3!/ 2!=3$
Macrostate 2: $3!/ 1!=6$
Macrostate 3: $3!/ 3!=1$
Now let's extend this argument to N atoms. We can assign a specific number of quanta of energy to the first atom in N ways, to the second in $\mathrm{N}-1$ ways, to the third in $\mathrm{N}-2$ ways, etc. So the total number of ways we can assign quanta to N atoms is N !. However, if some of the numbers of quanta are identical, the resulting macrostates will be indistinguishable. So we must reduce the number of microstates used to form a macrostate by $N_{a}$ !, where $N_{a}$ is the number of times a given number of quanta is repeated. Thus the number of microstates contributing to a macrostate can be written as $\mathrm{N}!/ \mathrm{N}_{\mathrm{a}}$ !. If there are two groups of quanta that contain the same number of quanta, the number of microstates contributing to this macrostate will be given by $\mathrm{N}!/\left(\mathrm{N}_{\mathrm{a}}!\mathrm{N}_{\mathrm{b}}!\right)$. The general formula will then become, letting $W$ equal the number of microstates contributing to a particular macrostate

$$
\begin{equation*}
W=\frac{N!}{\prod_{n_{q}} N_{n_{q}}!} \tag{9.3}
\end{equation*}
$$

Consider now two additional examples. First, consider the observable macrostates when five quanta of energy are distributed among five atoms. The macrostates are, (Fig. 9.2).

Macrostate 1: All five quanta to one atom- $5!/(1!* 4!)=5$
Macrostate 2: Four quanta to one atom, and 1 to another- $5!/(1!* 1!* 3!)=20$
Macrostate 3: Three quanta to one atom, 2 to another- $5!/(1!* 1!* 3!)=20$
Macrostate 4: Three quanta to one atom, 1 to a second and 1 to a third$5!/(1!* 2!* 2!)=30$
Macrostate 5: Two quanta to one atom, two quanta to a second, and 1 to a third$5!/(2!* 1!* 2!)=30$
Macrostate 6: Two quanta to one atom, and 1 quantum to each of 3 atoms$5!/(1!* 3!* 1!)=20$
Macrostate 7: One quantum to each atom-5!/(5!)=1
So there are a total of 126 microstates, but only 7 observable macrostates.
Now consider the case where we add five amore atoms but no more quanta. For ten atoms and five quanta, we have the same number of macrostates as above, but there are more indistinguishable microstates contributing to each because of the added atoms that do not receive a quantum of energy (Fig. 9.3). The calculation is

Macrostate 1: $10!/(1!* 9!)=10$
Macrostate 2: $10!/(1!* 1 * 8!)=10 * 9=90$
Macrostate 3: $10!/(1!* 1!* 8!)=10 * 9=90$
Macrostate 4: $10!/(1!* 2!* 7!)=10 * 9 * 8 / 2=360$

Fig. 9.2 Macrostate frequencies for five quanta in five atoms

Fig. 9.3 Macrostate frequencies for five quanta in ten atoms

Macrostate 5: $10!/(2!* 1!* 7!)=10 * 9 * 7 / 2=360$
Macrostate 6: $10!/(1!* 3!* 6!)=10 * 9 * 8 * 7 / 3 / 2=840$
Macrostate 7: $10!/(5!* 5!)=10 * 9 * 8 * 7 * 6 / 5 / 4 / 3 / 2=252$
Note that we only added five atoms or doubled the original number, but the total number of microstates increased to 2002, or an increase of almost a factor of 16 . Also, note that of the 2002 microstates possible, 840 or about $42 \%$ of them contributed to the most probable macrostate. If we assign an equal probability to each microstate, Macrostate 6 is 2.33 times as likely as its nearest competitors are.

### 9.2 Stirling's Approximation for Large Values of $\mathbf{N}$

Now since we will want to consider the number of atoms in a realistic macroscopic piece of material, which for a gas is on the order of $10^{20}-10^{27}$ atoms, we will need a better way to compute factorials than simply multiplying them out. Also since the magnitude of N ! goes up very rapidly as N increases, it will be useful to look at

Fig. 9.4 Comparison of Stirling's approximation to $\ln (\mathrm{N}!)$ to $\ln (\mathrm{N}!)(N=10$ to $N=100)$
$\ln (\mathrm{N}!)$ rather than simply $\mathrm{N}!$. Our formula for the natural logarithm of the number of microstates, $\ln (\mathrm{W})$, then becomes,

$$
\begin{equation*}
\ln (W)=\frac{\ln (N!)}{\sum_{n_{q}} \ln \left(N_{n_{q}}!\right)} \tag{9.4}
\end{equation*}
$$

And once we have calculated $\ln (\mathrm{W})$ it is straightforward to calculate W , but that can often be too large of a number to store on most calculators or computers. In most cases we will simply work with $\ln (\mathrm{W})$. Of course we really haven't helped ourselves very much as $\ln (\mathrm{N}!)$ is as difficult to calculate as $\mathrm{N}!$. However there exists a very accurate approximation to $\ln (\mathrm{N}!)$ developed by Stirling that gives $\ln (\mathrm{N}!)$ as

$$
\begin{equation*}
\operatorname{In}(N!) \sim N * \operatorname{In}(N)-N \tag{9.5}
\end{equation*}
$$

A comparison of Stirling's approximation and the actual $\ln (N!)$ is given in Fig. 9.4. Since it is hard to tell the difference between the two curves in Fig. 9.4, the fractional error in Stirling's approximation is plotted in Fig. 9.5.

It can be seen that the approximation is accurate to less than a percent by the time N reaches 100 . For the cases we will be interested when $N$ approaches $10^{20}$ or greater, Stirling's approximation is very accurate.

### 9.3 The Boltzmann Distribution Law

We saw from the coin flip problem and the five quanta distributed among ten atoms that the most probable macrostate tends to dominate as the number of microstates increases. If we are going to deal with very large numbers of atoms, the most probable macrostate will tend to dominate even more. So it would be useful to be able to find this macrostate very quickly. When we do this we are asking, what is the distribution of the $N_{n q}$ that define the most likely configuration macrostate. Now

Fig. 9.5 Fractional error in Stirling's approximation ( $N=10$ to $N=500$ )
when we are dealing with very large numbers of microstates, we will also have very significant numbers of macrostates. These macrostates can be packed so close together and ordered in such a way that $W$ can be thought of as a function of a configuration index for macrostates similar to the way it is presented in Fig. 9.3. We can let this variable be called $C$. Then if we think of $W$ as a continuous function of $C$, we can find the most likely macrostate by differentiating $W$, or $\ln W$, as a function of $C$.

$$
\begin{equation*}
\frac{d W}{d C} \tag{9.6}
\end{equation*}
$$

Our formula for $W$ is then,

$$
\begin{equation*}
W=\frac{N!}{N_{a}!\ldots N_{l}!N_{m}!N_{n}!\ldots N_{z}!} \tag{9.7}
\end{equation*}
$$

where the levels $l, m$, and $n$ are identified, and it is not implied that only $z$ levels are available but only there are some finite number of levels of interest. At the peak value of $W$ we will assume that the levels $1, \mathrm{~m}$, and n have the occupation numbers $N_{p} N_{m}$, and $N_{n}$. For a normal solid, the numbers $N_{p}, N_{m}$, and $N_{n}$ are assumed to be quite large. To get the derivative with respect to the configuration index $C$, we will then perturb the numbers $N_{p}, N_{m}$, and $N_{n}$ to see what a small change in C will have on $W$. Basically setting the derivative to zero means that small changes in C will have a negligible effect on W . However we must conserve energy in doing this, so let us transfer one atom from level $l$ to level $m$ and one atom from level $n$ to level $l$. If the levels are equally spaced in energy, this will conserve energy. Now we have

$$
N_{l}^{\prime}=N_{l}-1, \quad N_{m}=N_{m}+2, \quad \text { and } N_{n}^{\prime}=N_{n}-1
$$

where the primes indicate the new occupation numbers for the three levels. Our new configuration then will be,

$$
\begin{equation*}
W=\frac{N!}{N_{a}!\ldots\left(N_{l}-1\right)!\left(N_{m}+2\right)!\left(N_{n}-1\right)!\ldots N_{z}!} \tag{9.8}
\end{equation*}
$$

Since we assumed the original configuration was the max $W$ configuration, an infinitesimal change like we have just made should not change the value of $\boldsymbol{W}$ as at the peak $W, d W / d C=0$. Therefore, these two values of $W$ should be equal. We have,

$$
\frac{N!}{N_{a}!\ldots N_{l}!N_{m}!N_{n}!\ldots N_{z}!}=\frac{N!}{N_{a}!\ldots\left(N_{l}-1\right)!\left(N_{m}+2\right)!\left(N_{n}-1\right)!\ldots N_{z}!}
$$

Canceling common terms this becomes,

$$
\left\{\begin{array}{l}
N_{l}!* N_{m}!* N_{n}!=\left(N_{l}-1\right)!^{*}\left(N_{m}+2\right)!^{*}\left(N_{n}-1\right)!  \tag{9.9}\\
\frac{N_{l}!}{\left(N_{l}-1\right)!} * \frac{N_{n}!}{\left(N_{n}-1\right)!}=\frac{\left(N_{m}+2\right)!}{N_{m}!} \\
\frac{N_{l} *\left(N_{l}-1\right)!}{\left(N_{l}-1\right)!} * \frac{N_{n} *\left(N_{n}-1\right)!}{\left(N_{n}-1\right)!}=\frac{\left(N_{m}+2\right) *\left(N_{m}+1\right) N_{m}!}{N_{m}!} \\
N_{l} * N_{n}=\left(N_{m}+2\right) *\left(N_{m}+1\right)
\end{array}\right.
$$

Now the 1 and 2 are negligible compared to $\mathrm{N}_{\mathrm{m}}$ so this becomes

$$
\begin{equation*}
N_{l} * N_{n}=N_{m}^{2} \tag{9.10a}
\end{equation*}
$$

or

$$
\begin{equation*}
\frac{N_{l}}{N_{m}}=\frac{N_{m}}{N_{n}} \tag{9.10b}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{N_{k}}{N_{l}}=\frac{N_{l}}{N_{m}}=\frac{N_{m}}{N_{n}}=\frac{N_{n}}{N_{o}}=\frac{N_{o}}{N_{p}}=\ldots \tag{9.11}
\end{equation*}
$$

Basically, we have a geometric series. Now consider a system of atoms where the spacing between energy levels is not a constant. We will have,

$$
\begin{equation*}
\frac{\varepsilon_{n}-\varepsilon_{m}}{\varepsilon_{m}-\varepsilon_{l}}=\frac{p}{q} \tag{9.12}
\end{equation*}
$$

where $p$ and $q$ are small integers. Now let us withdraw $p+q$ units of energy from level $m$ and transfer $q$ of them to level $n$ and $p$ of them to level $l$. This change will maintain the total energy constant as we can see by writing the previous equation as,

$$
\begin{equation*}
\left(\varepsilon_{n}-\varepsilon_{m}\right) q+p\left(\varepsilon_{l}-\varepsilon_{m}\right)=0 \tag{9.13}
\end{equation*}
$$

Now if the original configuration was the maximum W configuration, we will have

$$
\begin{align*}
& \frac{N!}{N_{a}!\ldots \ldots N_{l}!N_{m}!N_{n}!\ldots . N_{z}!}=\frac{N!}{N_{a}!\ldots . .\left(N_{l}+p\right)!\left(N_{m}-p-q\right)!\left(N_{n}+q\right)!\ldots . N_{z}!} \\
& \frac{\left(N_{l}+p\right)!}{N_{l}!} \frac{\left(N_{n}+q\right)!}{N_{n}!}=\frac{N_{m}!}{\left(N_{m}-p-q\right)!} \\
& \frac{\left(N_{l}+p\right) \ldots .\left(N_{l}+1\right) N!}{N_{l}!} \cdot \frac{\left(N_{n}+q\right) \ldots \ldots\left(N_{n}+1\right) N_{m}!}{N_{n}!} \\
& =\frac{N_{m}\left(N_{m}-1\right) \ldots\left(N_{m}-p-q+1\right)\left(N_{m}-p-q\right)!}{\left(N_{m}-p-q\right)!} \\
& \left(N_{l}+p\right) \ldots\left(N_{l}+1\right)\left(N_{n}+q\right) \ldots\left(N_{n}+1\right)=N_{m}\left(N_{m}-1\right) \ldots\left(N_{m}-p-q+1\right) \tag{9.14}
\end{align*}
$$

Now since we chose $p$ and $q$ as small integer they are negligible once again when compared with $N_{p} N_{m}$, and $N_{n}$. This then gives,

$$
\begin{equation*}
N_{l}^{p} N_{n}^{q}=N_{m}^{p+q} \tag{9.15}
\end{equation*}
$$

Of course the equation we derived for uniform spacing can be represented by this equation with $\boldsymbol{p}=\mathbf{1}$ and $q=1$. This equation can then be written as,

$$
p \ln \left(\frac{N_{l}}{N_{m}}\right)=q \ln \left(\frac{N_{m}}{N_{n}}\right)
$$

or

$$
\begin{equation*}
\frac{1}{\varepsilon_{m}-\varepsilon_{l}} \ln \left(\frac{N_{l}}{N_{m}}\right)=\frac{1}{\varepsilon_{n}-\varepsilon_{m}} \ln \left(\frac{N_{m}}{N_{n}}\right)=\beta \tag{9.16}
\end{equation*}
$$

where $\beta$ is just a constant because we could write the same relationship for any set of adjoining levels. So we have

$$
\begin{equation*}
\ln \left(\frac{N_{n}}{N_{i}}\right)=\beta\left(\varepsilon_{i}-\varepsilon_{n}\right) \tag{9.17}
\end{equation*}
$$

and level $i$ and level $n$ are now not necessarily adjoining levels. So if we define the ground state level with the subscript $o$, we can write

$$
\ln \left(\frac{N_{n}}{N_{o}}\right)=-\beta \varepsilon_{n}
$$

or

$$
\begin{equation*}
\frac{N_{n}}{N_{o}}=e^{-\beta \varepsilon_{n}} \tag{9.18}
\end{equation*}
$$

which is the celebrated Boltzmann distribution law for the most likely configuration energy distribution.

### 9.4 Estimating the Width of the Most Probable Macrostate Distribution

With the Boltzmann distribution law stated, we can now realistically estimate the width of the peak configuration in configuration space. Let us choose a set of small parameters to quantify the relative change in the population numbers for each level. We will define,

$$
\begin{equation*}
\alpha_{n}=\frac{N_{n}^{\prime}-N_{n}}{N_{n}} \tag{9.19}
\end{equation*}
$$

If the population of a level increases, $\alpha$ will be positive, and if the population of a level decreases, $\alpha$ will be negative. Since we are only shifting the configuration slightly, we would expect $|\alpha| \ll 1$. We can write,

$$
\begin{equation*}
N_{n}^{\prime}-N_{n}=\alpha_{n} N_{n} \tag{9.20}
\end{equation*}
$$

Now since we have a fixed total number of atoms we must have,

$$
\begin{equation*}
\Delta N=\left(N_{o}^{\prime}-N_{o}\right)+\left(N_{1}^{\prime}-N_{1}\right)+\ldots \ldots=\sum_{n} \alpha_{n} N_{n}=0 \tag{9.21}
\end{equation*}
$$

And since we are considering no change in energy, we have,

$$
\begin{equation*}
\Delta E=\varepsilon_{o}\left(N_{o}^{\prime}-N_{o}\right)+\varepsilon_{1}\left(N_{1}^{\prime}-N_{1}\right)+\ldots \ldots=\sum_{n} \varepsilon_{n} \alpha_{n} N_{n}=0 \tag{9.22}
\end{equation*}
$$

Now we can write,

$$
N_{n}^{\prime}=N_{n}+\alpha_{n} N_{n}
$$

and

$$
\begin{equation*}
\frac{W}{W^{\prime}}=\frac{N!/ \prod_{n} N_{n}!}{N!/ \prod_{n}\left(N_{n}+\alpha_{n} N_{n}\right)!}=\frac{\prod_{n}\left(N_{n}+\alpha_{n} N_{n}\right)!}{\prod_{n} N_{n}!} \tag{9.23}
\end{equation*}
$$

Taking natural logarithms of both sides gives,

$$
\begin{equation*}
\ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n} \ln \left[\left(N_{n}+\alpha_{n} N_{n}\right)!\right]-\sum_{n} \ln \left[N_{n}!\right] \tag{9.24}
\end{equation*}
$$

All of the term should be large enough to qualify for Stirling's approximation, so
$\ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n}\left(N_{n}+\alpha_{n} N_{n}\right) \ln \left(N_{n}+\alpha_{n} N_{n}\right)-\sum_{n}\left(N_{n}+\alpha_{n} N_{n}\right)-\sum_{n} N_{n} \ln N_{n}+\sum_{n} N_{n}$
This can be written,

$$
\begin{aligned}
& \ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n} N_{n} \ln N_{n}-\sum_{n} N_{n}+\sum_{n} N_{n} \ln \left(1+\alpha_{n}\right)+\sum_{n} \alpha_{n} N_{n} \ln N_{n} \\
& +\sum_{n} \alpha_{n} N_{n} \ln \left(1+\alpha_{n}\right) N_{n}-\sum_{n} N_{n} \ln N_{n}+\sum_{n} N_{n}-\sum_{n} \alpha_{n} N_{n}
\end{aligned}
$$

Cancelling terms

$$
\ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n} N_{n} \ln \left(1+\alpha_{n}\right)+\sum_{n} \alpha_{n} N_{n} \ln N_{n}+\sum_{n} \alpha_{n} N_{n} \ln \left(1+\alpha_{n}\right)-\sum_{n} \alpha_{n} N_{n}
$$

and for $\left|\alpha_{n}\right| \ll 1, \ln \left(1+\alpha_{n}\right) \sim \alpha_{n}$
$\ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n} \alpha_{n} N_{n}+\sum_{n} \alpha_{n} N_{n} \ln N_{n}+\sum_{n} \alpha_{n}^{2} N_{n}-\sum_{n} \alpha_{n} N_{n}=\sum_{n} \alpha_{n} N_{n} \ln N_{n}+\sum_{n} \alpha_{n}^{2} N_{n}$
Now remembering the Boltzmann distribution law,

$$
\ln N_{n}=\ln N_{o}=\beta \varepsilon_{n}
$$

We have,

$$
\begin{equation*}
\ln \left(\frac{W}{W^{\prime}}\right)=\ln N_{o} \sum_{n} \alpha_{n} N_{n}-\sum_{n} \beta \varepsilon_{n} \alpha_{n} N_{n}+\sum_{n} \alpha_{n}^{2} N_{n} \tag{9.25}
\end{equation*}
$$

By the requirements to conserve atoms and energy, the first two summations must be identically zero. Therefore,

$$
\begin{equation*}
\ln \left(\frac{W}{W^{\prime}}\right)=\sum_{n} \alpha_{n}^{2} N_{n} \tag{9.26}
\end{equation*}
$$

Note that all of the terms in this summation are positive because $\alpha_{n}$ is squared. So let us define an RMS value by,

$$
\begin{equation*}
\bar{\alpha}=\left(\frac{\sum_{n} \alpha_{n}^{2} N_{n}}{N}\right)^{1 / 2} \tag{9.27}
\end{equation*}
$$

or

$$
\begin{align*}
& N \bar{\alpha}^{2}=\sum_{n} \alpha_{n}^{2} N_{n}  \tag{9.28}\\
& \ln \left(\frac{W}{W^{\prime}}\right)=N \bar{\alpha}^{2} \\
& \frac{W^{\prime}}{W}=e^{-N \bar{\alpha}^{2}} \tag{9.29}
\end{align*}
$$

Now consider a small sample of material that only contains $6 \times 10^{20}$ atoms, a millimole. In addition, consider a shift from the most likely configuration that involves an RMS change in occupation numbers that is one part in a billion $\left(10^{9}\right)$. We have,

$$
\begin{align*}
& \bar{\alpha}=1 \times 10^{-9} \\
& \bar{\alpha}^{2}=10^{-18}  \tag{9.30}\\
& \left(\frac{W^{\prime}}{W}\right)=e^{-\left(6 \times 10^{20} \cdot 10^{-18}\right)}=e^{-6 \times 10^{2}}=e^{-600}=10^{-260}
\end{align*}
$$

or a configuration whose occupation numbers differ from the maximum $W$ configuration by an RMS value of one part in a billion will be $10^{-260}$ times less likely to be observed than the maximum W configuration. Basically, the only measurable configuration that can be observed will look like the maximum W configuration.

### 9.5 Estimating the Variation of $\mathbf{W}$ with the Total Energy

Now let us consider how W changes with changes in the total energy available to a well defined number of atoms. We have,

$$
\begin{equation*}
W=\frac{N!}{\prod_{n} N_{n}!} \tag{9.31}
\end{equation*}
$$

- 

Differentiating,

$$
d \ln W=-\sum_{n} d \ln N_{n}!
$$

Applying Stirling's approximation,

$$
\begin{gather*}
d \ln N_{n}!=d\left(N_{n} \ln N_{n}-N_{n}\right)=N_{n} \frac{d N_{n}}{N_{n}}+\ln N_{n} d N_{n}-d N_{n}=\ln N_{n} d N_{n} \\
d \ln W=-\sum_{n} \ln N_{n} d N_{n} \tag{9.32}
\end{gather*}
$$

Moreover, for the most likely configuration, we have,

$$
\begin{gather*}
\ln N_{n}=\ln N_{o}-\beta \varepsilon_{n}  \tag{9.33}\\
d \ln W=-\ln N_{o} \sum_{n} d N_{n}+\beta \sum_{n} \varepsilon_{n} d N_{n} \tag{9.34}
\end{gather*}
$$

The first sum on the right hand side is identically zero for the fixed number of atoms under consideration. The second term on the right hand side is simply,

$$
\beta \sum_{n} \varepsilon_{n} d N_{n}=\beta \sum_{n} d\left(\varepsilon_{n} N_{n}\right)=\beta d \sum_{n} \varepsilon_{n} N_{n}=\beta d E
$$

So we have

$$
\begin{equation*}
d \ln W=\beta d E \tag{9.35}
\end{equation*}
$$

This can be integrated for a constant $\beta$ to give,

$$
\begin{align*}
& \ln W_{2}-\ln W_{1}=\beta\left(E_{2}-E_{1}\right) \\
& \ln \left(\frac{W_{2}}{W_{1}}\right)=\beta\left(E_{2}-E_{1}\right)  \tag{9.36}\\
& W_{2}=W_{1} e^{\beta\left(E_{2}-E_{1}\right)}
\end{align*}
$$

Thus $W$ the number of microstates contributing to a macrostate increases exponentially with increasing energy.

It is worth pointing out at this point that we have only demonstrated that this equation holds for a system of distinguishable objects like our fixed-in-place atoms, though it does in fact hold more generally. Several other restrictions or caveats still apply at this point. The first is the assumption that by transferring energy or heat to our system, there is no shift in the quantum levels of our oscillators. This is a reasonable assumption for oscillating atoms in a solid. In a gas where it can be shown that the energy levels are a function of the volume containing the atoms or
molecules, our result only applies to constant volume increases in energy. A second obvious restriction is that the addition of energy will cause no change in the number of atoms present due to chemical or nuclear reactions. Finally, we have assumed $\beta$ is constant. If $\beta$ changes, we have a different system.

### 9.6 Analyzing an Approach to Thermal Equilibrium

Now let us consider two solid bodies, X and Y , that will be brought together in thermal contact. Before they are brought together, they will be in the macrostates characterized by WX and WY microstates respectively. So if there are $\mathrm{W}_{\mathrm{X}}$ microstates in body X and $\mathrm{W}_{\mathrm{Y}}$ microstates in body Y , when the two bodies are considered jointly, there are a total of $W_{X} * W_{Y}$ microstates possible by combining each microstate in body X with each of the microstates in body Y. Now when the two bodies are brought into thermal contact and allowed to redistribute their energy between them, the number of possible microstates for the most likely configuration will change. If they were in equilibrium before thermal contact with different values of $W$, what will their final values of $W$ be.

For the approach to equilibrium and eventual equilibrium, the relevant expression is,

$$
\begin{equation*}
d\left(W_{X} * W_{Y}\right) \geq 0 \tag{9.37}
\end{equation*}
$$

During the approach to equilibrium, the product $W_{X} * W_{Y}$ must increase or remain constant. When it remains constant, the two bodies have reached an equilibrium state. We can rewrite this as,

$$
\begin{aligned}
& W_{Y} d W_{X}+W_{X} d W_{Y} \geq 0 \\
& \frac{d W_{X}}{W_{X}}+\frac{d W_{Y}}{W_{Y}} \geq 0
\end{aligned}
$$

or

$$
\begin{equation*}
d \ln W_{X}+d \ln W_{Y} \geq 0 \tag{9.38}
\end{equation*}
$$

and substituting for $d \ln (W)$ from above gives,

$$
\begin{equation*}
\beta_{X} d E_{X}+\beta_{Y} d E_{Y} \geq 0 \tag{9.39}
\end{equation*}
$$

Now if $X$ and $Y$ constitute an isolated system such that their combined energies can neither increase nor decrease as they come into thermal equilibrium, we must have,

$$
E_{X}+E_{Y}=\text { Cons } \tan t
$$

$$
d E_{X}+d E_{Y}=0
$$

Therefore, we have

$$
\begin{equation*}
\beta_{X} d E_{X}-\beta_{Y} d E_{X} \geq 0 \tag{9.40}
\end{equation*}
$$

Now suppose that the approach to equilibrium starts with body $Y$ at a higher temperature than body $X$ so that heat or energy flows from body $Y$ to body $X$. Then $d E_{X}$ must be greater than zero. Or,

$$
\begin{align*}
& \left(\beta_{X}-\beta_{Y}\right) d E_{X} \geq 0  \tag{9.41}\\
& \beta_{X} \geq \beta_{Y}
\end{align*}
$$

So as long as $\beta_{X}$ is greater that $\beta_{Y}$, energy will flow from body $Y$ to body $X$. When $\beta_{X}$ equals $\beta_{Y}$, equilibrium will be obtained.

### 9.7 The Physical Meaning of $\beta$

$\beta$ then appears to have the behavior of an inverse temperature. So we could write,

$$
\begin{equation*}
\beta=\frac{1}{T} \tag{9.42}
\end{equation*}
$$

but this would cause trouble dimensionally. Remember we had that

$$
\begin{equation*}
\frac{N_{n}}{N_{o}}=e^{-\beta \varepsilon_{n}} \tag{9.43}
\end{equation*}
$$

Therefore, $b$ must have the dimensions of energy. This simply means that we must multiply the temperature by a constant that converts temperature to energy. We have used a constant like this before and we called it Boltzmann's constant, $k=1.381 \times 10^{-23}$ joules $/$ K or $8.62 \times 10^{-5} \mathrm{eV} / \mathrm{K}$.

If we use this constant to define $\beta$, we have $\beta=1 / k T$ and,

$$
\begin{equation*}
\frac{N_{n}}{N_{o}}=e^{-\frac{\varepsilon_{n}}{k T}} \tag{9.44}
\end{equation*}
$$

We have also required that at the lowest energy level for any macroscopic system, all of the atoms must be in the ground state. We have chosen the energy of the ground state to be zero. Therefore, our formulation of $\beta$ as $1 / k T$ is consistent in that at absolute zero temperature, only the ground state will have a non-zero population.

### 9.8 The Concept of Entropy

Now for any isolated thermodynamic system we have asked that any changes that take place must have $d W \geq 0$. The direction of any spontaneous change will be that that causes W to increase and equilibrium will be attained when $W$ attains its maximum value. Now as we have shown, any value of W for a macroscopic system will be immense, so for convenience sake we will find it easier to talk about $\ln (W)$ and perform our analysis with $\ln (W)$. Note that $d \ln (W) \geq 0$ whenever $d W \geq 0$ and the equilibrium arguments apply to it as well.

Now consider once again when we combine two systems, X and Y . W for the combined system will be $W_{X^{*}} W_{Y}$, but $\ln (W)$ will be $\ln \left(W_{X}\right)+\ln \left(W_{Y}\right)$, so that $\ln (W)$ combines like any extensive property for thermodynamic systems. So we could define an extensive parameter for a macroscopic thermodynamic system as $S=\ln (W)$. We could then write that $\mathrm{S}_{\mathrm{XY}}=\mathrm{S}_{\mathrm{X}}+\mathrm{S}_{\mathrm{Y}}$. However we can do somewhat better by defining $S=k S=k \ln (W)$. This is Boltzmann's famous equation developed even before we were certain that atoms existed.

$$
\begin{equation*}
S=k \cdot \ln (W) \tag{9.45}
\end{equation*}
$$

Of course, $S$ will satisfy the requirements for an extensive system parameter. By incorporating the constant $k$, we will place our statistical definition of entropy on the same scale as our classical thermodynamic entropy scale. We have,

$$
\begin{align*}
& d \ln W=\beta d E \\
& k d \ln W=k \beta d E \\
& d(k \ln W)=k \frac{1}{k T} d E \\
& d S=\frac{d E}{T}=\frac{\delta Q}{T}=\frac{d U}{T} \tag{9.46}
\end{align*}
$$

Note also that

$$
\begin{equation*}
S \rightarrow 0 \text { as } T \rightarrow 0 \tag{9.47}
\end{equation*}
$$

So this definition of entropy also satisfies the Third Law of Thermodynamics, or the so called Nernst Postulate.

### 9.9 Partition Functions

Now let us return to the Boltzmann distribution law for distinguishable atoms in a solid. We have

$$
\begin{align*}
& \frac{N_{n}}{N_{o}}=e^{-\beta \varepsilon_{n}}  \tag{9.48}\\
& N_{n}=N_{o} e^{-\beta \varepsilon_{n}}
\end{align*}
$$

Then the total number of atoms or molecules is given by

$$
\begin{align*}
& N=N_{o}+N_{1}+N_{2}+N_{3}+\ldots . . \\
& N=N_{o} e^{-\beta \varepsilon_{o}}+N_{o} e^{-\beta \varepsilon_{1}}+N_{o} e^{-\beta \varepsilon_{2}}+N_{o} e^{-\beta \varepsilon_{3}} \cdots \cdots  \tag{9.49}\\
& N=N_{o}\left(e^{-\beta \varepsilon_{o}}+e^{-\beta \varepsilon_{1}}+e^{-\beta \varepsilon_{2}}+e^{-\beta \varepsilon_{3}} \ldots \ldots\right) \\
& N=N_{o} \sum_{q} e^{-\beta \varepsilon_{q}}
\end{align*}
$$

And we can write

$$
\begin{gather*}
N_{o}=\frac{N}{\sum_{q} e^{-\beta \varepsilon_{q}}} \\
N_{n}=\frac{N e^{-\beta \varepsilon_{n}}}{\sum_{q} e^{-\beta \varepsilon_{q}}} \\
Z=\sum_{q} e^{-\beta \varepsilon_{q}}=\text { Partition Function } \\
N_{n}=\frac{N}{Z} e^{-\beta \varepsilon_{n}} \tag{9.50}
\end{gather*}
$$

Note that if we choose $\varepsilon_{0}$ to be equal to $0, Z$ will always be greater than 1.0 in magnitude and the magnitude of the summation will depend on how widely spaced the energy levels are in units of $1 / \beta$.

### 9.10 Indistinguishable Objects

Everything we have done so far applies to distinguishable objects. That is each atom in a solid is located in one place in the crystal and it can be distinguished in space from all other atoms.

However, when we want to consider a dilute gas, all of the atoms or molecules are continuously moving about and it is impossible to assign an observational uniqueness to each of them. In addition, the energy of interest for each of the atoms or molecules is their kinetic energy. Therefore, we have,

$$
\begin{equation*}
\varepsilon=\frac{1}{2} m v^{2} \tag{9.51}
\end{equation*}
$$

The energy for a classical particle is not quantitized but rather is a continuous variable. More important is the fact that the speed and energy of a particle can have a definite value, but it can be traveling in an infinite number of directions. Thus there are many physically different locations and directions of movement that these atoms and molecules can have that are characterized by the same energy. When this happens, we say that the energy levels are degenerate.

To start let us constrain the atoms to move only in the $\mathrm{x}, \mathrm{y}$, or z direction. Then we will have for the occupation numbers the following,

$$
\begin{equation*}
N_{x i}=\frac{N}{Z} e^{-\beta\left(\frac{1}{2} m v_{x i}^{2}\right)} N_{y i}=\frac{N}{Z} e^{-\beta\left(\frac{1}{2} m v_{y i}^{2}\right)} N_{z i}=\frac{N}{Z} e^{-\beta\left(\frac{1}{2} m v_{z i}^{2}\right)} \tag{9.52}
\end{equation*}
$$

But $v_{x i}=v_{y i}=v_{z i}$ so we can write,

$$
\begin{align*}
& N_{x i}=N_{y i}=N_{z i} \\
& N_{i}=\frac{N}{Z} 3 e^{-\beta\left(\frac{1}{2} m v_{i}^{2}\right)} \tag{9.53}
\end{align*}
$$

where the three appears because the energy level is three-fold degenerate. In general, we can write this as

$$
\begin{align*}
& N_{i}=\frac{N}{Z} \omega_{i} e^{-\beta \varepsilon_{i}} \\
& Z=\sum_{i} \omega_{i} e^{-\beta \varepsilon_{i}} \tag{9.54}
\end{align*}
$$

$\omega_{i}$ is the number of the degeneracy of the $\boldsymbol{i}$ th energy level.
Now consider the following example. Let us take a cubic meter sphere of argon at $15^{\circ} \mathrm{C}$ and one atmosphere. The radius of the argon atom is approximately 0.181 nm . So it will occupy $2.5 \times 10^{-29} \mathrm{~m}^{3}$. Or in one cubic meter there will be room for $4.0 \times 10^{28}$ cubicles that could contain an argon atom. Now consider the direc-
tions that these atoms could move. For an atom at the center of a sphere containing one cubic meter, we can compare the solid angle formed by the projection of the atom's cross sectional area on the interior surface of the sphere with the total surface are of the sphere. There are approximately $1.17 \times 10^{19}$ locations that the atom moving from the center of the sphere to its inner surface that the atom could hit without overlapping with another location. That is there are $1.17 \times 10^{19}$ different directions that could be observed as distinct for this atom departing from the center of the sphere towards the outer wall. Of course, not all of the atoms can be located at the center of the sphere simultaneously. But as an atom is placed away from the center of the sphere its projected area on the near wall will increase and its projected area on the far wall will decrease, providing a somewhat compensating effect.

Therefore, there are approximately $4 \times 10^{47}$ locations in space and direction that an atom of argon can have in this one cubic meter sphere. At $15^{\circ} \mathrm{C}$ and one atmosphere pressure, there are about $2.5 \times 10^{24}$ atoms of argon. Thus for every atom of argon there are $1.6 \times 10^{23}$ locations that it can occupy with a specific energy level. The degeneracy is overwhelming.

Now if we take $n$ atoms with an energy $\varepsilon_{i}$ and place them in some subset of the available degenerate locations, most of the locations will be unoccupied and those that are occupied, will only contain one atom. The probability of two atoms being located in the same location in space and direction is infinitesimally small. (Obviously two atoms cannot not occupy the same physical space, so let each of the physical locations be large enough to accommodate ten atoms. Then instead of having $4 \times 10^{47}$ possibilities, there will only be $4 \times 10^{46}$ possibilities. The probability is still infinitesimally small of finding two atoms in one of these locations.)

The question now becomes "How many distinguishable configurations can be formed by placing $\boldsymbol{n}$ indistinguishable objects in $\boldsymbol{w}$ boxes?" The answer to this is straightforward and looks a lot like something we have seen before. The number of distinguishable configurations is given by,

$$
\begin{equation*}
W_{i}=\frac{\left(n_{i}+\omega_{i}\right)!}{n_{i}!\omega_{i}!} \tag{9.55}
\end{equation*}
$$

And since $\boldsymbol{n}_{\mathrm{i}}$ is considerably smaller than $\omega_{\mathrm{i}}$, we can express this in the following fashion

$$
\begin{align*}
W_{i} & =\frac{\left(n_{i}+\omega_{i}\right)\left(n_{i}-1+\omega_{i}\right)\left(n_{i}-2+\omega_{i}\right) \ldots\left(1+\omega_{i}\right)\left(\omega_{i}\right)!}{n_{i}!\omega_{i}!} \\
W_{i} & =\frac{\left(n_{i}+\omega_{i}\right)\left(n_{i}-1+\omega_{i}\right)\left(n_{i}-2+\omega_{i}\right) \ldots\left(1+\omega_{i}\right)!}{n_{i}!} \tag{9.56}
\end{align*}
$$

$\omega_{i}$ is much larger than $n_{i}$ so in the numerator it is reasonable to approximate every term by $\omega_{i}$ giving,

$$
\begin{equation*}
W_{i}=\frac{\left(\omega_{i}\right)^{n_{i}}}{n_{i}!} \tag{9.57}
\end{equation*}
$$

This equation applies to the ith energy level, which for the moment we will leave as quantitized. Then the overall number of states possible is the product of each of the number of states for each energy level or,

$$
\begin{equation*}
W=\Pi W_{i}=\frac{\Pi\left(\omega_{i}\right)^{n_{i}}}{\Pi n_{i}!} \tag{9.58}
\end{equation*}
$$

The above equation applies to an assembly of N indistinguishable units like gas molecules in free translation, whereas the previous equation

$$
\begin{equation*}
W=\frac{N!}{\Pi n_{i}!} \tag{9.59}
\end{equation*}
$$

applies to an assembly of identical but distinguishable units, like atoms in a crystal.
Now let us select three energy levels in an assembly and require that they are spaced such that

$$
\begin{equation*}
\frac{\varepsilon_{n}-\varepsilon_{m}}{\varepsilon_{m}-\varepsilon_{l}}=\frac{p}{q} \tag{9.60}
\end{equation*}
$$

where p and q are small integers and as before try to determine the most likely configuration.

We will transfer $q$ units of energy from level m to level n and $p$ units of energy from level $m$ to level $\mathbf{l}$.

Energy will be conserved as

$$
\begin{equation*}
q\left(\varepsilon_{n}-\varepsilon_{m}\right)+p\left(\varepsilon_{l}-\varepsilon_{m}\right)=0 \tag{9.61}
\end{equation*}
$$

Then for the most likely configuration, we must have that the derivative of $W$ with respect to small changes in the numbers of atoms with specific energies is zero. Or,
$\frac{\omega_{a}^{n_{a}} \ldots \omega_{l}^{n_{l}} \omega_{m}^{n_{m}} \omega_{n}^{n_{n}} \ldots \omega_{z}^{n_{z}}}{n_{a}!\ldots n_{l}!n_{m}!n_{n}!\ldots n_{z}!}=\frac{\omega_{a}^{n_{a}} \ldots \omega_{l}^{n_{l}+p} \omega_{m}^{n_{m}-p-q} \omega_{n}^{n_{n}+q} \ldots \omega_{z}^{n_{z}}}{n_{a}!\ldots\left(n_{l}+p\right)!\left(n_{m}-p-q\right)!\left(n_{n}+q\right)!\ldots n_{z}!}$
$\frac{1}{n_{l}!n_{m}!n_{n}!}=\frac{\omega_{l}^{p} \omega_{m}^{-p-q} \omega_{n}^{q}}{\left(n_{l}+p\right)!\left(n_{m}-p-q\right)!\left(n_{n}+q\right)!}$
$\frac{1}{n_{l}!\left(n_{m}-1\right)\left(n_{m}-2\right) \ldots\left(n_{m}-p-q\right)!n_{n}!}=\frac{\omega_{l}^{p} \omega_{m}^{-p-q} \omega_{n}^{q}}{\left(n_{l}+p\right)\left(n_{l}+p-1\right) \ldots n_{l}!\left(n_{m}-p-q\right)!\left(n_{n}+q\right)\left(n_{n}+q-1\right) \ldots n_{n}!}$
$\frac{1}{\left(n_{m}-1\right)\left(n_{m}-2\right) \ldots\left(n_{m}-p-q\right)!}=\frac{\omega_{l}^{p} \omega_{m}^{-p-q} \omega_{n}^{q}}{\left(n_{l}+p\right)\left(n_{l}+p-1\right) \ldots\left(n_{m}-p-q\right)!\left(n_{n}+q\right)\left(n_{n}+q-1\right) \ldots}$
$\frac{1}{n_{m}^{p+q}}=\frac{\omega_{l}^{p} \omega_{m}^{-p-q} \omega_{n}^{q}}{n_{l}^{p} n_{n}^{q}} \operatorname{Or}\left[\frac{n_{l} / \omega_{l}}{n_{m} / \omega_{m}}\right]^{p}=\left[\frac{n_{m} / \omega_{m}}{n_{n} / \omega_{n}}\right]^{q}$

This looks like a geometric progression of the quantities in braces so the Boltzmann distribution law becomes,

$$
\begin{equation*}
\frac{n_{i}}{\omega_{i}}=\frac{n_{0}}{\omega_{0}} e^{-\beta \varepsilon_{i}} \tag{9.63}
\end{equation*}
$$

This says that the average occupation of an energy level follows an exponential distribution. This is a little different from the result that we obtained for distinguishable units with localized atoms in a solid matrix. Now let us sum the number of atoms present.

$$
\begin{align*}
& N=n_{0}+n_{1}+n_{2}+n_{3} \ldots . .=n_{0}+\frac{n_{0}}{\omega_{0}} \omega_{1} e^{-\beta \varepsilon_{1}}+\frac{n_{0}}{\omega_{0}} \omega_{2} e^{-\beta \varepsilon_{2}} \ldots \\
& N=\frac{n_{0}}{\omega_{0}} \sum_{q} \omega_{q} e^{-\beta \varepsilon_{q}}=\frac{n_{0}}{\omega_{0}} Z  \tag{9.64}\\
& \frac{n_{0}}{\omega_{0}}=\frac{N}{Z} \quad \text { Or } \quad \frac{n_{i}}{\omega_{i}}=\frac{N}{Z} e^{-\beta \varepsilon_{i}}
\end{align*}
$$

Now note that $Z$ is only a function of the energy levels and the degeneracies of the energy levels.

$$
\begin{equation*}
Z=\sum_{q} e^{-\beta \varepsilon_{q}}=\sum_{i} \omega_{i} e^{-\beta \varepsilon_{i}} \tag{9.65}
\end{equation*}
$$

Therefore, $Z$ clearly represents the partition function per unit. Now if we have two units, we will have $Z_{\mathrm{T}}=Z_{1}{ }^{*} Z_{2}$. that is the total partition function must be the product of the individual partition functions per atom. If we have $N$ atoms than the total partition, function must be

$$
\begin{equation*}
Z_{\text {total }}=Z_{i}^{N} \tag{9.66}
\end{equation*}
$$

However since the units are not distinct we must take into account this fact and divide the total partition function by $N$ ! for the number of ways they can be rearranged without an observable difference. This gives

$$
\begin{equation*}
Z_{t r a n s}=\frac{Z_{i}^{N}}{N!} \tag{9.67}
\end{equation*}
$$

It should be pointed out that the $N$ ! factor only applies to the condition where the occupation of any given state is very much less than 1.0 so that there are far more states available than there are atoms or molecules to occupy them, so that the highest occupancy for any state is 1 unit. If this were not the case then we would have to replace the $N$ ! by $N!/ \Pi n_{i}!$. It should be pointed out that this form of the partition function only applies to the translational states of low-density gas molecules where
the number of states available far exceeds the number of atoms available to occupy them.

Now when we have multi-atom molecules it is possible for the molecules to store energy internally in terms of rotations and vibrations. Quantum mechanics states that these internal degrees of freedom are quantitized and therefore the number of states that can be occupied does not greatly exceed the number of atoms available. So if we write our partition function for a single unit, we will have

$$
\begin{align*}
\varepsilon_{i} & =\varepsilon_{i, \text { trans }}+\varepsilon_{i, \text { rot }}+\varepsilon_{i, v i b} \\
Z & =\sum_{i} e^{-\beta \varepsilon_{i}}=\sum_{i} e^{-\beta\left(\varepsilon_{i, \text { trans }}+\varepsilon_{i, \text { rot }}+\varepsilon_{i, v i b}\right)}  \tag{9.68}\\
Z & =\sum_{i} e^{-\beta \varepsilon_{i, \text { trans }}} \sum_{i} e^{-\beta \varepsilon_{i, \text { rot }}} \sum_{i} e^{-\beta \varepsilon_{i, v i b}}=Z_{\text {trans }} * Z_{r o t} * Z_{v i b}
\end{align*}
$$

Then when we consider the whole ensemble of units and take to products of the individual partition functions this becomes,

$$
\begin{equation*}
Z_{\text {total }}=\left[\frac{Z_{\text {trans }}^{N}}{N!}\right] * Z_{\text {rot }}^{N} * Z_{v i b}^{N} \tag{9.69}
\end{equation*}
$$

We do not apply the $N!$ factor to the rotation and vibration partition functions because we can distinguish which atom is vibrating or rotating. Having obtained the partition function for an Ideal gas, consider how thermodynamic parameters can be obtained from the partition function. First, consider the internal energy. We can write for the case of distinguishable units

$$
\begin{gather*}
U=E=n_{0} \varepsilon_{0}+n_{1} \varepsilon_{1}+n_{2} \varepsilon_{2}+\ldots . . \\
E=\varepsilon_{0} \frac{N}{Z} e^{-\beta \varepsilon_{0}}+\varepsilon_{1} \frac{N}{Z} e^{-\beta \varepsilon_{1}}+\varepsilon_{2} \frac{N}{Z} e^{-\beta \varepsilon_{2}}+\ldots . .  \tag{9.70}\\
E=\frac{N}{Z}\left(\varepsilon_{0} e^{-\beta \varepsilon_{0}}+\varepsilon_{1} e^{-\beta \varepsilon_{1}}+\varepsilon_{2} e^{-\beta \varepsilon_{2}} \ldots\right)=N \frac{\sum_{q} \varepsilon_{q} e^{-\beta \varepsilon_{q}}}{\sum_{q} e^{-\beta \varepsilon_{q}}}
\end{gather*}
$$

Now treating the $\varepsilon_{q}$ as constants, each of the terms in the numerator can be obtained by differentiating the similar term in the denominator with respect to $\beta$.

$$
\begin{equation*}
-\frac{d}{d \beta} e^{-\beta \varepsilon_{q}}=\varepsilon_{q} e^{-\beta \varepsilon_{q}} \tag{9.71}
\end{equation*}
$$

So we can write

$$
\begin{align*}
& E=-N \frac{\frac{d}{d \beta} \sum_{q} e^{-\beta \varepsilon_{q}}}{\sum_{q} e^{-\beta \varepsilon_{q}}}=-N \frac{1}{Z} \frac{d Z}{d \beta}=-N \frac{d \ln Z}{d \beta}  \tag{9.72}\\
& E=-\frac{d(N \ln Z)}{d \beta}=-\frac{d \ln Z^{N}}{d \beta}
\end{align*}
$$

Thus, we have a very clean expression for the internal energy in terms of the partition function. Consider now the partition function for translation for the Ideal Gas.

$$
\begin{equation*}
E=-\frac{d \ln \left(\frac{Z^{N}}{N!}\right)}{d \beta}=-\frac{d}{d \beta} \ln \left(\frac{1}{N!}\right)-\frac{d}{d \beta} \ln Z^{N} \tag{9.73}
\end{equation*}
$$

Nevertheless, $N!$ is a constant so the first term is zero and we have,

$$
\begin{equation*}
E=-N \frac{d}{d \beta} \ln Z \tag{9.74}
\end{equation*}
$$

In addition, this can be taken back a step further to obtain the original summation for the total internal energy. This works so long as the volume containing the gas is held constant. So for the translation partition function of an Ideal Gas, the constant volume restriction must be added. We have,

$$
\begin{equation*}
E=\left[-N \frac{d}{d \beta} \ln Z\right]_{V} \tag{9.75}
\end{equation*}
$$

Now noting that $\beta=1 / k T$

$$
\begin{align*}
& d \beta=-\frac{d T}{k T^{2}} \quad \frac{d T}{d \beta}=-k T^{2} \\
& E=-\left[\frac{d \ln Z}{d T}\right]_{V}\left[\frac{d T}{d \beta}\right]_{V}  \tag{9.76}\\
& E=k T^{2}\left[\frac{d \ln Z}{d T}\right]_{V}=U
\end{align*}
$$

Now consider entropy. We have

$$
\begin{equation*}
S=k \ln W \tag{9.77}
\end{equation*}
$$

For distinguishable units we had

$$
\begin{gather*}
W=\frac{N!}{\prod_{q} N_{q}!}  \tag{9.78}\\
\ln W=\ln N!-\sum_{q} \ln N_{q}!=N \ln N-N-\sum_{q} N_{q} \ln N_{q}+\sum_{q} N_{q} \\
\ln W=N \ln N-\sum_{q} N_{q} \ln N_{q}=N \ln N-\sum_{q} N_{q} \ln \frac{N}{Z} e^{-\beta \varepsilon_{q}} \\
\ln W=N \ln N-\sum_{q} N_{q} \ln \frac{N}{Z}-\sum_{q} N_{q}\left(-\beta \varepsilon_{q}\right) \\
\ln W=N \ln N-\ln \frac{N}{Z} \sum_{q} N_{q}+\beta \sum_{q} N_{q} \varepsilon_{q}  \tag{9.79}\\
\ln W=N \ln N-N \ln \frac{N}{Z}+\beta E=N \ln Z+\beta E \\
\ln W=\ln Z^{N}+\beta E=\ln Z_{\text {total }}+\beta E \\
S=k \ln Z^{N}+k \beta E=N k \ln Z+k \frac{1}{k T} E=N k \ln Z+\frac{E}{T}
\end{gather*}
$$

This gives an expression for the entropy in terms of the total energy and the partition function.

For indistinguishable units we have,

$$
\begin{equation*}
W=\frac{\prod_{q}\left(\omega_{q}\right)^{N_{q}}}{\prod_{q} N_{q}!} \tag{9.80}
\end{equation*}
$$

Following a derivation similar to the above, we obtain

$$
\begin{aligned}
& S=k \ln \left(\frac{Z^{N}}{N!}\right)+k \beta E \\
& \text { Or } \\
& S=k \ln Z_{\text {trans }}+k \beta E=k \ln Z_{\text {trans }}+\frac{E}{T}
\end{aligned}
$$

Using our previous result for the internal energy gives

$$
\begin{equation*}
S=k \ln Z_{\text {trans }}+k T\left[\frac{d \ln Z_{\text {trans }}}{d T}\right]_{V}=\frac{d}{d T}\left[k T \ln Z_{\text {trans }}\right]_{V} \tag{9.82}
\end{equation*}
$$

If we consider a gas composed of multi-atom molecules, then we must replace $\mathrm{Z}_{\text {trans }}$ with $\mathrm{Z}_{\text {total }}$. Therefore, we have,

$$
\begin{align*}
& S=\frac{d}{d T}\left[k T \ln Z_{\text {total }}\right]=\frac{d}{d T}\left[k T \ln Z_{\text {trans }} * Z_{\text {rot }} * Z_{v i b}\right] \\
& S=\frac{d}{d T}\left[k T \ln Z_{\text {trans }}+k T \ln Z_{\text {rot }}+k T \ln Z_{v i b}\right]  \tag{9.83}\\
& S=S_{\text {trans }}+S_{\text {rot }}+S_{\text {vib }}
\end{align*}
$$

Therefore, the entropy is factorable and separable into terms that correspond to the different mechanisms in the molecules.

### 9.11 Evaluation of Partition Functions

Now let us evaluate the translational partition function for an Ideal Gas. The energy of an individual atom or molecule is given by,

$$
\begin{equation*}
\varepsilon=\frac{1}{2} m v^{2}=\frac{m}{2}\left(v_{x}^{2}+v_{y}^{2}+v_{z}^{2}\right) \tag{9.84}
\end{equation*}
$$

Now quantum mechanics tells us that an atom, moving in a box can only have certain discrete energies. These energies are obtained by solving Schrodinger's wave equation in three dimensions. From a macroscopic standpoint, the discreteness of the energies is impossible to determine because the separation is infinitesimally small on compared to macroscopic dimensions. But when the wave equation is solved in a rectangular box, the allowed energies are given by the relation

$$
\begin{equation*}
\varepsilon=\frac{h^{2}}{8 m}\left[\frac{n_{x}^{2}}{L_{x}^{2}}+\frac{n_{y}^{2}}{L_{y}^{2}}+\frac{n_{z}^{2}}{L_{z}^{2}}\right] \tag{9.85}
\end{equation*}
$$

$h$ is Plank's constant and the L's are the lengths of the sides of the box. Consider a cubical box 10 cm on a side containing argon at room temperature. Then we have

$$
\begin{equation*}
\varepsilon=\frac{h}{8 m L^{2}}\left[n_{x}^{2}+n_{y}^{2}+n_{z}^{2}\right] \tag{9.86}
\end{equation*}
$$

The average energy of an atom is 0.025 eV and the mass is 40 amu . Plugging all of this in gives

$$
\begin{equation*}
\left[n_{x}^{2}+n_{y}^{2}+n_{z}^{2}\right] \approx 5 \times 10^{19} \tag{9.87}
\end{equation*}
$$

Therefore, the level of degeneracy is very comparable to the classical description given before for the sphere. However now we see how the volume containing the gas comes into the equation directly. The $L^{2}$ term in the denominator is essentially the volume to the two-thirds power. Much like the classical case, the energy can easily be separated into three terms, each of which will be associated with one of the three axes. Thus, we can write our partition function as a product of the partition functions for each of the three possible directions. For the x dimension we have

$$
\begin{align*}
& z_{x}=\sum_{n_{x}} e^{-\beta \frac{n_{x} h^{2}}{8 m L_{x}^{2}}}=\int_{0}^{\infty} e^{-\beta \frac{n_{x} h^{2}}{8 m L_{x}^{2}}} d n_{x}  \tag{9.88}\\
& z_{x}=\frac{L_{x}}{h} \sqrt{\frac{2 \pi m}{\beta}}
\end{align*}
$$

The $y$ and $z$ dimensions are identical so,

$$
\begin{equation*}
z=z_{x} * z_{y} * z_{z}=\left[\frac{2 \pi m}{\beta}\right]^{3 / 2} \frac{L_{x} L_{y} L_{z}}{h^{3}}=\left[\frac{2 \pi m}{h^{2} \beta}\right]^{3 / 2} V \tag{9.89}
\end{equation*}
$$

Now applying the relation for internal energy as a function of the partition function gives,

$$
\begin{align*}
& E=U=-\left[\frac{d \ln Z_{\text {trans }}}{d \beta}\right]=-\frac{d}{d \beta}\left[\ln \frac{Z_{\text {trans }}^{N}}{N!}\right] \\
& E=-\frac{d}{d \beta}\left[\ln \frac{1}{N!}\left(\frac{2 \pi m}{h^{2}}\right)^{3 N / 2} V^{N}\right]-\frac{d}{d \beta} \ln \left(\frac{1}{\beta}\right)_{V}^{3 N / 2} \tag{9.90}
\end{align*}
$$

For a constant volume all of the terms in the square brackets are constant so we have,

$$
\begin{equation*}
E=U=\frac{3 N}{2} \frac{d}{d \beta} \ln \beta=\frac{3 N}{2 \beta} \tag{9.91}
\end{equation*}
$$

The classical definition of the constant volume specific heat is

$$
\begin{equation*}
C_{V}=\left[\frac{d E}{d T}\right]_{V}=\frac{d}{d T}\left[\frac{3 N}{2 \beta}\right]_{V}=\frac{3 N}{2} \frac{d}{d T}\left[\frac{1}{\beta}\right] \tag{9.92}
\end{equation*}
$$

The classical value for a monatomic gas constant volume specific heat is

$$
C_{V}=12.47 \mathrm{~J} / \mathrm{gm}-\mathrm{mole} / \mathrm{K}=1.247 \times 10^{8} \mathrm{erg} / \mathrm{gm}-\mathrm{mole} / \mathrm{K}
$$

Therefore

$$
\begin{gather*}
\frac{3 N}{2} \frac{d}{d T}\left[\frac{1}{\beta}\right]=1.247 \times 10^{8} \frac{\mathrm{erg}}{\mathrm{gm}^{2}-\mathrm{mole}^{*} K}  \tag{9.93}\\
\frac{d}{d T}\left[\frac{1}{\beta}\right]=\frac{d}{d T}[k T]=k=\frac{2}{3} \frac{1.247 \times 10^{8} \frac{\mathrm{erg}}{\mathrm{gm-mole} *}}{6.022 \times 10^{23} \frac{\text { atoms }}{\text { gm-mole }}}=1.38 \times 10^{-16} \frac{\mathrm{erg}}{\text { atom }^{*} K}
\end{gather*}
$$

Thus, the value of Boltzmann's constant can be derived by considering the constant volume specific heat of a monatomic gas, which is a well measured and defined quantity.

$$
\begin{equation*}
k=1.38 \times 10^{-16} \mathrm{erg} / \mathrm{K}=1.38 \times 10^{-23} \mathrm{Joule} / \mathrm{K} \tag{9.94}
\end{equation*}
$$

Previously we had

$$
\begin{equation*}
E=\frac{3 N}{2 \beta} \tag{9.95a}
\end{equation*}
$$

This now gives

$$
\begin{equation*}
E=\frac{3}{2} N k T \quad \text { and } \quad C_{V}=\frac{3}{2} N k \tag{9.95b}
\end{equation*}
$$

Now let us introduce the thermodynamic potential most easily expressed in terms of the partition function. Consider the Helmholtz Free Energy defined by $F=E-T S$

$$
\begin{align*}
& F=E-T\left(k \ln Z+\frac{E}{T}\right)=E-k T \ln Z-E  \tag{9.96}\\
& F=-k T \ln Z
\end{align*}
$$

and we have for the monatomic Ideal Gas

$$
\begin{align*}
& F=-k T \ln \left(\frac{z^{N}}{N!}\right)=-k T[-\ln N!+N \ln z] \\
& F=-k T[-(N \ln N-N)+N \ln z]  \tag{9.97}\\
& F=-N k T[1+\ln (z / N)]
\end{align*}
$$

We can write the entropy as

$$
\begin{equation*}
S=\frac{E-F}{T}=\frac{\frac{3}{2} N k T+N k T[1+\ln (z / N)]}{T}=N k\left(\frac{5}{2}+\ln \frac{z}{N}\right) \tag{9.98}
\end{equation*}
$$

Substituting for z gives

$$
\begin{align*}
& S=N k\left\{\frac{5}{2}+\ln \left(\left[\frac{2 \pi k T}{h^{2}}\right]^{3 / 2} \frac{V}{N}\right)\right\} \quad N k=\Re \quad N m=M \\
& S=\Re\left\{\frac{5}{2}+\ln \left(\left[\frac{2 \pi M k T}{h^{2} N}\right]^{3 / 2} \frac{V}{N}\right)\right\} \tag{9.99}
\end{align*}
$$

This can be rewritten as

$$
\begin{equation*}
S=\Re \ln V+\frac{3}{2} \Re \ln T+\frac{3}{2} \Re \ln M+\left\{\Re\left(\frac{5}{2}+\ln \left[\frac{2 \pi k}{h^{2} N^{5 / 3}}\right]^{3 / 2}\right)\right\} \tag{9.100}
\end{equation*}
$$

This is a famous equation called the Sackur-Tetrode equation.
Now consider changes in S. If only the volume changes we have

$$
\begin{equation*}
S_{2}-S_{1}=\Re \ln V_{2}-\Re \ln V_{1}=\Re \ln \left(V_{2} / V_{1}\right) \tag{9.101}
\end{equation*}
$$

the exact relation we get from classical thermodynamics. If only the temperature changes, we get

$$
\begin{equation*}
S_{2}-S_{1}=\frac{3}{2} \Re \ln T_{2}-\frac{3}{2} \Re \ln T_{1}=\frac{3}{2} \Re \ln \left(T_{2} / T_{1}\right)=C_{V} \ln \left(T_{2} / T_{1}\right) \tag{9.102}
\end{equation*}
$$

Once again, this is the expected behavior from classical thermodynamics. The last two terms provide constants that allow us to calculate the entropy of a monatomic ideal gas from first principles or fundamental constants. This table taken from Nash's book and attributed to K. K. Kelley evidences the excellent agreement of this equation with the entropies determined by calorimetric measurements for the noble gases at 298 K and one atmosphere.

| Entropies (cal/gm-mole/K) |  |  |
| :--- | :--- | :--- |
| Noble gas | Calorimetric | Theoretical |
| Neon | $35.01+/-0.1$ | $34.95+/-0.01$ |
| Argon | $36.95+/-0.2$ | $36.99+/-0.01$ |
| Krypton | $39.17+/-0.1$ | $39.20+/-0.01$ |
| Xenon | $40.7+/-0.3$ | $40.54+/-0.01$ |

### 9.12 Maxwell-Boltzmann Velocity Distribution

Our Maxwell energy distribution is of the following form,

$$
\begin{align*}
& \frac{N_{i}}{\omega_{i}}=\frac{N}{Z} e^{-\frac{m v_{i}^{2}}{2 k T}} \\
& N_{i}=\frac{N}{Z} \omega_{i} e^{--\frac{m v_{i}^{2}}{2 k T}} \tag{9.103}
\end{align*}
$$

For the classical continuous velocity distribution, we can write this as

$$
\begin{equation*}
d N(v)=\frac{N}{Z} e^{-\frac{m v^{2}}{2 k T}} d \omega(v) \tag{9.104}
\end{equation*}
$$

In order to integrate this equation and determine the normalizations we need to determine a degeneracy function as a function of the velocity. The simplest answer to this question is to let the total number of degeneracies increase as the volume of velocity space. That simply says that

$$
\omega(v)=\frac{4}{3} \pi v^{3} \quad \mathrm{~d} \omega(v)=4 \pi v^{2} d v
$$

Then

$$
\begin{align*}
& d N(v)=\frac{N}{Z} e^{-\frac{m v^{2}}{2 k T}} 4 \pi v^{2} d v \\
& N=\int_{0}^{\infty} \frac{N}{Z} 4 \pi v^{2} e^{-\frac{m v^{2}}{2 k T}} d v \\
& 1=\frac{4 \pi}{Z} \int_{0}^{\infty} v^{2} e^{-\frac{m v^{2}}{2 k T}} d v=\frac{4 \pi}{Z}\left(\frac{2 k T}{m}\right)^{3 / 2} \int_{0}^{\infty} y^{2} e^{-y^{2}} d y  \tag{9.105}\\
& Z=4 \pi\left(\frac{2 k T}{m}\right)^{3 / 2} \int_{0}^{\infty} y^{2} e^{-y^{2}} d y=4 \pi\left(\frac{2 k T}{m}\right)^{3 / 2} \frac{1}{4} \sqrt{\pi} \\
& Z=\left(\frac{2 \pi k T}{m}\right)^{3 / 2}
\end{align*}
$$

Then taking $d N(v)=N(v) d v$, we have

$$
\begin{equation*}
N(v)=N\left(\frac{m}{2 \pi k T}\right)^{3 / 2} 4 \pi v^{2} e^{-\frac{m v^{2}}{2 k T}} \tag{9.106}
\end{equation*}
$$

This is the Maxwell Boltzmann velocity distribution.
The average velocity is given by

$$
\begin{equation*}
\bar{v}=\sqrt{\frac{8 k T}{\pi m}} \tag{9.107}
\end{equation*}
$$

The rms velocity is given by

$$
\begin{equation*}
v_{r m s}=\sqrt{\frac{3 k T}{m}} \tag{9.108}
\end{equation*}
$$

The most probable velocity is given by

$$
\begin{equation*}
v_{\mathrm{mode}}=\sqrt{\frac{2 k T}{m}} \tag{9.109}
\end{equation*}
$$

## Chapter 10 <br> Thermodynamic Relations

In this chapter, we will discuss mathematical relationship of thermodynamics in exact formulation using differential formation of these relations.

### 10.1 Thermodynamic Potentials

Classical thermodynamics has a very rich mathematical background. In a course aimed at engineering thermodynamics, it is not terribly useful to go into this analysis too deeply, but touching on some of the methods is worthwhile. Start by summarizing without proof some properties of the four common thermodynamic potentials. The first of these potentials is the internal energy, which is identified with the symbol $U$. The internal energy $U$ has been used for a good portion of this study to date. Though in the past it was considered it a function of many variables, its natural variables are $S$ and $V$. Normally it is written as,

$$
\begin{equation*}
U=U(S, V) \tag{10.1}
\end{equation*}
$$

If we differentiate $U$ with respect to $S$ and $V$, holding the other variable constant we get,

$$
\begin{equation*}
d U=\left.\frac{d U}{d S}\right|_{V} d S+\left.\frac{d U}{d V}\right|_{S} d V \tag{10.2}
\end{equation*}
$$

Also the combined First and Second Laws can be written

$$
\begin{equation*}
d U=T d S-p d V \tag{10.3}
\end{equation*}
$$

Then $T$ can be identified with $\left.\frac{d U}{d S}\right|_{V}$ and $-p$ with $\left.\frac{d U}{d V}\right|_{S}$.

The enthalpy was defined as,

$$
\begin{equation*}
H=U(S, V)+p V=H(S, p) \tag{10.4}
\end{equation*}
$$

So

$$
\begin{equation*}
d H=d U+p d V+V d p=T d s-p d V+p d V+V d p=T d s+V d p \tag{10.5}
\end{equation*}
$$

And

$$
\begin{equation*}
d H=\left.\frac{d H}{d S}\right|_{p} d S+\left.\frac{d H}{d P}\right|_{S} d p \tag{10.6}
\end{equation*}
$$

Once again, $T$ can be identified as $\left.\frac{d H}{d S}\right|_{p}$ and $V$ can be identified as $\left.\frac{d H}{d p}\right|_{S}$. Remember that the reason for choosing enthalpy as the thermodynamic potential of interest is that our system will be in contact with a pressure reservoir during the process of interest.

In addition to internal energy and enthalpy, two other thermodynamic potentials are sometimes of interest. The first is the Helmholtz Potential or Helmholtz Free Energy (The term Free Energy is a poor choice of words and only causes problems.). The Helmholtz Potential is useful when our system of interest is in contact with a thermal reservoir that holds the temperature constant during the process of interest. The Helmholtz Potential is defined as,

$$
\begin{align*}
& F=U-T S \\
& d F=d U-T d S-S d T=T d s-p d V-T d S-S d T=-p d V-S d T \\
& d F=\left.\frac{d F}{d V}\right|_{T} d V+\left.\frac{d F}{d T}\right|_{V} d T \\
& -S=\left.\frac{d F}{d T}\right|_{V} \\
& -p=\left.\frac{d F}{d V}\right|_{T} \tag{10.7}
\end{align*}
$$

Clearly, the natural variables for the Helmholtz Potential are $V$ and $T$.
The second new potential is the Gibbs Potential or Gibbs Free Energy (Bad choice of words.). This potential is useful when systems are in contact with the atmosphere and the pressure and temperature are held constant by using the atmosphere as a sink. The Gibbs potential is defined by,

$$
\begin{align*}
& G=H-T S \\
& d G=d H-T d S-S d T=T d s+V d p-T d S-S d T=V d p-S d T \\
& d G=\left.\frac{d G}{d p}\right|_{T} d p+\left.\frac{d G}{d T}\right|_{p} d T \\
& -S=\left.\frac{d G}{d T}\right|_{p} \\
& V=\left.\frac{d G}{d p}\right|_{T} \tag{10.8}
\end{align*}
$$

Now it may seem a little confusing why certain variables are chosen as the differential variables in the above equations. The simple answer is that only two variables are required to define the state of a simple system, and the two that are chosen should be the ones that make a particular process most transparent or provide the simplest solution.

The internal energy may be looked upon as the available work (or heat) from a constant volume system. The enthalpy may be looked upon as the available work from a system in contact with a pressure reservoir. The Helmholtz Potential is the available work from a system in contact with a temperature reservoir. In addition, the Gibbs Potential is the available work from a system in contact with a pressure and temperature reservoir.

The relationship for the internal energy as a function of the entropy can be inverted to give the entropy as a function of the internal energy and volume. The same can be done for the enthalpy. When either of these are accomplished, the resulting entropy function can be used to identify the direction of approach to equilibrium and the actual equilibrium state. The entropy function so defined will be maximized at equilibrium. Thus,

$$
\begin{align*}
& S=S(U, V) \\
& d S=\left.\frac{d S}{d U}\right|_{V} d U+\left.\frac{d S}{d V}\right|_{U} d V \\
& S=S(H, p) \\
& d S=\left.\frac{d S}{d H}\right|_{p} d H+\left.\frac{d S}{d p}\right|_{H} d p \tag{10.9}
\end{align*}
$$

Both of these expressions are useful in some of the algebraic manipulations of Classical Thermodynamics.

### 10.2 Maxwell Relations

At this point Classical Thermodynamics drifts off into a mathematical maze that is well defined but becomes more obscure equation by equation. ${ }^{1}$ Now having defined the four classic potentials, it is possible to apply the results of the Calculus of Several Variables to them to obtain differential relations between the various thermodynamic properties. Perhaps the most useful application of this calculus is to be able to express the derivatives, or rates of change of entropy. In terms of the rate of changes of more measurable variables, like pressure, temperature, and volume.

From the Calculus of Several Variables, remember that the order of differentiation doesn't matter when the differentiation is performed with respect to two independent variables provided the function and its derivatives are continuous. The state functions of thermodynamics satisfy these restrictions. Therefore for any $w=w(x, y)$,

$$
\begin{equation*}
\frac{\partial^{2} w}{\partial x \partial y}=\frac{\partial^{2} w}{\partial y \partial x} \tag{10.10}
\end{equation*}
$$

Also, consider the situation where there are four state variables, say $w, x, y$, and $z$, any two of which can be chosen as the independent variables for a simple compressible system. Start with $x$ as a function of $y$ and $w$.

$$
\begin{equation*}
d x=\left.\frac{d x}{d y}\right|_{w} d y+\left.\frac{d x}{d w}\right|_{y} d w \tag{10.11}
\end{equation*}
$$

Then choose $y$ to be a function of $z$ and $w$.

$$
\begin{equation*}
d y=\left.\frac{d y}{d z}\right|_{w} d z+\left.\frac{d y}{d w}\right|_{z} d w \tag{10.12}
\end{equation*}
$$

Now substitute Eq. 10.12 into Eq. 10.11 to get

$$
\begin{align*}
& d x=\left.\frac{d x}{d y}\right|_{w}\left(\left.\frac{d y}{d z}\right|_{w} d z+\left.\frac{d y}{d w}\right|_{z} d w\right)+\left.\frac{d x}{d w}\right|_{y} \\
& d w=\left.\left.\frac{d x}{d y}\right|_{w} \frac{d y}{d z}\right|_{w} d z+\left(\left.\frac{d x}{d w}\right|_{y}+\left.\left.\frac{d x}{d y}\right|_{w} \frac{d y}{d w}\right|_{z}\right) d w \tag{10.13}
\end{align*}
$$

But

$$
\begin{equation*}
d x=\left.\frac{d x}{d z}\right|_{w} d z+\left.\frac{d x}{d w}\right|_{z} d w \tag{10.14}
\end{equation*}
$$

${ }^{1}$ [1], Chap. 2.

So the following two relations must hold.

$$
\begin{gather*}
\left.\frac{d x}{d w}\right|_{z}=\left.\frac{d x}{d w}\right|_{y}+\left.\left.\frac{d x}{d y}\right|_{w} \frac{d y}{d w}\right|_{z}  \tag{10.15}\\
\left.\frac{d x}{d z}\right|_{w}=\left.\left.\frac{d x}{d y}\right|_{w} \frac{d y}{d z}\right|_{w} \tag{10.16}
\end{gather*}
$$

Equation 10.16 can be put in a more symmetrical form to yield.

$$
\begin{equation*}
\left.\left.\left.\frac{d x}{d y}\right|_{w} \frac{d y}{d z}\right|_{w} \frac{d z}{d x}\right|_{w}=1 \tag{10.17}
\end{equation*}
$$

Sometimes it is simply called the chain rule and can be extended to any number of variables.

Now consider a simple example for a real gas where its equation of state can be written as $v=v(T, p)$ or $p=p(T, v)$, before addressing the thermodynamic potentials. Differentials for these two equations can be written as

$$
\begin{align*}
& d v=\left.\frac{\partial v}{\partial p}\right|_{T} d p+\left.\frac{\partial v}{\partial T}\right|_{p} d T \\
& d p=\left.\frac{\partial p}{\partial v}\right|_{T} d v+\left.\frac{\partial p}{\partial T}\right|_{v} d T \tag{10.18}
\end{align*}
$$

Eliminating $d p$ between these two equations and collecting the coefficients of $d v$ and $d T$ gives,

$$
\begin{equation*}
\left[1-\left.\left.\frac{\partial v}{\partial p}\right|_{T} \frac{\partial p}{\partial v}\right|_{T}\right] d v=\left[\left.\left.\frac{\partial v}{\partial p}\right|_{T} \frac{\partial p}{\partial T}\right|_{v}+\left.\frac{\partial v}{\partial T}\right|_{p}\right] d T \tag{10.19}
\end{equation*}
$$

Now since changes in $d v$ and $d T$ are independent, both coefficients must be equal to zero. Therefore,

$$
\begin{align*}
& {\left[1-\left.\left.\frac{\partial v}{\partial p}\right|_{T} \frac{\partial p}{\partial v}\right|_{T}\right]=\left.0 \rightarrow \frac{\partial v}{\partial p}\right|_{T}=\frac{1}{\left.\frac{\partial p}{\partial v}\right|_{T}}} \\
& \left.\left.\frac{\partial v}{\partial p}\right|_{T} \frac{\partial p}{\partial T}\right|_{v}+\left.\frac{\partial v}{\partial T}\right|_{p}=\left.0 \rightarrow \frac{\partial p}{\partial T}\right|_{v}=-\frac{\left.\frac{\partial v}{\partial T}\right|_{p}}{\left.\frac{\partial v}{\partial p}\right|_{T}}=\frac{\alpha}{\kappa} \\
& \alpha=\left.\frac{1}{V} \frac{\partial V}{\partial T}\right|_{p} \text { Coefficient of Thermal Expansion } \\
& \kappa=-\left.\frac{1}{V} \frac{\partial V}{\partial p}\right|_{T} \text { Isothermal Compressibility } \tag{10.20}
\end{align*}
$$

Thus, the requirements for continuity of derivatives of state variables allow relationships between the derivatives themselves to be defined.

Example 10.1 Calculate the (a) Coefficient of Thermal expansion and (b) the Isothermal Compressibility for (1) an Ideal Gas and a real gas based on (2) a virial expansion, and (3) the Peng-Robinson equation of state.

## Solution

a) 1) Ideal Gas $\alpha=\left.\frac{1}{v} \frac{\partial}{\partial T} \frac{R T}{p}\right|_{p}=\frac{1}{v} \frac{R}{p}=\frac{1}{T}$
2) Virial Expansion

$$
\begin{aligned}
& v^{2}=\frac{R T}{p}(v+B) \\
& 2 v \frac{\partial v}{\partial T}=\frac{R T}{p} \frac{\partial v}{\partial T}+\frac{R}{p}(v+B) \\
& \left(2 v-\frac{R T}{p}\right) \frac{\partial v}{\partial T}=\frac{R}{p}(v+B) \\
& \frac{1}{v} \frac{\partial v}{\partial T}=\frac{R}{v p} \frac{(v+B)}{\left(2 v-\frac{R T}{p}\right)}=\frac{R}{v p} \frac{1+B / v}{1}=\frac{1}{T}(1+B / v)
\end{aligned}
$$

3) Peng-Robinson Equation
$p=\frac{R T}{v-b}-\frac{\alpha a}{v^{2}+2 b v-b^{2}}$
$v^{3}+b v^{2}-3 b^{2} v+b^{3}=\frac{R T}{p}\left(v^{2}+2 b v-b^{2}\right)-\alpha a(v-b)$
$\left(3 v^{2}+2 b v-3 b^{2}\right) \frac{\partial v}{\partial T}=\frac{R}{p}\left(v^{2}+2 b v-b^{2}\right)+\frac{R T}{p}(2 v+2 b) \frac{\partial v}{\partial T}-\alpha a \frac{\partial v}{\partial T}-a(v-b) \frac{\partial \alpha}{\partial T}$
$\left(3 v^{2}+2 b v-3 b^{2}-2 v^{2}-2 b v+\alpha a\right) \frac{\partial v}{\partial T}=\frac{R}{p}\left(v^{2}+2 b v-b^{2}\right)-a(v-b) \frac{\partial \alpha}{\partial T}$
$\frac{1}{v} \frac{\partial v}{\partial T}=\frac{1}{v} \frac{\frac{R}{p}\left(v^{2}+2 b v-b^{2}\right)-a(v-b) \frac{\partial \alpha}{\partial T}}{\left(1-3 b^{2}+\alpha a\right)}=\frac{1}{T} \frac{\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}+\alpha a\right)}-\frac{a(1-b / v)}{\left(1-3 b^{2}+\alpha a\right)} \frac{\partial \alpha}{\partial T}$
b) 1) Ideal gas $\kappa=-\left.\frac{1}{v} \frac{\partial v}{\partial p}\right|_{T}=-\frac{1}{v}\left(\frac{R T}{-p^{2}}\right)=\frac{1}{p}$
4) Virial Expansion

$$
\begin{aligned}
& v^{2}=\frac{R T}{p}(v+B) \\
& 2 v \frac{\partial v}{\partial p}=-\frac{R T}{p^{2}}(v+B)+\frac{R T}{p} \frac{\partial v}{\partial p} \\
& \left(2-\frac{R T}{v p}\right) \frac{\partial v}{\partial p}=-\frac{R T}{v p^{2}}(v+B)=\frac{\partial v}{\partial p}=-\frac{1}{p}(v+B) \\
& -\frac{1}{v} \frac{\partial v}{\partial p}=\frac{1}{p}(1+B / v)
\end{aligned}
$$

3) Peng Robinson

$$
\begin{aligned}
& v^{3}+v^{2} b-3 b^{2} v+b^{3}=\frac{R T}{p}\left(v^{2}+2 b v-b^{2}\right)-\alpha a(v-b) \\
& \left(3 v^{2}+2 b v-3 b^{2}\right) \frac{\partial v}{\partial p}=-\frac{R T}{p^{2}}\left(v^{2}+2 b v-b^{2}\right)-\alpha a \frac{\partial v}{\partial p}+\frac{R T}{p}(2 v+2 b) \frac{\partial v}{\partial p} \\
& \left(3 v^{2}-2 v^{2}+2 b v-2 b v-3 b^{2}-\alpha a\right) \frac{\partial v}{\partial p}=-\frac{R T}{p^{2}}\left(v^{2}+2 b v-b^{2}\right) \\
& -\frac{1}{v} \frac{\partial v}{\partial p}=\frac{1}{p} \frac{\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}-\alpha a\right)}
\end{aligned}
$$

Now consider the two derivative definitions that were obtained for the Helmholtz Potential.

$$
\begin{align*}
& -S=\left.\frac{d F}{d T}\right|_{V} \\
& -\left.\frac{d S}{d V}\right|_{T}=\frac{d^{2} F}{d T d V} \\
& -p=\left.\frac{d F}{d V}\right|_{T} \\
& -\left.\frac{d p}{d T}\right|_{V}=\frac{d^{2} F}{d V d T} \\
& \left.\frac{d p}{d T}\right|_{V}=\left.\frac{d S}{d V}\right|_{T} \tag{10.21}
\end{align*}
$$

This is known as the Third Maxwell relation and allows estimation of the change in entropy vs. pressure at constant temperature by measuring the change in pressure
vs. temperature at constant volume. The rest of the Maxwell relations are derived in a similar manner, and are given as,

$$
\begin{aligned}
& \left.\frac{\partial T}{\partial V}\right|_{S}=-\left.\frac{\partial p}{\partial S}\right|_{V} \text { First Maxwell Relation } \\
& \left.\frac{\partial T}{\partial p}\right|_{S}=\left.\frac{\partial V}{\partial S}\right|_{p} \quad \text { Second Maxwell Relation } \\
& \left.\frac{\partial S}{\partial p}\right|_{T}=-\left.\frac{\partial V}{\partial T}\right|_{p} \quad \text { Fourth Maxwell Relation. }
\end{aligned}
$$

### 10.3 Clapeyron Equation

The Third Maxwell relation above can be applied to obtain $h_{f g}$ at a point on the vapor dome identified by $p_{o}$ and $T_{o}$. Start with,

$$
\begin{align*}
& \left.\frac{d s}{d v}\right|_{T_{o}}=\frac{s_{g}-s_{f}}{v_{g}-v_{f}}=\frac{s_{f g}}{v_{f g}}=\left.\frac{d p}{d T}\right|_{v_{o}}  \tag{10.22}\\
& d h=T d s-v d p \\
& d p=0 \\
& \int d h=h_{f g}=\int T_{o} d s=T_{o} \Delta s=T_{o} s_{f g} \tag{10.23}
\end{align*}
$$

Then

$$
\begin{align*}
& \left.\frac{d p}{d T}\right|_{v_{o}}=\frac{h_{f g}}{T_{o} v_{f g}} \\
& h_{f g}=\left.T_{o} v_{f g} \frac{d p}{d T}\right|_{v_{o}} \tag{10.24}
\end{align*}
$$

Now the derivative can be evaluated from the saturated state tables using a central difference approximation.

$$
\begin{align*}
& \left.\frac{d p}{d T}\right|_{v_{o}}=\frac{h_{f g}}{T_{o} v_{f g}}  \tag{10.25}\\
& h_{f g}=\left.T_{o} v_{f g} \frac{d p}{d T}\right|_{v_{o}} \\
& \left.\frac{d p}{d T}\right|_{v_{o}}=\frac{p_{2}-p_{1}}{T_{2}-T_{1}} \tag{10.26}
\end{align*}
$$

At low pressures, this becomes the Clausius-Clapeyron equation by ignoring the value of $\mathrm{v}_{\mathrm{f}}$ and approximating $\mathrm{v}_{\mathrm{g}}$ by $\mathrm{RT} / \mathrm{p}$ (Ideal Gas).

$$
\begin{equation*}
\left.\frac{d p}{d T}\right|_{v_{o}}=\frac{p h_{f g}}{R T^{2}} \tag{10.27}
\end{equation*}
$$

This will allow extrapolating to pressures below those tabulated by rewriting this equation as,

$$
\begin{align*}
& \frac{d p}{p}=\frac{h_{f g} d T}{R T^{2}} \\
& \ln \left(\frac{p_{2}}{p_{1}}\right) \cong \frac{h_{f g}}{R}\left(\frac{1}{T_{1}}-\frac{1}{T_{2}}\right) \tag{10.28}
\end{align*}
$$

### 10.4 Specific Heat Relations Using the Maxwell Relations

The internal energy differential can be written

$$
\begin{equation*}
d u=\left.\frac{d u}{d T}\right|_{v} d T+\left.\frac{d u}{d v}\right|_{T} d v=C_{v} d T+\left.\frac{d u}{d v}\right|_{T} d v \tag{10.29}
\end{equation*}
$$

And considering

$$
\begin{aligned}
& s=s(T, v) \\
& d s=\left.\frac{d s}{d T}\right|_{v} d T+\left.\frac{d s}{d v}\right|_{T} d v
\end{aligned}
$$

Then

$$
\begin{align*}
& d u=T d s-p d v \\
& d u=T\left[\left.\frac{d s}{d T}\right|_{v} d T+\left.\frac{d s}{d v}\right|_{T} d v\right]-p d v=\left.T \frac{d s}{d T}\right|_{v} d T+\left[\left.\frac{d s}{d v}\right|_{T}-p\right] d v \tag{10.30}
\end{align*}
$$

So

$$
\begin{align*}
& C_{v}=\left.T \frac{d s}{d T}\right|_{v} \\
& \left.\frac{d u}{d v}\right|_{T}=\left.T \frac{d s}{d v}\right|_{T}-p=\left.T \frac{d p}{d T}\right|_{v}-p \quad \text { (3rd Maxwell Relation) } \\
& d u=C_{v} d T+\left[\left.T \frac{d p}{d T}\right|_{v}-p\right] d v \tag{10.31}
\end{align*}
$$

This allows calculation of $d u$, given an equation of state that relates $\boldsymbol{p}, \boldsymbol{v}$, and $\boldsymbol{T}$.
Approaching enthalpy the same way and writing.

$$
\begin{align*}
& s=s(T, p) \\
& d s=\left.\frac{d s}{d T}\right|_{p} d T+\left.\frac{d s}{d p}\right|_{T} d p \\
& d h=T d s+v d p=T\left[\left.\frac{d s}{d T}\right|_{p} d T+\left.\frac{d s}{d p}\right|_{T} d p\right]+v d p \\
& C_{p}=\left.T \frac{d s}{d T}\right|_{p} \\
& d h=C_{p} d T+\left[v-\left.T \frac{d v}{d T}\right|_{p}\right] d p \quad \text { (4th Maxwell Relation) } \tag{10.32}
\end{align*}
$$

This can be integrated to get $\boldsymbol{d} \boldsymbol{h}$ given an equation of state for $p, v$, and $T$.
Example 10.2 Demonstrate that the $d p$ correction term in the $d h$ equation for (1) an Ideal Gas is zero and (2) is non zero for the Peng Robinson equation.
Solution The $d p$ term in the $d h$ equation is given by $\left[v-\left.T \frac{d v}{d T}\right|_{p}\right] d p$

1. Ideal Gas $v-\left.T \frac{\partial v}{\partial T}\right|_{p}=v-T \frac{\partial}{\partial T} \frac{R T}{p}=v-T \frac{R}{p}=v-v=0$
2. Peng Robinson-From Example 2.1

$$
\begin{aligned}
& \frac{1}{v} \frac{\partial v}{\partial T}=\frac{1}{T} \frac{\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}+\alpha a\right)}-\frac{a(1-b / v)}{\left(1-3 b^{2}+\alpha a\right)} \frac{\partial \alpha}{\partial T} \\
& v-T \frac{\partial v}{\partial T}=v-\frac{v\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}+\alpha a\right)}-\frac{a(1-b / v) T v}{\left(1-3 b^{2}+\alpha a\right)} \frac{\partial \alpha}{\partial T}
\end{aligned}
$$

Now revisiting the two differential entropy equations above,

$$
d s=\left.\frac{d s}{d T}\right|_{v} d T+\left.\frac{d s}{d v}\right|_{T} d v=\frac{C_{v}}{T} d T+\left.\frac{d p}{d T}\right|_{v} d v
$$

And

$$
\begin{equation*}
d s=\left.\frac{d s}{d T}\right|_{p} d T+\left.\frac{d s}{d p}\right|_{T} d p=\frac{C_{p}}{T} d T-\left.\frac{d v}{d T}\right|_{p} d p \tag{10.33}
\end{equation*}
$$

These two equations will allow calculation of changes in entropy for real gases requiring only the specific heats as a function of temperature and a real gas equation of state.

### 10.5 The Difference Between the Specific Heats for a Real Gas

Now consider the difference between the specific heats for a real gas. From above

$$
C_{p}-C_{v}=\left.T \frac{d s}{d T}\right|_{p}-\left.T \frac{d s}{d T}\right|_{v}
$$

By Eq. 10.15

$$
\left.\frac{d s}{d T}\right|_{p}=\left.\frac{d s}{d T}\right|_{v}+\left.\left.\frac{d s}{d v}\right|_{T} \frac{d v}{d T}\right|_{p}
$$

So

$$
C_{p}-C_{v}=\left.\left.T \frac{d s}{d v}\right|_{T} \frac{d v}{d T}\right|_{p}
$$

So

$$
C_{p}-C_{v}=\left.\left.T \frac{d s}{d v}\right|_{T} \frac{d v}{d T}\right|_{p}
$$

and applying the Third Maxwell Relation again gives,

$$
\begin{equation*}
C_{p}-C_{v}=\left.\left.T \frac{d p}{d T}\right|_{v} \frac{d v}{d T}\right|_{p} \tag{10.34}
\end{equation*}
$$

For an ideal gas

$$
\left.\frac{d p}{d T}\right|_{v}=\left.\frac{R}{v} \frac{d v}{d T}\right|_{p}=\left.\left.\frac{R}{p} \mathrm{~T} \frac{d p}{d T}\right|_{v} \frac{d v}{d T}\right|_{p}=T \frac{R}{v} \frac{R}{p}=\frac{R T}{p v} R=R
$$

For an Ideal gas as expected. However this is not the case for a real gas.

Example 10.3 Based on Eq. 10.33 derive an expression for the difference in specific heats for a real gas using the Peng-Robinson equation.

Solution Equation 10.33 is

$$
C_{p}-C_{v}=\left.\left.T \frac{d p}{d T}\right|_{v} \frac{d v}{d T}\right|_{p}
$$

Evaluating the two derivatives

$$
\begin{aligned}
& p=\frac{R T}{v-b}-\frac{\alpha a}{v^{2}+2 b v-b^{2}} \\
& \left.\frac{\partial p}{\partial T}\right|_{v}=\frac{R}{v-b}-\frac{a}{v^{2}+2 b v-b^{2}} \frac{\partial \alpha}{\partial T} \\
& \frac{\partial \alpha}{\partial T}=\frac{\partial}{\partial T}\left[1+\kappa\left(1-\sqrt{T / T_{C}}\right)\right]^{2}=2 \alpha \frac{-\kappa}{2}\left(T / T_{c}\right)^{-1 / 2} \frac{1}{T_{c}}=-\alpha \kappa\left(\frac{1}{T T_{c}}\right)^{1 / 2} \\
& \left.\frac{\partial p}{\partial T}\right|_{v}=\frac{R}{v-b}+\frac{\alpha a \kappa}{v^{2}+2 b v-b^{2}}\left(\frac{1}{T T_{c}}\right)^{1 / 2} \\
& \left.\frac{\partial v}{\partial T}\right|_{p}=\frac{R}{p} \frac{\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}+\alpha a\right)}-\frac{a(v-b)}{\left(1-3 b^{2}+\alpha a\right)}\left(-\alpha \kappa\left(\frac{1}{T T_{c}}\right)^{1 / 2}\right) \\
& C_{p}-C_{v}=R\left[\frac{1}{v-b}+\frac{\alpha a \kappa}{R\left(v^{2}+2 b v-b^{2}\right)}\left(\frac{1}{T T_{c}}\right)^{1 / 2}\right] \\
& {\left[\frac{R}{p} \frac{\left(v^{2}+2 b v-b^{2}\right)}{\left(1-3 b^{2}+\alpha a\right)}+\frac{a \alpha \kappa(v-b)\left(\frac{1}{T T_{c}}\right)^{1 / 2}}{\left(1-3 b^{2}+\alpha a\right)}\right]}
\end{aligned}
$$

### 10.6 Joule-Thomson Coefficient

When a fluid passes through a throttling device, the enthalpy remains constant. Normally the temperature of the fluid will drop. However for real gases, the temperature may remain the same or it may increase. What happens depends on the value of what is called the Joule Thomson coefficient, $\boldsymbol{C}_{J T}$.

$$
\begin{equation*}
C_{J T}=\left.\frac{d T}{d p}\right|_{h} \tag{10.35}
\end{equation*}
$$

If $C_{J T}$ is positive, a temperature decrease follows a pressure decrease. If it is negative, a temperature increases results. Consider,

$$
\begin{align*}
& d h=C_{p} d T+\left[v-\left.T \frac{d v}{d T}\right|_{p}\right] d p \\
& 0=C_{p} d T+\left[v-\left.T \frac{d v}{d T}\right|_{p}\right] d p \\
& \left.\frac{d T}{d p}\right|_{h}=\frac{1}{C_{p}}\left[\left.T \frac{d v}{d T}\right|_{p}-v\right] \tag{10.36}
\end{align*}
$$

With a throttling valve it is relatively easy to measure a temperature increase or decrease, so this is one way of measuring $C_{p}$. Note also that for an Ideal Gas, the Joule-Thompson coefficient is always zero.

Example 10.4 Derive an expression for the Joule Thompson Coefficient for a gas obeying the real gas equation represented by a virial expansion.

Solution The Joule Thompson Coefficient is

$$
\begin{aligned}
& C_{J T}=\left.\frac{d T}{d p}\right|_{h}=\frac{1}{C_{p}}\left[\left.T \frac{d v}{d T}\right|_{p}-v\right] \\
& C_{J T}=\frac{1}{C_{p}}\left[T \frac{v}{T}(1+B / v)-v\right] \\
& C_{J T}=\frac{v}{C_{p}}(1+B / v)
\end{aligned}
$$

## Chapter 11 Combustion

Chemical combustion is the major source of energy used for transportation and the production of electricity. In this chapter, thermodynamic concepts important to the study of combustion are examined. Basic property relations for ideal gases and ideal-gas mixtures and first law of thermodynamics have been discussed in previous chapters. Some review of these concepts will be covered as they are integral to the study of combustion. Readers should refer to reference [1-5] at the end of this chapter for further information and details.

### 11.1 Introduction

Combustion is a rapid exothermic reaction that liberates substantial energy as heat and has the ability to propagate through a suitable medium. This propagation results from the strong coupling of the reaction with the molecular transport process. The chemistry and physics of combustion involves the destruction and rearrangement of certain molecules and a rapid energy release within a few millionths of second. Currently, the study of combustion is a mature discipline and an integral element of diverse research and development programs from fundamental studies of the physics of flames and high-temperature molecular chemistry to applied engineering projects involved with developments such as advanced coal-burning equipment and improved combustion furnaces, boilers, and engines. These developments are important in optimizing fuel use and controlling the emission of pollutants.

The study of combustion starts with the mass and energy balances that bound the combustion process. Then, the energy characteristics of various important fuel resources and their physical and chemical properties are considered. Finally the practical stoichiometry and thermochemical requirements that apply during combustion processes including chemical reactions, equilibrium compositions and temperatures are discussed.

Combustion is the conversion of a substance called a fuel into products of combustion by combination with an oxidizer. The combustion process is an exothermic chemical reaction, i.e., a reaction that releases energy as it occurs. Thus, combustion may be represented symbolically by:

## Fuel + Oxidizer $\rightarrow$ Products of combustion + Energy.

Here the fuel and the oxidizer are reactants, i.e., the substances present before the reaction takes place. This relation indicates that the reactants produce combustion products and energy. Either the chemical energy released is transferred to the surroundings as it is produced, or it remains in the combustion products in the form of elevated internal energy (temperature), or some combination thereof.

Fuels are evaluated, in part, based on the amount of energy or heat that they release per unit mass or per mole during combustion of the fuel. Such a quantity is known as the fuel's heat of reaction or heating value.

Heats of reaction may be measured in a calorimeter, a device in which chemical energy release is determined by transferring the released heat to a surrounding fluid. The amount of heat transferred to the fluid in returning the products of combustion to their initial temperature yields the heat of reaction. In combustion processes, the oxidizer is usually air but could be pure oxygen, an oxygen mixture, or a substance involving some other oxidizing element such as fluorine. Only oxygen based oxidizers will be considered in what follows. Chemical fuels exist in gaseous, liquid, or solid form. Natural gas, gasoline, and coal, are the most widely used examples of these three forms. Each is a complex mixture of reacting and inert compounds. The analysis process proceeds in three steps:

- Concepts and definitions related to element conservation,
- A definition of enthalpy that accounts for chemical bonds,
- First-law concepts defining heat of reaction, heating values, etc., and adiabatic flame temperature.

Actually, combustion is a result of dynamic, or time-dependent, events that occur on a molecular level among atoms, molecules, radicals and solid boundaries. The rapid reactions produce gradients that transport processes convert into heat and species fluxes that speed-up the reactions.

At the heart of fossil-fueled power plant operation is the combustion process. Through the combustion process, a modern power plant burns fuel to release the energy that generates steam-energy that ultimately is transformed into electricity. Yet, while the combustion process is one of a power plant's most fundamental processes, it is also one of the most complexes.

Combustion, or the conversion of fuel to useable energy, must be carefully controlled and managed. Only the heat released that is successfully captured by the steam is useful for generating power. Hence, the ability of the steam generator to successfully transfer energy from the fuel to steam is driven by the combustion process, or more precisely, the characteristics of the combustion process.

A chemical reaction may be defined as the rearrangement of atoms due to redistribution of electrons. In a chemical reaction the terms, 'reactants' and 'products' are frequently used. 'Reactants' comprise the initial constituents which start the
reaction while 'products' are the final constituents which are formed by the chemical reaction. Although the basic principles, which will be discussed in this chapter, apply to any chemical reaction, the focus will be on combustion.

### 11.2 Chemical Combustion

Combustion is a chemical process in which a substance reacts rapidly with oxygen and gives off heat. The original substance is called the fuel, and the source of oxygen is called the oxidizer. The fuel can be a solid, liquid, or gas. For most forms of transportation propulsion, the fuel is usually a liquid. The oxidizer, likewise, could be a solid, liquid, or gas, but is usually a gas (air). Rockets, on the other hand, usually carry their own oxidizer in addition to their fuel.

During combustion, new chemical substances are created from the fuel and the oxidizer. These substances will be called exhaust. Most of the exhaust comes from chemical combinations of the fuel and oxygen. When a hydrogen-carbon-based fuel (like gasoline) burns, the exhaust includes water (hydrogen + oxygen) and carbon dioxide (carbon + oxygen). However, the exhaust can also include chemical combinations from the oxidizer alone. If the gasoline is burned in air, which contains $21 \%$ oxygen and $78 \%$ nitrogen, the exhaust can also include nitrous oxides (NOX, nitrogen + oxygen). The temperature of the exhaust is high because of the heat that is transferred to the exhaust during combustion. Because of the high temperatures, exhaust usually occurs as a gas, but there can be liquid or solid exhaust products as well. Soot, for example, is a form of solid exhaust that occurs in some combustion processes.

During the combustion process, as the fuel and oxidizer are turned into exhaust products, heat is generated. Interestingly, some source of heat is also necessary to start combustion. Gasoline and air are both present in your automobile fuel tank; but combustion does not occur because there is no source of heat. Since heat is both required to start combustion and is itself a product of combustion, we can see why combustion takes place very rapidly. Once combustion gets started, we do not have to provide the heat source because the heat of combustion will keep things going. We do not have to keep lighting a campfire, it just keep burning.

To summarize, for combustion to occur three things must be present (Fig. 11.1):

1. A fuel to be burned,
2. A source of oxygen, and
3. A source of heat.

Because of combustion, exhaust products are created and heat is released. You can control or stop the combustion process by controlling the amount of the fuel available, the amount of oxygen available, or the source of heat.

Actually, combustion is a result of dynamic, or time-dependent, events that occur on a molecular level among atoms, molecules, radicals and solid boundaries. Therefore, this chapter presents chemical kinetics that includes kinetic theory of

## Combustion

gases, elementary reactions and reaction rate theory. Furthermore, the rapid reactions produce gradients that transport processes convert into heat and species fluxes that speed-up the reactions.

### 11.3 Combustion Equations

A simple chemical-reaction equation is the combustion of propane in a pure oxygen environment. The chemical reaction is represented by;

$$
\begin{equation*}
\mathrm{C}_{3} \mathrm{H}_{8}+5 \mathrm{O}_{2} \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O} \tag{11.1}
\end{equation*}
$$

Note that the number of moles on the left-hand side may not equal the number of moles on the right-hand side. However, the number of atoms of an element must remain the same, before, after, and during a chemical reaction; this demands that the mass of each element be conserved during combustion.

In writing the equation some knowledge of the products of the reaction was assumed. Complete combustion was assumed. The products of complete combustion of a hydrocarbon fuel will be $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$, Incomplete combustion results in products that contain $\mathrm{H}_{2}, \mathrm{CO}, \mathrm{C}$, and/or OH .

For a simple chemical reaction, such as Eq. 11.1, writing down a balanced chemical equation is straightforward. For reactions that are more complex the following systematic method proves useful [5]:

1. Set the number of moles of fuel equal to 1 .
2. Balance $\mathrm{CO}_{2}$ with number of C from the fuel.
3. Balance $\mathrm{H}_{2} \mathrm{O}$ with H from the fuel.
4. Balance $\mathrm{O}_{2}$ from $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$.

For the combustion of propane, it was assumed that the process occurred in a pure oxygen environment. Actually, such a combustion process normally occurs in air. Nominally air consists of $21 \% \mathrm{O}_{2}$ and $79 \% \mathrm{~N}_{2}$ by volume so that for each mole of $\mathrm{O}_{2}$ in a reaction there are 3.76 mol of $\mathrm{N}_{2}$.

$$
\begin{equation*}
\frac{79}{21}=3.76 \frac{\mathrm{~mol} \mathrm{~N}_{2}}{\mathrm{~mol} \mathrm{O}_{2}} \tag{11.2}
\end{equation*}
$$

Thus, on the (simplistic) assumption that $\mathrm{N}_{2}$ will not undergo any chemical reaction, Eq. 1.1 is replaced by

$$
\begin{equation*}
\mathrm{C}_{3} \mathrm{H}_{8}+5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 3 \mathrm{CO}_{2}+4 \mathrm{H}_{2} \mathrm{O}+18.8 \mathrm{~N}_{2} \tag{11.3}
\end{equation*}
$$

The minimum amount of air that supplies sufficient $\mathrm{O}_{2}$ for the complete combustion of the fuel is called Theoretical Air or Stoichiometric Air. When complete combustion is achieved with theoretical air, the products contain no $\mathrm{O}_{2}$, as in the reaction of Eq. 11.3. In practice, it is often found that if complete combustion is to occur, air must be supplied in an amount greater than theoretical air. This is due to the chemical kinetics and molecular activity of the reactants and products. The term percent theoretical air is used to compare the actual air provided to the combustion process compared to stoichiometric air (Eq. 11.4a).

$$
\begin{equation*}
\% \text { theoretical air }=100 \%+\% \text { excess air } \tag{11.4a}
\end{equation*}
$$

Slightly, insufficient air results in CO being formed; some hydrocarbons may result from larger deficiencies [5]. So in summary, a mixture of air and fuel is called Stoichiometric if it contains just sufficient oxygen for the complete combustion of the fuel. Moreover, the percentage of excess air is given by the following (Eq. 11.4b):

$$
\begin{equation*}
\text { Percentage excess air }=\frac{\text { Actual }(\mathrm{A} / \mathrm{F}) \text { ratio }- \text { Stoichiometric }(\mathrm{A} / \mathrm{F}) \text { ratio }}{\text { Stoichiometric }(\mathrm{A} / \mathrm{F}) \text { ratio }} \tag{11.4b}
\end{equation*}
$$

where A denotes Air while F denotes Fuel.
The parameter that relates the amount of air used in a combustion process is the air-fuel ratio $(A F)$, which is the ratio of the mass of air to the mass of fuel. The reciprocal is the fuel-air ratio (FA) (Eq. 11.5). Thus

$$
\begin{equation*}
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}} \quad F A=\frac{m_{\text {fuel }}}{m_{\text {air }}} \tag{11.5}
\end{equation*}
$$

Considering propane combustion with theoretical air as in (Eq. 11.3), the air-fuel ratio is (see Eq. 11.6).

$$
\begin{equation*}
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(5)(4.76)(29)}{(1)(44)}=15.69 \frac{\mathrm{Kg} \text { air }}{\mathrm{Kg} \text { fuel }} \tag{11.6}
\end{equation*}
$$

where the molecular weight of air is taken as $29 \mathrm{~kg} / \mathrm{kmol}$ and that of propane as $44 \mathrm{~kg} / \mathrm{kmol}$. If for the combustion of propane, $A F>15.69$, a Lean or Weak mixture occurs; if $A F<15.69$, a Rich mixture results.

For solid and liquid fuels the ratio are expressed by mass, while for gaseous fuels the ratios are normally expressed by volume. For boiler plant, the mixture is usually greater than $20 \%$ lean; for gas turbines, it can be as much as $300 \%$ lean. Petrol engines have to meet various conditions of load and speed, and operate over a wide range of mixture strengths. The following definition is then used (Eq. 11.7):

$$
\begin{equation*}
\text { Mixture strength }=\frac{\text { Stoichiometric }(\mathrm{A} / \mathrm{F}) \text { ratio }}{\text { Actual }(\mathrm{A} / \mathrm{F}) \text { ratio }} \tag{11.7}
\end{equation*}
$$

In this situation, the working values range between $80 \%$ (lean) and $120 \%$ (rich). Where fuels contain some oxygen (e.g. ethyl alcohol $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}$ ) this oxygen is available for the combustion process, and so the fuel requires a smaller supply of air [6].

The combustion of hydrocarbon fuels involves $\mathrm{H}_{2} \mathrm{O}$ in the products of combustion. The calculation of the dew point of the products is often of interest; it is the saturation temperature at the partial pressure of the water vapor. If the temperature drops below the dew point, the water vapor begins to condense. The condensate usually contains corrosive elements, and thus it is often important to ensure that the temperature of the products does not fall below the dew point.

Example 11.1 Butane is burned with dry air at an air-fuel ratio of 20. Calculate (a) the percent excess air, (b) the volume percentage of $\mathrm{CO}_{2}$ in the products, and (c) the dew-point temperature of the products.
Solution The reaction equation for theoretical air is

$$
\mathrm{C}_{4} \mathrm{H}_{10}+6.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+24.44 \mathrm{~N}_{2}
$$

a. The air-fuel ratio for theoretical air is

$$
A F=\frac{m_{\text {air }}}{m_{\text {fuel }}}=\frac{(6.5)(4.76)(29)}{(1)(58)}=15.47 \frac{\mathrm{Kg} \text { air }}{\mathrm{Kg} \text { fuel }}
$$

This represents $100 \%$ theoretical air. The actual air-fuel ratio is 20 . The excess air is then

$$
\% \text { excess air }=\left(\frac{A F_{a c t}-A F_{t h}}{A F_{t h}}\right)(100 \%)=\frac{20-15.47}{15.47}(100 \%)=29.28 \%
$$

b. The reaction equation with $129.28 \%$ theoretical air is

$$
C_{4} \mathrm{H}_{10}+(6.5)(1.2928)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right)+4 \mathrm{CO}_{2}+5 \mathrm{H}_{2} \mathrm{O}+1.903 \mathrm{O}_{2}+31.6 \mathrm{~N}_{2}
$$

The volume percentage is obtained using the total moles in the products of combustion. For $\mathrm{CO}_{2}$ we have

$$
\% \mathrm{CO}_{2}=\left(\frac{4}{42.5}\right)(100 \%)=9.41 \%
$$

c. To find the dew-point temperature of the products we need the partial pressure of the water vapor. It is found using the mole fraction to be

$$
p_{\mathrm{H}_{2} \mathrm{O}}=y_{\mathrm{H}_{2} \mathrm{O}} p_{\text {atm }}=\left(\frac{5}{42.5}\right) * 101.325 \mathrm{kPa}=11.76 \mathrm{kPa}
$$

where we have assumed an atmospheric pressure of 101.325 kPa . Using Appendix 14.2 we find the dew-point temperature to be $\mathrm{T}_{\mathrm{d}^{\circ} \mathrm{p}}=49^{\circ} \mathrm{C}$.

When a chemical reaction occurs, there may be considerable change in the chemical composition of a system. The problem this creates is that for a control volume the mixture that exits is different from the mixture that enters.

### 11.4 Mass and Mole Fractions

The amount of a substance present in a sample may be indicated by its mass or by the number of moles of the substance. A mole is defined as the mass of a substance equal to its molecular mass or molecular weight. Molecular weights for substances of interest are given in the Appendix. Compound molecular weights can be obtained by adding up the atomic weights of the constituents.

The composition of a mixture may be given as a list of the fractions of each of the substances present. Thus we define the mass fraction, of a component $i, m f_{i}$, as the ratio of the mass of the component, $m_{i}$, to the mass of the mixture (Eq. 11.8), $m$ :

$$
\begin{equation*}
m f_{i}=\frac{m_{i}}{m} \tag{11.8}
\end{equation*}
$$

It is evident that the sum of the mass fractions of all the components must be 1 . Thus (Eq. 11.9):

$$
\begin{equation*}
m f_{1}+m f_{2}+\ldots=1 \tag{11.9}
\end{equation*}
$$

The mole fraction of component $i, x_{i}$, is the ratio of the number of moles of component $i, n_{i}$, to the total number of moles in the mixture (Eq. 11.10), $n$ :
$x_{i}=\frac{n_{i}}{n}$

The total number of moles, $n$, is the sum of the number of moles of all the components of the mixture (Eq. 11.11):

$$
\begin{equation*}
n=n_{1}+n_{2}+n_{3} \ldots \tag{11.11}
\end{equation*}
$$

It follows that the sum of all the mole fractions of the mixture (Eq. 11.12) must equal 1.

$$
\begin{equation*}
x_{1}+x_{2}+\ldots=1 \tag{11.12}
\end{equation*}
$$

The mass of component $i$ in a mixture is the product of the number of moles of i and its molecular weight, $\mathrm{M}_{\mathrm{i}}$. The mass of the mixture is therefore the sum, $m=n_{1} M_{1}+n_{2} M_{2}+\cdots$ over all components of the mixture. Substituting $x_{i} n$ for $n_{i}$ , the total mass becomes (Eq. 11.13);

$$
\begin{equation*}
m=\left(x_{1} M_{1}+x_{2} M_{2}+\ldots\right) n \tag{11.13}
\end{equation*}
$$

But the average molecular weight of the mixture is the ratio of the total mass to the total number of moles. Thus, the average molecular weight is (see Eq. 11.14).

$$
\begin{equation*}
M=m / n=x_{1} M_{1}+x_{2} M_{2}+\ldots \tag{11.14}
\end{equation*}
$$

Example 11.2 Express the mass fraction of component 1 of a mixture in terms of: (a) the number of moles of the three components of the mixture, $n_{1}, n_{2}$, and $n_{3}$ , and (b) the mole fractions of the three components. (c) If the mole fractions of carbon dioxide and nitrogen in a three component gas containing water vapor are 0.07 and 0.38 , respectively, what are the mass fractions of the three components?

## Solution

a. Because the mass of i can be written as $m_{i}=n_{i} M_{i}$, the mass fraction of component $i$ can be written as:

$$
m f_{i}=\frac{n_{i} M_{i}}{n_{1} M_{1}+n_{2} M_{2}+n_{3} M_{3}+\ldots}
$$

For the first of the three components, $i=1$, this becomes:

$$
m f_{1}=\frac{n_{1} M_{1}}{n_{1} M_{1}+n_{2} M_{2}+n_{3} M_{3}}
$$

Similarly, for $i=2$ and $i=3$ :

$$
\begin{aligned}
& m f_{2}=\frac{n_{2} M_{2}}{n_{1} M_{1}+n_{2} M_{2}+n_{3} M_{3}} \\
& m f_{3}=\frac{n_{3} M_{3}}{n_{1} M_{1}+n_{2} M_{2}+n_{3} M_{3}}
\end{aligned}
$$

b. Substituting $n_{1}=x_{1} n_{1}, n_{2}=x_{2} n_{2}$, etc. in the earlier equations and simplifying, we obtain for the mass fractions:

$$
\begin{aligned}
& m f_{1}=x_{1} M_{1} /\left(x_{1} M_{1}+x_{2} M_{2}+x_{3} M_{3}\right) \\
& m f_{2}=x_{2} M_{2} /\left(x_{1} M_{1}+x_{2} M_{2}+x_{3} M_{3}\right) \\
& m f_{3}=x_{3} M_{3} /\left(x_{1} M_{1}+x_{2} M_{2}+x_{3} M_{3}\right)
\end{aligned}
$$

c. Identifying the subscripts 1,2 , and 3 with carbon dioxide, nitrogen, and water vapor, respectively, we have $x_{1}=0.07, x_{2}=0.38$, and $x_{3}=1-0.07-0.038=0.55$. Then:

$$
\begin{aligned}
m f_{1} & =(0.07)(0.44) /[(0.07)(44)+(0.38)(28)+(0.55)(18)] \\
& =(0.07)(0.44) /(23.62)=0.1304 \\
m f_{2} & =(0.38)(28) /(23.62)=0.4505 \\
m f_{3} & =(0.55)(18) /(23.62)=0.4191
\end{aligned}
$$

As a check we sum the mass fractions: $0.1304+0.4505+0.4191=1.0000$.
For a mixture of gases at a given temperature and pressure, the ideal gas law shows that $p V_{i}=n_{i} \Re T$ holds for any component, and $p V=n \Re T$ for the mixture as a whole. Forming the ratio of the two equations, we observe that the mole fractions have the same values as the volume fraction (Eq. 11.15):

$$
\begin{equation*}
x_{i}=V_{i} / V=n_{i} / n \tag{11.15}
\end{equation*}
$$

Similarly, for a given volume of a mixture of gases at a given temperature, $p V_{i}=n_{i} \Re T$ for each component and $p V=n \Re T$ for the mixture. The ratio of the two equations shows that the partial pressure of any component $i$ is the product of the mole fraction of $i$ and the pressure of the mixture (Eq. 11.16):

$$
\begin{equation*}
p_{i}=p n_{i} / n=p x_{i} \tag{11.16}
\end{equation*}
$$

Example 11.3 What is the partial pressure of water vapor in Example 11.2 if the mixture pressure is two atmospheres?

Solution The mole fraction of water vapor in the mixture of Example 11.2 is 0.55 . The partial pressure of the water vapor is therefore $(0.55)(2)=1.1 \mathrm{~atm}$.

### 11.5 Enthalpy of Formation

In order to deal with the heat produced in a chemical reaction, a reference point is required so that changes in enthalpy can be computed. The standard reference conditions are $25^{\circ} \mathrm{C}\left(77^{\circ} \mathrm{F}, 298 \mathrm{~K}, 537^{\circ} \mathrm{R}\right)$ and 1 atmosphere pressure. The enthalpy of a substance at the reference state is usually identified as $\boldsymbol{h}^{\boldsymbol{o}}$. At these conditions many of the elements in their normal form are defined to have a 0.0 enthalpy of
formation or heat of formation, $\boldsymbol{h}_{\boldsymbol{f}}^{\boldsymbol{f}}$. Typically this includes gases like oxygen, nitrogen, and hydrogen as well as the solid form of carbon. Other gases like carbon dioxide and water vapor have a negative heat of formation at standard conditions. This means that when they are formed by burning carbon with oxygen, or hydrogen with oxygen, a certain amount of energy will be given off. The reaction is exothermic. When oxygen, nitrogen, or hydrogen is decomposed to oxygen ions, nitrogen ions, or hydrogen ions energy is required. The heat of formation for these reactions is positive because energy must be added to the molecule break it down into ions. Therefore they are endothermic reactions.

$$
\begin{array}{ll}
\mathrm{H}_{2}+\frac{1}{2} \mathrm{O}_{2} \rightarrow 2 \mathrm{H}_{2} \mathrm{O} & -241,820 \mathrm{KJ} / \mathrm{Kg}-\mathrm{mol} \\
\mathrm{C}+\mathrm{O}_{2} \rightarrow \mathrm{CO}_{2} & -393,520 \mathrm{KJ} / \mathrm{Kg}-\mathrm{mol} \\
\mathrm{O}_{2} \rightarrow 2 \mathrm{O} & -249,170 \mathrm{KJ} / \mathrm{Kg}-\mathrm{mol} \\
\mathrm{~N}_{2} \rightarrow 2 \mathrm{~N} & -472,680 \mathrm{KJ} / \mathrm{Kg}-\mathrm{mol} \\
\mathrm{H}_{2} \rightarrow 2 \mathrm{H} & -218,000 \mathrm{KJ} / \mathrm{Kg}-\mathrm{mol}
\end{array}
$$

The negative sign for the heats of formation means that when the reaction occurred, energy was given up by the reactants.

The First Law for a chemical reaction can be written as Eq. 11.17;

$$
\begin{equation*}
Q=H_{p}-H_{R} \tag{11.17}
\end{equation*}
$$

$H_{P}$ is the enthalpy of the products of combustion that leave the combustion chamber and $H_{R}$ is the enthalpy of the reactants that enter the combustion chamber. If the reactants are stable elements and the reaction occurs at constant temperature and pressure at the reference state $\left(77^{\circ} \mathrm{F}\right.$ and 1 atm$)$ then the H's represent the heats of formation for the substances involved. If the temperature deviates from the reference state, each of the enthalpies must be corrected for the temperature changes.

The general equation for a flowing system is (Eq. 11.18):

$$
\begin{align*}
& Q-W s=\sum_{\text {prod }} N_{p}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)\right]_{p}-\sum_{\text {react }} N_{r}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)\right]_{r}  \tag{11.18}\\
& N_{p}=\text { moles of products } \quad N_{r}=\text { moles of reactants } \\
& h(T)-h^{o}=\text { Change in enthalpy from the reference state }
\end{align*}
$$

The general equation for a rigid chamber is (Eq. 11.19):

$$
\begin{align*}
& Q-W_{s}=U_{p}-U_{r} \\
&=\sum_{\text {prod }} N_{p}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)-p v\right]_{p}-\sum_{\text {react }} N_{r}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)-p v\right]_{r}  \tag{11.19}\\
& Q-W_{s}=U_{p}-U_{r} \\
&=\sum_{\text {prod }} N_{p}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)-\Re T\right]_{p}-\sum_{\text {react }} N_{r}\left[h_{f}^{o}+\left(h(T)-h^{o}\right)-\Re v\right]_{r} \\
& \text {-| } \Delta^{*}
\end{align*}
$$

The changes in enthalpy from the reference state can be calculated by the following techniques

For a solid or liquid $\Delta h=C \Delta T$.
For gases

1. $\Delta h=C_{p} \Delta T$
2. Use tabulated values for $\Delta h$
3. Use generalized charts for a real gas
4. Use tables for vapors like the steam tables

Example 11.4 Volumetric analysis of the products of combustion of an unknown hydrocarbon measured on a dry basis gives the following mole percents

$$
\begin{aligned}
\mathrm{CO}_{2} & =10.4 \% \\
\mathrm{CO} & =1.2 \% \\
\mathrm{O}_{2} & =2.8 \% \\
\mathrm{~N}_{2} & =85.6 \%
\end{aligned}
$$

Determine the composition of the hydrocarbon and the percent theoretical air.
Solution The combustion equation is

$$
\mathrm{C}_{a} \mathrm{H}_{b}+c\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 10.4 \mathrm{CO}_{2}+1.2 \mathrm{CO}+2.8 \mathrm{O}_{2}+85.6 \mathrm{~N}_{2}+d \mathrm{H}_{2} \mathrm{O}
$$

Writing equations to balance each of the species gives

$$
\begin{array}{lll}
\mathrm{C}: & \mathrm{a}=10.4+1.2 \quad \mathrm{a}=11.6 & \\
\mathrm{~N}: & 3.76 \mathrm{c}=85.6 & \mathrm{c}=22.8 \\
\mathrm{O}: & 2 \mathrm{c}=10.4(2)+1.2+2.8(2)+\mathrm{d} & \mathrm{~d}=2(22.8)-20.8-1.2-5.6=18 \\
\mathrm{~h}: & \mathrm{b}=2 \mathrm{~d}=36 &
\end{array}
$$

The actual equation for $100 \%$ theoretical air must be

$$
\mathrm{C}_{11.6} \mathrm{H}_{36}+20.6\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 11.6 \mathrm{CO}_{2}+77.5 \mathrm{~N}_{2}+18 \mathrm{H}_{2} \mathrm{O}
$$

22.8 mol of air were used and only 20.6 were needed, so \% Theoretical Air $=110.7 \%$

Example 11.5 Methane is burned with dry air at an air-fuel ratio of 5. Calculate the percent excess air and the percentage water vapor in the exhaust. Estimate the dew point temperature of the products.

Solution The combustion equation is

$$
\mathrm{CH}_{4}+2 \mathrm{O}_{2}+2(3.76) \mathrm{N}_{2} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}+2(3.76) \mathrm{N}_{2}
$$

The stoichiometric air-fuel mixture is $A F_{s t}=\frac{2(28.9669)}{16.043}=3.611$

The percent excess air is $100 *(5-3.611) / 3.611=38.47 \%$. So the balance equation is

$$
\mathrm{CH}_{4}+1.385\left(2 \mathrm{O}_{2}+2(3.76) \mathrm{N}_{2}\right) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}+0.77 \mathrm{O}_{2}+10.4 \mathrm{~N}_{2}
$$

There are $2+1+0.77+10.4=14.17 \mathrm{~mol}$ of products.
The mole percent of $\mathrm{H}_{2} \mathrm{O}$ in the exhaust is $2 / 14.17=14.1 \%$
The partial pressure of $\mathrm{H}_{2} \mathrm{O}$ in the exhaust is $(2 / 14.17)^{*} 101325=14.3 \mathrm{kPa}$
The saturation temperature (dew point) at 14.3 kPa is $326 \mathrm{~K}=53^{\circ} \mathrm{C}$.
Example 11.6 Gaseous methyl alcohol and air enter a combustion chamber at $25^{\circ} \mathrm{C}$ and 1 atm and leave at 550 K and 1 atm . Assume $150 \%$ theoretical air. Estimate the heat transfer to the chamber.

Solution The reaction equation is

$$
\mathrm{CH}_{3} \mathrm{OH}+1.5\left\{1.5\left[\mathrm{O}_{2}+(3.76) \mathrm{N}_{2}\right]\right\} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}+\mathrm{CO}_{2}+0.75 \mathrm{O}_{2}+2.25(3.76) \mathrm{N}_{2}
$$

The First Law gives

$$
Q=\sum_{\text {prod }} N_{p}\left(h_{f}^{o}+\Delta h\right)_{p}-\sum_{\text {react }} N_{r}\left(h_{f}^{o}+\Delta h\right)_{r}
$$

Products

| $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{h}_{\mathrm{f}}=-241,820$ | $\Delta \mathrm{~h}=\mathrm{h}(550)-\mathrm{h}(298)=17,489.1-8853.3=8635.8$ |
| :--- | :--- | :--- |
| $\mathrm{CO}_{2}$ | $\mathrm{~h}_{\mathrm{f}}=-393,520$ | $\Delta \mathrm{~h}=\mathrm{h}(550)-\mathrm{h}(298)=18,878.8-8378.4=10,500.4$ |
| $\mathrm{O}_{2}$ | $\mathrm{~h}_{\mathrm{f}}=0 \square$ | $\Delta \mathrm{~h}=\mathrm{h}(550)-\mathrm{h}(298)=15,363.4-7766.2=7597.2$ |
| $\mathrm{~N}_{2} \square$ | $\mathrm{~h}_{\mathrm{f}}=0$ | $\Delta \mathrm{~h}=\mathrm{h}(550)-\mathrm{h}(298)=15,095.3-7754.3=7431.0$ |

Reactants

$$
\mathrm{CH}_{3} \mathrm{OH} \quad \mathrm{~h}_{\mathrm{f}}=-200,890
$$

The balance equation is

$$
\begin{aligned}
Q= & 2 *(-241,820+8635.8)+(-393,520+10,500.4) \\
& +8.46 * 7431.0+0.75 * 7597.2-(-200,890) \\
Q= & -579,930 \frac{\mathrm{~kJ}}{\mathrm{kmol}} \text { of Methyl Alchol }
\end{aligned}
$$

The above calculation assumes the water in the exhaust is liquid which at the temperature of the exhaust products is not very likely. So an additional enthalpy must be added to the $\Delta \mathrm{h}$ for $\mathrm{H}_{2} \mathrm{O}$ to account for the vaporization of water.

$$
\Delta h_{f g}=2256.6 \mathrm{~kJ} / \mathrm{kg}=40,619.0 \mathrm{~kJ} / \mathrm{Kmol}
$$

Table 11.1 Selected enthalpies of combustion and enthalpies of vaporization

| Substance | Formula | Higher heating value $(\mathrm{kJ} / \mathrm{kmol})$ | $\mathrm{h}_{\mathrm{fg}}$ |
| :--- | :--- | :--- | :--- |
| Hydrogen | $\mathrm{H}_{2}(\mathrm{~g})$ | $-285,840$ |  |
| Carbon | $\mathrm{C}(\mathrm{s})$ | $-393,520$ |  |
| Carbon monoxide | $\mathrm{CO}(\mathrm{g})$ | $-282,990$ |  |
| Methane | $\mathrm{CH}_{4}(\mathrm{~g})$ | $-890,360$ |  |
| Acetylene | $\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})$ | $-1,299,600$ |  |
| Ethylene | $\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})$ | $-1,410,970$ |  |
| Ethane | $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$ | $-1,559,900$ |  |
| Propylene | $\mathrm{C}_{3} \mathrm{H}_{6}(\mathrm{~g})$ | $-2,058,500$ |  |
| Propane | $\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$ | $-2,220,000$ | 15,060 |
| n -Butane | $\mathrm{C}_{4} \mathrm{H}_{10}(\mathrm{~g})$ | $-2,877,100$ | 21,060 |
| n -Pentane | $\mathrm{C}_{5} \mathrm{H}_{12}(\mathrm{~g})$ | $-3,536,100$ | 26,410 |
| n -Hexane | $\mathrm{C}_{6} \mathrm{H}_{14}(\mathrm{~g})$ | $-4,194,800$ | 31,530 |
| n -Heptane | $\mathrm{C}_{7} \mathrm{H}_{16}(\mathrm{~g})$ | $-4,853,500$ | 36,520 |
| n -Octane | $\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g})$ | $-5,512,200$ | 41,460 |

Note that the heat of formation for nitrogen and oxygen is zero on both sides of the equation. If the methyl alcohol had entered as a liquid, we would have had to add its heat of vaporization to the reactant side of the equation further reducing the heat available per mole of the fuel.

### 11.6 Enthalpy of Combustion

With most hydrocarbons, normal combustion occurs with oxygen in the air. Therefore, the enthalpy change for the complete combustion of a substance with oxygen is called the heat of combustion. Several heats of combustion are tabulated below in Table 11.1. If the products of combustion contain water in the vapor state, an allowance for the heat required to vaporize the water must be included in the change in enthalpy from the reference state. If the products of combustion include water in the liquid state, the heat of vaporization is not subtracted and this gives the Higher Heating Value for the heat of combustion for this fuel.

### 11.7 Adiabatic Flame Temperature

In many cases, the heat released in the combustion reaction will determine the final temperature of the products and the gases present in the combustion chamber. The temperature achieved assuming no heat transfer to the surroundings is called the Adiabatic Flame Temperature. Since the change in enthalpy of the products will
depend on this temperature, the Adiabatic Flame Temperature must be found buy iteration. Note also that when a fuel is burned in air, the heat required to bring the nitrogen in the air up to the Adiabatic Flame Temperature must be included in the analysis. The Adiabatic Flame Temperature can be lowered by adding excess air above that required for complete combustion. Typically, this will be required due to peak temperature restrictions on the materials used for construction e.g. the strength of turbine blades downstream of the combustion process.

It is worth pointing out at this point that combustion in itself is an irreversible process and to achieve complete combustion typically requires a pressure loss in the combustion chamber. Since the major part of the fluid flowing through an air combustion chamber does not participate in the chemical reactions (primarily the nitrogen), the combustion process can be thought of as simply heating the working fluid. A nuclear heated heat exchanger can often accomplish the same heating with a lower pressure loss. However, in the nuclear heated system the temperature drops are in the opposite direction requiring heat exchanger walls to operate at a higher temperature than the combustion chamber walls.

Example 11.7 Calculate the enthalpy of combustion of gaseous octane and liquid octane assuming the reactants and products to be at the reference state of $25^{\circ} \mathrm{C}$ and 1 atmosphere. Assume liquid water in the products exiting the steady flow combustion chamber.

Solution The reaction is

$$
\mathrm{C}_{8} \mathrm{H}_{18}+12.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 8 \mathrm{CO}_{2}+9 \mathrm{H}_{2} \mathrm{O}+47 \mathrm{~N}_{2}
$$

Products

$$
\begin{array}{ll}
\mathrm{H}_{2} \mathrm{O} & \mathrm{~h}_{\mathrm{f}}=-285,830 \\
\mathrm{CO}_{2} & \mathrm{~h}_{\mathrm{f}}=-393,520 \\
\mathrm{~N}_{2} & \mathrm{~h}_{\mathrm{f}}=0
\end{array}
$$

Reactants

$$
\begin{array}{lll}
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{l}) & \mathrm{h}_{\mathrm{f}}=-208,450 & \mathrm{~h}_{\mathrm{fg}}=41,460 \\
\mathrm{C}_{8} \mathrm{H}_{18}(\mathrm{~g}) & \mathrm{h}_{\mathrm{f}}=-208,450 &
\end{array}
$$

Liquid Octane

$$
\mathrm{Q}=8(-393,520)+9(-285,830)-(208,450-41,460)=5.4707 \times 10^{6} \mathrm{~kJ} / \mathrm{kmol}
$$

Gaseous Octane

$$
\mathrm{Q}=8(-393,520)+9(-285,830)-(208,450)=5.5122 \times 10^{6} \mathrm{~kJ} / \mathrm{kmol}
$$

Example 11.8 Kerosene is burned with theoretical air in a jet engine. Estimate the adiabatic flame temperature. Kerosene can be treated as n-Dodecane- $\mathrm{C}_{12} \mathrm{H}_{26}$ and has a heat of formation of $-291,010 \mathrm{~kJ} / \mathrm{kmol}$.

Solution The balance equation is

$$
\mathrm{C}_{12} \mathrm{H}_{26}+18.5\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow 12 \mathrm{CO}_{2}+13 \mathrm{H}_{2} \mathrm{O}+69.5 \mathrm{~N}_{2}
$$

For the Adiabatic Flame Temperature $\boldsymbol{Q}=\boldsymbol{0}$, so
Products

$$
\begin{array}{lll}
\mathrm{H}_{2} \mathrm{O} & \mathrm{~h}_{\mathrm{f}}=-241,820 & \Delta \mathrm{~h}(\mathrm{H} 2 \mathrm{O})=? \\
\mathrm{CO}_{2} & \mathrm{~h}_{\mathrm{f}}=-393,520 & \Delta \mathrm{~h}(\mathrm{CO} 2) \boxminus ? \\
\mathrm{~N}_{2} & & \Delta \mathrm{~h}(\mathrm{~N} 2)=?
\end{array}
$$

Reactants

$$
\begin{gathered}
\mathrm{C}_{12} \mathrm{H}_{26} \quad \mathrm{~h}_{\mathrm{f}}=-291,010 \\
\mathrm{Q}=0=12\left(-393,520+\Delta h\left(\mathrm{CO}_{1}\right)\right)+13(-241820+\Delta h(H 2 O)) \\
+69.5 \Delta h(N 2)-(-291,010)
\end{gathered}
$$

At $25^{\circ} \mathrm{C}$ we would have

$$
\mathrm{Q}=12(-393,520)+13(-241,820)+291,010=7.5749 \times 10^{6} \mathrm{~kJ} / \mathrm{kmol}
$$

Treating all of the products as nitrogen the dominant product, we would have $94.5 \mathrm{~kg}-\mathrm{mol}$ of product. Thus, the change in enthalpy per mole is $80,158 \mathrm{~kJ} / \mathrm{kmol}$. At $25^{\circ} \mathrm{C}$ nitrogen has an enthalpy of $7754.3 \mathrm{~kJ} / \mathrm{kmol}$. So the gas tables are entered looking for an enthalpy of $87,912 \mathrm{~kJ} / \mathrm{kmol}$. This corresponds to a temperature of 2660 K . Then evaluating the $\Delta$ h's for $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ at 2660 K gives

$$
\begin{aligned}
& \Delta \mathrm{h}\left(\mathrm{H}_{2} \mathrm{O}\right)=116547.5-8853.3=107690.0 \\
& \Delta \mathrm{~h}\left(\mathrm{CO}_{2}\right)=140041.3-8378.4=131660.0 \\
& \Delta \mathrm{~h}\left(\mathrm{~N}_{2}\right)=87846.0-7754.3=80092.0
\end{aligned}
$$

At 2660 K the net heat balance is
$\mathrm{Q}=-7.5749 \times 10^{6}+13(107690.0)+12(131660.0)+69.5(80092.0)=97,138 \mathrm{~kJ} / \mathrm{kmol}$
Since it is positive, the temperature does not quite reach 2660 K . Now noting that both $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ had larger enthalpy changes than nitrogen, the number of moles can be adjusted to represent them with the all nitrogen model.

$$
\Delta \mathrm{h}\left(\mathrm{H}_{2} \mathrm{O}\right) / \Delta \mathrm{h}\left(\mathrm{~N}_{2}\right)=107690.0 / 80092=1.35
$$

$$
\Delta \mathrm{h}\left(\mathrm{CO}_{2}\right) / \Delta \mathrm{h}\left(\mathrm{~N}_{2}\right)=131660 / 80092=1.64
$$

So the new number of moles will be $\mathrm{N}=69.5+1.35(13)+1.64(12)=106.7$.
Dividing the $25^{\circ} \mathrm{C}$ enthalpy excess by 106.7 gives $7.5749 \times 10^{6} / 106.7=71,017 \mathrm{~kJ} /$ kmol.

Add this to the nitrogen enthalpy at $25^{\circ} \mathrm{C}$ to get $78,771 \mathrm{~kJ} / \mathrm{kmol}$. The gas table gives a temperature of about 2410 K .

$$
\begin{gathered}
\Delta \mathrm{h}\left(\mathrm{H}_{2} \mathrm{O}\right)=103045.9-8853.3=94,193 \\
\Delta \mathrm{~h}\left(\mathrm{CO}_{2}\right)=124671.2-8378.4=116,290.0 \\
\Delta \mathrm{~h}\left(\mathrm{~N}_{2}\right)=78,688.1-7754.3=70,934.0 \\
\mathrm{Q}=-7.5749 \times 10^{6}+13(94,193)+12(116,290)+69.5(70934)=-24,998 \mathrm{~kJ} / \mathrm{kmol}
\end{gathered}
$$

So now the temperature is bracketed. The new mole effectiveness ratios for $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ are 1.33 and 1.64 . Therefore, 2410 K is very close and in fact the best answer obtained by another iteration is $\mathrm{T}=2416.3 \mathrm{~K}$ which is probably 2 or 3 too many digits for the round offs that have been made in the solution process.

It is obvious that this would be a very stressing temperature, and so most jet engines are running at a mixture ratio quite a bit lower than stoichiometric.

## Chapter 12 <br> Heat Transfer

Thermodynamics deals with the transfer of heat to and from a working fluid and the performance of work by that fluid. Since the transfer of heat to a working fluid is central to thermodynamics, a short excursion into the technology of heat transfer is useful to tie thermodynamics to real world devices. Heat transfer processes are never ideal and a study of the technology of heat transfer will develop an understanding of the trade offs in the design of the devices that actually accomplish the heat transfer. Heat transfer technology provides the basis on which heat exchangers are designed to accomplish the actual transfer of thermal energy.

### 12.1 Fundamental Modes of Heat Transfer

There are three fundamental modes of heat transfer.

## 1. Conduction.

2. Convection.
3. Radiation.

The temperature distribution in any system or medium is controlled by the combined effects of these three modes of heat transfer. In most situations one mode dominates and temperature distributions and heat fluxes can be obtained very accurately by only considering that mode. In general, heat transfer can be a multidimensional time dependent phenomena. However, for heat engines, transient heat transfer effects are not usually as important as steady state heat transfer phenomena and they will be neglected in discussion that follows.

[^3]
### 12.2 Conduction

Conduction occurs in stationary materials as a result of the vibrations of atoms or molecules in the materials. It is governed by Fourier's law of heat conduction, which in one dimension is written as,

$$
\begin{equation*}
Q_{x}=-k A \frac{\partial T}{\partial x} \quad \text { Btu/h or } \quad \mathrm{W} \tag{12.1a}
\end{equation*}
$$

or

$$
\begin{equation*}
q_{x}=\frac{Q_{x}}{A}=-k \frac{\partial T}{\partial x} \quad \mathrm{Btu} / \mathrm{h} / \mathrm{ft}^{2} \quad \text { or } \quad \mathrm{W} / \mathrm{m}^{2} \tag{12.1b}
\end{equation*}
$$

Simply stated the heat flow per unit area is proportional to the negative of the temperature gradient. The proportionality constant is called the thermal conductivity and it has units of watts $/ \mathrm{meter} / \mathrm{K}$ or $\mathrm{Btus} / \mathrm{ft} /{ }^{\circ} \mathrm{R}$. The thermal conductivities of typical materials vary widely by material and it also depends on the temperature of the materials. Some typical values are given in the Appendix for solids, liquids, and gases.

### 12.3 Convection

Heat transfer by convection occurs as the result of a moving fluid coming in contact with a fixed surface. The moving fluid carries the heat and deposits it on the surface or draws it out of the surface. There are two types of convection. In forced convection, the fluid is being driven or forced along by some mechanism other than thermal gradients at the surface. In free convection the fluid is moved along by thermal gradients or temperature differences at the surface. Convection obeys Newton's law of cooling given by,

$$
\begin{gather*}
Q=h A\left(T_{f}-T_{w}\right)  \tag{12.2a}\\
q=h\left(T_{f}-T_{w}\right) \tag{12.2b}
\end{gather*}
$$

$q$ in this case is the heat flux per unit area at the wall. The symbol $h$ is identified as the film heat transfer coefficient. It has units of Watts $/ \mathrm{m}^{2} / \mathrm{K}$ or Btu/ $\mathrm{hr} / \mathrm{ft}^{2} / \mathrm{R}$. Where $k$ in Eq. 12.1b, the thermal conductivity, is a function of only the material and its temperature, $h$, the film heat transfer coefficient, depends on the properties of the fluid, the temperature of the fluid, and the flow characteristics. Multiple correlations have been determined for calculating an appropriate $h$ for most materials and flow situations.
||

### 12.4 Radiation

Radiation heat transfer takes place by means of electromagnetic waves transmitted from one body to another. It does not require a medium and so can transfer heat across a vacuum. It is governed by the Stefan-Boltzmann radiation heat transfer equation,

$$
\begin{gather*}
Q=\varepsilon \sigma A_{1-2}\left(T_{1}^{4}-T_{2}^{4}\right)  \tag{12.3a}\\
q=\varepsilon \sigma\left(T_{1}^{4}-T_{2}^{4}\right) \tag{12.3b}
\end{gather*}
$$

The heat transferred in this case depends on the difference in the fourth power of the temperature of the two bodies. It also depends on a universal constant, $\sigma$, call the Stefan-Boltzmann constant equal to $5.6697 \times 10^{-8} \mathrm{~W} / \mathrm{m}^{2} \mathrm{~K}^{4}$. The variable $\varepsilon$ depends on the surface material of the two bodies and can depend on their temperatures as well. It is called the emissivity and varies between 0.0 and 1.0. The area factor $\mathrm{A}_{1-2}$, is the area viewed by body 2 of body 1 , and can become fairly difficult to calculate. Note that because the temperatures are raised to the 4th power and then differenced, radiation heat transfer must always be calculated based on absolute temperatures ( K or ${ }^{\circ} \mathrm{R}$ ). Both conduction and convection depend only on the linear differences of temperature and any consistent temperature scale will work.

Radiation heat transfer is important at very high temperatures and in a vacuum. However, for most designs involving terrestrial power plants, the heat transfer is dominated by conduction and convection, so radiation will not be treated extensively in this text. In addition, to get good quantitative results in analyzing radiation heat transfer problems, accurate calculation of the view factors, or $\mathrm{A}_{1-2}$, is required. The effort involved is well beyond the level of this text. Siegel and Howell by these authors refer interested students to the text.

Before going into more detailed analysis of the modes of heat transfer, it will be useful to provide the definitions of a number of terms of importance. These are provided in Table 12.1 below.

Example 12.1 A constant temperature difference of $300^{\circ} \mathrm{F}\left(166.7^{\circ} \mathrm{C}\right)$ is maintained across the surfaces of a slab of $0.1-\mathrm{ft}(0.0306-\mathrm{m})$ thickness. Determine the rate of heat transfer per unit area across the slab for each of the following cases. The slab material is copper ( $k=220 \mathrm{Btu} / \mathrm{h} . \mathrm{ft} .{ }^{\circ} \mathrm{F}$ or $380.7 \mathrm{~W} / \mathrm{m}{ }^{\circ} \mathrm{C}$ ), aluminum ( $k=130 \mathrm{Btu} / \mathrm{h}$. $\mathrm{ft} .{ }^{\circ} \mathrm{F}$ or $225.7 \mathrm{~W} / \mathrm{m}{ }^{\circ} \mathrm{C}$ ), carbon steel ( $k=10 \mathrm{Btu} / \mathrm{h} . \mathrm{ft} .{ }^{\circ} \mathrm{F}$ or $17.3 \mathrm{~W} / \mathrm{m}{ }^{\circ} \mathrm{C}$ ), brick $\left(k=0.5 \mathrm{Btu} / \mathrm{h} . \mathrm{ft} .{ }^{\circ} \mathrm{F}\right.$ or $\left.0.865 \mathrm{~W} / \mathrm{m}{ }^{\circ} \mathrm{C}\right)$, and asbestos $\left(k=0.1 \mathrm{Btu} / \mathrm{h} . \mathrm{ft} .{ }^{\circ} \mathrm{F}\right.$ or 0.173 W/m ${ }^{\circ} \mathrm{C}$ )

Solution The Fourier law for one-dimensional heat conduction is given by Eq. 12.1b:

Table 12.1 Definitions for terms of importance for heat transfer

| Blackbody | A body with a surface emissivity of 1 . Such a body will emit all of the thermal radiation it can (as described by theory), and will absorb $100 \%$ of the thermal radiation striking it. Most physical objects have surface emissivities less than 1 and hence do not have blackbody surface properties |
| :---: | :---: |
| Density, $\rho$ | The amount of mass per unit volume. In heat transfer problems, the density works with the specific heat to determine how much energy a body can store per unit increase in temperature. Its units are $\mathrm{kg} / \mathrm{m}^{3}$ |
| Emissive power | The heat per unit time (and per unit area) emitted by an object. For a blackbody, this is given by the Stefan-Boltzmann relation $\sigma T^{4}$ |
| Graybody | A body that emits only a fraction of the thermal energy emitted by an equivalent blackbody. By definition, a graybody has a surface emissivity less than 1 , and a surface reflectivity greater than zero |
| Heat flux, $q$ | The rate of heat flowing past a reference datum. Its units are W/m ${ }^{2}$ |
| Internal energy, $e$ | A measure of the internal energy stored within a material per unit volume. For most heat transfer problems, this energy consists just of thermal energy. The amount of thermal energy stored in a body is manifested by its temperature |
| Radiation view factor, $F_{12}$ | The fraction of thermal energy leaving the surface of object 1 and reaching the surface of object 2 , determined entirely from geometrical considerations. Stated in other words, $F_{12}$ is the fraction of object 2 visible from the surface of object 1 , and ranges from zero to 1 . This quantity is also known as the Radiation Shape Factor. Its units are dimensionless |
| Rate of heat generation, $q_{\text {gen }}$ | A function of position that describes the rate of heat generation within a body. Typically, this new heat must be conducted to the body boundaries and removed via convection and/or radiation heat transfer. Its units are $\mathrm{W} / \mathrm{m}^{3}$ |
| Specific heat, $c$ | A material property that indicates the amount of energy a body stores for each degree increase in temperature, on a per unit mass basis. Its units are J/kg-K |
| Stefan-Boltzmann constant, $\sigma$ | Constant of proportionality used in radiation heat transfer, whose value is $5.669 \times 10^{-8 \mathrm{~W}} / \mathrm{m}^{2}-\mathrm{K}^{4}$. For a blackbody, the heat flux emitted is given by the product of $\sigma$ and the absolute temperature to the fourth power |
| Surface emissivity $\varepsilon$ | The relative emissive power of a body compared to that of an ideal blackbody. In other words, the fraction of thermal radiation emitted compared to the amount emitted if the body were a blackbody. By definition, a blackbody has a surface emissivity of 1 . The emissivity is also equal to the absorption coefficient, or the fraction of any thermal energy incident on a body that is absorbed |
| Thermal conductivity, $k$ | A material property that describes the rate at which heat flows within a body for a given temperature difference. Its units are W/m-k |
| Thermal diffusivity, $\alpha$ | A material property that describes the rate at which heat diffuses through a body. It is a function of the body's thermal conductivity and its specific heat. A high thermal conductivity will increase the body's thermal diffusivity, as heat will be able to conduct across the body quickly. Conversely, a high specific heat will lower the body's thermal diffusivity, since heat is preferentially stored as internal energy within the body instead of being conducted through it. Its units are $\mathrm{m}^{2} / \mathrm{s}$ |

For the problem considered here $q$ should be constant everywhere in the medium since there are no heat sources or heat sinks in the slab. The integration of this equation across the slab for constant $q$ and $k$ gives;

$$
\left.q x\right|_{0} ^{L}=-\left.k T\right|_{T_{1}} ^{T_{2}}
$$

or

$$
q=k \frac{T_{1}-T_{2}}{L} \quad \mathrm{Btu} / \mathrm{h} \cdot \mathrm{ft}^{2}\left(\mathrm{orW} / \mathrm{m}^{2}\right)
$$

In the present problem $T_{1}-T_{2}=300^{\circ} \mathrm{F}, L=0.1 \mathrm{ft}$, and $k$ is specified for each material considered. Then, the heat fluxes, for copper, aluminum, carbon steel, brick, and asbestos, respectively, are given as $6.6 \times 10^{5}, 3.9 \times 10^{4}$, and $3 \times 10^{2} \mathrm{Btu} / \mathrm{h} . \mathrm{ft}^{2}$ (or $20.8 \times 10^{5}, 12.3 \times 10^{5}, 9.5 \times 10^{4}, 4.7 \times 10^{3}$, and $\left.9.5 \times 10^{2} \mathrm{~W} / \mathrm{m}^{2}\right)$. Note that the heat transfer rate is higher with a larger thermal conductivity.

Example 12.2 A fluid at $500^{\circ} \mathrm{F}\left(260^{\circ} \mathrm{C}\right)$ flows over a flat plate, which is kept at a uniform temperature of $100^{\circ} \mathrm{F}\left(82.2^{\circ} \mathrm{C}\right)$. If the heat transfer coefficient $h$ for convection is $20 \mathrm{Btu} / \mathrm{h} . \mathrm{ft}^{2} .{ }^{\circ} \mathrm{F}\left(113.5 \mathrm{~W} / \mathrm{m}^{2}{ }^{\circ} \mathrm{C}\right)$, determine the heat transfer rate per unit area of the plate from the fluid into the plate.

Solution Heat transfer by convection between a fluid and a solid surface is given by Eq. 12.2b

$$
q=h\left(T_{f}-T_{w}\right) \quad \text { Btu/h.ft }{ }^{2}\left(\text { or W } / \mathrm{m}^{2}\right)
$$

Taking $h=20 \mathrm{Btu} / \mathrm{h} . \mathrm{ft}^{2} .{ }^{\circ} \mathrm{F}$ (or $113.5 \mathrm{~W} / \mathrm{m}^{2}{ }^{\circ} \mathrm{C}$ ) and $T_{1}-T_{2}=500-100=400^{\circ} \mathrm{F}$ (or $222.2^{\circ} \mathrm{C}$ ), the heat flux at the wall becomes

$$
q=20 \times 400=8 \times 10^{3} \mathrm{Btu} / \mathrm{h} . \mathrm{ft}^{2}\left(\text { or } 25.2 \mathrm{~kW} / \mathrm{m}^{2}\right)
$$

Example 12.3 Two identical bodies radiate heat to each other. One body is at $30^{\circ} \mathrm{C}$ and the other at $250^{\circ} \mathrm{C}$. The emissivity of both is 0.7 . Calculate the net heat transfer per square meter.
Solution Using Eq. 12.3a, we can write the following analysis;

$$
\begin{aligned}
Q & =\varepsilon \sigma A\left(T_{1}^{4}-T_{2}^{4}\right) \\
& =0.7 \times 56.7 \times 10^{-9} \times 1 \times\left(523^{4}-303^{4}\right) \\
& =2635 \mathrm{~W}
\end{aligned}
$$

### 12.5 Heat Conduction in a Slab

The most general form of the steady state heat conduction equation occurs when the material through which the heat is transported also has an internal source of heat. So consider the slab geometry defined by Fig. 12.1.

The heat balance equation for a volume given by Adx will be,
Heat conducted out of Adx-Heat conducted into Adx $=$ Heat generated within Adx

Now assuming the overall heat flow is from left to right, the heat conducted into Adx will be given by

$$
q_{i n}=-\left.k A \frac{d T}{d x}\right|_{x}
$$

The heat conducted out will be

$$
\begin{aligned}
& q_{\text {out }}=-\left.k A \frac{d T}{d x}\right|_{x+d x}=-A\left[\left.k \frac{d T}{d x}\right|_{x}+\left.\frac{d}{d x} k \frac{d T}{d x}\right|_{x} d x+\left.\frac{1}{2} \frac{d^{2}}{d x^{2}} k \frac{d T}{d x}\right|_{x} d x^{2} \ldots\right] \\
& q_{\text {out }} \approx-A\left[\left.k \frac{d T}{d x}\right|_{x}+\left.\frac{d}{d x} k \frac{d T}{d x}\right|_{x} d x\right]
\end{aligned}
$$

Then identifying the heat generation rate per unit volume as $\mathrm{Q}(\mathrm{x})$ the balance equation becomes

$$
\begin{gathered}
q_{\text {out }}-q_{\text {in }}=Q(x) A d x=-A\left[\left.k \frac{d T}{d x}\right|_{x}+\left.\frac{d}{d x} k \frac{d T}{d x}\right|_{x} d x\right]+\left.k A \frac{d T}{d x}\right|_{x} \\
Q(x) d x=-\left.\frac{d}{d x} k \frac{d T}{d x}\right|_{x} d x
\end{gathered}
$$

Fig. 12.1 Slab with internal heat source

If $k$ is not a function of position or temperature then,

$$
\begin{equation*}
\frac{Q(x)}{k}=-\frac{d^{2} T}{d x^{2}}=-\nabla^{2} T(x) \tag{12.4}
\end{equation*}
$$

This is a form of the classic Poisson's equation. The $\nabla^{2}$ operator is indicated because when the equation is generalized to two or three dimensions, the two or three-dimensional version of this operator gives the correct form of the equation. Of course, if the heat source is not present then the equation reduces to Laplace's equation.

$$
\begin{equation*}
\nabla^{2} T=0 \tag{12.5}
\end{equation*}
$$

### 12.6 Heat Conduction in Curve-Linear Geometries

Solving the two or three dimensional heat transfer equation is a difficult problem in the general case. However, for most heat transfer situations of interest to nuclear engineering one-dimensional solutions are usually all that is required. However, many times those solutions require the equation to be written in curvi-linear geometry, either cylindrical or spherical coordinates. Poisson's equation in cylindrical coordinates is

$$
\begin{equation*}
\frac{Q(r)}{k}=-\left(\frac{1}{r} \frac{d}{d r} r \frac{d T}{d r}\right)=-\left(\frac{1}{r} \frac{d T}{d r}+\frac{d^{2} T}{d r^{2}}\right) \tag{12.6}
\end{equation*}
$$

And in spherical coordinates,

$$
\begin{equation*}
\frac{Q(\rho)}{k}=-\left(\frac{1}{\rho^{2}} \frac{d}{d \rho} \rho^{2} \frac{d T}{d \rho}\right)=-\left(\frac{2}{\rho} \frac{d T}{d \rho}+\frac{d^{2} T}{d \rho^{2}}\right) \tag{12.7}
\end{equation*}
$$

Now integrating Poisson's Equation for a constant Q in cylindrical coordinates gives

$$
\begin{gathered}
\int_{r_{1}}^{r} Q r d r=-k \int_{r_{1}}^{r} \frac{1}{r} \frac{d}{d r} r \frac{d T}{d r} r d r=-k\left[r \frac{d T}{d r}-\left.r_{1} \frac{d T}{d r}\right|_{r_{1}}\right] \\
Q\left(\frac{r^{2}}{2}-\frac{r_{1}^{2}}{2}\right)=\left.k r_{1} \frac{d T}{d r}\right|_{r_{1}}-k r \frac{d T}{d r}
\end{gathered}
$$

Note that the first term on the right hand side is simply the heat being transferred into or out of the surface at $r_{1}$. Separating terms and integrating again gives,

$$
\begin{align*}
& \frac{Q r^{2}}{2}-\frac{Q r_{1}^{2}}{2}-\left.k r_{1} \frac{d T}{d r}\right|_{r_{1}}=-k r \frac{d T}{d r} \\
& \frac{Q r}{2} d r-\left(\frac{Q r_{1}^{2}}{2}+\left.k r_{1} \frac{d T}{d r}\right|_{r_{1}}\right) \frac{d r}{r}=-k d T  \tag{12.8}\\
& Q\left(\frac{r^{2}}{4}-\frac{r_{1}^{2}}{4}\right)-\left(\frac{Q r_{1}^{2}}{2}-\left.k r_{1} \frac{d T}{d r}\right|_{r_{1}}\right) \ln \left(\frac{r}{r_{1}}\right)=k\left(T_{1}-T\right)
\end{align*}
$$

There are two unknown constants of integration in this case, namely the heat flux on the surface at $r=r_{I}$ and the temperature $T_{l}$ on that surface. Since the outer surface has not been specified yet, and there will be boundary conditions on it, both of the inner boundary constants cannot be specified independent of the outer surface boundary conditions. In the fuel pin case where $r_{l}$ is taken as 0 , the derivative term at $r_{1}$ must be zero and the equation simplifies to,

$$
\begin{align*}
& \frac{Q r_{2}^{2}}{4}=k\left(T_{1}-T_{2}\right) \\
& O r  \tag{12.9}\\
& Q \pi r_{2}^{2}=4 \pi k\left(T_{1}-T_{2}\right)
\end{align*}
$$

The term on the left hand side is simply the linear heat rate and $T_{1}$ is a function of $T_{2}$ and this heat rate. A boundary condition at $r_{2}$ is required in order to specify $T_{2}$. Normally the boundary condition at $r_{2}$ is given in terms of some kind of a heat flux, or a derivative boundary condition. It would be unrealistic to set $T_{2}$ to a specified value because that would assume that the heat flux could be adjusted to hold it at this value. A second simplification of Eq. 12.8 occurs for the case of no heat production in the region of interest. In that case, Eq. 12.9 simplifies to

$$
\begin{gather*}
-\left(\left.k \frac{d T}{d r}\right|_{r_{1}}\right) r_{1} \ln \left(\frac{r}{r_{1}}\right)=k\left(T_{1}-T\right) \\
T_{2}-T_{1}=\left.\frac{d T}{d r}\right|_{r_{1}} r_{1} \ln \left(\frac{r_{2}}{r_{1}}\right)=-\frac{q_{1}}{k} r_{1} \ln \left(\frac{r_{2}}{r_{1}}\right) \tag{12.10}
\end{gather*}
$$

Example 12.3 Consider a fuel pin with a linear heat rate of $300 \mathrm{~W} / \mathrm{cm}$ and a radius of 0.41 cm and a thermal conductivity of $2.0 \mathrm{~W} / \mathrm{m} / \mathrm{K}$. Neglect the clad for the present. It is cooled by water flowing by with a bulk temperature of 585 K and a film heat transfer coefficient $20,000 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}$. Estimate the surface temperature of the fuel pin and its centerline temperature.

Solution First obtain the volumetric heat rate

$$
Q=\frac{300 \mathrm{~W} / \mathrm{cm}}{\pi(0.41)^{2}}=568 \mathrm{~W} / \mathrm{cm}^{3}
$$

Then the heat flux into the fluid is given by

$$
\begin{aligned}
& 300 \mathrm{~W} / \mathrm{cm} * 100=\pi 2 r * h\left(T_{s}-T_{b}\right)=\pi * 2 * 0.0041 * 20,000 *\left(T_{s}-585\right) \\
& T_{s}=585+\frac{30,000}{2 * \pi * 0.0041 * 20,000}=643.2 \mathrm{~K}
\end{aligned}
$$

Then applying Eq. 12.9 gives

$$
\begin{aligned}
& Q \pi r^{2}=4 \pi k\left(T_{1}-T_{s}\right)=300=4 \pi * \frac{2.0}{100}\left(T_{1}-643.2\right) \\
& T_{1}=643.2+\frac{300}{4 \pi^{*} 0.02}=1836.6 \mathrm{~K}
\end{aligned}
$$

Example 12.4 Hot water is flowing through a thick tube and is being cooled by water flowing on the outside of the tube. The temperature of the hot water is 600 K . The temperature of the cold water is 400 K . The film heat transfer coefficient for the hot water is $20,000 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}$ and the film heat transfer coefficient for the cold water is $100,000 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}$. The tube is 3 mm thick with an inner diameter of 1.5 cm and has a thermal conductivity of $16.7 \mathrm{~W} / \mathrm{m} / \mathrm{K}$. Calculate the surface temperatures of the tube.

Solution The key is realizing that the same amount of heat is flowing through all three materials. We have

$$
\begin{aligned}
& q=h_{\text {cold }}\left(T_{\text {outer surface }}-T_{\text {cold water }}\right) \\
& q=\frac{k}{r_{1} \ln \frac{r_{2}}{r_{1}}}\left(T_{\text {inner surface }}-T_{\text {outer surface }}\right) \\
& q=h_{\text {hot }}\left(T_{\text {hot water }}-T_{\text {inner surface }}\right)
\end{aligned}
$$

$$
\begin{aligned}
& 20,000\left(600-T_{\text {innersurface }}\right)=\frac{16.7}{0.00273}\left(T_{\text {innersurface }}-T_{\text {outersurface }}\right) \\
& 100,000\left(T_{\text {outersurface }}-400\right)=\frac{16.7}{0.00273}\left(T_{\text {innersurface }}-T_{\text {outersurface }}\right) \\
& 3.269\left(600-T_{i s}\right)=T_{i s}-T_{\text {os }} \quad 1961.4=4.269 T_{i s}-T_{\text {os }} \\
& T_{\text {os }}=4.269 T_{i s}-1961.4 \quad 16.347\left(T_{\text {os }}-400\right)=T_{i s}-T_{\text {os }} \\
& 6538.8=17.347 T_{\text {os }}-T_{\text {is }} \\
& 6538.8=17.347\left(4.269 T_{\text {is }}-1961.4\right)-T_{\text {is }} \\
& 6538.8+17.347 * 1961.4=(17.347 * 4.269-1) T_{\text {is }}
\end{aligned}
$$

$$
T_{i s}=555.24 \mathrm{~K} \quad T_{o s}=4.269 * 555.24-1961.4=408.9 \mathrm{~K}
$$

Now consider the integral of the Poisson Equation in spherical geometry.

$$
\begin{aligned}
& \int_{r_{1}}^{r} Q r^{2} d r=-k \int_{r_{1}}^{r} \frac{1}{r^{2}} \frac{d}{d r} r^{2} \frac{d T}{d r} r^{2} d r \\
& Q\left(\frac{r^{3}}{3}-\frac{r_{1}^{3}}{3}\right)=-k\left(r^{2} \frac{d T}{d r}-\left.r_{1}^{2} \frac{d T}{d r}\right|_{r_{1}}\right) \\
& \frac{Q r}{3} d r-\left(\frac{Q r_{1}^{3}}{3}+\left.k r_{1}^{2} \frac{d T}{d r}\right|_{r_{1}}\right) \frac{d r}{r^{2}}=-k d T \\
& Q\left(\frac{r^{2}}{6}-\frac{r_{1}^{2}}{6}\right)+\left(\frac{Q r_{1}^{3}}{3}+\left.k r_{1}^{2} \frac{d T}{d r}\right|_{r_{1}}\right)\left(\frac{1}{r}-\frac{1}{r_{1}}\right)=k\left(T_{1}-T\right)
\end{aligned}
$$

Then for the case where $r_{1}=0$, this reduces to

$$
\begin{equation*}
\frac{Q r_{2}^{2}}{6}=k\left(T_{1}-T_{2}\right) \tag{12.11}
\end{equation*}
$$

Note that a heat rate per sphere could be defined as

$$
Q_{\text {sphere }}=\frac{4}{3} \pi r^{3} Q
$$

In addition, Eq. 12.11 can be written as

$$
Q_{\text {sphere }}=8 \pi r_{2} k\left(T_{1}-T_{2}\right)
$$

And for the case of no heat generation within the shell,

$$
\begin{equation*}
\left.k \frac{d T}{d r}\right|_{r_{1}} r_{1}^{2}\left(\frac{1}{r_{2}}-\frac{1}{r_{1}}\right)=k\left(T_{1}-T_{2}\right) \tag{12.12}
\end{equation*}
$$

Example 12.5 Estimate the maximum amount of heat that can be generated per spherical particle with a radius of 0.5 mm contained in a shell of pyrolytic carbon 0.1 mm thick. The outer surface of the particle will be maintained at $700^{\circ} \mathrm{K}$ by a very efficient heat removal system. The peak temperature allowed for the uranium dioxide in the fuel particle is $1800^{\circ} \mathrm{K}$. The average thermal conductivity for uranium dioxide is $3.0 \mathrm{~W} / \mathrm{m} / \mathrm{K}$. The average thermal conductivity for pyrolytic carbon is $2.0 \mathrm{~W} / \mathrm{m} / \mathrm{K}$.

Solution For the sphere

$$
Q_{\text {sphere }, \max }=8 \pi r_{2} k\left(T_{1}-T_{2}\right)=8 \pi * 0.0005 * 3.0 *\left(1800-T_{s}\right)=0.0377\left(1800-T_{s}\right)
$$

For the shell

$$
\begin{aligned}
& \left.k \frac{d T}{d r}\right|_{r_{1}} r_{1}^{2}\left(\frac{1}{r_{2}}-\frac{1}{r_{1}}\right)=k\left(T_{1}-T_{2}\right) \\
& \left.4 \pi r_{1}^{2} k \frac{d T}{d r}\right|_{r_{1}}=4 \pi r_{1}^{2} \frac{k}{r_{1}^{2}\left(\frac{1}{r_{2}}-\frac{1}{r_{1}}\right)}\left(T_{s}-700\right) \\
& Q_{\text {sphere, } \max }=-4 \pi \frac{2.0}{\left(\frac{1}{0.0006}-\frac{1}{0.0005}\right)}\left(T_{s}-700\right) \\
& Q_{\text {sphere, } \max }=0.0754\left(T_{s}-700\right)
\end{aligned}
$$

Then

$$
\begin{aligned}
T_{s} & =700+\frac{Q_{\text {sphere }, \max }}{0.0754} \\
Q_{\text {spher }, \max } & =0.0377\left(1800-700-\frac{Q_{\text {sphere }, \max }}{0.0754}\right) \\
1.5 Q_{\text {sphere }, \max } & =41.47 \\
Q_{\text {sphere }, \max } & =27.6 \mathrm{~W}
\end{aligned}
$$

### 12.7 Convection

Convection is more complicated than conduction and depends much more on the configuration of the heat transfer media than conduction. However, it has been analyzed in detail for many different configurations and as a result, efficient prediction of convection results depends on finding the correct analysis for the problem under consideration.

There are several ways of categorizing convection results. The most basic is dividing convection into forced convection and free convection. In forced convection, a pressure drop drives the heat transport media or fluid and the velocity of the fluid does not depend on the heat transfer or thermal gradients. In free convection, there is no pressure drop driving the fluid and its velocity develops because of the buoyancy of the fluid and thermal gradients. Forced convection is by far the most common in heat exchangers and nuclear reactors.

The second way of dividing convection is into internal flows and external flows. Internal flows are typically flows with in a pipe or pipe-like structure. The flow is confined and there is no free surface. External flows deal with flows on a surface and are generally bounded on only one side. However, pipes or other confining media can be so large that what happens on one surface is not influenced by other confining surfaces and therefore the flow can be treated as an external flow.

### 12.8 Boundary Layer Concept

In most convection situations, the transition from the bulk temperature of the fluid to the temperature of the confining surface occurs over a very short distance very close to the surface. The velocity of the fluid and its temperature must match the velocity of the wall, usually zero, and the temperature of the wall. The transition from the bulk fluid velocity and the bulk fluid temperature occurs over a very thin region in the fluid called the boundary layer. A physical description of the boundary layer is provided in Fig. 12.2.

Figure 12.2 describes the development of the velocity and thermal boundary layers over a flat plate. The outer boundaries of each are defined by where the velocity reaches $99 \%$ of its free stream value and the temperature difference between the fluid and the wall reaches $99 \%$ of its ultimate value. There is no reason that the two boundary layers should be the same thickness, but sometimes they are taken to be so to simplify the analysis. In the case of the external flow over a flat plate, both boundary layers start at zero thickness at the start of the plate and grow continuously along the plate. In order to predict the heat transfer on the plate, it is important to track the growth of the velocity boundary layer as well as the thermal boundary layer.

At the start of the flat plate, the velocity profile varies in a very smooth manner almost parabolic in the distance from the plate. The fluid flows in smooth layers over the plate with each layer moving in a stable manner. This is called laminar flow. The heat transfer is basically by a conduction mechanism between layers. As the fluid travels down the plate, eventually the layers become unstable and packets of fluid move transverse to the plate in random motions. The flow becomes turbulent. In this case, the packets of fluid transport heat as they move within the boundary layer. The transition from laminar flow to turbulent flow is controlled by the ration of the inertia forces in the boundary layer to the viscous forces in the boundary layer. This ratio is given by

Fig. 12.2 Velocity and thermal boundary layers for laminar flow over a flat plane [5]

Fig. 12.3 Boundary layer concept for flow along a flat plate [5]

$$
\begin{equation*}
\mathrm{Re}=\frac{\text { InertiaForce }}{\text { ViscousForce }}=\frac{\rho V^{2} / L}{\mu V / L^{2}}=\frac{\rho V L}{\mu}=\frac{V L}{v} \tag{12.13}
\end{equation*}
$$

Moreover, it is called the Reynolds number after Osborne Reynolds who first recognized its importance in characterizing the flow through pipes. Note that it is dimensionless and is simply a number. Typically around $\mathrm{Re}=2300$ flow over a smooth plate will transition from laminar to turbulent flow. Of course, this can vary depending on the roughness of the plate and the smoothness of the flow upstream of the plate. A better description of the phenomena in a transitioning boundary layer is presented in Fig. 12.3.

Since heat transfer in the turbulent boundary layer is greater, it is often desirable to "trip" the boundary layer near the front of the plate by adding roughness or irregularities to cause an immediate transition to turbulent flow. However, turbulent flow does cause a greater drag on the flat plate and will cause a greater friction force attempting to slow the flow over the plate. The trade between increased heat transfer and increased drag will be important to the design of heat exchangers. The drop in pressure required to obtain the desired heat transfer represents the mechanical cost of the heat transfer.

The flow over a curved surface complicates the boundary layer flow even more. Consider Fig. 12.4. The fluid approaches the curved body from the left. As the fluid

Fig. 12.4 Boundary layer separation for flow over a curved body [5]

Fig. 12.5 Flow around a circular cylinder as Reynolds number varies [5]
approaches, the pressure builds up in the fluid as the body slows it down. Then as the fluid flows over the body, the pressure decreases due to flow speeding up. The boundary layer on the front surface is compressed because of the higher pressure but expands as the pressure decreases. Eventually as the flow turns the corner and moves down the backside of the body, the flow separates due to a loss of energy in the boundary layer. This produces a low pressure on the backside of the curved body increasing the drag that the fluid sees significantly.

A quantitative description of the flows across a cylinder as a function of the Reynolds number is given by Fig. 12.5. Note that in this case the Reynolds number used to categorize the flows is based on the diameter of the cylinder.

$$
\begin{equation*}
\operatorname{Re}=\frac{\rho V D}{\mu} \tag{12.14}
\end{equation*}
$$

Flow over a flat plate, or over a curved surface (circular cylinder), provide the basis for most film heat transfer correlations for forced convection in external flows. Free convection produces significantly different boundary layer phenomena and additional variables come into play. The free convection scenario of most interest is on a vertical flat plate, or tube, and gravitational forces and the buoyancy of the fluid become important. Two typical scenarios are described in Fig. 12.6.

The flow is significantly more complicated than that in forced convection.
Moving on to internal flow heat transfer, the development of the flow pattern for laminar flow is described in Fig. 12.7.

At the entrance to the tube, the flow is uniform across the tube surface area. However, the boundary layer builds up on all internal surfaces until there is no flow outside of the boundary layer. When this occurs, the velocity profile within the tube takes on a parabolic shape and maintains that shape for the rest of the tube length. Typically, the region near the entrance while the flow is developing varies from 10 to 60 diameters for very smooth tubes. If the flow is turbulent, the velocity profile is much flatter. Once again, the transition from laminar to turbulent flow occurs at a Reynolds number of approximately 2300 . Since turbulent flows generally give the better heat transfer, roughness at the entrance may be included to transition to turbulent flow at a significantly lower Reynolds number.

Heat transfer to or from the fluid flowing in the tube depends on the surface conditions of the tube. Two surface conditions are usually used to characterize the heat transfer to the fluid. The first condition is that of a uniform surface temperature

Fig. 12.6 The velocity boundary layer for free convection on a vertical plate [5]
for the tube. In this case, since the tube surface temperature does not change the difference between the fluid mean temperature and the surface temperature decays

Fig. 12.7 Development of the flow pattern at the entrance of a circular tube [5]

Fig. 12.8 a Mean fluid and surface temperatures-constant surface temperature. b Mean fluid and surface temperatures-constant heat flux
exponentially from the difference at the inlet. The second condition is that of a uniform heat flux into or out of the tube along its length. For this case, the mean fluid temperature increases or decreases linearly from the inlet, and the surface temperature of the tube moves to a constant difference from the mean fluid temperature after entrance effects have died out. Typical results for both conditions are shown in Fig. 12.8a and b.

As should be obvious, heat transfer by convection can be very different depending on the geometry of the situation and the flow pattern. Fortunately, a great deal of work has been competed in the past and heat transfer correlations are available for most problems of interest. These correlations or solutions for various flow patterns and conditions are normally expressed in terms of dimensionless groups of parameters relevant to the convection problem of interest.

### 12.9 Dimensionless Numbers or Groups

Much like the Reynolds number that represents the ratio of inertial forces to viscous forces there are a number of dimensionless groups that allow analysis of many convective heat transfer problems based on general solutions. The second of these dimensionless numbers that is of interest is the Prandtl number. It is the ratio of the kinematic viscosity to the thermal diffusivity or the ratio of the momentum and thermal diffusivities.

$$
\begin{equation*}
\operatorname{Pr}=\frac{v}{\alpha}=\frac{\mu / \rho}{k / \rho C_{p}}=\frac{\mu C_{p}}{k} \tag{12.15}
\end{equation*}
$$

For a Prandtl number of 1.0 , the thermal boundary layer and velocity boundary layer are the same thickness.

Typical values for some fluids are,

| Air | $\sim 0.71$ |
| :--- | :--- |
| Water | $\sim 0.8-2.0$ |
| Liquid metals | $\sim 0.003-0.03$ |
| Oils | $\sim 100-50,000$ |

Flow patterns and heat transfers are generally so different for the three ranges of Prandtl numbers above that different heat transfer correlations will be required for each of the three ranges. Corrections based on Prandtl numbers will be useful within the three different ranges.

Perhaps the most important dimensionless group for convection heat transfer is the Nusselt number. The Nusselt number represents the ratio of convection to pure conduction heat transfer and is given by,

$$
\begin{equation*}
N u=\frac{h L}{k} \tag{12.16}
\end{equation*}
$$

Most heat transfer correlations would relate the Nusselt number to other dimensionless numbers characterizing the flow pattern of interest. Then the film heat transfer coefficient h , can be calculated knowing the thermal conductivity of the fluid and the appropriate length of interest. Often the length of interest will be the diameter of the tube through which the flow is passing or an equivalent diameter for non-circular flow paths. This introduces a term that allows conversion of non-circular flow paths to equivalent ones called the hydraulic diameter. The hydraulic diameter is defined as four times the flow area divided by the wetted perimeter of the flow channel.

$$
\begin{equation*}
D_{h}=\frac{4 A}{P_{\text {wetted }}} \tag{12.17}
\end{equation*}
$$

The Nusselt number is the direct connection to the calculation of the film heat transfer coefficient.

A modified form of the Nusselt number that is often used instead is the Stanton number. The Stanton number is defined as the Nusselt number divided by the Reynolds number and the Prandtl number.

$$
\begin{gather*}
S t=\frac{N u}{\mathrm{Re}^{*} \operatorname{Pr}} N u=S t * \mathrm{Re}^{*} \operatorname{Pr}  \tag{12.18}\\
S t=\frac{h}{\rho V C_{p}} \tag{12.19}
\end{gather*}
$$

The Stanton number is particularly useful for fluids that have Prandtl numbers close to 1.0 .

An additional number that is often used to correlate heat transfer is the Peclet number. It is simply the product of the Reynolds number and the Prandtl number.

$$
\begin{equation*}
\operatorname{Pe}=\operatorname{Re}^{*} \operatorname{Pr}=\rho V L / \mu * C_{p} \mu / k=\frac{V L}{C_{p} / \rho k}=\frac{V L}{\alpha} \tag{12.20}
\end{equation*}
$$

Since the pressure drop through a channel is the mechanical energy that must be paid in order to accomplish heat transfer, it is essential to have correlations that predict the pressure drops. This introduces another set of dimensionless numbers. The first of these is the friction factor given by

$$
\begin{equation*}
f=\frac{\Delta p}{(L / D)\left(\rho V^{2} / 2\right)} \tag{12.21}
\end{equation*}
$$

Note that L/D is also a dimensionless number and in using any correlation, it is important to know if this ratio was included when the friction factor correlation was developed. Obviously the pressure drop will be greater the longer the flow channel.

The second parameter of interest for predicting pressure drops is the coefficient of friction. It is defined by

$$
\begin{equation*}
C_{f}=\frac{\tau_{s}}{\rho V^{2} / 2} \tag{12.22}
\end{equation*}
$$

$\tau_{s}$ is the wall shear stress. The coefficient of friction is more fundamental than the friction factor and can be applied to geometries other that internal flow in tubes.

These dimensionless parameters are enough to address most forced convection heat transfer situations. Additional parameters will be required for high speed flows or for free convection. For details on these parameters and how they are used refer to a standard heat transfer text such as Incropera et al. in the References section.

Example 12.6 Estimate the friction pressure drop in a PWR flow channel if the flow rate of the water is $1.25 \mathrm{~m} / \mathrm{s}$ and the effective temperature is 600 K . The hydraulic diameter for the channel is 1.18 cm and its length is 363 cm . The friction factor is given by

$$
f=0.184 \operatorname{Re}_{D}^{-1 / 5}
$$

Solution Calculating the fluid properties

$$
\begin{gathered}
\rho=648.9 \mathrm{~kg} / \mathrm{m}^{3} \\
C_{p}=7000.0 \\
\mu=8.10 E-5 \\
k=0.497 \\
\operatorname{Re}=\frac{648.9 * 1.25 * 0.0118}{8.10 E-5}=118,164 \\
f=0.184 \operatorname{Re}_{D}^{-0.2}=\frac{0.184}{118,163^{0.2}}=0.0178 \\
\Delta p=L / D \frac{\rho V^{2}}{2} f=\frac{363}{1.18} \frac{648.9 * 1.25^{2}}{2} 0.0178=5.55 \mathrm{kPa}
\end{gathered}
$$

### 12.10 Correlations for Common Geometries

Over a Flat Plate The two correlations of interest for a flat plate will be those that give the average coefficient of friction and the average Nusselt number for a plate of length L [1]. For laminar flow and an isothermal plate they are

$$
\begin{gather*}
C_{f, L}=1.328 \operatorname{Re}_{L}^{-1 / 2}  \tag{12.23}\\
N u_{L}=0.664 \operatorname{Re}_{L}^{1 / 2} \operatorname{Pr}^{1 / 3} \tag{12.24}
\end{gather*}
$$

These equations apply to gases and liquids with Prandtl numbers near 1.0. The properties should be evaluated at the average temperature between that of the fluid and that of the plate. For fluids with very small Prandtl numbers, a better Nusselt number correlations is,

$$
\begin{equation*}
N u_{L}=1.13 P e_{L}^{1 / 3} \tag{12.25}
\end{equation*}
$$

which is good for Prandtl numbers less than 0.05 and Peclet numbers greater than 100.

For turbulent flow over a flat isothermal plate the friction factor is given by,

$$
\begin{equation*}
C_{f, L}=0.1184 \mathrm{Re}^{-1 / 5} \tag{12.26}
\end{equation*}
$$

The Nusselt number is given by

$$
\begin{equation*}
N u_{L}=0.0592 \operatorname{Re}_{L}^{4 / 5} \operatorname{Pr}^{1 / 3} \tag{12.27}
\end{equation*}
$$

Of course, for smooth flow at the front of the flat plate the first part of the heat transfer will have to be calculated with the laminar equations up until the transition point (nominally $\operatorname{Re} \sim 2300$ ) and then the turbulent equations used thereafter. If the front edge of the flat plate is rough, enough no laminar regions will exist and the turbulent equations can be used for the whole length of the plate.

For the case of a flat plate with a constant heat flux, the equation for the Nusselt number in laminar flow is,

$$
\begin{equation*}
N u_{L}=0.906 \operatorname{Re}_{L}^{1 / 2} \operatorname{Pr}^{1 / 3} \tag{12.28}
\end{equation*}
$$

And the equation for turbulent flow with a constant heat flux is,

$$
\begin{equation*}
N u_{L}=0.616 \operatorname{Re}_{L}^{4 / 5} \operatorname{Pr}^{1 / 3} \tag{12.29}
\end{equation*}
$$

Example 12.7 Many early reactors were built with flat plate aluminum fuel elements. Calculate the film heat transfer coefficient and coefficient of friction for flow across a flat plate 0.5 m in length at a water velocity of $1.5 \mathrm{~m} / \mathrm{s}$. The bulk water temperature is 350 K and the fuel plate surface temperature is 365 K . Assume a constant heat flux from the plate.

Solution Evaluating the water properties at the mid film temperature 357.5 K

$$
\begin{aligned}
\rho & =973.7-\frac{357.5-350}{400-350}(973.7-937.2)=973.7-0.15 * 36.5=968.2 \mathrm{~kg} / \mathrm{m}^{3} \\
C_{p} & =4195.0+0.15 *(4256-4195)=4204.2 \mathrm{~J} / \mathrm{kg} / \mathrm{K} \\
\mu & =3.43 E-04-0.15 *(3.43-2.17) E-04=3.24 E-04 \mathrm{~N} * \mathrm{~s} / \mathrm{m}^{2} \\
k & =0.668+0.15 *(0.688-0.668)=0.672 \mathrm{~W} / \mathrm{m} / \mathrm{K} \\
\operatorname{Re} & =\frac{968.2 * 1.5 * 0.5}{3.24 E-4}=2,241,204 \\
\operatorname{Pr} & =\frac{3.24 E-4 * 4204.2}{0.672}=2.027
\end{aligned}
$$

Clearly the flow is turbulent and for a constant heat flux,

$$
\begin{aligned}
N u_{L} & =0.616 \operatorname{Re}_{L}^{4 / 5} \operatorname{Pr}^{1 / 3}=0.616 * 2241204^{0.8} 2.027^{0.3333}=93,810.3 \\
h & =\frac{0.672}{0.5} 93,810.3=126,081 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}
\end{aligned}
$$

The coefficient of friction is

$$
C_{f, L}=0.1184 \mathrm{Re}^{-1 / 5}=\frac{0.1184}{2241204^{0.2}}=0.00636
$$

Along Circular Tubes The same two correlations are of interest for flow in and around circular tubes, though the friction factor usually replaces the coefficient of friction. The friction factor for fully developed laminar flow is given by [1],

$$
\begin{equation*}
f=\frac{64}{\operatorname{Re}_{D}} \tag{12.30}
\end{equation*}
$$

For fully developed turbulent flow there are two correlations.

$$
\begin{align*}
& f=0.316 \operatorname{Re}_{D}^{-1 / 4} \text { below } \operatorname{Re}=20,000  \tag{12.31}\\
& f=0.184 \operatorname{Re}_{D}^{-1 / 5} \text { above } \operatorname{Re}=20,000
\end{align*}
$$

For an isothermal boundary condition on the inside of the tube, the laminar flow correlation for fully developed flow is,

$$
\begin{equation*}
N u_{D}=3.66 \tag{12.32}
\end{equation*}
$$

For a constant heat flux, the laminar flow correlation is,

$$
\begin{equation*}
N u_{D}=4.36 \tag{12.33}
\end{equation*}
$$

For turbulent flow with small to moderate temperature differences between the surface and the fluid mean temperature the Dittus-Boelter correlation is,

$$
\begin{equation*}
N u_{D}=0.023 \operatorname{Re}_{D}^{4 / 5} \operatorname{Pr}^{n} \tag{12.34}
\end{equation*}
$$

Where $n=0.4$ if the fluid is being heated and $n=0.3$ if the fluid is being cooled. This correlation is satisfactory if $0.6<\operatorname{Pr}<160, \operatorname{Re}_{D}>10,000$, and $L / D>10$.

For large temperature differences, a slightly better correlation is given by

$$
\begin{equation*}
N u_{D}=0.027 \operatorname{Re}_{D}^{4 / 5} \operatorname{Pr}^{1 / 3}\left(\frac{\mu}{\mu_{s}}\right) \tag{12.35}
\end{equation*}
$$

which, is good for $0.7<\operatorname{Pr}<16,700, \operatorname{Re} e_{D} 10,000$, and $L / D>10$. All properties except $\mu_{s}$ are evaluated at the mean fluid temperature.

In this case these two correlations may be applied to both a constant surface temperature condition and a constant heat flux condition.

Fig. 12.9 Flow channel between four tubes

All of the above correlations were developed for flow within tubes. For the flow along the outside of tubes in an array, a simple trick is used to apply these correlations to this case. Consider the array of four tubes in Fig. 12.9 below.

The flow channel between the tubes can be treated as flow within a cylindrical tube if the hydraulic diameter is adjusted properly. The hydraulic diameter is calculated as,

$$
\begin{equation*}
D_{h}=\frac{4 * \text { Area }}{\text { Wetted Perimeter }}=\frac{4 *\left(p^{2}-\pi r^{2}\right)}{2 \pi r} \tag{12.36}
\end{equation*}
$$

Then all of the above correlations apply. Note that this model assumes no cross flow, all of the flow is exactly along the tubes.

Example 12.8 At a point in a Boiling Water Reactor (BWR) the water temperature is $270^{\circ} \mathrm{C}$ and the clad surface temperature is $300^{\circ} \mathrm{C}$. The diameter of the fuel rods is 1.25 cm and they are spaced on a square matrix with a pitch of 1.62 cm . The water is flowing at the rate of $2 \mathrm{~m} / \mathrm{s}$. Calculate the film heat transfer coefficient using the correlation for a large temperature drop across the thermal boundary layer.
Solution For a large temperature drop, the properties are evaluated at the mean fluid temperature, in this case $285^{\circ} \mathrm{C}$.

$$
\begin{aligned}
\rho & =831.3-\frac{558-500}{600-500}(831.3-648.9)=831.3-0.58 * 182.4=725.5 \mathrm{~kg} / \mathrm{m}^{3} \\
C_{p} & =4660.0+0.58 *(7000-4660)=6017.2 \mathrm{~J} / \mathrm{kg} / \mathrm{K} \\
\mu & =1.18 E-04-0.58 *(1.18-0.810) E-4=9.65 E-5 N^{*} \mathrm{~s} / \mathrm{m}^{2} \\
k & =0.642-0.58 *(0.642-0.497)=0.558 \mathrm{~W} / \mathrm{m} / \mathrm{K} \\
\operatorname{Pr} & =\frac{\mu C_{p}}{k}=\frac{9.65 E-5 * 6017.2}{0.558}=1.0406 \\
\mu_{s} & =1.18 E-04-0.73 *(1.18-0.810) E-4=9.099 E-5 \mathrm{~N} * \mathrm{~s} / \mathrm{m}^{2}
\end{aligned}
$$

The hydraulic diameter is calculated as

$$
\begin{aligned}
D_{h} & =\frac{4^{*}\left(p^{2}-\pi r^{2}\right)}{2 \pi r}=\frac{4\left(1.62^{2}-\pi\left(\frac{1.25}{2}\right)^{2}\right.}{\pi 1.25}=1.423 \mathrm{~cm} \\
\operatorname{Re} & =\frac{725.5 * 2 * 0.01423}{9.65 E-5}=213,966 \\
N u_{D} & =0.027 \operatorname{Re}_{D}^{4 / 5} \operatorname{Pr}^{1 / 3}\left(\frac{\mu}{\mu_{s}}\right)=0.027 * 213,966^{0.8} 1.0406^{0.333} \frac{9.65}{9.099}=533.25 \\
h & =\frac{k}{D_{h}} N u_{D}=\frac{0.558}{0.01423} 533.25=20,910 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}
\end{aligned}
$$

Across a Circular Tube For flow across a circular tube the concept of separately describing laminar and turbulent coefficients does not make sense. The flow rapidly transitions and separates at all but the lowest Reynolds numbers. The data for the drag coefficient defined as

$$
\begin{equation*}
C_{D}=\frac{F_{D}}{A_{f} \rho \frac{V^{2}}{2}} \mathrm{~A}_{f}=\text { tube frontal area, } F_{D}=\text { drag force } \tag{12.37}
\end{equation*}
$$

A plot of the drag coefficient vs, Reynolds number is given in Fig. 12.10.
An engineering correlation for the heat transfer for a single tube in cross flow is given by,

$$
\begin{equation*}
N u_{D}=C \operatorname{Re}_{D}^{m} \operatorname{Pr}^{1 / 3} \tag{12.38}
\end{equation*}
$$

Fig. 12.10 Drag coefficient for flow across a single circular [5]

Table 12.2 Coefficients for Eq. 12.37

| $\operatorname{Re}_{\mathrm{D}}$ | C | m |
| :--- | :--- | :--- |
| $0.4-4$ | 0.989 | 0.330 |
| $4-40$ | 0.911 | 0.385 |
| $40-4000$ | 0.683 | 0.466 |
| $4000-40,000$ | 0.193 | 0.618 |
| $40,000-400,000$ | 0.027 | 0.805 |

where C and m are given in the following table for ranges of Reynolds numbers (Table 12.2).

This correlation is good for both a constant surface temperature and a constant heat flux.

Across Tube Bundles In addition to flow through tubes and across one tube, a common geometry is flow across banks of tubes. In this case, there are two common configurations as described in Fig. 12.11. Either the tubes are lined up directly behind each other, or they are staggered. The relevant parameters to describe the geometry are the tube's diameter, $D$, the spacing between the tubes in a plane perpendicular to the flow, $S_{T}$, and the spacing between rows, $S_{L}$. The Nusselt number is given by

$$
\begin{equation*}
N u_{D}=1.13 C_{1} \operatorname{Re}_{D, \max }^{m} \operatorname{Pr}^{1 / 3} \tag{12.39}
\end{equation*}
$$

The Reynolds number is based on the maximum fluid velocity computed from

$$
\begin{equation*}
V_{\max }=\frac{S_{T}}{S_{T}-D} V_{\infty} \tag{12.40}
\end{equation*}
$$

for the inline configuration and for the staggered configuration if A 1 is less than A 2 . It will occur at A2 if

Fig. 12.11 Tube banks. a Inline. b Staggered

$$
2\left(S_{D}-D\right)<\left(S_{T}-D\right) \quad \mathrm{S}_{D}=\sqrt{S_{T}^{2}+S_{L}^{2}}
$$

In which case

$$
\begin{equation*}
V_{\max }=\frac{S_{T}}{2\left(S_{D}-D\right)} V \tag{12.41}
\end{equation*}
$$

The constants for Eq. 12.39 are given in Table 12.3 above. This equation and table were developed for banks of tubes with more than ten rows. For less than ten rows, the Nusselt number must be corrected according to Eq. 12.42 below and Table 12.4.

$$
\begin{equation*}
N u_{D,<10}=C_{2} N u_{D, \geq 10} \tag{12.42}
\end{equation*}
$$

The table of values for $\mathrm{C}_{2}$ is given below.
The pressure drop across a bank of tubes is given by

$$
\begin{equation*}
\Delta p=N_{L} \chi\left(\rho V_{\max }^{2} / 2\right) f \tag{12.43}
\end{equation*}
$$

Fig. 12.12 Friction factor and $\chi$ for aligned tube banks [1]

Fig. 12.13 Friction factor and $\chi$ for staggered tube banks [1]

The friction factor for aligned tube banks is given in Fig. 12.12 and for staggered tube banks in Fig. 12.13.

The parameter $\chi$ is also given in the inserted sub-plots in Figs. 12.12 and 12.13.

Example 12.9 Calculate the effective film heat transfer coefficient and the friction factor for a tube bank of staggered tubes with the following dimensions.

Tube Diameter $=3 \mathrm{~cm}$
Spacing Transverse to the Flow $=6 \mathrm{~cm}$
Spacing Parallel to the Flow $=6 \mathrm{~cm}$
Entering Flow Velocity $=50 \mathrm{~m} / \mathrm{s}$
Fluid is Water (steam) at 500 K and 15 kPa
Eight rows of tubes
Solution Begin by calculating $\mathrm{V}_{\text {max }}=6 /(6-3)=2 * \mathrm{~V}_{\text {enter }}=100 \mathrm{~m} / \mathrm{s}$
Then $\operatorname{Re}_{d, \text { max }}=\frac{100 * 0.03}{5.75965 * 1.70 E-5}=30,639$
$\mathrm{S}_{\mathrm{T}} / \mathrm{D}=2.0 \mathrm{~S}_{\mathrm{L}} / \mathrm{D}=2.0$ For staggered tubes $\mathrm{C}_{1}=0.482 \mathrm{~m}=0.556$
Equation 12.39 gives

$$
\begin{aligned}
& N u=1.13 C_{1} \operatorname{Re}_{D, \max }^{m} \operatorname{Pr}^{1 / 3}=1.13 * 0.482 * 30,639^{0.556} * 1 \\
& N u=170 \\
& \text { Correcting for } 8 \text { tubes gives } \quad N u=0.98 * 170=166.6
\end{aligned}
$$

Then $h=\frac{k}{D} N u=\frac{0.0339}{0.03} 166.6=188.2 \mathrm{~W} / \mathrm{m}^{2} / \mathrm{K}$
The pressure drop is given by Eq. 12.43.

$$
\Delta p=N_{L} \chi\left(\rho V \max ^{2} / 2\right) f
$$

From Fig. 12.13 at a $\operatorname{Re}$ of $30,639 f=0.21$ and $\chi=1.05$

$$
\Delta p=8 * 1.05 * \frac{100^{2}}{5.75965 * 2} * 0.21=1.531 \mathrm{kPa}
$$

### 12.11 Enhanced Heat Transfer

Newton's law of cooling is given by

$$
Q=A h\left(T_{f}-T_{w}\right)
$$

When no more improvements in the film heat transfer coefficient, h , can be made, the heat transfer rate can still be increased by increasing the heat transfer area. This is usually accomplished by adding fins to the heat transfer surfaces. This is very common when one fluid is a liquid and the other fluid is a gas. The automobile

Fig. 12.14 Fin on a vertical surface

radiator is a common example. A typical geometry for a fin attached to a vertical surface is shown in Fig. 12.14.

The cross sectional area of the fin is given by $A_{c}=w^{*} t$, and the perimeter of the fin is given by $P=2 w+2 t$. Detailed analysis of the heat transfer from the fin to the fluid is given in Incropera et al. for many different boundary conditions, but a good approximation for many finned situations is given by the solution,

$$
\begin{align*}
& q_{f}=M \tanh m L_{c} \\
& M=\sqrt{h P k A_{c}}\left(T_{f}-T_{w}\right) m=\sqrt{\frac{h P}{k A_{c}}}  \tag{12.44}\\
& L_{c}=L+t / 2
\end{align*}
$$

It is also a reasonable approximation for fins around a tube that extend out an amount equal to the radius of the tube.

The utility of adding fins to a surface has to be evaluated in terms their heat transfer effectiveness. The fin heat transfer effectiveness is defined by

$$
\begin{align*}
& \varepsilon_{f}=\frac{\text { Heat transferred through the fin }}{\text { Heat transferred through the base area without the fin }} \\
& \varepsilon_{f}=\frac{q_{f}}{h A_{c}\left(T_{f}-T_{w}\right)}=\frac{\sqrt{h P k A_{c}}\left(T_{f}-T_{w}\right)}{h A_{c}\left(T_{f}-T_{w}\right)}=\sqrt{\frac{P k}{h A_{c}}} \tag{12.45}
\end{align*}
$$

Another measure of fin performance is given by the fin efficiency. In this case the heat transferred by the fin is compared with the heat that could be transferred if the entire fin were at the wall temperature.

$$
\begin{equation*}
\eta_{f}=\frac{M \tanh m L}{h P L\left(T_{f}-T_{w}\right)}=\frac{\sqrt{h P k A_{c}}\left(T_{f}-T_{w}\right) \tanh m L}{h P L\left(T_{f}-T_{w}\right)}=\frac{\tanh m L}{m L} \tag{12.46}
\end{equation*}
$$

In the end, the important parameter of interest in transferring heat is the overall performance of the heat transfer surface with the fins attached. Since adding one fin is not the optimal solution usually, an array of fins will be added with the spacing between the fins identified as S . Then the overall surface efficiency is given by

$$
\begin{align*}
& \eta_{o}=\frac{q_{\text {total }}}{q_{\max }}=\frac{q_{\text {wall surface }}+q_{\text {fins }}}{h\left(A_{\text {wall sufface }}+A_{\text {fins }}\right)\left(T_{f}-T_{w}\right)}=\frac{\left[N \eta_{f} h A_{f}+N h\left(S^{*} w\right)\right]\left(T_{f}-T_{w}\right)}{N h A_{f}+N h\left(S^{*} w\right)\left(T_{f}-T_{w}\right)}  \tag{12.47}\\
& \eta_{o}=\frac{\eta_{f} A_{f}+S^{*} w}{A_{f}+S^{*} w}=\frac{N}{N} \frac{\eta_{f} A_{f}+S^{*} w}{A_{f}+S^{*} w}=\frac{N \eta_{f} A_{f}+\left(A_{t}-N A_{f}\right)}{A_{t}}=1-\frac{N A_{f}}{A_{t}}\left(1-\eta_{f}\right)
\end{align*}
$$

Note that $A_{t}$ is the total surface area of the fins and the remaining wall surface that is exposed to the fluid. $A_{f}$ is simply the surface are of one fin. Then Newton's law of cooling can be written as

$$
\begin{equation*}
Q=\eta_{o} h A_{t}\left(T_{f}-T_{w}\right) \tag{12.48}
\end{equation*}
$$

and the increased heat transfer effectiveness is represented by the increased surface are and the overall surface efficiency.

Example 12.10 Estimate the overall surface effectiveness for heat transfer from a 1 m by 1 m copper radiation that has 3 cm fins extending into the airflow. The 3 cm fins are 1 mm thick and run the length of the 1 m dimension. They are spaced 9 mm apart. The wall temperature is 600 K and the air temperature is 350 K . Assume turbulent flow at a Reynolds number of 5000 .

Solution The Nusselt numberError! Bookmark not defined. for turbulent airflow over a flat plate is

$$
\begin{gathered}
N u_{L}=0.0592 \mathrm{Re}^{\frac{4 / 5}{\mathrm{~L}} \mathrm{Pr}} \operatorname{Pr}=0.0592 * 5000^{4 / 5} 0.7^{1 / 3}=47.85 \\
h=\frac{k}{L} N u=\frac{0.03}{1} 47.85=1.44 \quad m=\sqrt{\frac{h P}{k A_{c}}}
\end{gathered}
$$

$\mathrm{P}=2^{*} 1 \mathrm{~m}=2 \mathrm{~m} \quad \mathrm{~A}_{\mathrm{c}}=1 \mathrm{~m} * 0.001 \mathrm{~m}=0.001 \mathrm{~m}^{2} \quad \mathrm{k}=379 \mathrm{~W} / \mathrm{m} / \mathrm{K}$

$$
m=\sqrt{\frac{1.44 * 2}{379 * 0.001}}=2.757 \quad \eta_{f}=\frac{\tanh m L}{m L}=\frac{\tanh 2.757 * 0.03}{2.757 * 0.03}=0.9977
$$

For a 1 m high plate there will be 100 fins spaced 9 mm apart with a thickness of 1 mm . The total area will be
$A_{t}=100 *(0.009+2 * 0.03) 1.0=6.9$ sqm
Then the overall effectiveness is given by

$$
\eta_{o}=1.0-\frac{100 * 2 * 0.03 * 1}{6.9}(1-0.9977)=99.8
$$

### 12.12 Pool Boiling and Forced Convection Boiling

A good starting point to analyze mechanism of heat transfer in a boiling system is given by the subject of pool boiling. The most common situation and the simplest form of boiling is pool boiling in which boiling occurs is where a solid surface in contact with a liquid is brought to a temperature above the saturation temperature of the liquid and immersed below the free surface of the liquid causes boiling. This process is also called saturated (or bulk) boiling because liquid is maintained at saturation temperature. On the other hand, when the main body of the liquid in the immediate vicinity of the heated surface is at, slightly above, or below the saturation temperature the situation is called sub-cooled (or local) boiling because the vapor bubbles that are formed at the hot metal surface either collapse without leaving the surface or collapse immediately upon leaving the surface.

When the liquid is significantly below saturation temperature and the heater temperature is low, that is the only time that free convection occurs.

Although the heat transfer mechanism of pool boiling is reasonably understood by engineers and investigators of this field, and their findings were extensively discussed in different literatures, it is still not an easy task to theoretically analyze and predict characteristic of an even simple boiling system. For example, one of the pioneers of this subject Nukiyama experimentally managed to establish the characteristic of pool boiling phenomena. He deduced both the heat flux and the temperature from measurements of current and voltage of a submersed electrical element inside a body of saturated water and initiated boiling on the surface of the wire. Since then other scientists have done further investigation of this phenomenon and their fact findings for pool boiling of water at atmospheric pressure is illustrating in Fig. 12.15. This figure demonstrate the variation of the heat transfer coefficient as a function of the temperature difference between the wall surface $T_{w}$ and the liquid saturation $T_{s}$ temperatures in the pool boiling of a liquid at saturation temperature

The Fig. 12.15 shows six different regions where the plot going through each division forms slope which is different from those in other region. Events that taking in each region is described as below;

1. In this region, no vapor bubbles are formed because the energy transfer from the heated surface to the saturated liquid is by free convection from the free surface.
2. In this region, bubbles begin to form at the hot surface of the wire, but as soon as they are separated from the surface, they will dissipate in the liquid.
3. In this region, bubbles are detached from the electrical wire surface and they rise to the surface of the liquid where they will dissipate.

Fig. 12.15 Principal boiling regimes in pool boiling of water at atmospheric pressure and saturation temperature $\mathrm{T}_{\mathrm{s}}$ from an electrically heated platinum wire. (From Faber and Scorah [5])
4. In this region, the bubble formation is taking place rapidly, that bubbles begin to coalesce before they detached, consequently a large fraction of the heating surface is blanketed by an unstable film of vapor, which causes an abrupt loss in the heat flux and in the boiling heat transfer coefficient. This is an unstable region and it signifies transition from nucleate boiling to film boiling. (Fig. 12.17).
5. In this region, the heat flux decreases to a minimum level and the wire surface is blanketed with a stable film of vapor and it is called the stable film boiling region.
6. In this region, both heat flux and the heat transfer coefficient increases with $T_{w}-T_{s}$ because the wire surface temperature in this region is sufficiently high for thermal radiation effects to augment heat transfer through the vapor film. It is significant to mention that in this region, the boiling also takes place as stable film boiling but radiation effects are dominant.

If the heat flux $q$ is also plotted as a function of the temperature difference $T_{w}-T_{s}$, the general shape of the heat-flux curve (Fig. 12.16) would be similar to that of the heat transfer coefficient curve that is shown in Fig. 12.15.

Free convection is the process that the heat transfer from the heater (i.e. electrical element or wire) surface to the saturated liquid takes place. In this region, the heater surface is only a few degrees above the saturation temperature of the liquid, but the

Fig. 12.16 The poll boiling curve [5]
flow produced by free convection in the liquid is sufficient to remove the heat from the surface. The heat transfer correlation, then are in form of

$$
\begin{equation*}
\mathrm{Nu}=f(\mathrm{Gr}, \mathrm{Pr}) \tag{12.49}
\end{equation*}
$$

And as soon as we can determine the heat transfer coefficient $h$, then the heat flux for the free convection regime can be obtained from the following relationship as;

$$
\begin{equation*}
q=h\left(T_{w}-T_{s a t}\right) \tag{12.50}
\end{equation*}
$$

Free convection, transition to boiling, and changes in the boiling mechanism can best be seen in Fig. 12.16.

The figure shows a plot of heat flux versus the temperature difference $\left(T_{w}-T_{\text {sat }}\right)$ between a horizontal cylindrical heater surface and the saturation temperature of the surrounding liquid. This curve presents the results of common pool boiling experiment of electrically conduction wire, which is submerged in a stationary pool of water at saturation temperature and atmospheric pressure. As we can see in Fig. 12.16 for values of $\left(T_{w}-T_{\text {sat }}\right)<10^{\circ} \mathrm{F}$ (point A to B on curve) the heat flux is the value that is predicated for free convection with no phase change. Evaporation takes place at the pool free surface and if we consider the water as liquid then this event occurs at the surface of electric heater less than approximately $10^{\circ} \mathrm{F}$ above the saturation temperature of water.

The heater surface in most cases exceeds the saturation temperature of the liquid (i.e. water) by some perceptible amount before noticeable boiling commences. There requires and excessive temperature that is explained by the Eq. 12.51 below, depends on the type of fluid and the pressure.

Fig. 12.17 Nucleate pool boiling from a horizontal cylindrical heater at low heat flux [5]

$$
\begin{equation*}
R=\frac{2 \sigma T_{\text {sat }}}{\rho_{v} h_{f g}\left(T_{v}-T_{s a t}\right)} \tag{12.51}
\end{equation*}
$$

Where
$R$ : Bubble radius
$\sigma$ : Surface tension
$T_{\text {sat }}$ : Saturated temperature
$T_{v}$ : Vapor temperature
$\rho_{v}$ : Vapor density
$h_{f g}$ : Specific enthalpy of vaporization
Additionally, the type and condition of filament surface is significant since these factors determine the number and the size of the small vapor and gas bubbles from which bubble growth should begin.

Between point B and C as it can be seen on Fig. 12.16 where the temperature difference $\left(T_{w}-T_{\text {sat }}\right)$ is approximately equal to $10^{\circ} \mathrm{F}$, the curve shows a sharp increase in the slope, which is indication of large increase in the heat transfer coefficient, which is due to the inception of nucleate boiling at the heater surface. Figure 12.17 is showing such nucleate boiling regime from a horizontal cylindrical heater where the liquid near the heater has gained sufficient superheat to cause significant numbers of bubble to come to live and grow.

When a liquid changes phase and converts to vapor at the free surface of a liquid, the process is referred to as evaporation. However, when the phase changes in a vigorous manner within the bulk of a liquid, the process is called boiling.

A boiling process may take place in certain designated purposes such as;

1. The generation of large quantities of vapor, as in a steam power plant or in chemical processing, or
2. The production of large heat fluxes with moderate temperature differences.

From what we know these two objectives may not be related, since heat fluxes are required to provide the latent heat of vaporization designated as $h_{f g}$ and necessary
when generating large quantities of vapor within instrument of reasonable size. When the phase change in a liquid is taking place without significant rising of liquid temperature due to energy being put into it, then the large heat fluxes in boiling are possible.

The second general situation under which boiling occurs called forced convection boiling. In this case, there is the added complexity of the forced flow of liquid through the tube or past the surface on which boiling occurs.

### 12.13 Nucleate Boiling Regime

The process of originating a bubble is referred to as nucleation. The term nucleate boiling is used since the vapor bubbles are formed at discrete nucleation sites and Fig. 12.17 has picture such process from a horizontal electric heater.

The nucleate boiling regime can be separated into two distinct regions in which bubbles are formed on the surface of the electrical heater. Utilizing Fig. 12.15 where it shows a region designated as II, bubbles start to form at the favored sites on the heater surface, but as soon as the bubbles are detached from the surface, they dissipated in the liquid. In region III, the nucleation sites are numerous and the bubbles are generating at very high rate that causes continuous vapor columns to appear. As result, very high heat fluxes can be obtained in this region. In the nucleate boiling regime, the heat flux increases rapidly with increasing temperature difference ( $T_{w}-T_{\text {sat }}$ ) until the peak heat flux is reached and the burnout point can be defined at that peak, which is departure from nucleate boiling (DNB), or critical heat flux (CHF). As soon as the peak heat flux is exceeded, an extremely large temperature difference is needed to realize the resulting heat flux. Such extreme temperature difference may cause the burning up, or melting down of conducting heating filament. If the number of active nucleation sites increases, the interaction between the bubbles may become important and will affect the heat transfer within the region where this process takes place. Although one should consider other variables such as state of the fluid and properties of filament materials in a heat transfer analysis among other factors in the nucleate boiling regime. One empirical equation that is correlating the heat flux in the entire nucleate boiling regime with various parameters in relation to forced convection presented by Rohsenow as follows;

$$
\begin{equation*}
\frac{c_{p l} \Delta T}{h_{g f} \operatorname{Pr}_{l}^{n}}=C_{s f}\left[\frac{q}{\mu_{l} h_{f g}} \sqrt{\frac{\sigma^{*}}{g\left(\rho_{l}-\rho_{v}\right)}}\right]^{0.33} \tag{12.52}
\end{equation*}
$$

Where
$c_{p l} \mathrm{~h} \quad$ Specific heat of saturation liquid, $\mathrm{J} /\left(\mathrm{kg} .{ }^{\circ} \mathrm{C}\right)$
$C_{s f} \mathrm{~g}$ Constant, to be determined from experimental data that depends on heating surface-fluid combination.
$h_{g f}$ o Latent heat of vaporization, $\mathrm{J} / \mathrm{kg}$.

Table 12.5 Values of the coefficient $\mathrm{C}_{\text {sf }}$ of Eq. 12.52 for water surface combination. (Source: Evaluation of constants for the Rohsenow pool-boiling correlation. J Heat Transf 90:239-247)

$q$ o Boiling heat flux, W/m².
$\Delta T=T_{w}-T_{\text {sat }}$, Temperature difference between wall and saturation temperature, ${ }^{\circ} \mathrm{C}$. $\propto_{q} \quad$ Viscosity of saturated liquid, $\mathrm{kg} /(\mathrm{m} \mathrm{s})$.
$\rho_{l}, \rho_{v}=\quad$ Density of liquid and saturated vapor, respectively, $\mathrm{kg} / \mathrm{m}^{3}$.
$\sigma^{*} \quad$ Surface tension of liquid-vapor interface, $\mathrm{N} / \mathrm{m}$.
In Eq. 12.52 the exponent $n$ and the coefficient $C_{s f}$ are the two provisions for adjusting the correlation for the liquid-surface combination. Table 12.5 lists the experimentally determined values $C_{s f}$ for water boiling on a variety of surfaces. The value of $n$ for water should be taken as 1 .

Table 12.6 gives the value of vapor-liquid surface tension for water at different saturation temperatures.

Example 12.11 During the boiling of saturated water at $T_{s}=100^{\circ} \mathrm{C}$ with an electric heating element, a heat flux of $q=7 \times 10^{5} \mathrm{~W} / \mathrm{m}^{2}$ is achieved with a temperature difference of $\Delta T=T_{w}-T_{\text {sat }}=10.4^{\circ} \mathrm{C}$. What is the value of the constant $\mathbf{C}_{\mathrm{sf}}$ in Eq. 12.52?

Solution The physical properties of saturated water and vapor are taken as

$$
\begin{aligned}
& c_{p l}=4216, \mathrm{~J} /\left(\mathrm{kg}^{\circ} \mathrm{C}\right) \quad h_{g f}=2257 \times 10^{3} \mathrm{~J} / \mathrm{kg} . \\
& \rho_{l}=960.6 \mathrm{~kg} / \mathrm{m}^{3} \quad \rho_{v}=0.6 \mathrm{~kg} / \mathrm{m} \\
& \underset{l}{\operatorname{Pr}}=1.74 \quad \mu_{l}=0.282 \times 10^{-3} \mathrm{~kg} /(\mathrm{ms}) \\
& \sigma^{*}=58.8 \times 10^{-3} \mathrm{~N} / \mathrm{m} \quad g=9.81 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

These numerical values are substitute into Eq. 12.52 with $n=1$, we get

$$
\begin{aligned}
& \frac{c_{p l} \Delta T}{h_{g f} \operatorname{Pr}_{l}^{n}}=C_{s f}\left[\frac{q}{\mu_{l} h_{f g}} \sqrt{\frac{\sigma^{*}}{g\left(\rho_{l}-\rho_{v}\right)}}\right]^{0.33} \\
& \frac{(4216)(10.4)}{\left(2257 \times 10^{3}\right)(1.74)}=C_{s f}\left[\frac{\left(7 \times 10^{5}\right)}{\left(0.282 \times 10^{-3}\right)\left(2257 \times 10^{3}\right)} \sqrt{\frac{58.8 \times 10^{-3}}{9.81(960.6-0.6}}\right]^{0.33} \\
& \mathbf{C}_{\mathbf{s f}}=0.008
\end{aligned}
$$

Example 12.12 A brass heating element of surface area $A=0.04 \mathrm{~m}^{2}$, maintained at a uniform temperature $T_{\mathrm{w}}=112^{\circ} \mathrm{C}$, is immersed in a saturated water at atmospheric pressure at temperature $T_{\mathrm{s}}=100^{\circ} \mathrm{C}$. Calculate the rate of evaporation.

Solution The physical properties of saturated water and vapor at $100^{\circ} \mathrm{C}$ were given in Example 12.11. Introducing these properties into Eq. 12.52 with $n=1$ and $\Delta T=T_{w}-T_{\text {sat }}=112-100=12^{\circ} \mathrm{C}$, obtaining the coefficient $\mathrm{C}_{s f}$ for water brass from Table 12.5 as $\mathrm{C}_{\mathrm{sf}}=0.006$, the heat flux becomes;

$$
\begin{aligned}
q & =\left(\frac{c_{p l} \Delta T}{h_{g f} \operatorname{Pr}_{l}^{n} C_{s f}}\right)^{3} \mu_{l} h_{f g} \sqrt{\frac{g\left(\rho_{l}-\rho_{v}\right)}{\sigma^{*}}} \\
& =\left[\frac{(4216)(12)}{\left(2257 \times 10^{3}\right)}\right]^{3}\left(0.282 \times 10^{-3}\right)\left(2257 \times 10^{3}\right) \sqrt{\frac{(9.81)(060.6-0.6)}{\left(58.8 \times 10^{-3}\right)}} \\
& =2521.23 \mathrm{~kW} / \mathrm{m}^{2}
\end{aligned}
$$

The total rate of heat transfer is

$$
\begin{aligned}
Q & =\operatorname{area} \times q \\
& =(0.04)(2521.23)=100.85 \mathrm{~kW}
\end{aligned}
$$

The rate of evaporation is

$$
\begin{aligned}
\dot{m} & =\frac{Q}{h_{f g}} \\
& =\frac{100.85 \times 10^{3}}{2257 \times 10^{3}}=0.0447 \mathrm{~kg} / \mathrm{s}=160.9 \mathrm{~kg} / \mathrm{h}
\end{aligned}
$$

### 12.14 Peak Heat Flux

The correlation that is found in Eq. 12.52 is enough to provide information about the heat flux in nucleate boiling, but it cannot to predicate the peak heat flux. To be able to have the knowledge of such information in a nucleate boiling regime is of interest because of burnout consideration. As we described before, if the heat flux exceeds the peak heat flux, the burnout situation takes place. This is the circumstances that the transition from the nucleate to stable film boiling regime takes place, in which, depending on the kind of fluid, boiling may occur at temperature difference well above the melting point of the heating surface. The following correlation by expert in the field for determination of the peak flux heat was proposed:

$$
\begin{equation*}
q_{\max }=F\left(L^{\prime}\right) \times 0.131 \rho_{v}^{1 / 2} h_{f g}\left[\sigma^{*} g\left(\rho_{l}-\rho_{v}\right)\right]^{1 / 4} \tag{12.53}
\end{equation*}
$$

where
$h_{g f}=\quad$ Latent heat of vaporization, $\mathrm{J} / \mathrm{kg}$.
$g=\quad$ Gravitational acceleration, $\mathrm{m} / \mathrm{s}^{2}$.
$q_{\max }=$ Peak heat flux, $\mathrm{W} / \mathrm{m}^{2}$.
$\rho_{l}, \rho_{v}=$ density of liquid and saturated vapor, respectively, $\mathrm{kg} / \mathrm{m}^{3}$.
$\sigma^{*}=\quad$ Surface tension of liquid-vapor interface, $\mathrm{N} / \mathrm{m}$.
and $F\left(L^{\prime}\right)$ is a correction factor that depends on heat geometry and is provided in Table 12.7.

The dimensionless characteristic length of $L^{\prime}$ of the heater is defined as;

$$
\begin{equation*}
L^{\prime}=L \sqrt{\frac{g\left(\rho_{l}-\rho_{v}\right)}{\sigma^{*}}} \tag{12.54}
\end{equation*}
$$

Table 12.7 Correction factor $F\left(L^{\prime}\right)$ for use in Eq. 12.53. (Based on Lienhard and coworkers)

| Heater geometry | $\mathrm{F}\left(\mathrm{L}^{\prime}\right)$ | Remarks |
| :--- | :--- | :--- |
| Infinite flat plate facing up | 1.14 | $L^{\prime} \geq 2.7 ; L$ is the heat width or diameter |
| Horizontal cylinder | $0.89+2.27 \mathrm{e}^{-3.44} \sqrt{L^{\prime}}$ | $L^{\prime} \geq 0.15 ; L$ is the cylinder radius |
| Large sphere | 0.84 | $L^{\prime} \geq 4.26 ; L$ is the sphere radius |
| Small sphere | $1.734 /\left(L^{\prime}\right)^{1 / 2}$ | $0.15 \leq L^{\prime} \leq 4.26: L$ is the sphere radius |
| Large finite body | $\sim 0.90$ | $L^{\prime} \geq 4 ; L=($ volume $) /$ (surface area $)$ |

where $L$ is the characteristic dimension of the heater and other quantities are defined as before. In Eq. 12.53 the physical properties of the vapor are evaluated at $\mathrm{T}_{\mathrm{f}}=1 / 2\left(\mathrm{~T}_{\mathrm{w}}+\mathrm{T}_{\text {sat }}\right)$. The enthalpy of evaporation $h_{f g}$ and the liquid properties must be evaluated at the saturated temperature of the liquid.

Example 12.13 Water at saturation temperature and atmospheric pressure is boiled in the nucleate boiling regime with a large plate heating element facing up. Calculate the peak heat flux.

Solution The physical properties of saturated water and vapor at $100^{\circ} \mathrm{C}$ were given in Example 12.11. Introducing these properties into Eq. 12.53, with the correction factor $F\left(L^{\prime}\right)=1.14$ obtained from Table 12.7 for a large plate heating element facing up, the peak heat flux $q_{\text {max }}$ is determined as;

$$
\begin{aligned}
q_{\max }= & F\left(L^{\prime}\right) \times 0.131 \rho_{v}^{1 / 2} h_{f g}\left[\sigma^{*} g\left(\rho_{l}-\rho_{v}\right)\right]^{1 / 4} \\
= & (1.14)(0.131)(0.6)^{1 / 2}\left(2257 \times 10^{3}\right) \\
& \times\left\{\left(58.8 \times 10^{-3}\right)(9.81)(960.6-0.6)\right\}^{1 / 4} \\
= & 1.27 \times 10^{6} \mathrm{~W} / \mathrm{m}^{2}=1.27 \mathrm{MW} / \mathrm{m}^{2}
\end{aligned}
$$

Example 12.14 Water at atmospheric pressure and saturation temperature is boiled in a $25-\mathrm{cm}$ diameter, eclectically heated, mechanically polished, stainless-steel pan. The heated surface of the pan is maintained at a uniform temperature $T_{\mathrm{w}}=116^{\circ} \mathrm{C}$.
a. Calculate the surface heat flux.
b. Calculate the rate of evaporation from the pan.
c. Calculate the peak heat flux.

Solution The physical properties of saturated water and vapor for $\Delta T=T_{w}-T_{v}$ $=16^{\circ} \mathrm{C}$ are taken as;

$$
\begin{array}{ll}
c_{p l}=4216, \mathrm{~J} /\left(\mathrm{kg}^{\circ} \mathrm{C}\right) & h_{g f}=2257 \times 10^{3} \mathrm{~J} / \mathrm{kg} \\
\rho_{l}=960.6 \mathrm{~kg} / \mathrm{m}^{3} & \rho_{v}=0.6 \mathrm{~kg} / \mathrm{m}^{3} \\
\operatorname{Pr}_{l}=1.74 & \mu_{l}=0.282 \times 10^{-3} \mathrm{~kg} /(\mathrm{ms}) \\
\sigma^{*}=58.8 \times 10^{-3} \mathrm{~N} / \mathrm{m} & \mathrm{~g}=9.81 \mathrm{~m} / \mathrm{s}^{2}
\end{array}
$$

a. Equating 12.52 is used to compute the surface heat flux for water $\mathrm{n}=1$ and using Table 12.5, we have $C_{s f}=0.0132$ for water-mechanically polished stainless steel. Introducing all the numerical values into Eq. 12.53, we obtain;

$$
\frac{(4216)(16)}{\left(2257 \times 10^{3}\right)(1.74)}=0.0132\left[\frac{q}{\left(0.282 \times 10^{-3}\right)\left(2257 \times 10^{3}\right)} \sqrt{\frac{58.8 \times 10^{-3}}{(9.81)(960.6-0.6}}\right]^{0.33}
$$

Then the surface heat flux becomes

$$
q=5.61 \times 10^{5} \mathrm{~W} / \mathrm{m}^{2}
$$

b. The total rate of heat transfer becomes

$$
\begin{aligned}
Q & =\text { Area } \times q=\left(\frac{\pi}{4} \times(0.25)^{2}\right)\left(5.61 \times 10^{5}\right) \\
& =0.275 \times 10^{5} \mathrm{~W} \text { or J/s }
\end{aligned}
$$

The rate of evaporation becomes

$$
\begin{aligned}
\dot{m} & =\frac{Q}{h_{f g}} \\
& =\frac{0.275 \times 10^{5}}{22.57 \times 10^{3}} \times 3600=43.9 \mathrm{~kg} / \mathrm{h}
\end{aligned}
$$

c. To calculate the peak heat flux, we use Eq. 12.53 with the factor $F\left(L^{\prime}\right)$ taken from Table 12.7 for infinite flat plate facing up being equal to 1.14 , which is valid for

$$
L^{\prime}=L \sqrt{\frac{g\left(\rho_{l}-\rho_{v}\right)}{\sigma^{*}}} \geq 2.7
$$

For $L=0.25 \mathrm{~m}$ and other quantities as given above, we have $L^{\prime}=100$, which is larger than the specified lower bound 2.7.
Hence for $q_{\text {max }}$ we have;

$$
\begin{aligned}
q_{\max }= & F\left(L^{\prime}\right) \times 0.131 \rho_{v}^{1 / 2} h_{f g}\left[\sigma^{*} g\left(\rho_{l}-\rho_{v}\right)\right]^{1 / 4} \\
= & (1.14)(0.13)(0.6)^{1 / 2}\left(2257 \times 10^{3}\right) \\
& \times\left\{\left(58.8 \times 10^{-3}\right)(9.81)(960.6-0.6)\right\}^{1 / 4} \\
= & 1.27 \times 10^{6} \mathrm{~W} / \mathrm{m}^{2}=1.27 \mathrm{MW} / \mathrm{m}^{2}
\end{aligned}
$$

Note that $q=5.61 \times 10^{5} \mathrm{~W} / \mathrm{m}^{2}$ is well below the peak heat flux $1.27 \times 10^{6} \mathrm{~W} / \mathrm{m}^{2}$ or $\mathrm{J} /\left(\mathrm{m}^{2} . \mathrm{s}\right)$.

### 12.15 Film Boiling Regime

As soon as the nucleate boiling region ends and the unstable film boiling region begins after the peak heat flux is reached. Using Fig. 12.15, knowing that there are no correlations are available for the prediction of heat flux in this unstable region until the minimum point in the boiling curve is reached and the stable film boiling
region starts. In the region V and VI where we are within the stable film-boiling region, the heating surface is separated from the liquid by a vapor layer across which heat must be transferred. Due to low thermal conductivity of vapor in this region, large temperature differences are needed in order to have proper heat transfer, therefore, heat transfer in this region is generally avoided when high temperatures are involved. However, stable film boiling has numerous applications in the boiling of cryogenic fluids.

Bromley developed a theory to predict the heat transfer coefficient for stable film boiling on the outside of a horizontal cylinder and the basic analysis is very similar to Nusselt's theory for film-wise consideration on a horizontal tube. The result of his study for the average heat transfer coefficient $h_{0}$ for stable film boiling, in absence of radiation, is given by;

$$
\begin{equation*}
h_{0}=0.62\left[\frac{k_{v}^{3}\left(\rho_{l}-\rho_{v}\right) g h_{f g}}{\mu_{v} D_{0} \Delta T}\left(1+\frac{0.4 c_{\rho v} \Delta T}{h_{f g}}\right)\right]^{1 / 4} \tag{12.55}
\end{equation*}
$$

where

| $h_{0}=$ | Average boiling heat transfer coefficient in absence of radiation, $\mathrm{W} /\left(\mathrm{m}^{2} .{ }^{\circ} \mathrm{C}\right)$ |
| :---: | :---: |
| $h_{g f}=$ | Latent heat of vaporization, $\mathrm{J} / \mathrm{kg}$. |
| $g=$ | Gravitational acceleration, $\mathrm{m} / \mathrm{s}^{2}$. |
| $k_{v}=$ | Thermal conductivity of saturated vapor, $\mathrm{W} /\left(\mathrm{m} .{ }^{\circ} \mathrm{C}\right)$. |
| $\rho_{l}, \rho_{v}=$ | density of liquid and saturated vapor, respectively, $\mathrm{kg} / \mathrm{m}^{3}$. |
| $D_{0}=$ | Outside diameter of tube, m. |
| $c_{\rho v}=$ | Specific heat of saturated vapor, $\mathrm{J} /\left(\mathrm{kg} .{ }^{\circ} \mathrm{C}\right)$. |
| $\mu_{v}=$ | Viscosity of saturated vapor, $\mathrm{kg} /(\mathrm{m} \mathrm{s})$. |
| $\Delta T=T_{w}-T_{\text {sat }}$, | temperature difference between wall and saturation temperatures, ${ }^{\circ} \mathrm{C}$. |

and the physical properties of vapor must be evaluated at $T_{f}=1 / 2\left(T_{w}+T_{\text {sat }}\right)$. In addition, the enthalpy of evaporation $h_{f g}$ and the liquid density $\rho_{l}$ should be evaluated at the saturation temperature $T_{\text {sat }}$ of the liquid.
Example 12.15 Water at saturation temperature $\mathrm{T}_{\mathrm{s}}=100^{\circ} \mathrm{C}$ and atmospheric pressure is boiled with an electrically heated horizontal platinum wire of diameter $\mathrm{D}=0.2 \mathrm{~cm}$. Boiling takes place with a temperature difference of $\mathrm{T}_{\mathrm{w}}-\mathrm{T}_{\mathrm{s}}=454^{\circ} \mathrm{C}$ in the stable film boiling range. Calculate the film boiling heat transfer coefficient and the heat flux, in the absence of radiation.

Solution The physical properties of vapor are evaluated at $\mathrm{T}_{\mathrm{f}}=1 / 2\left(\mathrm{~T}_{\mathrm{w}}+\mathrm{T}_{\text {sat }}\right)=(554$ $+100) / 2=327^{\circ} \mathrm{C}=600^{\circ} \mathrm{K}$

$$
\begin{array}{rr}
c_{\rho v} & =20262026 \mathrm{j} / \mathrm{kg}{ }^{\circ} \mathrm{C}
\end{array} k_{v}=0.0422 \mathrm{~W} /\left(\mathrm{m}^{\circ} \mathrm{C}\right) ~ 子 \rho_{v}=0.365 \mathrm{~kg} / \mathrm{m}^{3} .
$$

and the liquid density and $h_{g f}$ are evaluated at the saturation temperature $\mathrm{T}_{\mathrm{s}}=100^{\circ} \mathrm{C}$ as;

$$
\rho_{l}=960.6 \mathrm{~kg} / \mathrm{m}^{3} \quad h_{g f}=2257 \times 10^{3} \mathrm{~J} / \mathrm{kg}
$$

The heat transfer coefficient $h_{0}$ for stable film boiling without the radiation effects is computed from Eq. 12.55 as:

$$
\begin{aligned}
h_{0}= & 0.62\left[\frac{k_{v}^{3}\left(\rho_{l}-\rho_{v}\right) g h_{f g}}{\mu_{v} D_{0} \Delta T}\left(1+\frac{0.4 c_{\rho v} \Delta T}{h_{f g}}\right)\right]^{1 / 4} \\
= & 0.62\left[\frac{(0.0422)^{3}(0.365)(960.6-0.365)(98.1)\left(2257 \times 10^{3}\right)}{\left(2.067 \times 10^{-5}\right)(0.002)(454)}\right. \\
& \left.\quad \times\left(1+\frac{(0.4)(2026)(454)}{2257 \times 10^{3}}\right)\right]^{1 / 4} \\
= & 270.3 \mathrm{~W} /\left(\mathrm{m}^{2} .{ }^{\circ} \mathrm{C}\right)
\end{aligned}
$$

## Chapter 13 <br> Heat Exchangers

A heat exchanger is a heat transfer device that exchanges heat between two or more process fluids. Heat exchangers have widespread industrial and domestic applications. Many types of heat exchangers have been developed for use in steam power plants, chemical processing plants, building heat and air conditioning systems, transportation power systems and refrigeration units.

The actual design of heat exchangers is a complicated problem. It involves more than heat-transfer analysis alone. Cost of fabrication and installation, weight, and size play important roles in the selection of the final design from a total cost of ownership point of view. In many cases, although cost is an important consideration, size and footprint often tend to be the dominant factors in choosing a design.

### 13.1 Heat Exchangers Types

Most heat exchangers may be classified as one of several basic types. The four most common types, based on flow path configuration, are illustrated in Fig. 13.1 below [1].

1. In concurrent, or parallel-flow, units the two fluid streams enter together at one end, flow through in the same direction, and leave together at the other end;
2. In countercurrent, or counter-flow, units the two streams move in opposite directions.
3. In single-pass crossflow units one fluid moves through the heat transfer matrix at right angles to the flow path of other fluid.
4. In multipass crossflow units one fluid stream shuttles back and forth across the flow path of the other fluid stream, usually giving a crossflow approximation to counterflow.

Fig. 13.1 Types of flow path configuration through heat exchanger

The most important difference between these four basic types lies in the relative amounts of heat transfer surface area required to transfer the desired amount of heat between the two fluids.

Figure 13.2 below shows the relative area required for each type as a function of the change in temperature of the fluid with the largest temperature change requirement for a typical set of conditions. In the region in which the fluid temperature

Fig. 13.2 The required relative heat transfer surface area as a function of the ratio of the temperature rise (or drop) in the fluid stream having the greater change in temperature to the difference in temperature between the inlet streams
change across the heat exchanger is a small percentage of the difference in temperature between the two entering fluid streams, all the units require roughly the same area. The parallel-flow heat exchanger is of interest primarily for applications in this region. Cross-flow units have a somewhat broader range of application, and are peculiarly suited to some types of heat exchanger construction that have special advantages. The counter-flow heat exchanger requires the least area. Furthermore, it is the only type that can be employed in the region in which the temperature change in one or both of the fluid streams closely approaches the temperature difference between the entering fluids streams.

In addition, heat exchangers may be classified as direct contact or indirect contact. In the direct-contact type, heat transfer takes place between two immiscible fluids, such as a gas and a liquid, coming into direct contact. For example, cooling towers, jet condensers for water vapor, and other vapors utilizing water spray are typical examples of direct-contact exchangers.

An Immiscible Fluids are incapable of is being mixed or blended together. Immiscible liquids that are shaken together eventually separate into layers. Oil and Water are typical immiscible fluids.

In the indirect-contact type of heat exchangers, such as automobile radiators, the hot and cold fluids are separated by an impervious surface, and they are referred to as surface heat exchangers. There is no mixing of the two fluids.

### 13.2 Classification of Heat Exchanger by Construction Type

Heat exchangers also can be classified according to their construction features. For example, there are tubular, plate, plate-fin, tube-fin, and regenerative exchangers. An important performance factor for all heat exchangers is the amount of heat transfer surface area within the volume of the heat exchanger. This is called its compactness factor and is measured in square meters per cubic meter.

### 13.2.1 Tubular Heat Exchangers

Tubular exchangers are widely used, and they are manufactured in many sizes, flow arrangements, and types. They can accommodate a wide range of operating pressures and temperatures. The ease of manufacturing and their relatively low cost have been the principal reason for their widespread use in engineering applications. A commonly used design, called the shell-and-tube exchanger, consists of round tubes mounted on a cylindrical shell with their axes parallel to that of the shell.

Figure 13.3 illustrates the main features of a shell-and tube exchanger having one fluid flowing inside the tubes and the other flowing outside the tubes. The principle components of this type of heat exchanger are the tube bundle, shell, front and rear end headers, and baffles. The baffles are used to support the tubes, to direct the fluid flow approximately normal to the tubes, and to increase the turbulence of the shell fluid. There are various types of baffles, and the choice of baffle type, spacing, and geometry depends on the flow rate allowable shell-side pressure drop, tube support requirement, and the flow-induced vibrations. Many variations of shell-and-tube exchanger are available; the differences lie in the arrangement of flow configurations and in the details of construction.

Fig. 13.3 A shell-and-tube heat exchanger; one shell pass and one tube pass [2]

Fig. 13.4 Shell-and-tube heat exchangers. a One shell pass and two tube passes. b Two shell passes and four tube passes [3]

Baffled heat exchangers with one shell pass and two tubes passes and with two shell passes and four tube passes are shown in Figs. 13.4a [3] and b [3], respectively [3].

The character of the fluids may be liquid-to-liquid, liquid-to-gas, or gas-to-gas. Liquid-to-liquid exchangers have the most common applications. Both fluids are pumped through the exchangers; hence, the heat transfer on both the tube side and the shell side is by forced convection. Since the heat transfer coefficient is high with the liquid flow, generally there is no need to use fins [2].

The liquid-to-gas arrangement is also commonly used; in such cases, the fins usually are added on the gas side of the tubes, where the heat transfer coefficient is low.

Gas-to-gas exchangers are used in the exhaust-gas and air preheating recuperators for gas gas-turbine systems, cryogenic gas-liquefaction systems, and steel furnaces. Internal and external fins generally are used in the tubes to enhance heat transfer.

### 13.2.2 Plate Heat Exchangers

As the name implies, plate heat exchangers usually are constructed of thin plates. The plates may be smooth or may have some form of corrugation. Since the plate geometry cannot accommodate as high pressure and/or temperature differentials as
a circular tube, it is generally designated for moderate temperature and/or pressure differentials. The compactness factor for plate exchangers ranges from about 120 to $230 \mathrm{~m}^{2} / \mathrm{m}^{3}$.

### 13.2.3 Plate Fin Heat Exchangers

The compactness factor can be significantly improved (i.e., up to about $6000 \mathrm{~m}^{2 /}$ $\mathrm{m}^{3}$ ) by using the plate-fin type of heat exchanger. Figure 13.5 illustrates typical plate-fin configurations. Flat plates separate louvered or corrugated fins. Crossflow, counterflow, or parallel-flow arrangements can be obtained readily by properly arranging the fins on each side of the plate. Plate-fin exchangers are generally used for gas-to-gas applications, but they are used for low-pressure applications not exceeding about 10 atm (that is, 1000 kPa ). The maximum operating temperatures are limited to about $800^{\circ} \mathrm{C}$. Plate-fin heat exchangers have also been used for cryogenic applications.

### 13.2.4 Tube Fin Heat Exchangers

When a high operating pressure or an extended surface is needed on one side, tubefin exchangers are used. Figure 13.6 illustrates two typical configurations, one with round tubes and the other with flat tubes. Tube-fin exchangers can be used for a wide range of tube fluid operating pressures not exceeding about 30 atm and operating temperatures from low cryogenic applications to about $870^{\circ} \mathrm{C}$. The maximum compactness ratio is somewhat less than that obtainable with plate-fin exchangers.

Fig. 13.5 Plate-fin heat exchangers. (Courtesy of Harrison Radiator Division of General Motors Corporation)

Fig. 13.6 Tube fin heat exchangers. (Courtesy of Harrison Radiator Division of General Motors Corporation)

The tube-fin heat exchangers are used in gas turbine, nuclear, fuel cell, automobile, airplane, heat pump, refrigeration, electronics, cryogenics, air conditioning, and many other applications.

### 13.2.5 Regenerative Heat Exchangers

Regenerative heat exchangers use a heat transfer matrix that is heated by one fluid and then cooled by the second fluid. The flow over the matrix is switched as a function of time with both fluids flowing over the same surfaces of the matrix. They have seen little use in fixed station power plants and will not be emphasized here.

### 13.3 Condensers

Condensers are used for such varied applications as steam power plants, chemical processing plants, and nuclear electric plants for space vehicles. The major types include the surface condensers, jet condensers, and evaporative condensers. The most common type is the surface condenser, which has the feed-water system [4]. Figure 13.7 shows a section through a typical two-pass surface condenser for a large steam turbine in a power plant. Since the steam pressure at the turbine exit is only $1.0-2.0$ in Hg absolute, the steam density is very low and the volume rate of flow is extremely large. To minimize the pressure loss in transferring steam from the turbine to the condenser, the condenser is normally mounted beneath and attached to the turbine. Cooling water flows horizontally inside the tubes, while the steam

Fig. 13.7 Section through a typical two-pass surface condenser for a large plant. (Courtesy of Allis-Chalmers Manufacturing Company)
flows vertically downward from the large opening at the top and passes transversely over the tubes. Note that provision is made to aspirate cool air from the regions just above the center of the hot well. This is important because the presence of noncondensable gas in the steam reduces the heat transfer coefficient for condensation.

### 13.4 Boilers

Steam boilers are one of the earliest applications of heat exchangers. The term steam generator is often applied to boiler in which the heat source is a hot fluid stream rather than the products of combustion.

An enormous variety of boiler types exist, ranging from small units for house heating applications to huge, complex, expensive units for modern power stations.

### 13.5 Classification According to Compactness

The ratio of the heat transfer surface area on one side of the heat exchanger to the volume can be used as a measure of the compactness of heat exchangers. A heat exchanger having a surface area density on any one side greater than about $700 \mathrm{~m}^{2} / \mathrm{m}^{3}$ quite arbitrarily is referred to as a compact heat exchanger regardless of
its structural design. For example, automobile radiators having an area density approximately $1100 \mathrm{~m}^{2} / \mathrm{m}^{3}$ and the glass ceramic heat exchangers for some vehicular gas-turbine engines having an area density approximately $6600 \mathrm{~m}^{2} / \mathrm{m}^{3}$ are compact heat exchangers. The human lungs, with an area density of about $20,000 \mathrm{~m}^{2} / \mathrm{m}^{3}$, are the most compact heat-and-mass exchanger. The very fine matrix regenerator for the Stirling engine has an area density approaching that of the human lung.

On the other hand extreme of the compactness scale, plane tubular and shell-andtube type exchangers, having an area density in the range of $70-500 \mathrm{~m}^{2} / \mathrm{m}^{3}$, are not considered compact [2].

The incentive for using compact heat exchangers lies in the fact that a high value of compactness reduces the volume for a specified heat exchanger performance.

When heat exchangers are to be employed for automobiles, marine uses, aircraft, aerospace vehicles, cryogenic systems, and refrigeration and air conditioning, the weight and size-hence the compactness-become important. To increase the effectiveness or the compactness of heat exchangers, fins are used. In a gas-to-liquid heat exchanger, for example, the heat transfer coefficient on the gas side is an order of magnitude lower than for the liquid side. Therefore, fins are used on the gas side to obtain a balanced design; the heat transfer surface on the gas side becomes much more compact.

### 13.6 Types of Applications

Heat exchangers are often classified based on the application for which they are intended, and special terms are employed for major types. These terms include boiler, steam generator, condenser, radiator, evaporator, cooling tower, regenerator, recuperator, heater, and cooler. The specialized requirements of the various applications have led to the development of many types of construction, some of which are unique to particular applications [5].

### 13.7 Cooling Towers

In locations where the supply of water is limited, heat may be rejected to the atmosphere very effectively by means of cooling towers such as that Fig. 13.8 here. A fraction of the water sprayed into these towers evaporates, thus cooling the balance. Because of the high heat of vaporization of water, the water consumption is only about $1 \%$ as much as would be the case if water were taken from a lake or a stream and heated 10 or $20^{\circ} \mathrm{F}$.

Cooling towers may be designed so that the air moves through them by thermal convection, or fans may be employed to provide forced air circulation. To avoid contamination of the process water, shell-and-tube heat exchangers are sometimes employed to transmit heat from the process water to the water recirculated through the cooling tower.

Fig. 13.8 a Vertical induced draft-cooling tower. (Courtesy Foster Wheeler Corp.) [1]. b Schematic of cooling tower. c Forced convection cooling tower with draft induced by a fan [1]

### 13.8 Regenerators and Recuperators

The thermal efficiency of both gas-turbine power plants can be greatly increased if heat can be extracted from the hot gases that are leaving the gas turbine and added to the air being supplied to the combustion chamber. For a major gain in thermal efficiency, it is necessary to employ a very large amount of heat transfer surface area. This is particularly noticeable in gas-turbine plants, where even with counterflow the size of the heat exchanger required for good performance is inclined to be large compared to the size of the turbine and compressor. This characteristic can be observed even in the small, portable gas turbine (about 3 ft in diameter) shown in Fig. 13.9. Note that in this device the hot combination gases leave the radial in-flow turbine wheel at the right end of the shaft and enter a set of heat exchanger cores arranged in parallel around the central axis.

Figure 13.10 shows a close-up view of one of these cores. In each core, the hot gases from the turbine flow roughly radially outward through one set of gas passages. Air from the centrifugal compressor wheel at the center of the shaft flows to the right through the space just inside of the outer casing and axially into the other set of gas passages through the core. The air being heated makes two passes, flowing first to the right in the outer portion of the core and then back to the left through the inner portion, thus giving a two-pass crossflow approximation to counterflow (The flow passages through the combustion chamber are not shown in this view).

As can be seen in Fig. 13.10, the heat exchanger core is constructed of alternate layers of flat and corrugated sheets. The flat sheets separate the hot and cold fluid streams, while the corrugated sheets act as fins that roughly triple the heat transfer

Fig. 13.9 A small gas-turbine power plant fitted with a recuperator to improve the fuel economy. (Courtesy of AiResearch Manufacturing Co.) [5]

Fig. 13.10 A brazed plate-fin recuperator core for the gas turbine of Fig. 13.9. (Courtesy of AiResearch Manufacturing) [5]

surface area per unit of volume. Note also that the axis of the corrugations is at right angles in alternate layers to provide a crossflow pattern for the two fluid streams.

One of several recuperator units to be mounted in parallel in a much larger gas turbine plants is shown in Fig. 13.11. The hot exhaust gas from the turbine enters vertically at the bottom, flows upward through the heat transfer matrix, and discharges vertically from the top. The air from the compressor enters a large circular port at the top at the right end, flows vertically downward in pure counterflow, and leaves a second circular port at the bottom to flow to the combustion chamber. The hot exhaust gas passages are formed by corrugated sheets sandwiched between flat plates that extend all the way from the bottom to the top of the unit. The air to be

Fig. 13.11 A welded steel recuperator for a large gas-turbine power plant. (Courtesy Harrison Radiator Division, General Motors Corp) [5]
heated flows horizontally from the long plenum at the top into the spaces between the walls of the exhaust gas passages. Curved space strips guide the air through a $90^{\circ}$ bend and then downward between the heated walls. A similar header arrangement is used at the bottom. Note that both the flow passage area and the heat transfer surface area for the hot exhaust gas are about three times as great as the corresponding values for the air being heated. This comes about because the two fluid streams differ in density by a factor of about four.

The air pre-heaters in steam power plants are usually quite different from the units just described for gas turbines. Rotary regenerators are often used. These consist of a cylindrical drum filled with a heat transfer matrix made of alternately flat and corrugated sheets. The drum is mounted so that the hot gas heats a portion of the matrix as it passes from the furnace to the stack. The balance of the matrix gives up its stored heat to the fresh air in route from the forced draft fans to the furnace. The ducts are arranged so that the two gas streams move through the drum in counterflow fashion while it is rotated, so that the temperature of any given element of the metal matrix fluctuates relatively little as it is cycled from the hot to the cold gas streams.

In the steam- and gas-turbine power plant fields a distinction is sometimes made between air pre-heaters that involve a conventional heat transfer matrix with continuous flow on both sides of a stationary heat transfer surface and those through which the fluids flow periodically, the hot fluid heating one section of the matrix while the cold fluid is removing heat from another section. Where this distinction is made, the term regenerator is applied to the periodic-flow type of heat exchanger, since this term has long been applied to units of this type employed for blast furnaces and steel furnaces, whereas the term recuperator is applied to units through which the flow is continuous.

Recuperators are used for gas turbine, but the gas turbines installed until the mid1970's suffered from low efficiency and poor reliability. In the past, large coal and nuclear power plants dominated the base-load electric power generation (Point 1 in Fig. 13.12). Base load units are on line at full capacity or near full capacity almost all of the time. They are not easily nor quickly adjusted for varying large amounts of load because of their characteristics of operation [6]. However, there has been a historic shift toward natural gas-fired turbines because of their higher efficiencies, lower capital costs, shorter installation times, better emission characteristics, the abundance of natural gas supplies, and shorter start up times (Point 1 in Fig. 13.12). Now electric utilities are using gas turbines for base-load power production as well as for peaking, making capacity at maximum load periods and in emergencies, situations because they are easily brought on line or off line (Point 2 in Fig. 13.12). The construction costs for gas-turbine power plants are roughly half that of comparable conventional fossil fuel steam power plants, which were the primary base-load power plants until the early 1980's, but peaking units are much higher in energy output costs. A recent gas turbine manufactured by General Electric uses a turbine inlet temperature of $1425^{\circ} \mathrm{C}\left(2600^{\circ} \mathrm{F}\right)$ and produces up to 282 MW while achieving a thermal efficiency of $39.5 \%$ in the simple-cycle mode. Over half of all power plants to be installed in the near future are forecast to be gas turbine or combined gas-steam turbine types (Fig. 13.12).

Fig. 13.12 A gas-turbine engine with recuperator

In gas turbine engines with the Brayton Cycle that includes recuperator, the temperature of the exhaust gas leaving the turbine is often considerably higher than the temperature of the air leaving the compressor. Therefore, the high-pressure air leaving the compressor can be heated by transferring heat to it from the hot exhaust gases in a counter-flow heat exchanger, which is also known as a regenerator or recuperator [See Fig. 13.13 on point-1]. Gas turbine regenerators are usually con-

Fig. 13.13 T-s diagram of a Brayton cycle with regeneration
structed as shell-and-tube type heat exchangers using very small diameter tubes, with the high-pressure air inside the tubes and low-pressure exhaust gas in multiple passes outside the tubes [7]. The thermal efficiency of the Brayton cycle increases as a result of regeneration since the portion of energy of the exhaust gases that is normally rejected to the surroundings is now used to preheat the air entering the combustion chamber. This, in turn, decreases the heat input (thus fuel) requirements for the same net work output. Note, however, that the use of a regenerator is recommended only when the turbine exhaust temperature is higher than the compressor exit temperature. Otherwise, heat will flow in the reverse direction (to the exhaust gases), decreasing the efficiency. This situation is encountered in gas turbines operating at very high-pressure ratios [Point 1 on Fig. 5].

The highest temperature occurring within the regenerator is the temperature of the exhaust gases leaving the turbine and entering the regenerator (Point 1 on Fig. 13.13). The gas turbine recuperator receives air from the turbine compressor at pressures ranging from 73.5 to 117 psia and temperatures from 350 to $450^{\circ} \mathrm{F}$ (Point 3 on Fig. 13.13). Under no conditions can the air be preheated in the regenerator to a temperature above this value. In the limiting (ideal) case, the air will exit the regenerator at the inlet temperature of the exhaust gases. Air normally leaves the regenerator at a lower temperature (Point 1 on Fig. 13.13). Gas turbine exhaust gas passes over the other side of the recuperator at exhaust temperatures ranging from 750 to $1000^{\circ} \mathrm{F}$. Compressor air temperatures are now raised to higher temperatures up to about $750-900^{\circ} \mathrm{F}$ as it enters the combustor. Turbine exhaust gases are then reduced to between 500 and $650^{\circ} \mathrm{F}$ from the original 750 to $1000^{\circ} \mathrm{F}$. This heat recovery contributes appreciably to the turbine fuel rate reduction and increase in efficiency (Point 3 on Fig. 13.13). The regenerator is well insulated and any changes in kinetic and potential energies are neglected.

A regenerator with a higher effectiveness will save a greater amount of fuel since it will preheat the air to a higher temperature prior to combustion [Point 1 on Fig. 4]. However, achieving a higher effectiveness requires the use of a larger regenerator, which carries a higher price tag and causes a larger pressure drop because shaft horsepower is reduced. Pressure drop through the regenerator or recuperator is important and should be kept as low as practical on both sides. Generally, the air pressure drop on the high-pressure side should be held below $2 \%$ of the compressor total discharge pressure. The gas pressure drop on the exhaust side (hot side) should be held below 4 in . of water. Therefore, the use of a regenerator with a very high effectiveness cannot be justified economically unless the savings from the fuel costs exceed the additional expenses involved. The effectiveness of most regenerators used in practice is below 0.85 . The thermal efficiency of an ideal Brayton cycle with regeneration depends on the ratio of the minimum to maximum temperatures as well as the pressure ratio. Regeneration is most effective at lower pressure ratios and low minimum-to-maximum temperature ratios.

Gas-to-air recuperators (or regenerators) are also used on marine type industrial, and utility open-cycle gas turbine applications. In this application, recuperator receives air from the turbine compressor at pressure and temperature ranging as above, where gas turbine exhaust gas passes over the other side of the recuperator at exhaust temperature, depending on the turbine. The air side (high pressure side)
of the recuperator is in the system between the compressor and the combustor and compressor air is raised to a higher temperature up what is mentioned in above as it enters the combustor. Obviously, pressure drop through the regenerator or recuperator is important and should be kept as low as practical on both sides.

### 13.9 Heat Exchanger Analysis: Use of the LMTD

Utilizing the Log Mean Temperature Difference (LMTD) method is one way to design or to predict the performance of a heat exchanger, it is essential to relate the total heat transfer rate to measurable quantities such as the inlet and outlet fluid temperatures, the overall heat transfer coefficient, and the total surface area for heat transfer. Two such relations may readily be obtained by applying overall energy balances to the hot and cold fluids, as shown in Fig. 13.14. In particular, if $q$ is the total rate of heat transfer between the hot and cold fluids and there is negligible heat transfer between the exchanger and its surroundings, as well as negligible potential and kinetic energy changes, application of the steady flow energy equation, gives;

$$
\begin{equation*}
q_{\text {total }}=\dot{m}_{h}\left(h_{h, i}-h_{h, o}\right) \tag{13.1a}
\end{equation*}
$$

and

$$
\begin{equation*}
q_{\text {total }}=\dot{m}_{c}\left(h_{c, o}-h_{c, i}\right) \tag{13.1b}
\end{equation*}
$$

Where $h$ is the fluid enthalpy. The subscripts $h$ and $c$ refer to the hot and cold fluids, whereas the subscripts $i$ and $o$ designate the fluid inlet and outlet conditions. If the fluids are not undergoing a phase change and constant specific heats are assumed, these expressions reduce to

$$
\begin{equation*}
q_{\text {total }}=\dot{m}_{h} c_{p, h}\left(T_{h, i}-T_{h, o}\right) \tag{13.2a}
\end{equation*}
$$

and

$$
\begin{equation*}
q_{\text {total }}=\dot{m}_{c} c_{p, c}\left(T_{c, o}-T_{c, i}\right) \tag{13.2b}
\end{equation*}
$$

Fig. 13.14 Heat transfer between two moving fluids separated by a solid boundary
where the temperatures appearing in the expressions refer to the mean fluid temperatures at the designated locations. Note that Eqs. 13.1 and 13.2 are independent of the flow arrangement and heat exchanger type.

Now consider the heat transfer at a particular point, $x$, on the heat transfer surface. At $x$ there will be a bulk hot fluid temperature given by $T_{f, h}(x)$, a wall surface temperature on the hot fluid side given by $T_{s, h}(x)$, a wall surface temperature on the cold fluid side given by $T_{s, c}(x)$, and a cold fluid bulk temperature given by $T_{f, c}(x)$. The total temperature drop from the hot fluid at $x$ to the cold fluid at $x$ is given by

$$
\begin{aligned}
\Delta T & =T_{f, h}(x)-T_{f, c}(x)=T_{f, h}(x)-T_{s, h}(x)+T_{s, h}(x)-T_{s, c}(x)+T_{s, c}(x)-T_{f, c}(x) \\
& =\Delta T_{f, h}+\Delta T_{s}+\Delta T_{f, c}
\end{aligned}
$$

Then the heat flux leaving the hot fluid is given by

$$
\frac{d q(x)}{d x}=h_{f, h} A_{f, h}\left(T_{f, h}(x)-T_{s, h}(x)\right)=h_{f, h} d A_{f, h} \Delta T_{f, h}(x) \quad \Delta T_{f, h}(x)=\frac{\frac{d q(x)}{d x}}{h_{f, h} d A_{f, h}}
$$

The heat flux crossing the wall between the two fluids is given by,

$$
\frac{d q(x)}{d x}=\frac{k_{s}}{\delta_{s}} d A_{s}\left(T_{s, h}(x)-T_{s, c}(x)\right)=\frac{k_{s}}{\delta_{s}} d A_{s} \Delta T_{s}(x) \quad \Delta T_{s}(x)=\frac{\frac{d q(x)}{d x}}{\frac{k_{s}}{\delta_{s}} d A_{s}}
$$

And the heat flux into the cold fluid is given by,

$$
\frac{d q(x)}{d x}=h_{f, c} d A_{f, c}\left(T_{s, c}(x)-T_{f, c}(x)\right)=h_{f, c} d A_{f, c} \Delta T_{f, c}(x) \quad \Delta T_{f, c}(x)=\frac{\frac{d q(x)}{d x}}{h_{f, c} d A_{f, c}}
$$

Then the difference in the bulk temperatures of the two fluids can be written as

$$
\begin{align*}
T_{f, h}(x)-T_{f, c}(x) & =\frac{\frac{d q(x)}{d x}}{h_{f, h} d A_{f, h}}+\frac{\frac{d q(x)}{d x}}{\frac{k_{s}}{\delta_{s}} d A_{s}}+\frac{\frac{d q(x)}{d x}}{h_{f, c} d A_{f, c}}  \tag{13.3}\\
& =\frac{d q(x)}{d x}\left[\frac{1}{h_{f, h} d A_{f, h}}+\frac{\delta_{s}}{k_{s} d A_{s}}+\frac{1}{h_{f, c} d A_{f, c}}\right]
\end{align*}
$$

Note that $\delta_{s}$ will depend on the geometry. For slab or plate geometry

$$
\delta_{s}=\Delta t \quad \text { the wall thickness }
$$

For cylindrical geometry typical of tubes,

$$
\delta_{s}=r_{\text {in }} \ln \left(\frac{r_{\text {out }}}{r_{\text {in }}}\right) \quad r_{\text {out }}-r_{\text {in }}=\text { the tube wall thickness }
$$

Also note that the differential areas do not all have to be equal. There will be a slight difference if the bounding surface is a tube, but the addition of fins to either the hot or the cold side could change the effective area significantly and that is the area that must be used in Eq. 13.3. Also, note that the areas are areas per unit length. That is why they have been written as $d A$.

$$
\begin{aligned}
& T_{f, h}(x)-T_{f, c}(x)=\frac{d q(x)}{d x}\left(\frac{1}{U \frac{d A}{d x}}\right) \frac{1}{U \frac{d A}{d x}}=\frac{1}{h_{f, h} d A_{f, h}}+\frac{\delta_{s}}{k_{s} d A_{s}}+\frac{1}{h_{f, c} d A_{f, c}} \\
& \frac{d q(x)}{d x}=U \frac{d A}{d x}\left(T_{f, h}-T_{f, c}\right)
\end{aligned}
$$

Then the heat lost by the hot fluid is given by

$$
\begin{equation*}
\frac{d q(x)}{d x}=-\dot{m}_{f, h} C_{p, h} \frac{d T_{f, h}(x)}{d x} \tag{13.4}
\end{equation*}
$$

And the heat gained by the cold fluid is given by

$$
\begin{equation*}
\frac{d q(x)}{d x}=\dot{m}_{f, c} C_{p, c} \frac{d T_{f, c}(x)}{d x} \tag{13.5}
\end{equation*}
$$

Combining these two equations gives

$$
\frac{d T_{f, h}(x)}{d x}-\frac{d T_{f, c}(x)}{d x}=-\frac{d q(x)}{d x}\left(\frac{1}{\dot{m}_{h} C_{p, h}}+\frac{1}{\dot{m}_{c} C_{p, c}}\right)=-U \frac{d A}{d x}\left(T_{f, h}-T_{f, c}\right)
$$

$$
\begin{aligned}
& \Delta T(x)=T_{f, h}(x)-T_{f, c}(x) \\
& \frac{d \Delta T(x)}{d x}=-U \frac{d A}{d x} \Delta T\left(\frac{1}{\dot{m}_{h} C_{p, h}}+\frac{1}{\dot{m}_{c} C_{p, c}}\right)
\end{aligned}
$$

$$
\frac{d \Delta T(x)}{\Delta T(x)}=-U\left(\frac{1}{\dot{m}_{h} C_{p, h}}+\frac{1}{\dot{m}_{c} C_{p, c}}\right) d A \quad \frac{d A}{d x} d x=d A
$$

Integrating gives

$$
\begin{equation*}
\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)=-U A\left(\frac{1}{\dot{m}_{h} C_{p, h}}+\frac{1}{\dot{m}_{c} C_{p, c}}\right) \tag{13.6}
\end{equation*}
$$

Now for the hot fluid flowing from left to right Eq. 13.2a becomes

$$
q_{\text {total }}=\dot{m}_{h} C_{p, h}\left(T_{f, h, 1}-T_{f, h, 2}\right) \frac{1}{\dot{m}_{h} C_{p, h}}=\frac{\left(T_{f, h, 1}-T_{f, h, 2}\right)}{q_{\text {total }}}
$$

In addition, for the cold fluid also flowing from left to right (parallel flow) Eq. 13.2b becomes

$$
q_{\text {total }}=\dot{m}_{c} C_{p, c}\left(T_{f, c, 2}-T_{f, c, 1}\right) \frac{1}{\dot{m}_{c} C_{p, c}}=\frac{\left(T_{f, c, 2}-T_{f, c, 1}\right)}{q_{\text {total }}}
$$

Plugging these into Eq. 13.3 gives

$$
\begin{align*}
& \ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)=-U A\left(\frac{T_{f, h, 1}-T_{f, h, 2}}{q_{\text {total }}}+\frac{T_{f, c, 2}-T_{f, c, 1}}{q_{\text {total }}}\right) \\
&=\frac{U A}{q_{\text {total }}}\left(T_{f, h, 2}-T_{f, c, 2}-T_{f, h, 1}+T_{f, c, 1}\right) \\
& \ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)=\frac{U A}{q_{\text {total }}}\left(\Delta T_{2}-\Delta T_{1}\right) \quad q_{\text {total }}=U A \frac{\left(\Delta T_{2}-\Delta T_{1}\right)}{\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)} \\
& q_{\text {total }}=U A \Delta T_{l m} \quad \Delta T_{l m}=\frac{\left(\Delta T_{2}-\Delta T_{1}\right)}{\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)} \tag{13.7}
\end{align*}
$$

This looks a lot like Newton's law of cooling with $\Delta T_{l m}$ playing the role of the standard $\Delta T . \Delta T_{l m}$ is called the log-mean temperature difference.

Now consider the counter flow arrangement. In this case Eq. 13.5 becomes,

$$
\frac{d q(x)}{d x}=-\dot{m}_{f, c} C_{p, c} \frac{d T_{f, c}(x)}{d x}
$$

Moreover, Eq. 13.6 becomes,

$$
\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)=-U A\left(\frac{1}{\dot{m}_{h} C_{p, h}}-\frac{1}{\dot{m}_{c} C_{p, c}}\right)
$$

Then Eq. 13.2 b becomes

$$
q_{\text {total }}=\dot{m}_{c} c_{p, c}\left(T_{f, c, 1}-T_{f, c, 2}\right)
$$

This gives

$$
\begin{aligned}
\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right) & =-U A\left(\frac{T_{f, h, 1}-T_{f, h, 2}}{q_{\text {total }}}-\frac{T_{f, c, 1}-T_{f, c, 2}}{q_{\text {total }}}\right) \\
& =\frac{U A}{q_{\text {total }}}\left(T_{f, h, 2}-T_{f, c, 2}-T_{f, h, 1}+T_{f, c, 1}\right) \\
\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right) & =\frac{U A}{q_{\text {total }}}\left(\Delta T_{2}-\Delta T_{1}\right) \quad q_{\text {total }}=U A \frac{\left(\Delta T_{2}-\Delta T_{1}\right)}{\ln \left(\frac{\Delta T_{2}}{\Delta T_{1}}\right)}
\end{aligned}
$$

which is the identical equation for the parallel flow heat exchanger. It is important to remember how the $\Delta T$ 's are defined.

$$
\begin{aligned}
& \text { Parallel Flow } \Delta T_{1}=T_{f, h . i n}-T_{f, c, \text { in }} \quad \Delta T_{2}=T_{f, h, \text { out }}-T_{f, c, \text { out }} \\
& \text { Counter Flow } \Delta T_{1}=T_{f, h . \text { in }}-T_{f, c, \text { out }} \quad \Delta T_{2}=T_{f, h, \text { out }}-T_{f, c, \text { in }}
\end{aligned}
$$

Example 13.1 A counterflow, concentric tube heat exchanger is used to cool the lubricating oil for a large industrial gas turbine engine. The flow rate of cooling water through the inner tube ( $D_{i}=25 \mathrm{~mm}$ ) is $0.2 \mathrm{~kg} / \mathrm{s}$, while the flow rate of oil through the outer annulus ( $D_{0}=45 \mathrm{~mm}$ ) is $0.1 \mathrm{~kg} / \mathrm{s}$. The oil and water enter at temperatures of 100 and $30^{\circ} \mathrm{C}$, respectively. How long must the tube be made if the outlet temperature of the oil is to be $60^{\circ} \mathrm{C}$ ? (The steel tube that separates the two flows is so thin that the temperature drop across it may be neglected.). See Fig. 13.15.

Fig. 13.15 Schematic of Example 13.1 [5]

## Solution

## Known

Fluid flow rates and inlet temperature for a counter-flow, concentric tube heat exchanger of prescribed inner and outer diameter

## Find

Tube length to achieve a desired hot fluid outlet temperature.

## Assumptions

| 1.0 | Negligible heat loss to the surroundings |
| :--- | :--- |
| 2.0 | Negligible kinetic and potential energy changes |
| 3.0 | Constant properties |
| 4.0 | Negligible tube wall thermal resistance and fouling factors |
| 5.0 | Fully developed conditions for the water and oil $(U$ independent of $x)$ |

Properties Table A-5, unused engine oil ( $\left.\bar{T}_{h}=80{ }^{\circ} \mathrm{C}=353 \mathrm{~K}\right)$ :

$$
\mathrm{c}_{p}=2131 \mathrm{j} / \mathrm{kg} \cdot \mathrm{~K}, \mu=3.25 \times 10^{-2} \mathrm{~N} \cdot \mathrm{~s} / \mathrm{m}^{2}, k=0.138 \mathrm{~W} / \mathrm{m} \cdot \mathrm{~K} .
$$

Table A-6, water ( $\left.\bar{T}_{c} \approx 35{ }^{0} \mathrm{C}=308 \mathrm{~K}\right)$ :

$$
\mathrm{c}_{p}=4178 \mathrm{j} / \mathrm{kg} \cdot \mathrm{~K}, \mu=725 \times 10^{-6} \mathrm{~N} \cdot \mathrm{~s} / \mathrm{m}^{2}, k=0.625 \mathrm{~W} / \mathrm{m} \cdot \mathrm{~K}, \operatorname{Pr}=4.85
$$

Analysis The required heat transfer rate may be obtained from the overall energy balance for the hot fluid, Eq. 13.1a

$$
\begin{aligned}
& q=\dot{m}_{h} c_{p, h}\left(T_{h, i}-T_{h, o}\right) \\
& q=0.1 \mathrm{~kg} / \mathrm{s} \mathrm{x} 2131 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{~K}(100-60)^{0} \mathrm{C}=8524 \mathrm{~W}
\end{aligned}
$$

Applying Eq. 13.2b, the water outlet temperature is

$$
\begin{aligned}
T_{c, o} & =\frac{q}{\dot{m}_{c} c_{p, c}}+T_{c, i} \\
T_{c, o} & =\frac{8524 \mathrm{~W}}{0.2 \mathrm{~kg} / \mathrm{s} \mathrm{x} 2131 \mathrm{~J} / \mathrm{kg} \cdot \mathrm{~K}}+30{ }^{\circ} \mathrm{C}=40.2{ }^{\circ} \mathrm{C}
\end{aligned}
$$

Accordingly, use of $\bar{T}_{c}=35{ }^{\circ} \mathrm{C}$ to evaluate the water properties was a good choice. The required heat exchanger length may now be obtained from Eq. 13.7,

where $A=\pi D_{i} L$

$$
\Delta T_{l m}=\frac{\left(T_{h, i}-T_{c, o}\right)-\left(T_{h, o}-T_{c, i}\right)}{\ln \left[\left(T_{h, i}-T_{c, o}\right) /\left(T_{h, o}-T_{c, i}\right)\right]}=\frac{59.8-30}{\ln (59.8 / 30)}=43.2^{\circ} \mathrm{C}
$$

The overall heat transfer coefficient is

$$
U=\frac{1}{\left(1 / h_{i}\right)+\left(1 / h_{o}\right)}
$$

For water flow through the tube,

$$
\begin{aligned}
\dot{m} & =\rho A V \frac{\dot{m}}{A}=\rho V \quad \operatorname{Re}_{D}=\frac{\dot{m}_{c} D_{i}}{A \mu}=\frac{4 \dot{m}}{\pi D_{i} \mu} \\
& =\frac{4 \times 0.2 \mathrm{~kg} / \mathrm{s}}{\pi(0.025 \mathrm{~m}) 725 \times 10^{-6} \mathrm{~N} \cdot \mathrm{~s} / \mathrm{m}^{2}}=14,050
\end{aligned}
$$

Accordingly, the flow is turbulent and the convection coefficient may be computed from Eq. 12.34.

$$
\begin{aligned}
& N u_{D}=0.023 \operatorname{Re}_{D}^{4 / 5} \mathrm{Pr} \\
& N u_{D}=0.023(14,050)^{4 / 5}(4.85)^{0.4}=90
\end{aligned}
$$

Hence

$$
h_{i}=N u_{D} \frac{k}{D_{i}}=\frac{90 \times 0.625 \mathrm{~W} / \mathrm{m} \cdot \mathrm{~K}}{0.025 \mathrm{~m}}=2250 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K}
$$

For the flow of oil through the annulus, the hydraulic diameter is,

$$
D_{h}=\frac{4 A}{P}=\frac{4\left(\pi r_{o}^{2}-\pi r_{i}^{2}\right)}{2 \pi\left(r_{o}-r_{i}\right)}=2\left(r_{o}-r_{i}\right)=D_{o}-D_{i}
$$

and the Reynolds number is

$$
\begin{aligned}
\operatorname{Re}_{D} & =\frac{\rho u_{m} D_{h}}{\mu}=\frac{\dot{m}\left(D_{o}-D_{i}\right)}{A \mu}=\frac{\dot{m}\left(D_{o}-D_{i}\right)}{\mu \pi\left(D_{o}^{2}-D_{i}^{2}\right) / 4} \\
\operatorname{Re}_{D} & =\frac{4 \dot{m}}{\pi\left(D_{o}+D_{i}\right) \mu}=\frac{4(0.1 \mathrm{~kg} / \mathrm{s})}{\pi(0.045+0.025) 3.25 \times 10^{-2} \mathrm{~kg} / \mathrm{s} \cdot \mathrm{~m}}=56.0
\end{aligned}
$$

The annular flow is therefore laminar. For a constant heat flux the laminar correlation is Eq. 12.33.

$$
N u_{i}=\frac{h_{o} D_{h}}{k}=4.36
$$

and

$$
h_{o}=4.36 \frac{0.138 \mathrm{~W} / \mathrm{m} \cdot \mathrm{~K}}{0.020 \mathrm{~m}}=30.1 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K}
$$

The overall convection coefficient is then

$$
U=\frac{1}{\left(1 / 2250 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K}\right)+\left(1 / 30.1 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K}\right)}=29.7 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K}
$$

and from the rate equation it follows that

$$
L=\frac{q}{U \pi D_{i} \Delta T_{l m}}=\frac{8524 \mathrm{~W}}{29.7 \mathrm{~W} / \mathrm{m}^{2} \cdot \mathrm{~K} \pi(0.025 \mathrm{~m})\left(43.2^{0} \mathrm{C}\right)}=84.6 \mathrm{~m}
$$

## Comments

1. The hot side convection coefficient controls the rate of heat transfer between the two fluids, and the low value of $h_{o}$ is responsible for the large value of $L$.
2. Because $h_{i} \gg h_{o}$, the tube wall temperature will follow closely that of the coolant water.

Many heat exchangers have been designed based on a log-mean temperature difference. However, there are some problems with proceeding based on the log-mean temperature difference equation. First, it says nothing about cross flow heat exchangers, which are very common due to the ease of construction of this type of exchanger. Secondly, it often requires iterative calculations for a design if all of the inlet and exit temperatures are not known a priori. In the example above, had the outlet temperature of the oil not been specified, an iterative solution would have been required. Iterative solutions can certainly be accurate, but they often require more work. Thirdly, the log-mean temperature difference method does not provide a feel for the maximum heat transfer possible given the entering conditions of the fluids. Sometimes this is an important parameter to understand, if the design is to be optimized.

### 13.10 Effectiveness-NTU Method for Heat Exchanger Design

A better method has been developed for heat exchanger design that uses some of the preceding analysis. This method is called the effectiveness-NTU (Number of Transfer Unit) method. ${ }^{1}$ It starts by considering the fluid heat transfer capacity rates defined as

$$
\begin{align*}
& \text { Cold Fluid Capacity Rate } \quad C_{c}=\dot{m}_{c} C_{p, c} \quad W / K  \tag{13.8}\\
& \text { Hot Fluid Capacity Rate } \quad C_{h}=\dot{m}_{h} C_{p, h} \quad W / K
\end{align*}
$$

Then the maximum amount of heat that can be transferred between the two fluids is the Minimum Fluid Capacity Rate times the difference in temperature of the hot fluid entering the exchanger and the cold fluid entering the exchanger. Or

$$
\begin{align*}
& C_{\min }=\min \left(C_{c}, C_{h}\right)  \tag{13.9}\\
& q_{\max }=C_{\min }\left(T_{h, i n}-T_{c, i n}\right)
\end{align*}
$$

Then the heat exchanger effectiveness is defined as

$$
\begin{equation*}
\varepsilon=\frac{q_{a c t}}{q_{\max }}=\frac{C_{h}\left(T_{h, \text { in }}-T_{h, \text { out }}\right)}{C_{\min }\left(T_{h, \text { in }}-T_{c, \text { in }}\right)}=\frac{C_{c}\left(T_{c, \text { in }}-T_{c, \text { out }}\right)}{C_{\min }\left(T_{h, \text { in }}-T_{c, \text { in }}\right)} \tag{13.10}
\end{equation*}
$$

The number of heat exchanger transfer units is then defined as

$$
\begin{equation*}
N T U=\frac{U A}{C_{\min }} \tag{13.11}
\end{equation*}
$$

where $U$ and $A$ are defined as above. The heat Capacity-Rate Ratio is defined as,

$$
\begin{equation*}
C_{r}=\frac{C_{\min }}{C_{\max }} \tag{13.12}
\end{equation*}
$$

Then in general it is possible to express the effectiveness as

$$
\varepsilon=\varepsilon\left(N T U, C_{r}, \text { Flow Arrangement }\right)
$$

[^4]Different functions for $\varepsilon$ have been developed for many flow arrangements. ${ }^{2}$ The three main flow arrangements of interest are parallel flow, counter flow, and cross flow.

Parallel Flow For parallel flow the expression is

$$
\begin{equation*}
\varepsilon=\frac{1-e^{-N T U\left(1+C_{r}\right)}}{1+C_{r}} \tag{13.13}
\end{equation*}
$$

There are two interesting limits,

$$
\begin{array}{ll}
C_{r} \rightarrow 0 & \varepsilon=1-e^{-N T U}  \tag{13.14}\\
C_{r} \rightarrow 1 & \varepsilon=\frac{1}{2}
\end{array}
$$

The $C_{r}=0$ limit corresponds to one fluid vaporizing or condensing and the heat capacity rate for this fluid becomes immense. The other limit $C_{r}=1.0$ corresponds to both fluids having the same Heat Capacity Rate.

## Counter Flow

$$
\begin{equation*}
\varepsilon=\frac{1-e^{-N T U\left(1-C_{r}\right)}}{1-C_{r} e^{-N T U\left(1-C_{r}\right)}} \tag{13.15}
\end{equation*}
$$

Addressing the same two limits

$$
\begin{array}{ll}
C_{r} \rightarrow 0 & \varepsilon=1-e^{-N T U} \\
C_{r} \rightarrow 1 & \varepsilon=\frac{N T U}{1+N T U} \tag{13.16}
\end{array}
$$

The $C_{r}=0$ limit is the same but the $C_{r}=1$ limit is twice as effective for large values of NTU. This essentially is the known performance advantage of counter flow heat exchangers.
Cross Flow Cross flow has to be broken down into three different types. The performance is different depending on whether or not the fluids are allowed to mix with themselves as they move through the exchanger. A typical tube and shell exchanger would have the fluid moving through the tubes described as unmixed and the fluid moving through the shell would be mixed.

[^5]Cross Flow—Both Fluids Unmixed This case requires a series numerical solution and the curves for values of various $C_{r}$ values are given in Kays and London. For the case of $C_{r}=0$, the solution is the same as for counter flow and parallel flow.

$$
C_{r}=0 \quad \varepsilon=1-e^{-N T U}
$$

However all of the curves for any value of $C_{r}$ asymptotically approach 1.0 like the counter flow exchanger. For all $C_{r}>0$ the effectiveness is less than for a counter flow exchanger with the same $C_{r}$.
Cross Flow-One Fluid Mixed For the case of

$$
\begin{align*}
& C_{\max }=C_{\text {unmixed }} \quad C_{\min }=C_{\text {mixed }} \\
& \varepsilon=1-e^{-\Gamma / C_{r}} \quad \Gamma=1-e^{-N T U C_{r}} \tag{13.17}
\end{align*}
$$

And for the case of

$$
\begin{align*}
& C_{\max }=C_{\text {mixed }} \quad C_{\min }=C_{\text {unmixed }}  \tag{13.18}\\
& \varepsilon=\frac{1-e^{-\Gamma^{\prime} C_{r}}}{C_{r}} \quad \Gamma^{\prime}=1-e^{-N T U}
\end{align*}
$$

Once again for $C_{r}=0$, this gives the same behavior as the counter flow heat exchanger. For $C_{r}=1.0$, it gets complicated but it is important to note that if a choice is possible it is better to have the fluid with the smaller heat capacity rate to be the mixed fluid (Eq. 13.17).

Cross Flow-Both Fluids Mixed The closed form solution is

$$
\begin{equation*}
\varepsilon=\frac{N T U}{\frac{N T U}{\left(1-e^{-N T U}\right)}+\frac{C_{r} N T U}{1-e^{-N T U C_{r}}}-1} \tag{13.19}
\end{equation*}
$$

As always, for the case of $C_{r}=0$, the results are the same as the counter flow exchanger.

For $C_{r}=1.0$ as NTU becomes large, the effectiveness goes to $1 / 2$. However this is the only case that a better effectiveness can be obtained at a lower NTU. The effectiveness actually decreases after an NTU of about 3-5.

There are many other configurations reported by Kays and London, but these three are the most important. The availability of solutions for the common cross flow case of one fluid mixed makes this technique very useful.

Example 13.2 Consider a gas-to-gas recuperator of the shell and tube design.
The tubes are 2 cm diameter tubes spaced on 4 cm centers with a 2 mm thickness made of aluminum. The flow cross section is a 2 m by $2 \mathrm{~m}^{2}$. The pressure ratio for the compressor is 20 . Both fluids are air and the cold fluid is in the tubes. The hot fluid enters at $783^{\circ} \mathrm{K}$ and exits at $670^{\circ} \mathrm{K}$ and is atmospheric pressure. The cold fluid enters at $655^{\circ} \mathrm{K}$ and exits at $768^{\circ} \mathrm{K}$ and is at 20 atmospheres. The flow rate is $2.5 \mathrm{E}+5 \mathrm{~kg} / \mathrm{h}$, for a 10 MW power plant.

Solution Start with the hot fluid-Calculate Re No.

$$
\begin{aligned}
& N \text { tubes }=2401, A_{\text {flow }}=2^{2}-2401 * \pi(0.012)^{2}=2.9138 \mathrm{~m}^{2} \\
& \dot{m}=\rho A V \quad \rho \mathrm{~V}=\frac{\dot{m}}{A}=\frac{69.44 \mathrm{~kg} / \mathrm{s}}{2.9138}=23.8 \mathrm{~kg} / \mathrm{s} / \mathrm{m}^{2} \\
& \mu=3.65 E-5 \quad \mathrm{D}=\frac{4\left(0.04^{2}-\pi 0.012^{2}\right)}{2 \pi 0.012}=0.0609 \mathrm{~m} \\
& \operatorname{Re}=\frac{23.8 * 0.0609}{3.7 E-05}=39,789.2
\end{aligned}
$$

This is clearly in the turbulent range.
Using the same equations, the cold fluid $R e=56,731.1$

$$
\begin{gathered}
P r_{\text {hot }}=C_{p} m / k=1078.8 * 3.65 E-5 / 0.0564=0.697 \\
P r_{\text {cold }}=C_{p} m / k=1076.7 * 3.25 E-5 / 0.050=0.700 \\
N u_{\text {hot }}=0.023 * 39,789.2^{0.8} * 0.697^{0.3}=98.7 \\
h_{\text {hot }}=98.7 * 0.0564 / 0.0609=91.5 \mathrm{w} / \mathrm{m}^{2} / l \\
N u_{\text {cold }}=0.023 * 56,731.1^{0.8} * 0.700^{0.4}=127.0 \\
h_{\text {cold }}=127.0 * 0.0500 / 0.02=316.0 \mathrm{w} / \mathrm{m}^{2} / \mathrm{l}
\end{gathered}
$$

This allows us to calculate UA as a function of L

$$
A_{h o t}=2 \pi(0.012) * 2401 * L=724.8 * L m^{2}
$$

$$
\begin{aligned}
& A_{\text {cold }}=2 \pi(0.01) * 2401 * L=603.4 * L m^{2} \\
& A_{\text {tube }}=2 \pi(0.011) * 2401 * L=663.74 * L m^{2} \otimes \\
& \frac{1}{U A}=\left(\frac{1}{h_{\text {hot }} A}+\frac{t}{k A}+\frac{1}{h_{\text {cold }} A}\right) \\
& =\frac{1}{91.5(724.8) L}+\frac{0.002}{218(663.74) L}+\frac{1}{316(603.4) L} \\
& =(1.508 E-5+1.38 E-8+5.25 E-6) / L=\frac{2.03 E-5}{L} w / K \\
& \dot{Q}=8.46 E+6 \mathrm{w} \quad \Delta \mathrm{~T}_{\text {in }}=15 K \quad \Delta \mathrm{~T}_{\text {out }}=15 K \\
& \Delta T_{\text {lmn }}=15 K \quad \dot{Q}=\left(\frac{U A}{L}\right) L \Delta T_{\text {lmn }} \quad L=\frac{\dot{Q}}{(U A / L) \Delta T_{\text {lmn }}} \\
& L=\frac{8.46 E+6}{4.92 E+4 * 15}=11.5 m
\end{aligned}
$$

Now try the NTU-Effectiveness method

$$
\begin{gathered}
C_{\text {hot }}=2.5 E+5 / 3600 * 1078.8=7.49 E+04 \\
C_{\text {cold }}=2.5 E+5 / 3600 * 1076.7=7.48 E+04=C_{\min } \\
C_{r}=0.998 \sim 1.0 \quad \varepsilon=N T U /(N T U+1) \quad N T U=\varepsilon /(1-\varepsilon) \\
\varepsilon=\frac{C_{h o t}\left(T_{h, \text { in }}-T_{h, \text { out }}\right)}{C_{\min }\left(T_{h, \text { in }}-T_{c, \text { in }}\right)}=\frac{7.49 E+4 *(783-670)}{7.48 E+4 *(783-655)}=0.8846 \\
N T U=7.67 \quad \frac{N T U}{L}=\frac{U A / L}{C_{\min }}=0.6576 \quad \mathrm{~L}=\frac{7.67}{0.6576}=11.66 \mathrm{~m}
\end{gathered}
$$

Note that the largest resistance to heat transfer was in the hot side convection and the resistance of the tube wall was negligible.

So add fins to the hot side channel by putting a 2 mm thick web between the tubes. See Fig. 13.16.

First, recalculate the hydraulic diameter for the hot side
Treating the webs as wetted perimeter gives a new $D_{h}=0.0329 \mathrm{~m}$

Fig. 13.16 Web channel

This gives a new

$$
\begin{gathered}
R e=21,521.3 \\
N u=60.4 \\
h=104.0
\end{gathered}
$$

Dividing the web in half for a fin for each tube,

$$
\begin{gathered}
w=0.01, t=0.002, P=0.02, A=0.00002, m=21.79 L=0.008 \\
m L=0.1743 h_{\text {fin }}=0.9899 h_{o}=0.9915 A_{\text {tot }}=0.1394 \\
h_{o} * A_{\text {tot }}=0.1382 A_{\text {hot }} / A_{\text {cold }}=2.1997 A_{\text {hot }} / L=1327 . \therefore
\end{gathered}
$$

The cold side and tube resistances don't change, so

$$
\frac{1}{U A}=\frac{1}{1.25 E-5^{*} L} L=\frac{\dot{Q}}{U A \mathrm{q}_{L} \Delta T_{l m n}}=\frac{8.47 E+6}{7.98 E+4 * 15}=7.1
$$

Now to get the pressure drops

$$
\begin{aligned}
& C_{f, \text { hot }}=0.046 \mathrm{Re}^{-0.2}=0.046 * 21521.3^{-0.2}=6.25 E-3 \\
& C_{f, \text { cold }}=0.046 \mathrm{Re}^{-0.2}=0.046 * 56731.1^{-0.2}=5.15 E-3
\end{aligned}
$$

This gives

$$
\begin{aligned}
\tau_{\text {hot }} & =6.25 E-3 * \frac{1}{2} \rho V^{2}=\frac{3.13 E-3}{\rho_{\text {hot }}}\left(\frac{\dot{m}}{A}\right)_{\text {hot }}^{2} \\
\tau_{\text {cold }} & =5.15 E-3 * \frac{1}{2} \rho V^{2}=\frac{2.58 E-3}{\rho_{\text {cold }}}\left(\frac{\dot{m}}{A}\right)_{\text {cold }}^{2} \\
\rho_{\text {hot }} & =\frac{101325 * 28.9669}{8314.4 * 783}=0.451 \mathrm{~kg} / \mathrm{m}^{3} \\
\rho_{\text {cold }} & =\frac{20 * 101325 * 28.9669}{768 * 8314.4}=9.193 \mathrm{~kg} / \mathrm{m}^{3} \\
\tau_{\text {hot }} & =\frac{3.13 E-3}{0.451}(23.83)_{\text {hot }}^{2}=3.941 \text { Pascals } \\
\tau_{\text {cold }} & =\frac{2.58 E-3}{9.193}(92.1)_{\text {cold }}^{2}=2.38 \text { Pascals }
\end{aligned}
$$

Clearly these pressure drops are negligible compared to atmospheric pressure. This says that the heat exchanger could be made a lot more compact by adding more surface area per unit volume $-\mathrm{m}^{2} / \mathrm{m}^{3}$.

### 13.11 Special Operating Conditions

It is useful to note certain special conditions under which heat exchangers may be operated. Figure 13.14a shows temperature distributions for a heat exchanger in which the hot fluid has a heat capacity rate, $C_{h} \equiv \dot{m}_{h} C_{p, h}$, which is much larger than that of the cold fluid, $C_{c} \equiv \dot{m}_{c} C_{p, c}$.

For this case the temperature of the hot fluid remains approximately constant throughout the heat exchanger, while the temperature of the cold fluid increases. The same condition is achieved if the hot fluid is a condensing vapor. Condensation occurs at constant temperature, and, for all practical purposes, $C_{h} \rightarrow \infty$. Conversely, in an evaporator or a boiler (Fig. 13.14b), it is the cold fluid that experiences a change in phase and remains at a nearly uniform temperature $\left(C_{c} \rightarrow \infty\right)$. The same effect is achieved without phase change if $C_{h} \ll C_{c}$. Note that, with condensation or evaporation, the heat rate is given by Eqs. 13.1a or 13.1b, respectively. Conditions illustrated in Fig. 13.17a or b also characterize an internal tube flow (or single stream heat exchanger) exchanging heat with a surface at constant temperature or an external fluid at constant temperature.

The third special case (Fig. 13.17c) involves a counterflow heat exchanger for which the heat capacity rates are equal ( $C_{h}=C_{c}$ ). The temperature difference $\Delta T$ must then be constant throughout the exchanger, in which case $\Delta T_{1}=\Delta T_{2}=\Delta T_{l m}$.

Fig. 13.17 Special heat exchanger conditions. a $C_{h} \gg C_{c}$ or a condensing vapor. b An evaporating liquid or $C_{h} \ll C_{c}$. c A counterflow heat exchanger with equivalent fluid heat capacities $C_{h}=C_{c}$ [5]

### 13.12 Compact Heat Exchangers

A heat exchanger is quite arbitrarily referred to as a compact heat exchanger, providing that it has a surface area density greater than about $700 \mathrm{~m}^{2} / \mathrm{m}^{3}$.

A special and important class of heat exchangers is used to achieve a very large ( $\geq 400 \mathrm{~m}^{2} / \mathrm{m}^{3}$ for liquids and $\geq 700 \mathrm{~m}^{2} / \mathrm{m}^{3}$ for gases) heat transfer surface area per unit volume. Termed compact heat exchangers, these devices have dense arrays of finned tubes or plates and are typically used when at least one of the fluids is a gas, and hence is characterized by a small convection coefficient. The tubes may be flat or circular, as in Figs. 13.18a, b, and c, respectively, and the fins may be plate or circular, as in Figs. 13.15a, b and c, respectively. Parallel-plate heat exchangers may be finned or corrugated and may be used in single-pass (Fig. 13.15d) or multipass (Fig. 13.15e) modes of operation. Flow passages associated with compact heat exchangers are typically small ( $D_{h} \leq 5 \mathrm{~mm}$ ), $D_{h}$ is the magnitude of the hydraulic diameter and the flow is often laminar. Many of the geometries are far too complicated to apply deterministic methods to predict their performance. So many for these compact heat exchangers have had their performance determined experimentally.

Kays and London [7] have studied a wide variety of configurations for heat transfer matrices, and catalogued their heat transfer and pressure drop characteristics. Figure 13.19 shows typical heat transfer materials for compact heat exchangers [5]. Figure 13.19a shows a circular finned-tube array with fins on individual tubes; Fig. 13.19b shows a plain plate-fin matrix formed by corrugation, and Fig. 13.19c shows a finned flat-tube matrix [5].

Fig. 13.18 Compact heat exchanger cores. a Fin-tube (flat tubes, continuous plate fins). b Fintube (circular tubes, continuous plate fins). c Fin-tube (circular tubes, circular fins). d Plate-fin (single pass). e Plate-fin (multipass) [5]

Fig. 13.19 Typical heat transfer matrices for compact heat exchangers. a Circular finned-tube matrix. b Plain plate-fin matrix. c Finned flat-tube matrix [5]

The heat transfer and pressure drop characteristics of such configurations for use as compact heat exchangers have been determined experimentally as explained above. Figs. 13.20, 13.21 and 13.22 show typical heat transfer and friction factor data for three different configurations.

Note that the principal dimensionless groups governing these correlations are the Stanton, Prandtl, and Reynolds numbers [5].

$$
\begin{equation*}
S t=\frac{h}{G c_{p}} \quad \operatorname{Pr}=\frac{c_{p} \mu}{k} \quad \operatorname{Re}=\frac{G D_{h}}{\mu} \tag{13.20}
\end{equation*}
$$

Fig. 13.20 Heat transfer and friction factor for flow across plate-finned circular tube matrix. (Courtsy of Kays and London)

Here $G$ is the mass velocity defined as

$$
\begin{equation*}
G=\frac{m}{A_{\min }} \mathrm{kg} /\left(m^{2} . s\right) \tag{13.21}
\end{equation*}
$$

where $m=$ total mass flow rate of fluid $(\mathrm{kg} / \mathrm{s})$ and $A_{\text {min }}=$ minimum free-flow cross-sectional area $\left(\mathrm{m}^{2}\right)$ regardless of where this minimum occurs.

The magnitude of the hydraulic diameter $D_{h}$ for each configuration is specified on Figs. 13.17-13.19. The hydraulic $D_{h}$ is defined as;

$$
\begin{equation*}
D_{h}=4 \frac{L A_{\min }}{A} \tag{13.22}
\end{equation*}
$$

Fig. 13.21 Heat transfer and friction factor for flow across finned flat-tube matrix. (Courtsy of Kays and London)
where $A$ is the total heat transfer area and the quantity $L A_{\text {min }}$ can be regarded as the minimum free-flow passage volume, since $L$ is the flow length of the heat exchanger matrix.

Thus, once the heat transfer and the friction factor charts such as those shown in Fig. 13.20 are available for a specified matrix and the Reynolds number Re for the flow is given, the heat transfer coefficient $h$ and the friction $f$ for flow across the matrix can be evaluated. Then the rating and sizing problem associated with the heat exchanger matrix can be performed by utilizing either the LMTD or the effectiveness-NTU method of analysis.

Fig. 13.22 Heat transfer and friction factor for flow across circular finned-tube matrix. (Courtsey of Kays and London)

## Chapter 14 <br> Gas Power Cycles

An important application of thermodynamics is the analysis of power cycles through which the energy absorbed as heat can be continuously converted into mechanical work. A thermodynamic analysis of the heat engine cycles provides valuable information regarding the design of new cycles or for improving the existing cycles. In this chapter, various gas power cycles are analyzed under some simplifying assumptions.

### 14.1 Introduction

Two most important areas application of thermodynamics are power generation and refrigeration and they both are usually accomplished by system that operate on thermodynamic a cycle.

Thermodynamically, the word of "cycle" is used in a procedure or arrangement in which some material goes through a cyclic process and one form of energy, such as heat at an elevated temperature from combustion of a fuel, is in part converted to another form, such as mechanical energy of a shaft, the remainder being rejected to a lower temperature sink that is also known as heat cycle.

Thermodynamic cycle is defined as a process in which a working fluid undergoes a series of state changes and finally returns to its initial state. A cycle plotted on any diagram of properties forms a closed curve (Fig. 14.1).

Note that a reversible cycle consists only of reversible processes. The area enclosed by the curve plotted for a reversible cycle on a p-v diagram represents the net work of the cycle as we explained in preceding chapters as follow:

- The work is done on the system, if the state changes happen in an anticlockwise manner.
- The work is done by the system, if the state changes happen in a clockwise manner.

Fig. 14.1 Schematic of a closed cycle

The purpose of a thermodynamic cycle is either to produce power, or to produce refrigeration/pumping of heat. Therefore, the cycles are broadly classified as follows:
A. Heat engine or power cycles.
B. Refrigeration/heat pump cycles.

A thermodynamic cycle requires, in addition to the supply of incoming energy;

1. A working substance, usually a gas or vapor;
2. A mechanism in which the processes or phases can be carried through sequentially; and
3. A thermodynamic sink to which the residual heat can be rejected.

The cycle itself is a repetitive series of operations.
Any thermodynamic cycle is essentially a closed cycle in which, the working substance undergoes a series of processes and is always brought back to the initial state.

However, some of the power cycles operate on open cycle. It means that the working substance is taken into the unit from the atmosphere at one end and is discharged into the atmosphere after undergoing a series of processes at the other end. The following are illustrations of heat engines operating on open cycle:

- Petrol and diesel engines in which the air and fuel are taken into the engine from a fuel tank and products of combustion are exhausted into the atmosphere.
- Steam locomotives in which the water is taken in the boiler from a tank and steam is exhausted into the atmosphere.

The basic processes of the cycle, either is open or closed, are heat addition, heat rejection, expansion, and compression. These processes are always present in a cycle even though there may be differences in working substance, the individual processes, pressure ranges, temperature ranges, mechanisms, and heat transfer arrangements.

Many cyclic arrangements, using various combinations of phases but all seeking to convert heat into work, were proposed by many investigators whose names are attached to their proposals. For example, the Diesel, Otto, Rankine, Brayton, Stirling, Ericsson, and Atkinson cycles. Not all proposals are equally efficient in the conversion of heat into work. However, they may offer other advantages, which have led to their practical development for various applications. See also Brayton cycle; Carnot cycle; Diesel cycle; Otto cycle; Stirling engine; Thermodynamic processes.

Fig. 14.2 Graphic illustration of thermal efficiency

Essentially, such devices do not form a cycle. However, they can be analyzed by adding imaginary processes to bring the state of the working substance, thus completing a cyclic. Note that the terms closed and open cycles that are used here do not mean closed system cycle and open system cycle. In fact, the processes both in closed and open cycles could either be closed or open system processes.

There is a basic pattern of processes common to power-producing cycles. There is a compression process wherein the working substance undergoes an increase in pressure and therefore density. There is an addition of thermal energy from a source such as a fossil fuel, a fissile fuel (fissile material is one that is capable of sustaining a chain reaction of nuclear fission), or solar radiation. Work is done by the system on the surroundings during an expansion process. There is a rejection process where thermal energy is transferred to the surroundings. The algebraic sum of the energy additions and abstractions is such that some of the thermal energy is converted into mechanical work.

Different types of working fluids are employed in the power plants. The nature of the working fluids can be classified into two groups:
a. Vapors.
b. Gases.

The power cycles are accordingly classified into two groups as:

1. Vapor power cycles in which the working fluid undergoes a phase change during the cyclic process.
2. Gas power cycles in which the working fluid does not undergo any phase change.

In the thermodynamic analysis of power cycles, our main interest lies in estimating the energy conversion efficiency or the thermal efficiency. The thermal efficiency of a heat engine is defined as the ratio of the network output $W$ delivered to the energy absorbed as heat $Q$ and mathematically is presented by symbol $\eta$ and can be written as:

$$
\begin{equation*}
\eta=\frac{W}{Q} \tag{14.1}
\end{equation*}
$$

and it can be illustrated as Fig. 14.2 below;
In this depiction, we identify the followings;

Fig. 14.3 Illustration of actual vs. ideal cycle in a $P-v$ diagram

LTER = Low Temperature Energy Reservoir<br>HTER = High Temperature Energy Reservoir

Using these definitions and refer to Fig. 14.2, the Equation of 14.1 can be written more precisely as follow;

$$
\begin{equation*}
\eta=\frac{W}{Q_{1}} \tag{14.2}
\end{equation*}
$$

where $Q_{1}$ is the heat supplied at high temperature.
A procedure or arrangement in which one form of energy, such as heat at an elevated temperature from combustion of a fuel, is in part converted to another form, such as mechanical energy on a shaft, and the remainder is rejected to a lowertemperature sink as low-grade heat.

Heat engines, depending on how the heat is supplied to the working fluid, are categorized in two types as;

## A. External combustion. <br> B. Internal combustion.

In external combustion engines, such as steam power plants, heat is supplied to the working fluid from an external source such as a furnace, a geothermal well, a nuclear reactor, or even the sun [1].

In internal combustion engines, such as automobile engines, this is done by burning the fuel within the system boundaries [1].

Our study of gas power cycles will involve the study of those heat engines in which the working fluid remains in the gaseous state throughout the cycle. We often study the ideal cycle in which internal irreversibilities and complexities (the actual intake of air and fuel, the actual combustion process, and the exhaust of products of combustion among others) are removed. We will be concerned with how the major parameters of the cycle affect the performance of heat engines. The performance is often measured in terms of the cycle efficiency of $\eta_{t h}$ as ratio of network $W_{n e t}$ and energy as heat of $Q_{i n}$. See Fig. 14.3 where one can observe Actual Cycle versus and

Fig. 14.4 Basic thermodynamic cycle

Ideal Cycle in a $P-v$ diagram and using the Eq. 14.1, and referring to Fig. 14.4 below, mathematically we can show that;

$$
\begin{equation*}
\eta_{t h}=\frac{W_{n e t}}{Q_{i n}} \tag{14.3}
\end{equation*}
$$

Several cycles utilize a gas as the working substance, the most common being the Otto cycle and the diesel cycle used in internal combustion engines. We are touching upon some of these cycles in this chapter such as Otto and others such as Brayton, Carnot, etc. and we will expand on them among other cycles for further evaluation as well.

### 14.1.1 Open Cycle

When internal combustion engine operation is examined, it is seen to differ in the process of heat supply for a typical heat engine cycle because there is a permanent change in the working fluid during combustion. Therefore, the fluid does not pass through a cycle so the internal combustion engine is often referred to as an "open cycle" device, not a cyclic thermodynamic heat engine.

The term "open cycle", while meaningless from a thermodynamic perspective, refers to the fact that energy is supplied to the engine from outside in the form of petroleum fuel and the unconverted portion of energy remaining in the spent combustion mixture is exhausted to the environment. "Closing the cycle", i.e. returning the rejected products to the starting point where they can be reused, is left for nature to accomplish-hence the term "open cycle" is coming to play.

An internal combustion engine is therefore a device for releasing mechanical energy from petroleum fuel using air as the working medium rather than a heat engine for processing air in a thermodynamic cycle. Heat, as such, is not supplied to the

Fig. 14.5 Illustration of a thermodynamic closed cycle

internal combustion engine, so it cannot be a heat engine in the sense described in most thermodynamic references.

A simulated heat engine cycle can be constructed to correspond approximately to the operation of an internal combustion engine by substitution of analogous heat transfer processes for some of the actual engine processes. The specific mechanism of such heat transfer is neglected because the simulation is only a theoretical model of the engine, not an actual device. Such cycles, called air standard cycles, which are subject of study in Sect. 13.3 of this chapter, are useful in the elementary study of internal combustion engines.

### 14.1.2 Closed Cycle

Thermodynamic cycles can be categorized yet another way closed and open cycles and open cycle was described in Sect. 13.1.1. In closed cycles, the working fluid is returning to the initial state at the end of the cycle and is recirculated. By the same talking, in open cycles, the working fluid is renewed at the end of each cycle instead of being recirculated. For example, in automobile engines, the combustion gases are exhausted and replaced by fresh air-fuel mixture at the end of each cycle. The engine operates on a mechanical cycle, but the working fluid does not go through a complete thermodynamic cycle [1] (Fig. 14.5).

As we said before, any thermodynamic cycle is essentially a closed cycle in which, the working substance undergoes a series of processes and is always brought back to the initial state.

### 14.2 Gas Compressors and Brayton Cycle

The work in a gas compressor is calculated by,

If we assume that the gas in the compressor is calorically perfect, then we have,

$$
\begin{equation*}
\dot{W}_{\text {comp }}=\dot{m} C_{p}\left(T_{e}-T_{i}\right) \tag{14.5}
\end{equation*}
$$

In many cases, this is a reasonable approximation. For noble gases, it is very accurate because they are calorically perfect. For air and similar working fluids, it is reasonable because the temperature rise is not that great and an average value of $C_{p}$ is usually adequate. However the average value of $C_{p}$ should be chosen based on a temperature between $T_{e}$ and $T$, not one at 300 K .

If then we assume that a compressor operates isentropically (adiabatic and reversible), the exit temperature can be related to the pressure rise in the compressor as shown below in Eq. 14.6;

$$
\begin{align*}
& T_{e}=T_{i}\left(\frac{p_{e}}{p_{i}}\right)^{\frac{\gamma-1}{\gamma}} \\
& \dot{W}=\dot{m} C_{p}\left[T_{e}-T_{i}\right]=\dot{m} C_{p} T_{i}\left[\frac{T_{e}}{T_{i}}-1\right]=\dot{m} \frac{\gamma R}{\gamma-1} T_{i}\left[\left(\frac{p_{e}}{p_{i}}\right)^{\frac{\gamma-1}{\gamma}}-1\right] \tag{14.6}
\end{align*}
$$

There are basically three types of compressors, reciprocating, centrifugal flow, and axial flow. In a reciprocating or positive displacement compressor, a piston slides in a cylinder and valves open and close to admit low-pressure fluid and exhaust high-pressure fluid. In centrifugal flow and axial flow compressors, the fluid enters at one end and is compressed by rotating blades and exits at the opposite end of the compressor. In the centrifugal flow compressor, the flow is in a radially outward direction and the compression is achieved by forcing the flow against the outer annulus of the compressor. In an axial flow compressor, a set of rotating blades move the flow through the compressor, acting as airfoils. They force the flow through an increasingly narrower channel, thus increasing the density and pressure. Gasoline and diesel engines are examples of reciprocating compressors, as are positive displacement pumps. Water pumps are examples of centrifugal flow compressors, similar to the rotor in a washing machine. Jet engine compressors are typically axial flow compressors. Reciprocating compressors require no priming and can reach very high pressures, but only moderate flow rates. Centrifugal flow and axial flow compressors usually require priming and can reach very high flow rates, but moderate pressures.

In this section we discuss the Brayton Thermodynamic Cycle which is used in all gas turbine engines. The Fig. 14.6 shows a T-s diagram of the Brayton Cycle. Using the turbine engine station numbering system, we begin with free stream conditions at station $\mathbf{0}$. In cruising flight, the inlet slows the air stream as it is brought to the compressor face at station 2. As the flow slows, some of the energy associated with the aircraft velocity increases the static pressure of the air and the flow is compressed. Ideally, the compression is isentropic and the static temperature is also

## Ideal Brayton Cycle <br> T-s diagram

Fig. 14.6 Illustration of Brayton cycle. (Courtesy of NASA)
increased as shown on the plot. The compressor does work on the gas and increases the pressure and temperature isentropically to station 3 the compressor exit. Since the compression is ideally isentropic, a vertical line on the T-s diagram describes the process. In reality, the compression is not isentropic and the compression process line leans to the right because of the increase in entropy of the flow. The combustion process in the burner occurs at constant pressure from station 3 to station 4. The temperature increase depends on the type of fuel used and the fuel-air ratio. The hot exhaust is then passed through the power turbine in which work is done by the flow from station 4 to station 5. Because the turbine and compressor are on the same shaft, the work done on the turbine is exactly equal to the work done by the compressor and, ideally, the temperature change is the same. The nozzle then brings the flow isentropically (adiabatic and reversible) back to free stream pressure from station 5 to station 8. Externally, the flow conditions return to free stream conditions, which complete the cycle. The area under the T-s diagram is proportional to the useful work and thrust generated by the engine. The T-s diagram for the ideal Brayton Cycle is shown here:

The Brayton cycle analysis is used to predict the thermodynamic performance of gas turbine engines.

As we know the gas turbine is another mechanical system that produces power and it may operate on a cycle when used as an automobile or truck engine, or on a closed cycle when used in a nuclear power plant [2].

Usage of Brayton process in a simple gas turbine cycle can be describe by first in an open cycle operation where air enters the compressor, and passes through a

Fig. 14.7 Illustration of Brayton components for open and closed cycles

Fig. 14.8 Illustration of the Brayton cycle on P-V and T-s diagram
constant-pressure combustion chamber, then goes through turbine, and then exits as product of combustion to the atmosphere, as shown in Fig. 14.7a. Similar situation can be studied when the combustion chamber a heat exchanger gets add on to the loop of Fig. 14.7a, in order to organize a closed cycle as it can be seen in Fig. 14.7b. Energy from some external source enters the cycle and additional heat exchanger that has been added on into the loop, transfers heat from the cycle so that the air can be returned to its initial state, as clearly can be seen in Fig. 14.7b.

The Brayton cycle is a theoretical cycle for simple gas turbine. This cycle consists of two isentropic and two constant pressure processes. Figure 14.8 shows the Brayton cycle on $P-V$ and $T-S$ coordinates. The cycle is similar to the Diesel cycle in compression and heat addition. The isentropic expansion of the Diesel cycle is further extended followed by constant pressure heat rejection.

The following notation gives the thermal efficiency in mathematical format for ideal cycle used to model the gas turbine, which utilizing isentropic compression and expansion in Brayton process as:

$$
\begin{equation*}
\eta_{t h}=\frac{\text { Heat added }- \text { Heat rejected }}{\text { Heat added }}=\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{14.7a}
\end{equation*}
$$

$$
\begin{align*}
\eta_{t h} & =\frac{m C_{p}\left(T_{3}-T_{1}\right)-m C_{p}\left(T_{4}-T_{1}\right)}{m C_{p}\left(T_{3}-T_{2}\right)} \\
& =1-\frac{T_{4}-T_{1}}{T_{3}-T_{2}}  \tag{14.7b}\\
& =1-\frac{T_{1}}{T_{2}} \frac{\left(T_{4} / T_{1}\right)-1}{\left(T_{3} / T_{2}\right)-1}
\end{align*}
$$

Using the following isentropic process and relations that we have;

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{P_{2}}{P_{1}}\right)^{\frac{\gamma-1}{\gamma}} \text { and } \frac{T_{3}}{T_{4}}=\left(\frac{P_{3}}{P_{4}}\right)^{\frac{\gamma-1}{\gamma}} \tag{14.7c}
\end{equation*}
$$

For ideal gas and observation P-V diagram of Fig. 14.8a obviously shows that we can state $P_{2}=P_{3}$ and $P_{1}=P_{4}$ as result, using the Eq. 14.7 c , will induced the following;

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\frac{T_{3}}{T_{4}} \text { or } \frac{T_{4}}{T_{1}}=\frac{T_{3}}{T_{2}} \tag{14.7d}
\end{equation*}
$$

Then the Thermal efficiency $\eta_{t h}$ from Eq. 14.7 a can be reduced to the following form as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{4}}{T_{3}}=1-\frac{T_{1}}{T_{2}} \tag{14.7e}
\end{equation*}
$$

Now if we introduce a term of the pressure ration $r_{2}=P_{2} / P_{1}$ the thermal efficiency from Eq. 14.7 e will take a form of the following;

$$
\begin{gather*}
\frac{T_{4}}{T_{3}}=\frac{T_{4}}{T_{3}}=\frac{V_{2}}{V_{1}}=\frac{1}{r_{p}^{\gamma-1}}  \tag{14.7f}\\
\frac{1}{r_{p}^{\gamma-1}}=\left(\frac{V_{2}}{V_{1}}\right)^{\gamma-1}\left\{\left(\frac{P_{1}}{P_{2}}\right)\right\}^{(\gamma-1) / \gamma}=\left(r_{p}\right)^{\frac{\gamma-1}{\gamma}}  \tag{14.7~g}\\
\eta_{\text {th }}=1-\frac{T_{1}}{T_{2}}=1-\left(\frac{P_{1}}{P_{2}}\right)^{(\gamma-1) / \gamma} \tag{14.7h}
\end{gather*}
$$

or

$$
\begin{equation*}
\eta_{t h}=1-r_{p}^{(1-\gamma) / \gamma} \tag{14.7i}
\end{equation*}
$$

Note that the above final expression for thermal efficiency $\eta_{t h}$ in both form of Eqs. 14.7 h and 14.7 i were obtained based on assumption of using constant specific heats. For more accurate calculations the gas tables should be utilized.

In actual gas turbine the compressor and the turbine are not isentropic and some losses are taking place. These losses, usually in the neighborhood of $85 \%$, significantly reduce the efficiency of the gas turbine engine [3].

Considering all the above we can see that the back work ratio is defined for a Brayton system as $W_{\text {comp }} / W_{\text {turb }}$. This an important feature of the gas turbine that limits thermal efficiency, that is required for compressor to have high work and is measured by this ration. This can actually be fairly large approaching 1.0. If the compressor is too inefficient, the Brayton Cycle will not work. Only when efficient air compressors were developed was the jet engine feasible.

Example 14.1 Air enters the compressor of a gas turbine at 100 kPa and $25^{\circ} \mathrm{C}$. For a pressure ratio of 5 and a maximum temperature of $850^{\circ} \mathrm{C}$ determine the back work ratio and the thermal efficiency using the Brayton cycle.

Solution To find the back work ration we can see that;

$$
\frac{W_{\text {comp }}}{W_{\text {turb }}}=\frac{C_{p}\left(T_{2}-T_{1}\right)}{C_{p}\left(T_{3}-T_{4}\right)}=\frac{T_{2}-T_{1}}{T_{3}-T_{4}}
$$

The temperatures are $T_{1}=273+25=298 \mathrm{~K}, T_{2}=273+850=1123 \mathrm{~K}$, and

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{(\gamma-1) / \gamma}=(298)(5)^{0.2857}=472.0 \mathrm{~K}
$$

and

$$
T_{4}=T_{3}\left(\frac{P_{4}}{P_{5}}\right)^{(\gamma-1) / \gamma}=(1123)\left(\frac{1}{5}\right)^{0.2857}=709.1 \mathrm{~K}
$$

The back work ratio is then given by;

$$
\frac{W_{\text {comp }}}{W_{\text {turb }}}=\frac{472.0-298}{1123-709}=0.420 \operatorname{or} 42.0 \%
$$

The thermal efficiency is

$$
\eta_{t h}=1-r^{(1-\gamma) / \gamma}=1-(5)^{-0.2857}=0.369 \operatorname{or} 36.9 \%
$$

Example 14.2 In an air-standard Brayton cycle with a pressure ratio of 8, the pressure and temperature at the start of the compression are 100 kPa and 300 K . The maximum allowed temperature in the cycle is 1200 K . Determine the energy added per kg air, the work done per kg air and the thermal efficiency of the cycle. Use figure below (Fig. 14.9).

Solution The air-standard Brayton cycle is shown on a P-V diagram in Figure above. The pressure ratio $r_{p}$ of the Brayton cycle is given by;

Fig. 14.9 Sketch of Example 14.2

$$
r_{p}=\frac{P_{2}}{P_{1}}=8
$$

In addition to pressure ratio, the other data given is $P_{1}=100 \mathrm{kPa}, T_{1}=300 \mathrm{~K}, T_{3}=1200 \mathrm{~K}$.
The temperature $T_{2}$ of air after isentropic compression process $1 \rightarrow 2$ is given by

$$
T_{2}=T_{1}\left(\frac{P_{2}}{P_{1}}\right)^{\frac{\gamma-1}{\gamma}}=300(8)^{\frac{0.4}{1.4}}=543.4 \mathrm{~K}
$$

The energy

$$
q_{1}=C_{p}\left(T_{3}-T_{2}\right)=1.0047(1200-543.4)=659.69 \mathrm{~kJ} / \mathrm{kg}
$$

The thermal efficiency $\eta_{t h}$ of the Brayton cycle is given by;

$$
\eta_{t h}=1-\left(\frac{1}{r_{p}}\right)^{(1-\gamma) / \gamma}=1-\left(\frac{1}{8}\right) \frac{0.4}{1.4}=0.448
$$

The network done $W_{\text {net }}$ per kg air is given by;

$$
W_{\text {net }}=q_{1} \eta_{t h}=(6.59 .69) \times(0.448)=295.54 \mathrm{~kJ} / \mathrm{kg}
$$

### 14.3 The Non-Ideal Brayton Cycle

The Ideal Air Standard Brayton Cycle assumes isentropic compression and expansion processes. So far this has not been achieved in any real device. The isentropic efficiency for these processes is defined as

$$
\begin{aligned}
& \text { Isentropicefficiency(compression) }=\frac{\Delta h_{\text {isentropic }}}{\Delta h_{\text {actual }}} \\
& \text { Isentropicefficiency(expansion) }=\frac{\Delta h_{\text {actual }}}{\Delta h_{\text {isentropic }}}
\end{aligned}
$$

Unfortunately the isentropic efficiency of a compressor or turbine will depend on the pressure ratio for the device. In doing parametric or design studies it is more useful to define an efficiency that does not depend on the pressure ratio, but only on the manufacturing tolerances and efficiencies of individual stages. This small stage, or infinitesimal stage, efficiency is called the polytropic efficiency.

Consider the combined First and Second Law for an infinitesimal process.

$$
\begin{equation*}
d h=v d p+T d s \tag{14.8}
\end{equation*}
$$

The term Tds represents a heat flow for the process. During a compression, the inefficiency of the process represents a heat flow into the system. For an expansion the inefficiency represents a heat flow out of the system. So on an infinitesimal basis we can write,

$$
\begin{align*}
& d h=v d p+(T d s)={ }^{v d p} / e_{c, p o l y} \quad \text { foracompressor }  \tag{14.9}\\
& d h=v d p+(-T d s)=e_{t, \text { poly }} * v d p \quad \text { foraturbine }
\end{align*}
$$

then these two equations can be integrated similar to the way the isentropic relation was integrated. For an isentropic expansion of a calorically perfect ideal gas we have,

$$
\begin{aligned}
v d p & =\frac{R T}{p} d p \\
d h & =c_{p} d T=\frac{R T}{p} d p \\
\frac{d T}{T} & =\frac{R}{C_{p}} \frac{d p}{p}=\frac{\gamma-1}{\gamma} \frac{d p}{p} \\
\left(\frac{T_{2}}{T_{1}}\right) & =\left(\frac{p_{2}}{p_{1}}\right)^{\frac{\gamma-1}{\gamma}}
\end{aligned}
$$

For a polytropic compression we have,

$$
\begin{aligned}
v d p & =\frac{R T}{e_{c, p o l y} p} d p \\
d h & =c_{p} d T=\frac{R T}{e_{c, p o l y} p} d p \\
\frac{d T}{T} & =\frac{R}{C_{p}} \frac{d p}{p}=\frac{\gamma-1}{e_{c, p o l y} \gamma} \frac{d p}{p} \\
\left(\frac{T_{2}}{T_{1}}\right) & =\left(\frac{p_{2}}{p_{1}}\right)^{\frac{\gamma-1}{e_{c, p o l y} \gamma}}
\end{aligned}
$$

And for a polytropic expansion we have,

$$
\begin{aligned}
v d p & =\frac{e_{t, p o l y} R T}{p} d p \\
d h & =c_{p} d T=\frac{e_{t, p o l y} R T}{p} d p \\
\frac{d T}{T} & =\frac{R}{C_{p}} \frac{d p}{p}=\frac{e_{t, p o l y}(\gamma-1)}{\gamma} \frac{d p}{p} \\
\left(\frac{T_{2}}{T_{1}}\right) & =\left(\frac{p_{2}}{p_{1}}\right)^{\frac{e_{t, p o l y}(\gamma-1)}{\gamma}}
\end{aligned}
$$

Now for a calorically perfect gas, the isentropic efficiency of a compressor is given by,

$$
\eta_{c, \text { isen }}=\frac{C_{p}\left(T_{\text {out }, \text { isen }}-T_{\text {in }}\right)}{C_{p}\left(T_{\text {out }, \text { actual }}-T_{\text {in }}\right)}=\frac{\frac{T_{\text {out }, \text { isen }}}{T_{\text {in }}}-1}{\frac{T_{\text {out }, \text { actual }}}{T_{\text {in }}}-1}=\frac{\left(\frac{p_{\text {out }}}{p_{\text {in }}}\right)^{\frac{\gamma-1}{\gamma}}-1}{\left(\frac{p_{\text {out }}}{p_{\text {in }}}\right)^{\frac{\gamma-1}{\gamma e_{c, p o l y ~}}}}
$$

And the isentropic efficiency of a turbine is given by,

$$
\eta_{t, \text { isen }}=\frac{C_{p}\left(T_{\text {out }, \text { actual }}-T_{\text {in }}\right)}{C_{p}\left(T_{\text {out }, \text { isen }}-T_{\text {in }}\right)}=\frac{\frac{T_{\text {out }, \text { actual }}}{T_{\text {in }}}-1}{\frac{T_{\text {out }, \text { isen }}}{T_{\text {in }}}-1}=\frac{\left(\frac{p_{\text {out }}}{p_{\text {in }}}\right)^{\frac{e_{t, p o l y}(\gamma-1)}{\gamma}}-1}{\left(\frac{p_{\text {out }}}{p_{\text {in }}}\right)^{\frac{\gamma-1}{\gamma e_{c, p o l y}}}}
$$

Fig. 14.10 Gas turbine cycle on a T-s diagram for Example 14.3

Example 14.3 A gas turbine operates in ambient conditions of $14.677 \mathrm{psi}, 17^{\circ} \mathrm{C}$, and the maximum cycle temperature is limited to 1000 K . The compressor, which has a polytropic efficiency of $88 \%$, is driven by the gas generator turbine, and a separate power turbine is geared to the power output on a separate shaft; both turbines have polytropic efficiencies of $90 \%$. There is a pressure loss of 2.9 psi bar between the compressor and the gas generator turbine inlet. Neglecting all other losses, and assuming negligible kinetic energy changes, calculates:
a. The compressor pressure ratio which will give maximum specific power output;
b. The isentropic efficiency of the power turbine.

For the gases in both turbines, take $c_{p}=1.15 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$ and $\gamma=1.33$.
For air take $c_{p}=1.005 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$ and $\gamma=1.4$.

## Solution

a. The cycle is shown on a $T-s$ diagram in Fig. 14.10.

Let $\frac{p_{2}}{p_{1}}=r$. From Eq. 14.17, we can write;

$$
T_{2}=T_{1} r^{(\gamma-1) / \gamma \eta_{\infty c}}=(17+273) \times r^{0.4 / 1.4 \times 0.88}=290 r^{0.325}
$$

Now

$$
\begin{aligned}
& p_{3}=p_{2}-0.2=\left(p_{1} \times r\right)-0.2=1.012 \times r-0.2 \\
& p_{5}=p_{1}=14.677
\end{aligned}
$$

$$
\text { or } \frac{p_{3}}{p_{5}}=\frac{14.677 r-2.9}{14.677}=r-0.198
$$

Since the polytropic efficiency of both turbines is the same then, using Eq. 14.14, provides;

$$
\begin{aligned}
\frac{T_{3}}{T_{5}} & =\frac{\left(p_{3}\right)^{(\gamma-1) \eta_{\infty} / \gamma}}{\left(p_{1}\right)}=(r-0.198)^{0.9 / 4} \\
T_{5} & =\frac{1000}{(r-0.198)^{0.225}}
\end{aligned}
$$

Turbine specific power output $=c_{p}\left(T_{3}-T_{5}\right)$

$$
\begin{aligned}
& =1.15\left(1000-\frac{1000}{(r-0.198)^{0.225}}\right) \\
& =1150\left[1-(r-0.198)^{-0.225}\right]
\end{aligned}
$$

$$
\begin{aligned}
\text { Compressor specific power output } & =c_{p}\left(T_{2}-T_{1}\right) \\
& =1.005\left(290 r^{0.325}-290\right) \\
& =291.5\left(r^{0.325}-1\right)
\end{aligned}
$$

Net specific power output

$$
\dot{W}=1150\left[1-(r-0.198)^{-0.225}\right]-291.5\left(r^{0.325}-1\right)
$$

To find the maximum of the above relation, we set $d \dot{W} / d r=0$ so we get

$$
0.225 \times 1150 \times(r-0.198)^{-1.225}=0.325 \times 291.5 \times r^{-0.675}
$$

Trial and error, or graphical, solution gives $r=6.65$
The compressor pressure ratio for maximum specific power output $=6.65$
b. $T_{2}=290 r^{0.325}=290(6.65)^{0.325}=536.8 \mathrm{~K}$

Now we can write the following
Gas turbine power output = Compressor power input
Therefore

$$
1.15\left(1000-T_{4}\right)=1.005(536.8-290)
$$

i.e.

$$
T_{4}=784.3 \mathrm{~K}
$$

Then

$$
\frac{p_{3}}{p_{4}}=\frac{\left(T_{3}\right)^{\gamma /(\gamma-1) \eta_{\infty e}}}{\left(T_{4}\right)}=\frac{(1000)^{4 / 0.9}}{(7843.3)}=2.944
$$

Also

$$
p_{3}=6.65 p_{1}-0.290=(6.65 \times 1.012)-0.290=4.73 \mathrm{bar}
$$

Therefore

$$
p_{4}=\frac{4.73}{2.944}=1.607 \mathrm{bar}
$$

Then

$$
\begin{gathered}
\frac{T_{4}}{T_{5}}=\frac{\left(p_{4}\right)^{(\gamma-1) / \eta_{\infty e} \mathrm{q}_{\gamma}}}{\left(p_{5}\right)}=\frac{(1.607)^{0.9 / 4}}{(14.677)}=1.110 \\
\frac{T_{4}}{T_{5 s}}=\frac{\left(p_{4}\right)^{(\gamma-1) / \gamma}}{\left(p_{5}\right)}=\frac{(1.607)^{0.25}}{(14.677)}=1.123
\end{gathered}
$$

Using the relationship for turbine isentropic efficiency, $\eta_{T}$ as below;
Power turbine isentropic efficiency $\eta_{P T}=\frac{c_{p}\left(T_{4}-T_{5}\right)}{c_{p}\left(T_{4}-T_{5 s}\right)}=\frac{\left(T_{4}-T_{5}\right)}{\left(T_{4}-T_{5 s}\right)}$
Then we can write

$$
\eta_{P T}=\frac{\left(T_{4}-T_{5}\right)}{\left(T_{4}-T_{5 s}\right)}=\frac{1-\left(T_{5} / T_{4}\right)}{1-\left(T_{5 s} / T_{4}\right)}=\frac{1-(1 / 1.11)}{1-(1 / 1.123)}=0.905 \mathrm{or} 90.5 \%
$$

### 14.4 The Air Standard Cycle

It is important to note that air standard cycle apply to the performance of an internal combustion engine because once the fuel ignites; it releases its energy as heat. If the process of combustion is ignored and the heat released is considered as heat applied during the appropriate portion of an air standard cycle, the heat conversion process in the internal combustion engine can be examined with standard thermodynamic methods.

It is equally important to remember, however, that the air standard cycle is not an internal combustion engine, so one must be careful not to carry the analogy too far. Some individuals attempt to apply limitations and requirements for closed cycles to processes that are not closed. This can easily lead to an incorrect analysis of the
open process because an open process by definition can gain or lose heat in the system by means that a closed cycle cannot.

To further analyze an air cycle in studying internal combustion engine performance characteristics through use of air standard cycles involves making a number of simplifying assumptions. It involves simulating engine operation with the help of thermodynamics to formulate mathematical expressions which can then be solved in order to obtain the relevant information.

The method of solution will depend upon the complexity of the formulation of the mathematical expressions, which in turn will depend upon the assumptions that have been introduced in order to analyze the processes in the engine. The more the assumptions, the simpler will be the mathematical expressions and the easier the calculations, but the lesser will be the accuracy of the final results.

Any device that operated in a thermodynamic cycle, absorbs thermal energy from a source, rejects a part of it to a sink and presents the difference between the energy absorbed and energy rejected as work to the surroundings is called a heat engine.

A heat engine is, thus, a device that produces work. In order to achieve this purpose, the air cycle heat engine-working medium undergoes the following processes:

1. A compression process where the working medium absorbs energy as work
2. A heat addition process where the working medium absorbs energy as heat from a source.
3. An expansion process where the working medium transfers energy as work to the surroundings.
4. A heat rejection process where the working medium rejects energy as heat to a sink.

If the working medium does not undergo any change of phase during its passage through the cycle, the heat engine is said to operate in a non-phase change cycle. A phase change cycle is one in which the working medium undergoes changes of phase. Air standard cycles, using air as the working medium are examples of nonphase change cycles while the steam and vapor compression refrigeration cycles are examples of phase change cycles.

We will consider several engines that operate in a cycle using primarily air as a working fluid. To do this we will make several approximations:

1. Air is the working fluid throughout the entire cycle. The mass of the small amount of injected fuel is negligible.
2. There is no inlet or exhaust process.
3. Combustion is replaced by a heat transfer process.
4. Heat transfer to the surroundings replaces the exhaust process used to restore air to its original state. Since we will start by considering open cycles, the return to initial conditions relies on the atmosphere to complete this part of the cycle. When we analyze a nuclear Brayton system, we will close the loop and completely contain the main loop working fluid. We will use a heat exchanger to bring the working fluid back to the compressor inlet conditions.
5. All processes will be assumed to be quasi equilibrium.
6. Air will be assumed to be a calorically perfect gas, so that we can use constant specific heats. For nuclear systems that use helium or a combination of noble gases this is not an approximation.

When we talk about reciprocating engines, one of the parameters that will be of most interest is the compression ratio. It is the ratio of the volume at bottom dead center of the piston movement divided by the volume at top dead center of the piston movement.

$$
\begin{equation*}
r=\frac{V_{B D C}}{V_{T D C}} \tag{14.10}
\end{equation*}
$$

Another characteristic of reciprocating engines is the Mean Effective Pressure. It is defined in terms of the work output of a cycle and the difference in volumes for the piston.

$$
\begin{equation*}
W_{\text {cycle }}=M E P\left(V_{B D C}-V_{T D C}\right) \tag{14.11}
\end{equation*}
$$

Since the air standard analysis is the simplest and most idealistic way of modeling an internal combustion engine, such cycles are also called ideal cycles and the engine running on such cycles are called ideal engines.

In order that the analysis such as above to be made as simple as possible, certain assumptions have to be made, which are listed below. These assumptions result in an analysis that is far from correct for most actual combustion engine processes, but the analysis is of considerable value for indicating the upper limit of performance. The analysis is also a simple means for indicating the relative effects of principal variables of the cycle and the relative size of the apparatus.

Assumptions:

1. The working medium is a perfect gas with constant specific heats and molecular weight corresponding to values at room temperature.
2. No chemical reactions occur during the cycle. The heat addition and heat rejection processes are merely heat transfer processes.
3. The processes are reversible.
4. Losses by heat transfer from the apparatus to the atmosphere are assumed to be zero in this analysis.
5. The working medium at the end of the process (cycle) is unchanged and is at the same condition as at the beginning of the process (cycle).

When selecting an idealized process one is always faced with the fact that the simpler the assumptions, the easier the analysis, but the farther the result from reality. The air cycle has the advantage of being based on a few simple assumptions and of lending itself to rapid and easy mathematical handling without recourse to thermodynamic charts or tables or complicated calculations. On the other hand, there is

Fig. 14.11 Sketch of Example 14.4

always the danger of losing sight of its limitations and of trying to employ it beyond its real usefulness.

Example 14.4 An engine operates with air on the cycle in figure below with isentropic $1 \rightarrow 2$ and $3 \rightarrow 4$. If the compression ratio is 12 , the minimum pressure is 200 kPa , and the maximum pressure is 10 MPa determine (a) the percent clearance and (b) the MEP (Fig. 14.11).

## Solution

a. The percent clearance is given by;

$$
c=\frac{V_{2}}{V_{1}-V_{2}}(100)
$$

But the compression ratio is $r=V_{1} / V_{2}$. Thus we have,

$$
c=\frac{V_{2}}{12 V_{2}-V_{2}}(100)=\frac{100}{11}=9.09 \%
$$

b. To determine the MEP we must calculate the area under the $P-V$ diagram. This is equivalent to calculating the work. The work from $3 \rightarrow 4$ is, using $P V^{\gamma}=C$;

$$
W_{3 \rightarrow 4}=\int P d V=C \int \frac{d V}{V^{\gamma}}=\frac{C}{1-\gamma}\left(V_{4}^{1-\gamma}-V_{3}^{1-\gamma}\right)=\frac{P_{4} V_{4}-P_{3} V_{3}}{1-\gamma}
$$

where $C=P_{4} V_{4}^{\gamma}=P_{3} V_{3}^{\gamma}$. But we know that $V_{4} / V_{3}=12$, so

$$
W_{3 \rightarrow 4}=\frac{V_{3}}{1-\gamma}\left(12 P_{4}-P_{3}\right)
$$

Likewise, the work from $1 \rightarrow 2$ is

$$
W_{1 \rightarrow 2}=\frac{V_{2}}{1-\gamma}\left(P_{2}-12 P_{1}\right)
$$

Since no work occurs in the two constant-volume processes, we find, using $V_{2}=V_{3}$

$$
W_{\text {cycle }}=\frac{V_{2}}{1-\gamma}\left(12 P_{4}-P_{3}+P_{2}-12 P_{1}\right)
$$

The pressures $P_{2}$ and $P_{4}$ are found as follows;

$$
P_{2}=P_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma}=(200)(12)^{1.4}=1665 \mathrm{kPa}
$$

and

$$
P_{4}=P_{3}\left(\frac{V_{3}}{V_{4}}\right)^{\gamma}=(1000)\left(\frac{1}{12}\right)^{1.4}=308
$$

hence

$$
W_{\text {cycle }}=\frac{V_{2}}{-0.4}[(12)(308)-1000+1665-(12)(200)]=20070 V_{2}
$$

But $W_{\text {cycle }}=(\operatorname{MEP})\left(V_{1}-V_{2}\right)=(\operatorname{MEP})\left(12 V_{1}-V_{2}\right)$; equating the two expressions yields

$$
\mathrm{MEP}=\frac{20070}{11}=1824 \mathrm{kPa}
$$

### 14.5 Equivalent Air Cycle

A particular air cycle is usually taken to represent an approximation of some real set of processes which the user has in mind. Generally speaking, the air cycle representing a given real cycle is called an Equivalent Air Cycle. The equivalent cycle has, in general, the following characteristics in common with the real cycle, which it approximates:

1. A similar sequence of processes.
2. Same ratio of maximum to minimum volume for reciprocating engines or maximum to minimum pressure for gas turbine engines.
3. The same pressure and temperature at a given reference point.
4. An appropriate value of heat addition per unit mass of air.

Now under above circumstances that that both Air Standard Cycles and Equivalent Air Cycle are mentioned and taken under consideration, we now can study and describe other known gas power engine cycles, which are subject of next few sections.

Fig. 14.12 Steady flow Carnot engine

Fig. 14.13 Reciprocating Carnot engine

Process $1 \rightarrow 2$ : isothermal

### 14.6 Carnot Cycle

A Carnot gas cycle operating in a given temperature range is shown in the $T-s$ diagram in Fig. 14.12a. One way to carry out the processes of this cycle is through the use of steady-state, steady-flow devices as shown in Fig. 14.12b. The isentropic expansion process 2-3 and the isentropic compression process 4-1 can be simulated quite well by a well-designed turbine and compressor respectively, but the isothermal expansion process $1-2$ and the isothermal compression process $3-4$ are most difficult to achieve. Because of these difficulties, a steady-flow Carnot gas cycle is not practical.

The Carnot gas cycle could also be achieved in a cylinder-piston apparatus (a reciprocating engine) as shown in Fig. 14.13b. The Carnot cycle on the p-v diagram

Fig. 14.14 Carnot cycle on $P-V$ and $T-S$ diagrams
is as shown in Fig. 14.13a, in which processes 1-2 and 3-4 are isothermal while processes 2-3 and 4-1 are isentropic. We know that the Carnot cycle efficiency is given by the expression.

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{L}}{T_{H}}=1-\frac{T_{4}}{T_{1}}=1-\frac{T_{3}}{T_{2}} \tag{14.12}
\end{equation*}
$$

The cycle associated with the Carnot engine is shown in Fig. 14.13 in above, using an ideal gas as the working substance. It is composed of the following four reversible processes [1]:

Process $1 \rightarrow 2$ An Isothermal Expansion. Heat is transferred reversibly from the high-temperature reservoir at the constant temperature $T_{H}$. The piston in the cylinder is withdrawn and the volume increases
Process $2 \rightarrow 3$ An Isentropic (Adiabatic Reversible Expansion). The cylinder is completely insulated so that no heat transfer occurs during this reversible process. The piston continues to be withdrawn, with the volume increasing

Process $3 \rightarrow 4$ An isothermal compression. Heat is transferred reversibly to the low-temperature reservoir at the constant temperature $T_{L}$. The piston compresses the working substance, with the volume decreasing
Process $4 \rightarrow 1 \quad$ An adiabatic reversible compression. The completely insulated cylinder allows no heat transfer during this reversible process. The piston continues to compress the working substance until the original volume, temperature, and pressures are reached, thereby completing the cycle

Applying the first law of thermodynamic to the Carnot cycle presented in Fig. 14.14, we see that;

$$
\begin{equation*}
W_{\text {net }}=Q_{H}-Q_{L} \tag{14.13}
\end{equation*}
$$

where $Q_{L}$ is assumed to be a positive value for the heat transfer to the low-temperature reservoir. This allows us to write the thermal efficiency for the Carnot cycle as;

$$
\begin{equation*}
\eta_{t h}=\frac{Q_{H}-Q_{L}}{Q_{H}}=1-\frac{Q_{L}}{Q_{H}} \tag{14.14}
\end{equation*}
$$

Under the above condition Eq. 14.10 sometimes can be expressed as the following form;

$$
\begin{equation*}
\eta_{\text {Carnot }}=1-\frac{T_{L}}{T_{H}} \tag{14.15}
\end{equation*}
$$

Also based on the Potter and Somerton [1], the following examples will be used to prove the following three postulates:

1. It is impossible to construct an engine, operating between two given temperature reservoirs, that is more efficient than the Carnot engine.
2. The efficiency of a Carnot engine is not dependent on the working substance used or any particular design feature of the engine.
3. All reversible engines, operation between two given temperature reservoir, have the same efficiency as a Carnot engine operating between the same two temperature reservoirs.

Since the working fluid is an ideal gas with constant specific heats, we have, for the isentropic process; we have the following relationship as;

$$
\begin{equation*}
\frac{T_{1}}{T_{4}}=\left(\frac{V_{4}}{V_{1}}\right)^{\gamma-1} \text { and } \frac{T_{2}}{T_{3}}=\left(\frac{V_{3}}{V_{2}}\right)^{\gamma-1} \tag{14.16}
\end{equation*}
$$

Now, $T_{1}=T_{2}$ and $T_{4}=T_{3}$, therefore we can conclude that;

$$
\begin{equation*}
\frac{V_{4}}{V_{1}}=\frac{V_{3}}{V_{2}}=r_{\mathrm{v}}=\text { Compressionorexpansionvolumeratio } \tag{14.17}
\end{equation*}
$$

Then, Carnot cycle efficiency using the ratio in above, may be written as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{1}{r_{\mathrm{v}}^{\gamma-1}} \tag{14.18}
\end{equation*}
$$

From the Eq. 14.18 in above, it can be observed that the Carnot cycle efficiency increases as $r$ increases. This implies that the high thermal efficiency of a Carnot cycle is obtained at the expense of large piston displacement. In addition, for isentropic processes we have,

$$
\begin{equation*}
\frac{T_{1}}{T_{4}}=\left(\frac{P_{1}}{P_{4}}\right)^{\frac{\gamma-1}{\gamma}} \text { and } \frac{T_{2}}{T_{3}}=\left(\frac{P_{2}}{P_{3}}\right)^{\frac{\gamma-1}{\gamma}} \tag{14.19}
\end{equation*}
$$

Since, $T_{1}=T_{2}$ and $T_{4}=T_{3}$, we have

$$
\begin{equation*}
\frac{P_{1}}{P_{4}}=\frac{P_{2}}{P_{3}}=r_{p}=\text { Pressure ratio } \tag{14.20}
\end{equation*}
$$

Fig. 14.15 Working of Carnot engine

Therefore, Carnot cycle efficiency may be written as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{1}{r_{p}^{\frac{\gamma-1}{\gamma}}} \tag{14.21}
\end{equation*}
$$

From the Eq. 14.21 in above, it can be observed that, the Carnot cycle efficiency can be increased by increasing the pressure ratio. This means that Carnot cycle should be operated at high peak pressure to obtain large efficiency. See Fig. 14.15.

Example 14.5 A Carnot engine delivers 10 kW of power while absorbing energy as heat from a source at $1000^{\circ} \mathrm{C}$. It rejects energy as heat to a sink at $27^{\circ} \mathrm{C}$. Determine the energy absorbed and the energy rejected per second by the engine.

Solution We know that the thermal efficiency $\eta_{t h}$ of a Carnot engine is given by;

$$
\begin{aligned}
\eta_{t h} & =1-\frac{T_{2}}{T_{1}}=\frac{\dot{W}}{\dot{Q}_{1}}=1-\frac{(273+27)^{\circ} \mathrm{K}}{(273+1000)^{\circ} \mathrm{K}}=0.7643 \\
& =0.7643=\frac{\dot{W}}{\dot{Q}_{1}}=\frac{10 \times 10^{3}}{\dot{Q}_{1}} \quad \dot{Q}_{1}=13.084 \mathrm{~kW}
\end{aligned}
$$

But $\dot{W}=\dot{Q}_{1}-\dot{Q}_{2}$ or $\dot{Q}_{2}=\dot{Q}_{1}-\dot{W}=13,084-10=3.084 \mathrm{~kW}$.
Therefore the energy absorbed per second by the engine is equal to $13.084 \mathrm{~kJ} / \mathrm{s}$. The energy rejected per second by the engine is equal to $3.084 \mathrm{~kJ} / \mathrm{s}$.

Fig. 14.16 Otto cycle on $P-V$ and $T$ - $S$ diagrams

### 14.7 Otto Cycle

The air-standard-Otto cycle is the idealized cycle for the spark-ignition internal combustion engines. This cycle is shown above on $P-V$ and $T-s$ diagrams. The spark-ignition engine is modeled with this Otto cycle.

The Otto cycle $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ consists of following four processes:

$$
\begin{array}{ll}
\text { Process } 1 \rightarrow 2 & \text { Reversible adiabatic compression of air } \\
\text { Process } 2 \rightarrow 3 & \text { Heat addition at constant volume } \\
\text { Process } 3 \rightarrow 4 & \text { Reversible adiabatic expansion of air } \\
\text { Process } 4 \rightarrow 1 & \text { Heat rejection at constant volume }
\end{array}
$$

Since processes $1 \rightarrow 2$ and $3 \rightarrow 4$ are adiabatic processes, the heat transfer during the cycle takes place only during processes $2 \rightarrow 3$ and $4 \rightarrow 1$ respectively. Mathematically speaking the processes for the Otto cycle are described on the two charts that are shown in Fig. 14.16. Therefore, thermal efficiency $\eta_{t h}$ can be written as;

$$
\begin{equation*}
\eta_{t h}=\frac{\text { Net Workdone }}{\text { Net Heat Added }}=\frac{\dot{W}_{n e t}}{\dot{Q}_{i n}} \tag{14.22}
\end{equation*}
$$

Note that the two heat transfer processes is taking place during the constant-volume processes, for which the work is zero and this results that Eq. 14.22 to take the following form of;

$$
\begin{equation*}
\eta_{t h}=\frac{\text { Heat Added }- \text { Heat Rejected }}{\text { Heat Added }}=\frac{\dot{Q}_{\text {in }}-\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} 1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{14.23}
\end{equation*}
$$

Consider ' $m$ ' kg of working fluid, and assume each quantity in Eq. 14.23 to be positive process, then we have;

$$
\left\{\begin{array}{l}
\text { Heat Added }=\dot{Q}_{\text {in }}=m C_{\mathrm{v}}\left(T_{3}-T_{2}\right)  \tag{14.24}\\
\text { Heat Rejected }=\dot{Q}_{\text {out }}=m C_{\mathrm{v}}\left(T_{4}-T_{1}\right)
\end{array}\right.
$$

Substitution of the set of Eq. 14.24 into 14.23 , we can write;

$$
\begin{equation*}
\eta_{t h}=1-\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}}=1-\frac{m C_{\mathrm{v}}\left(T_{3}-T_{2}\right)}{m C_{\mathrm{v}}\left(T_{4}-T_{1}\right)}=1-\frac{T_{3}-T_{2}}{T_{4}-T_{1}} \tag{14.25}
\end{equation*}
$$

Equation 14.25 can be rearranged and be presented as follow;

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{1}}{T_{2}}\left[\frac{T_{4} / T_{1}-1}{T_{3} / T_{2}-1}\right] \tag{14.26}
\end{equation*}
$$

For an isentropic (reversible adiabatic) processes $3 \rightarrow 4$ and $1 \rightarrow 2$, we can write the following form for Eq. 14.26;

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1} \text { and } \frac{T_{3}}{T_{4}}=\left(\frac{V_{4}}{V_{3}}\right)^{\gamma-1} \tag{14.27}
\end{equation*}
$$

But using the fact that $V_{1}=V_{4}$ and $V_{3}=V_{2}$, we see that

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\frac{T_{3}}{T_{4}} \text { or } \frac{T_{1}}{T_{2}}=\frac{T_{4}}{T_{3}} \tag{14.28}
\end{equation*}
$$

Utilizing the relationships of Eq. 14.28 allows writing the Eq. 14.24 to obtain the final form of thermal efficiency $\eta_{t h}$ as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{1}}{T_{2}}=1-\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1} \tag{14.29}
\end{equation*}
$$

Defining the parameter $r=V_{1} / V_{2}$ that is called as Compression Ratio (CR), then Eq. 14.28 can be simplifies as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{1}{r^{\gamma-1}} \tag{14.30}
\end{equation*}
$$

From the Eq. 14.15, it can be observed that the efficiency of the Otto cycle is mainly the function of compression ratio for the given ratio of $C_{p}$ and $C_{\mathrm{v}}$. If we plot the variations of the thermal efficiency with increase in compression ratio for different gases, the curves are obtained as shown in Fig. 14.17. Beyond certain values of compression ratios, the increase in the thermal efficiency is very small, because the curve tends to be asymptotic. However, practically the compression ratio of petrol

Fig. 14.17 Effect of CR and $\gamma$ on efficiency for Otto cycle

engines is restricted to maximum of nine or ten due to the phenomenon of knocking at high compression ratios. Same equation also indicates that, the higher the compression ratio, the higher the thermal efficiency.

Example 14.6 A spark-ignition engine is proposed to have a compression ratio of 10 while operating with a low temperature of $200^{\circ} \mathrm{C}$ and a low pressure of 200 kPa . If the work output is to be $1000 \mathrm{~kJ} / \mathrm{kg}$, calculate the maximum possible thermal efficiency and compare with that of a Carnot cycle. Also calculate the MEP (See next Section for MEP).

Solution The Otto cycle provides the model for this engine. The maximum possible thermal efficiency for the engine would be;

$$
\eta_{t h}-1-\left(\frac{1}{r}\right)^{\gamma-1}=1-\left(\frac{1}{10}\right)^{0.4}=0.602 \text { or } 60.2 \%
$$

Since processes $1 \rightarrow 2$ is isentropic, we find that

$$
T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1}=(473)(8)^{0.4}=1188 \mathrm{~K}
$$

The net work for the cycle is given by;

$$
W_{\text {net }}=W_{1 \rightarrow 2}+W_{2 \rightarrow 3}^{0}+W_{3 \rightarrow 4}+W_{4 \rightarrow 1}^{0}=C_{\mathrm{v}}\left(T_{1}-T_{2}\right)+C_{\mathrm{v}}\left(T_{1}-T_{2}\right)
$$

or

$$
1000=(0.717)\left(473-1188+T_{3}-T_{4}\right)
$$

But, for the isentropic process $3 \rightarrow 4$;

$$
T_{3}=T_{4}\left(\frac{V_{4}}{V_{3}}\right)^{\gamma-1}=\left(T_{4}\right)(10)^{0.4}=2.512 T_{4}
$$

Solving the last two equations simultaneously (a practice left for the readers), we find $T_{3}=3508 \mathrm{~K}$ and $T_{4}=1397 \mathrm{~K}$, so that (applying Eq. 14.15);

$$
\eta_{\text {carnot }}=1-\frac{T_{L}}{T_{H}}=1-\frac{473}{3508}=0.865 \text { or } 86.5 \%
$$

The Otto cycle efficiency is less than that of a Carnot cycle operating between the limiting temperatures because the heat transfer processes in the Otto cycle are not isothermal.

$$
W_{\text {net }}=(\mathrm{MEP})\left(V_{1}-V_{2}\right)
$$

We have

$$
V_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(473)}{200}=0.6788 \mathrm{~m}^{3} / \mathrm{kg} \quad \text { or } \quad V_{2}=\frac{V_{1}}{10}
$$

Thus;

$$
\mathrm{MEP}=\frac{W_{\text {net }}}{V_{1}-V_{2}}=\frac{1000}{(0.9)(0.6788)}=1640 \mathrm{kPa}
$$

### 14.7.1 Mean Effective Pressure (Otto Cycle)

Generally, it is defined as the ratio of the net work done to the displacement volume of the piston.

Let us consider ' $m \mathrm{~m}$ ' kg of working substance.

$$
\begin{align*}
\text { Net Work Done } & =m C_{\mathrm{v}}\left\{\left(T_{3}-T_{2}\right)-\left(T_{4}-T_{1}\right)\right\}  \tag{14.31}\\
\text { Displacement Volume } & =\left(V_{1}-V_{2}\right) \\
& =V_{1}\left(1-\frac{1}{r}\right)=\frac{m R T_{1}}{P_{1}}\left(\frac{r-1}{r}\right)  \tag{14.32}\\
& =\frac{m C_{\mathrm{v}}(\gamma-1) T_{1}}{P_{1}}\left\{\frac{r-1}{r}\right\}
\end{align*}
$$

Knowing that by now $R$ is Universal Ideal Gas Constant and $\gamma=C_{p} / C_{\mathrm{v}}$ is the Specific Heat Index, their relation between each other is defined as;

$$
\begin{equation*}
R=C_{p}-C_{\mathrm{v}}=C_{\mathrm{v}}(\gamma-1) \tag{14.33}
\end{equation*}
$$

Substituting for Eq. 14.33 into 14.32 will result in an equation and relation for Mean Efficiency Pressure (MEP) defined as;

$$
\begin{align*}
\text { MEP } & =\frac{m \ell_{\mathrm{v}}\left[\left(T_{3}-T_{2}\right)-\left(T_{4}-T_{1}\right)\right]}{\frac{m \ell_{\mathrm{v}}(\gamma-1)}{P_{1}}\left\{\left(\frac{r-1}{r}\right)\right\}}  \tag{14.34}\\
& =\left(\frac{1}{\gamma-1}\right)\left(\frac{P_{1}}{T_{1}}\right)\left(\frac{r}{r-1}\right)\left\{\left(T_{3}-T_{2}\right)-\left(T_{4}-T_{1}\right)\right\}
\end{align*}
$$

Now,

$$
\begin{equation*}
T_{2}=T_{1}(r)^{\gamma-1} \tag{14.35}
\end{equation*}
$$

Let,

$$
\begin{equation*}
r_{p}=\frac{P_{3}}{P_{2}}=\frac{T_{3}}{T_{2}}=\text { PressureRatio } \tag{14.36}
\end{equation*}
$$

Or,

$$
\begin{equation*}
T_{3}=\frac{P_{3}}{P_{2}} T_{2}=r_{p} T_{2}=r_{p} r^{\gamma-1} T_{1} \text { for } V=C \tag{14.37}
\end{equation*}
$$

So,

$$
\begin{equation*}
T_{4}=T_{3}\left(\frac{1}{r}\right)^{\gamma-1}=r_{p} r^{\gamma-1} T_{1}\left(\frac{1}{r}\right)^{\gamma-1}=r_{p} T_{1} \tag{14.38}
\end{equation*}
$$

Then,

$$
\begin{align*}
\text { MEP } & =\frac{P_{1} r}{(r-1)(\gamma-1)}\left\{\left(r_{p} r^{\gamma-1}-r^{\gamma-1}\right)-\left(r_{p}-1\right)\right\} \\
& =P_{1} r\left\{\left(\frac{r^{\gamma-1}\left(r_{p}-1\right)-\left(r_{p}-1\right)}{(\gamma-1)(r-1)}\right)\right\}  \tag{14.39}\\
\text { MEP } & =P_{1} r\left\{\frac{\left(r^{\gamma-1}-1\right)\left(r_{p}-1\right)}{(r-1)(\gamma-1)}\right\} \tag{14.40}
\end{align*}
$$

Example 14.7 Consider an air-standard Otto cycle with a compression ratio of 8 . At the beginning of the compression stroke, the temperature is 300 K and pressure is 100 kPa . Thermal energy $q$ is supplied at $1840 \mathrm{~kJ} / \mathrm{kg}$. Given that $C_{\mathrm{v}}$ for air is $0.7176 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$, determine:
a. The temperature and pressure at the terminal points of all the processes.

## b. The thermal efficiency.

c. The work done per kilogram air, and
d. The mean effective pressure.

Solution It is given that $T_{1}=300 \mathrm{~K} ; P_{1}=100 \mathrm{kPa}$ and $r_{0}=\frac{V_{1}}{V_{2}}=8$
a. Process $1 \rightarrow 2$ is isentropic. Therefore,

$$
\begin{gathered}
P V^{\gamma}=\text { constant } \\
T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1}=300(8)^{0.4}=689.2 \mathrm{~K} \\
P_{2}=P_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma}=100(8)^{1.4}=1837.9 \mathrm{kPa}
\end{gathered}
$$

Process $2 \rightarrow 3$ is a constant volume process. Hence,

$$
q=u_{3}-u_{2}=C_{\mathrm{v}}\left(T_{3}-T_{2}\right)
$$

Therefore,

$$
1840=0.7176\left(T_{3}-689.2\right) \operatorname{or} T_{3}=3253.5 \mathrm{~K}
$$

For a constant volume process;

$$
\begin{gathered}
\frac{P_{3}}{T_{3}}=\frac{P_{2}}{T_{2}} \\
P_{3}=\frac{T_{3} P_{2}}{T_{2}}=\frac{3253.5 \times 1837.9}{689.2}=8676.1 \mathrm{kPa}
\end{gathered}
$$

$3 \rightarrow 4$ is an isentropic process. Hence

$$
\begin{aligned}
& T_{4}=T_{3}\left(\frac{V_{3}}{V_{4}}\right)^{\gamma-1}=3253.5\left(\frac{1}{8}\right)^{0.4}=1416.2 \mathrm{~K} \\
& P_{4}=P_{3}\left(\frac{V_{3}}{V_{4}}\right)^{\gamma-1}=8676.1\left(\frac{1}{8}\right)^{1.4}=472.1 \mathrm{kPa}
\end{aligned}
$$

b. The thermal efficiency $\eta_{t h}$ is given by Eq. 14.29 , so we have;

$$
\eta_{t h}=1-\left(\frac{1}{r}\right)^{\gamma-1}=1-\left(\frac{1}{8}\right)^{0.4}=0.565
$$

c. The work done per kilogram air is;

$$
\text { Workdone }=q \eta_{t h}=1840(0.565)=1039.6
$$

d. The mean effective pressure can be calculated as follow;

$$
\begin{gathered}
V_{1}=\frac{N R T_{1}}{P_{1}}=\frac{8.314 \times 10^{3} \times 300}{28.97 \times 10^{5}}=0.861 \mathrm{~m}^{3} / \mathrm{kg} \\
V_{2}={ }^{V_{1}} / r=0.861 / 8=0.1076 \mathrm{~m}^{3} / \mathrm{kg} \\
\mathrm{MEP}={ }^{1039.6} /(0.861-0.1076)=1379.88 \mathrm{kPa}
\end{gathered}
$$

### 14.8 Diesel Cycle

The engines in use today, which are known as diesel engines, are far diverged from the original design by Diesel in 1892 who worked on the idea of spontaneous ignition of powered coal, which was blasted into the cylinder by compressed air. Air standard diesel cycle is an idealized cycle for diesel engines and if air is compressed to a high enough pressure ratios, typically above 14 or greater, no spark will be required to ignite the fuel. This process is as shown on $P-V$ and $T-s$ diagrams in Fig. 14.15 below.

The Diesel cycle $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ consists of following four processes:

| Process $1 \rightarrow 2$ | Reversible adiabatic compression |
| :--- | :--- |
| Process $2 \rightarrow 3$ | Constant pressure heat addition |
| Process $3 \rightarrow 4$ | Reversible adiabatic compression |
| Process $4 \rightarrow 1$ | Constant volume heat rejection |

Consider ' $m$ ' kilogram of fluid. Since the compression and expansion processes are reversible adiabatic processes, we can write,

As before the, using Fig. 14.18, we can write, the thermal efficient $\eta_{t h}$ as the following form;

$$
\begin{equation*}
\eta_{t h}=\frac{\dot{W}_{\text {net }}}{\dot{Q}_{i n}}=\frac{\dot{Q}_{\text {in }}-\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}}=1+\frac{\dot{Q}_{\text {out }}}{\dot{Q}_{\text {in }}} \tag{14.41}
\end{equation*}
$$

Fig. 14.18 Illustration of a diesel cycle

For constant-volume and the constant-pressure process, we have;

$$
\begin{equation*}
\dot{Q}_{\text {out }}=\dot{m} C_{v}\left(T_{4}-T_{1}\right) \operatorname{and} \dot{Q}_{\text {in }}=\dot{m} C_{p}\left(T_{3}-T_{2}\right) \tag{14.42}
\end{equation*}
$$

Substituting for Eq. 14.41 the quantities that are define in Eq. 14.42, we have;

$$
\begin{equation*}
\eta_{t h}=1-\frac{C_{v}\left(T_{4}-T_{1}\right)}{C p\left(T_{3}-T_{2}\right)}=1-\frac{\left(T_{4}-T_{1}\right)}{\gamma\left(T_{3}-T_{2}\right)}=1-\frac{1}{\lambda}\left(\frac{\left(T_{4}-T_{1}\right)}{\left(T_{3}-T_{2}\right)}\right) \tag{14.43}
\end{equation*}
$$

Equation 14.43 can be written as;

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{1}}{\gamma T_{2}}\left[\frac{T_{4 /}-1}{T_{3 /}-1}\right]=1-\frac{1}{r^{\gamma-1}} \frac{r-1}{\lambda(r-1)} \tag{14.44}
\end{equation*}
$$

From Eq. 14.44 we can conclude the followings;

$$
\begin{equation*}
T_{2}=T_{1} r^{\gamma-1} \text { orr } r=\frac{V_{1}}{V_{2}}=\frac{V_{4}}{V_{2}} \tag{14.45}
\end{equation*}
$$

Defining the cutoff ratio as;

$$
\begin{equation*}
\text { cutoffratio }=r_{c}=\frac{T_{3}}{T_{2}}=\frac{V_{3}}{V_{2}} \tag{14.46}
\end{equation*}
$$

Then we have;

$$
\begin{equation*}
T_{3}=r_{c} T_{2}=r_{c} T_{1} r^{\gamma-1} \tag{14.47}
\end{equation*}
$$

$$
\begin{align*}
T_{4} & =T_{3}\left(\frac{V_{3}}{V_{4}}\right)^{\gamma-1}=T_{3}\left(\frac{V_{4}}{V_{3}}\right)^{\gamma-1} \\
& =T_{3}\left(\frac{V_{4}}{V_{2}} \frac{V_{2}}{V_{3}}\right)^{\gamma-1}=T_{3}\left(\frac{r}{r_{c}}\right)^{1-\gamma}  \tag{14.48}\\
& =r_{c} T_{1} r^{\gamma-1}\left(\frac{r}{r_{c}}\right)^{1-\gamma}
\end{align*}
$$

Simplified version of the above equation will be;

$$
\begin{equation*}
T_{4}=r_{c}^{\gamma} T_{1} \tag{14.49}
\end{equation*}
$$

Hence

$$
\begin{align*}
\eta_{t h} & =1-\frac{1}{\gamma}\left\{\frac{r_{c}^{\gamma} T_{1}-T_{1}}{r_{c} r^{\gamma-1} T_{1}-r^{\gamma-1} T_{1}}\right\}  \tag{14.50}\\
& =1-r^{1-\gamma}\left\{\frac{r_{c}^{\gamma}-1}{\gamma\left(r_{c}-1\right)}\right\}
\end{align*}
$$

From the above equation, it is observed that, the thermal efficiency of the diesel engine can be increased by increasing the compression ratio, $r$, by decreasing the cut-off ratio, $a_{2}$, or by using a gas with large value of $\gamma$. Since the quantity $\left(r^{\gamma}-1\right) / \gamma\left(r_{p}-1\right)$ in above equation is always greater than unity, the efficiency of a Diesel cycle is always lower than that of an Otto cycle having the same compression ratio. However, practical Diesel engines uses higher compression ratios compared to petrol engines.

Example 14.8 A diesel engine has an inlet temperature and pressure of $15^{\circ} \mathrm{C}$ and 1 bar respectively. The compression ratio is $12 / 1$ and the maximum cycle temperature is $1100^{\circ} \mathrm{C}$. Calculate the air standard thermal efficiency based on the diesel cycle.
Solution Referring to Figure below, $T_{1}=15+273=288 \mathrm{~K}$ and $T_{3}=1100+273=$ 1373K. From Eq. 14.48, we that (Fig. 14.19);

$$
\frac{T_{2}}{T_{1}}=\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1}=r_{c}^{\gamma-1}=12^{0.4}=2.7
$$

Then we have;

$$
T_{2}=2.7 \times 288=778 \mathrm{~K}
$$

At constant pressure from 2 to 3 , since $P V=R T$ for a perfect gas, then

Fig. 14.19 Illustration of Example 14.8

$$
\frac{T_{3}}{T_{2}}=\frac{V_{3}}{V_{2}}
$$

i.e.

$$
\frac{V_{3}}{V_{2}}=\frac{1373}{778}=1.765
$$

Therefore

$$
\frac{V_{4}}{V_{3}}=\frac{V_{4} V_{2}}{V_{2} V_{4}}=\frac{V_{1} V_{2}}{V_{2} V_{3}}=12 \times \frac{1}{1.765}=6.8
$$

Then using Eq. 14.47 again;

$$
\frac{T_{3}}{T_{4}}=\left(\frac{V_{4}}{V_{3}}\right)^{\gamma-1}=r_{c}^{\gamma-1}=6.8^{0.4}=2.153
$$

i.e.

$$
T_{4}=\frac{1373}{2.153}=638 \mathrm{~K}
$$

Then from Eq. 14.42, per kilogram of air, we can write;

$$
Q_{1}=C_{p}\left(T_{3}-T_{2}\right)=1.005(1373-778)=598 \mathrm{~kJ} / \mathrm{kg}
$$

Also from same equation, per kilogram of air, the heat rejected is

$$
Q_{2}=C_{v}\left(T_{4}-T_{1}\right)=0.718(638-288)=251
$$

Therefore from Eq. 14.42, we can write;

$$
\eta_{t h}=\frac{598-251}{598}=0.58 \mathrm{or} 58 \%
$$

### 14.8.1 Mean Effective Pressure (Diesel Cycle)

We just show the steps without any description of each step since the process is straight forward;

$$
\begin{gather*}
\text { MEP }=\frac{\text { Networkdone }}{\text { Displacementvolume }}  \tag{14.51}\\
=\frac{m C_{p}\left(T_{3}-T_{2}\right)-m C_{v}\left(T_{4}-T_{1}\right)}{V_{1}-V_{2}} \\
V_{1}-V_{2}=V_{1}\left(1-\frac{V_{2}}{V_{1}}\right)=V_{1}\left(1-\frac{1}{r}\right) \\
=m R T_{1}\left(\frac{r-1}{r}\right)  \tag{14.52}\\
=\frac{m C_{v}(\gamma-1)}{P_{1}}\left(\frac{r-1}{r}\right) \\
\text { MEP }=\frac{m C_{p}\left(T_{3}-T_{2}\right)-m C_{v}\left(T_{4}-T_{1}\right)}{m C_{v} T_{1}\left(\frac{\gamma-1}{P_{1}}\right)\left(\frac{r-1}{r}\right)}  \tag{14.53}\\
=\left(\frac{P_{1} r}{r-1}\right)\left(\frac{1}{\gamma-1}\right)\left\{\gamma\left(\frac{T_{3}-T_{2}}{T_{1}}\right)-\left(\frac{T_{4}-T_{1}}{T_{1}}\right)\right\} \\
=P_{1} r\left\{\frac{\gamma r^{\gamma-1}\left(r_{c}-1\right)-\left(r_{c}^{\gamma}-1\right)}{(r-1)(\gamma-1)}\right\}
\end{gather*}
$$

Example 14.9 A Diesel cycle operates with a compression ratio of 16 and a cut-off ratio of 2 . At the beginning of the compression stoke, the air is at 1 bar and 300 K . Determine;
a. The maximum temperature and pressure of the cycle.
b. The energy added per kg air, and
c. The mean effective pressure of the (MEP) cycle.

Solution The given data for the air-standard Diesel cycle is;

$$
r_{0}=16 r_{c}=2 P_{1}=1 T_{1}=300 \mathrm{~K}
$$

a. The temperature of air after isentropic compression, using Eq. 14.45 is given by

$$
T_{2}=T_{1} r_{0}^{\gamma-1}=300(16)^{0.4}=909.43
$$

We know that the cut-off ratio $r_{c}$ is given by Eq. 14.45 as $r_{c}=\frac{V_{3}}{V_{2}}=\frac{T_{3}}{T_{2}}$.
Therefore,

$$
T_{3}=T_{2} r_{c}=909 \times 2=1819.86 \mathrm{~K}
$$

That is, the maximum temperature $T_{3}$ of the cycle is 1818.06 K .
The pressure of air after isentropic compression is given by $P_{2}=P_{1} r_{0}^{\gamma}=1(16)^{1.4}=$ 48.5 bar.

The energy addition, in the Diesel cycle takes place at constant pressure. Therefore, $P_{3}=P_{2}$. Hence, the maximum pressure $P_{3}$ of the cycle is 48.5 bar.
b. The heat energy added is given;

$$
q_{1}=C_{p}\left(T_{3}-T_{2}\right)=1.0047(1818.86-909.43)=913.7 \mathrm{~kJ} / \mathrm{kgair}
$$

c. The mean efficient effective pressure (MEP), $p_{m}$ is given by Eq. 14.52;

$$
p_{m}=\frac{1(1.4)(16)^{1.4}(2-1)-16\left(2^{1.4}-1\right)}{0.4 \times 15}=6.947 \mathrm{bar}
$$

### 14.9 Comparison of Otto and Diesel Cycles

The Otto and Diesel cycles can be compared on the basis of either the compression ratio or the maximum temperature and pressure of the cycle. Figure 14.20 shows the Otto and Diesel Cycles having the same compression ratio, both of them reject the same quantity of energy $Q_{2}$ to the surroundings. We know that;

$$
\begin{equation*}
\int d Q=\int T d s \tag{14.54}
\end{equation*}
$$

That is, the area under the curve on a $T$-s diagram represents the heat interaction. In Fig. 14.20, the Otto cycle is representing by 1234 and the Diesel cycle is shown by 123 '4. Either cycles have the same compression ratio $V_{2} / V_{1}$ and reject the same

Fig. 14.20 a $P$ - $V$ diagram for Otto $(1 \rightarrow 2 \rightarrow 3 \rightarrow 4)$ and diesel cycle $\left(1 \rightarrow 2 \rightarrow 3^{\prime} \rightarrow 4\right)$. b $T$-s diagram for Otto cycle $(1 \rightarrow 2 \rightarrow 3 \rightarrow 4)$ and diesel cycle $\left(1 \rightarrow 2 \rightarrow 3^{\prime} \rightarrow 4\right)$

Table 14.1 Difference between actual diesel and the Otto engines

| Otto engine | Diesel engine |
| :--- | :--- |
| Homogenous mixture of fuel and air formed <br> in the carburetor is supplied to engine cylinder | No carburetor is used. Air alone is supplied to <br> the engine cylinder. Fuel is injected directly <br> into the engine cylinder at the end of compres- <br> sion stroke by means of a fuel injector. Fuel- <br> air mixture is heterogeneous |
| Ignition is initiated by means of an electric <br> spark plug | No spark plug is used. Compression ratio is <br> high and the high temperature of air ignites <br> fuel |
| Power output is controlled by varying the <br> mass of fuel-air mixture by means of a throttle <br> valve in the carburetor | No throttle value is used. Power output is <br> controlled only by means of the mass of fuel <br> injected by the fuel injector |

quantity of energy $Q_{2}$ during the constant volume process $4 \rightarrow 1$ (shown by the hatched area under the curve $4 \rightarrow 1$ on the $T$-s diagram) [4].

The Table 14.1 below summarizes these comparisons.
The efficiency of the cycle then is given by;

$$
\begin{equation*}
\eta=1-\frac{Q_{2}}{Q_{1}} \tag{14.55}
\end{equation*}
$$

From this equation we see that, for the same value of $Q_{2}$, the efficiency will be higher for higher values of $Q_{1}$. On the $T$-s diagram, the area under the curve $2 \rightarrow 3$ represents $Q_{1}$ for the Otto cycle and the area under the curve $2 \rightarrow 3^{\prime}$ represents $Q_{1}$, for the Diesel cycle. Since $Q_{1}$ for the Otto cycle is greater than for Diesel cycle, we find that;

Fig. 14.21 aP-V diagram for Otto cycle $(1 \rightarrow 2 \rightarrow 3 \rightarrow 4)$ and dieselcycle $\left(1 \rightarrow 2^{\prime} \rightarrow 3 \rightarrow 4\right)$ .b T-s diagram for Otto cycle $(1 \rightarrow 2 \rightarrow 3 \rightarrow 4)$ and diesel cycle $\left(1 \rightarrow 2^{\prime} \rightarrow 3 \rightarrow 4\right)$

$$
\begin{equation*}
\eta_{\text {Otto }}>\eta_{\text {Diesel }} \tag{14.56}
\end{equation*}
$$

The Otto and Diesel cycles for the same maximum temperature and pressure (state 3) and for the same quantity of energy rejection $Q_{2}$ are shown in Fig. 14.21. The Otto cycle is represented by 1234 and the Diesel cycle is illustrated as 1234 . From the T-s diagram it can be observed that $Q_{1}$, the area under the curve $2^{\prime} \rightarrow 3$ for the Diesel cycle, is greater than $Q_{1}$, the area under the curve $2 \rightarrow 3$ for the Otto cycle when $Q_{2}$ is the same for both the cycles. Therefore;

$$
\begin{equation*}
\eta_{\text {Diesel }}>\eta_{\text {Otto }} \tag{14.57}
\end{equation*}
$$

### 14.10 Dual Cycle

With increasing crude oil prices, concern about energy security and calls for reduction in greenhouse gases, energy use in the future will be a large priority. One method for reducing oil consumption is through increased efficiency of the internal combustion engine. A significant loss in this engine is the exhaust energy which is approximately $20-40 \%$ of the fuel potential. Research has indicated that there exists a capability to increase the brake thermal efficiency of the engine system by using this exhaust in a separate thermodynamic cycle. By simulating an engine and dual cycle system in a novel architecture, this project intends to demonstrate a proof of concept that can reduce engine emissions while increasing thermal efficiency.

Combustion in the Otto cycle is based on a constant volume process; in Diesel cycle, it is based on a constant pressure process. But combustion in actual sparkignition engine requires a finite amount of time if the process is to be completed.

Fig. 14.22 Illustration of dual cycle on $P-V$ and $T-s$ diagrams

For this reason, combustion in Otto cycle does not actually occur under the constant volume condition. Similarly, in compression-ignition engines, combustion in Diesel cycle does not actually occur under the constant pressure condition, because of the rapid and uncontrolled combustion process.

The operation of the reciprocating internal combustion engines represent a compromise between the Otto and the Diesel cycle, and can be described as a Dual combustion cycle. Heat transfer to the system may be considered to occur first at constant volume and then at constant pressure. Such a cycle is called Dual cycle. Sometime another name for Dual Cycle is known as Limited Pressure Cycle, which is shown in Fig. 14.22 based on $P-V$ and $T-s$ diagrams. Here the heat addition occurs partly at constant volume and partly at constant pressure. This cycle is a closer approximation to the behavior of the actual Otto and Diesel engines because in the actual engines, the combustion process does not occur exactly at constant volume or at constant pressure but rather as in the dual cycle.

The Dual cycle is composed of the following five processes and they are as follows:

Process $1 \rightarrow 2$ Reversible adiabatic compression (isentropic compression)
Process $2 \rightarrow 3$ Constant volume heat addition
Process $3 \rightarrow 4$ Constant pressure heat addition
Process $4 \rightarrow 5 \quad$ Reversible adiabatic expansion (isentropic expansion)
Process $5 \rightarrow 1$ Constant volume heat rejection (removing)

$$
\begin{align*}
& \text { Heat Energy Supplied }=m C_{v}\left(T_{3}-T_{2}\right)+m C_{p}\left(T_{4}-T_{3}\right)  \tag{14.58a}\\
& \qquad \text { Heat Energy Rejected }=m C_{v}\left(T_{5}-T_{1}\right) \tag{14.58b}
\end{align*}
$$

$$
\begin{equation*}
\text { Net Work Done }=m C_{v}\left(T_{3}-T_{2}\right)+m C_{p}\left(T_{4}-T_{3}\right)-m C_{v}\left(T_{5}-T_{1}\right) \tag{14.59}
\end{equation*}
$$

Then Thermal efficiency $\eta_{t h}$ is given by;

$$
\begin{gather*}
\eta_{t h}=\frac{m C_{v}\left(T_{3}-T_{2}\right)+m C_{p}\left(T_{4}-T_{3}\right)-m C_{v}\left(T_{5}-T_{1}\right)}{m C_{v}\left(T_{3}-T_{2}\right)+m C_{p}\left(T_{4}-T_{3}\right)}  \tag{14.60a}\\
\eta_{t h}=1-\frac{\left(T_{5}-T_{1}\right)}{\left(T_{3}-T_{2}\right)+\gamma\left(T_{4}-T_{3}\right)} \tag{14.60b}
\end{gather*}
$$

Let $r_{p}=\frac{P_{3}}{P_{2}}, r_{c}=\frac{V_{4}}{V_{3}}$ and $r=\frac{V_{1}}{V_{2}}$, then we have

$$
\begin{gather*}
T_{2}=T_{1} r^{\gamma-1}  \tag{14.61a}\\
T_{3}=T_{2} r_{p}=T_{1} r^{\gamma-1} r_{p}  \tag{14.61b}\\
T_{4}=T_{3} r_{c}=T_{1} r^{\gamma-1} r_{p} r_{c}  \tag{14.61c}\\
\frac{T_{5}}{T_{4}}=\left(\frac{V_{4}}{V_{5}}\right)^{\gamma-1}=\left(\frac{V_{4}}{V_{2}} \cdot \frac{V_{2}}{V_{5}}\right)^{\gamma-1}=\left(\frac{r_{c}}{r}\right)^{\gamma-1}  \tag{14.61d}\\
T_{5}=T_{4}\left(\frac{r_{c}}{r}\right)^{\gamma-1} \tag{14.61e}
\end{gather*}
$$

Form all the above analysis we can write the following steps to calculate the final form of the thermal efficiency $\eta_{t h}$ as;

$$
\begin{align*}
\eta_{t h} & =1-\frac{\left(T_{1} r^{\gamma} r_{p} r_{c}-T_{1}\right)}{\left\{\left(T_{1} r^{\gamma-1} r_{p}-T_{1} r^{\gamma-1}\right)+\gamma\left(T_{1} r^{\gamma-1} r_{p} r_{c}-T_{1} r^{\gamma-1} r_{p}\right)\right\}} \\
& =1-\frac{\left(r^{\gamma} r_{p} r_{c}-1\right)}{\left\{\left(r^{\gamma-1} r_{p}-r^{\gamma-1}\right)+\gamma\left(r^{\gamma-1} r_{p} r_{c}-r^{\gamma-1} r_{p}\right)\right\}}  \tag{14.62}\\
& =1-\frac{1}{r^{\gamma-1}\left\{\frac{\left(r^{\gamma} r_{p} r_{c}-1\right)}{\left(r_{p}-1\right) \gamma r_{p}\left(r_{c}-1\right)}\right\}}
\end{align*}
$$

From the above equation, it is observed that, a value of $r_{p}>1$ results in an increased efficiency for a given value of $r_{c}$ and $\gamma$. Thus the efficiency of the dual
cycle lies between that of the Otto cycle and the Diesel cycle having the same compression ratio.

### 14.10.1 Mean Effective Pressure for Dual Cycle

We just going to show analytical process here for MEP;

$$
\begin{gather*}
\text { MEP }=\frac{\text { WorkDone }}{\text { DisplacementVolume }}  \tag{14.63a}\\
\text { MEP }=\frac{m C_{v}\left(T_{3}-T_{2}\right)+m C_{p}\left(T_{4}-T_{3}\right)-m C_{v}\left(T_{5}-T_{1}\right)}{\left(V_{1}-V_{2}\right)} \tag{14.63b}
\end{gather*}
$$

But

$$
\begin{equation*}
V_{1}-V_{2}=\frac{m C_{v}(\gamma-1) T_{1}}{P_{1}}\left(\frac{r-1}{r}\right) \tag{14.63c}
\end{equation*}
$$

Then we have;

$$
\begin{align*}
\text { MEP } & =\frac{P_{1} r}{(r-1)(\gamma-1)}\left\{\frac{\left(T_{3}-T_{2}\right)}{T_{1}}+\frac{\gamma\left(T_{4}-T_{3}\right)}{T_{1}}-\frac{\left(T_{2}-T_{1}\right)}{T_{1}}\right\} \\
& =\frac{P_{1} r}{(r-1)(\gamma-1)}\left\{r^{\gamma-1}\left(r_{p}-1\right)+\gamma r^{\gamma-1} r_{p}\left(r_{c}-1\right)-\left(r_{p} r_{c}^{\gamma}-1\right)\right\}  \tag{14.63d}\\
& =\frac{P_{1} r}{(r-1)(\gamma-1)}\left\{r^{\gamma-1}\left(r_{p}-1\right)+\gamma r_{p}\left(r_{c}-1\right)-\left(r_{p} r_{c}^{\gamma}-1\right)\right\}
\end{align*}
$$

Example 14.10 A Dual cycle, which operates on air with a compression ratio of 16, has a low pressure of 200 kPa and a low temperature of $200^{\circ} \mathrm{C}$. If the cutoff ratio is 2 and the pressure ratio is 1.3 , calculate;
a. The thermal efficiency,
b. The heat input
c. The work output, and
d. The MEP

## Solution

a. Using Eq. 14.60, we have;

$$
\eta_{t h}=1-\frac{1}{(16)^{0.4}} \frac{(1.3)(2)^{1.4}-1}{(1.4)(1.3)(2-1)+1.3-1}=0.622 \mathrm{or} 62.2 \%
$$

b. The heat input is found from Eq. 14.56 , where we also use Eq. 14.59, then we have;

$$
\begin{aligned}
& T_{2}=T_{1}\left(\frac{V_{1}}{V_{2}}\right)^{\gamma-1}=(473)(16)^{0.4}=1434 \mathrm{~K} \\
& T_{3}=T_{2}\left(\frac{P_{3}}{P_{2}}\right)=(1434)(1.3)=1864 \mathrm{~K} \\
& T_{4}=T_{3}\left(\frac{V_{4}}{V_{3}}\right)=(1864)(2)=3728 \mathrm{~K}
\end{aligned}
$$

Therefore

$$
q_{\text {in }}=(0.717)(1864-1434)+(1.00)(3728-1864)=2172 \mathrm{~kJ} / \mathrm{kg}
$$

c. The work output is found from Eq. 14.57 as;

$$
w_{\text {out }}=\eta_{\text {th }} q_{\text {in }}=(0.622)(2172)=3728 \mathrm{~kJ} / \mathrm{kg}
$$

d. Finally to find the MEP, since we have;

$$
V_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(473)}{200}=0.6788 \mathrm{~m}^{3} / \mathrm{kg}
$$

Then

$$
\mathrm{MEP}=\frac{w_{\text {out }}}{V_{1}\left(1-V_{2} / V_{1}\right)}=\frac{1350}{(0.6788)(15 / 16)}=2120 \mathrm{kPa}
$$

### 14.11 Stirling Cycle

The Stirling and Ericsson cycles, although not extensively used to model actual engines, are presented here and next section respectively, to illustrate the effective use of regenerate and that is why, sometime are called Regenerative Cycle, a heat exchanger which utilizes waste heat.

The Stirling and Ericsson cycles are not used to model real engines as they are difficult to achieve in practice. The advantage of both is that they can achieve efficiencies approaching the true Carnot efficiency. They do this by extracting the heat produced in the compressor and transferring it to the turbine. This is done through a device called a regenerator. But the compressor and turbine are treated as isothermal, which is very difficult to achieve in practice.

The Carnot cycle has a low mean effective pressure because of its very low work output. Hence, one of the modified forms of the cycle to produce higher mean ef-

Fig. 14.23 Illustration of stirling cycle processes on $P-V$ and $T-s$ diagrams
fective pressure whilst theoretically achieving full Carnot cycle efficiency is the Stirling cycle. It consists of two isothermal and two constant volume processes. The heat rejection and addition take place at constant temperature. The $P-V$ and $T-s$ diagrams for the Stirling cycle are shown in Fig. 14.23.

The Stirling Cycle Processes are describes as follows;
a. The air is compressed isothermally from state 1 to $2\left(T_{L}\right.$ to $\left.T_{H}\right)$.
b. The air at state-2 is passed into the regenerator from the top at a temperature $T_{1}$
. The air passing through the regenerator matrix gets heated from $T_{L}$ to $T_{H}$.
c. The air at state-3 expands isothermally in the cylinder until it reaches state-4.
d. The air coming out of the engine at temperature $T_{H}$ (condition 4) enters into regenerator from the bottom and gets cooled while passing through the regenerator matrix at constant volume and it comes out at a temperature $T_{L}$, at condition 1 and the cycle is repeated.
e. It can be shown that the heat absorbed by the air from the regenerator matrix during the process $2 \rightarrow 3$ is equal to the heat given by the air to the regenerator matrix during the process $4 \rightarrow 3$, and then the exchange of heat with external source will be only during the isothermal processes.
Now we can write, Net work done to be;

$$
\begin{equation*}
W_{n e t}=Q_{S}-Q_{R} \tag{14.64}
\end{equation*}
$$

Where $Q_{s}$ is the heat supplied during the isothermal process $3 \rightarrow 4$ and $Q_{R}$ is the Heat rejected during the isothermal compression process $1 \rightarrow 2$.

$$
\begin{align*}
Q_{s} & =P_{3} V_{3} \ln \left(\frac{V_{4}}{V_{3}}\right) r=\frac{V_{4}}{V_{3}}=C R  \tag{14.65}\\
& =m R T_{H} \ln (r)
\end{align*}
$$

and

$$
\begin{align*}
Q_{R} & =P_{1} V_{1} \ln \left(\frac{V_{1}}{V_{2}}\right) r=\frac{V_{1}}{V_{2}}=C R  \tag{14.66}\\
& =m R T_{L} \ln (r)
\end{align*}
$$

Then equation by substituting Eqs. 14.63 and 14.64 into Eq. 14.64, we have;

$$
\begin{equation*}
W_{\text {net }}=m R \ln (r)\left[T_{H}-T_{L}\right] \tag{14.67}
\end{equation*}
$$

Now, the thermal efficiency $\eta_{t h}$ is given by;

$$
\begin{equation*}
\eta_{t h}=\frac{W_{\text {net }}}{Q_{S}}=\frac{m R \ln (r)\left(T_{H}-T_{L}\right)}{m R \ln (r)\left(T_{H}\right)} \frac{\left(T_{H}-T_{L}\right)}{\left(T_{H}\right)} \tag{14.68a}
\end{equation*}
$$

or

$$
\begin{equation*}
\eta_{t h}=1-\frac{T_{L}}{T_{H}} \tag{14.68b}
\end{equation*}
$$

It is interesting to note that the thermal efficiency of the String cycle is the same as the efficiency of a Carnot cycle when both are working with the same temperature limits. It is not possible to obtain $100 \%$ efficient regenerator and hence there will be always $10-20 \%$ loss of heat in the regenerator, which decreases the cycle efficiency. Considering regenerator efficiency, the efficiency of the cycle can be written as;

$$
\begin{equation*}
\eta_{t h}=\frac{R \ln (r)\left(T_{H}-T_{L}\right)}{R T_{H} \ln (r)+\left(1-\eta_{R}\right) C_{V}\left(T_{H}-T_{L}\right)} \tag{14.69}
\end{equation*}
$$

Where, $\eta_{R}$ is the Regenerator Efficiency.
Example 14.11 A Stirling cycle, which operates on air with a compression ratio of 10. If the low pressure is 30 psia , the low temperature is $200^{\circ} \mathrm{F}$, and the high temperature is $1000^{\circ} \mathrm{F}$, calculate the work done and the heat input.
Solution For the Stirling cycle using $P-V$ diagram of Fig. 14.19 the work output is;

$$
\begin{aligned}
W_{\text {out }} & =W_{3 \rightarrow 4}+W_{1 \rightarrow 2}=R T_{3} \ln \frac{V_{4}}{V_{3}}+R T_{1} \ln \frac{V_{2}}{V_{1}} \\
& =(53.3)[1460 \ln (10)+660 \ln (0.1)]
\end{aligned}
$$

For the isothermal process and using Eq. 14.66 will provide us;

$$
\eta_{t h}=1-\frac{T_{L}}{T_{H}}=1-\frac{660}{1460}=0.548
$$

Fig. 14.24 Schematic diagram of air-standard Ericsson cycle

### 14.12 Ericsson Cycle

To overcome the difficulty associated with the constant volume regeneration, Ericsson developed a constant pressure regeneration cycle, which is named after him. The Air-Standard schematic layout and Ericsson cycle are shown in Figs. 14.24 and 14.25 respectively.

The thermal efficiency of the Ericsson cycle can be calculated easily and steps are shown as follows.

The Ericsson cycle consists of two isothermal and two constant pressure processes.

The processes are:

| Process $1 \rightarrow 2$ | Reversible isothermal compression |
| :--- | :--- |
| Process $2 \rightarrow 3$ | Constant pressure heat addition |
| Process $3 \rightarrow 4$ | Reversible isothermal expansion |
| Process $4 \rightarrow 1$ | Constant pressure heat rejection |

The heat addition and rejection take place at constant pressure as well as isothermal processes. Since the process 2-3 and 3-4 are parallel to each other on the T-s diagram, the net effect is that the heat need to be added only at constant temperature $T_{3}=T_{4}$ and rejected at the constant temperature $T_{1}=T_{2}$. The cycle is shown on $P-V$ and $T-s$ diagrams in Fig. 14.22. The advantage of the Ericsson cycle over the

Fig. 14.25 Illustration of Ericsson a $P-V$ diagram and $\mathbf{b} T-S$ diagram

Carnot and Stirling cycles is its smaller pressure ratio for a given ratio of maximum to minimum specific volume with higher mean effective pressure.

The thermal efficiency of Ericsson cycle is given by, (derivation is same as that of Stirling cycle),

$$
\begin{equation*}
\eta_{t h}=\frac{T_{H}-T_{L}}{T_{H}}=\left[1-\frac{T_{L}}{T_{H}}\right] \tag{14.70}
\end{equation*}
$$

The Ericsson cycle does not find practical application in piston engines but is approached by a gas turbine employing a large number of stages with heat exchangers, insulators and reheaters.

Example 14.12 An Ericsson cycle operates on air with a compression ratio of 10. For a low pressure 200 kPa , low temperatures of $100^{\circ} \mathrm{C}$, and a high temperature of $600^{\circ} \mathrm{C}$, calculate the work output and the heat input.

Solution For the Ericsson cycle the work output is

$$
W_{\text {out }}=W_{1 \rightarrow 2}+W_{2 \rightarrow 3}+W_{3 \rightarrow 4}+W_{4 \rightarrow 1}=R T_{1} \ln \frac{V_{2}}{V_{1}}+P_{2}\left(V_{3}-V_{2}\right)+R T_{3} \ln \frac{V_{4}}{V_{3}}+P_{1}\left(V_{1}-V_{4}\right)
$$

We must calculate $P_{2}, V_{1}, V_{2}, V_{3}$, and $V_{4}$. Then we have;

$$
V_{1}=\frac{R T_{1}}{P_{1}}=\frac{(0.287)(373)}{200}=0.5353 \mathrm{~m}^{3} / \mathrm{kg}
$$

For the constant pressure process $4 \rightarrow 1$,

$$
\frac{T_{4}}{V_{4}}=\frac{T_{1}}{V_{1}} \text { or } \frac{873}{V_{4}}=\frac{373_{1}}{0.5353_{1}} \Rightarrow V_{4}=1.253 \mathrm{~m}^{3} / \mathrm{kg}
$$

From the definition of the compression ratio, $V_{4} / V_{2}=10$, giving $V_{2}=0.1253 \mathrm{~m}^{3} / \mathrm{kg}$. Using the ideal-gas law, we have

$$
P_{3}=P_{2}=\frac{R T_{2}}{V_{2}}=\frac{(0.25)(373)}{0.1253}=854.4 \mathrm{kPa}
$$

The final necessary property is $V_{3}=R T_{3} / P_{3}=(0.287)(873) / 854.4=0.2932 \mathrm{~m}^{3} / \mathrm{kg}$. The expression for work output gives;

$$
\begin{aligned}
& W_{\text {out }}=(0.287)(373) \ln \frac{0.1253}{0.5353}+(854.4)(0.2932-0.1253) \\
& +0.287 \times 873 \ln \frac{1.253}{0.2932}+(200)(0.5353-1253)=208 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

Finally

$$
\eta_{\text {th }}=1-\frac{T_{L}}{T_{H}}=1-\frac{378}{873}=0.573 \text { and } q_{\text {in }}=\frac{\text { Wout }}{\eta_{\text {th }}}=\frac{208}{0.573} \mathrm{~kJ} / \mathrm{kg}
$$

### 14.13 Atkinson Cycle

Atkinson cycle is an ideal cycle for Otto engine exhausting to a gas turbine. In this cycle the isentropic expansion $(3 \rightarrow 4)$ of an Otto cycle $(1 \rightarrow 2 \rightarrow 3 \rightarrow 4)$ is further allowed to proceed to the lowest cycle pressure to increase the work output. With this modification the cycle is known as Atkinson cycle. The cycle is shown on $P-V$ and $T-s$ diagrams in Fig. 14.26.

Processes involved are:

$$
\begin{array}{ll}
\text { Process } 1 \rightarrow 2 & \text { Reversible adiabatic compression (v1 to v2) } \\
\text { Process } 2 \rightarrow 3 & \text { Constant volume heat addition } \\
\text { Process } 3 \rightarrow 4 & \text { Reversible adiabatic expansion (v3 to v4) } \\
\text { Process } 4 \rightarrow 1 & \text { Constant pressure heat rejection }
\end{array}
$$

The thermal efficiency is calculated as follows;

$$
\begin{align*}
& \text { Heat supplied }=C_{v}\left(T_{3}-T_{2}\right)  \tag{14.71a}\\
& \text { Heat rejected }=C_{p}\left(T_{4}-T_{1}\right) \tag{14.71b}
\end{align*}
$$

Net work done $=C_{v}\left(T_{3}-T_{2}\right)-C_{p}\left(T_{4}-T_{1}\right)$

Fig. 14.26 Atkinson cycle on $P-V$ and $T-s$ diagrams

$$
\begin{gather*}
\eta_{t h}=\frac{C_{v}\left(T_{3}-T_{2}\right)-C_{p}\left(T_{4}-T_{1}\right)}{C_{v}\left(T_{3}-T_{2}\right)}  \tag{14.73a}\\
\eta_{t h}=1-\frac{\gamma\left(T_{4}-T_{1}\right)}{\left(T_{3}-T_{2}\right)} \tag{14.73b}
\end{gather*}
$$

Let, $r=\frac{V_{1}}{V_{2}}=C R$ then we can write

$$
\begin{gather*}
T_{2}=T_{1} r^{\gamma-1} \\
\frac{T_{3}}{T_{2}}=\frac{P_{3}}{P_{2}}=r_{p}=\text { Pressure ration }  \tag{14.75}\\
T_{3}=T_{2} r_{p}=T_{1} r^{\gamma-1} r_{p}  \tag{14.76}\\
\frac{T_{3}}{T_{4}}=\left(\frac{P_{3}}{P_{4}}\right)^{\frac{\gamma-1}{\gamma}}=\left(\frac{P_{3}}{P_{1}}\right)^{\frac{\gamma-1}{\gamma}}=\left(\frac{P_{3}}{P_{2}} \cdot \frac{P_{2}}{P_{1}}\right)^{\frac{\gamma-1}{\gamma}}=r_{p}^{\frac{\gamma-1}{\gamma}} \cdot r^{\gamma-1} \tag{14.77}
\end{gather*}
$$

Since,

$$
\begin{gather*}
\frac{P_{2}}{P_{1}}=\left(\frac{V_{1}}{V_{2}}\right)^{\gamma}=r^{\gamma}  \tag{14.78}\\
T_{4}=\frac{T_{3}}{\frac{\gamma-1}{\gamma}}=\frac{T_{1} r_{p} r^{\gamma-1}}{\frac{\gamma-1}{\gamma}}=T_{1} r_{p}^{\frac{1}{\gamma}} \tag{14.79}
\end{gather*}
$$

Fig. 14.27 Lenoir cycle on $P-V$ and $T-s$ diagrams

$$
\begin{equation*}
\eta_{t h}=1-\lambda\left[\frac{r_{p}^{\frac{1}{\gamma}}-1}{\left(r_{p}-1\right) r^{\gamma-1}}\right] \tag{14.80}
\end{equation*}
$$

### 14.14 Lenoir Cycle

The Lenoir cycle is an idealized thermodynamic cycle often utilized to model a pulse jet engine. The Lenoir cycle is of interest because combustion (or heat addition) occurs without compression of the charge. Fig. 14.27a and b show the $P-V$ and $T-s$ diagrams.

The Lenoir cycle consists of the following processes:

## Process $1 \rightarrow 2$ Constant volume heat addition

Process $2 \rightarrow 3$ Reversible adiabatic expansion
Process $3 \rightarrow 4$ Constant pressure heat rejection
No compression process
According to the cycle, the piston is at the top dead center, point 1 , when the charge is ignited (or heat is added). The process is at constant volume so the pressure rises to point 2 . From 2 to 3 , expansion takes place and from 3 to 1 heat is rejected at constant pressure.

The thermal efficiency can be derived as follows:

$$
\begin{equation*}
\text { Heat supplied }=Q_{s}=C_{v}\left(T_{2}-T_{1}\right) \tag{14.81a}
\end{equation*}
$$

$$
\begin{equation*}
\text { Heat rejected }=Q_{r}=C_{p}\left(T_{3}-T_{1}\right) \tag{14.81b}
\end{equation*}
$$

$$
\begin{equation*}
\text { Since Net work done }=W_{\text {net }}=Q_{s}-Q_{r}=C_{v}\left(T_{2}-T_{1}\right)-C_{p}\left(T_{3}-T_{1}\right) \tag{14.82}
\end{equation*}
$$

Thus

$$
\begin{gather*}
\eta_{t h}=\frac{C_{v}\left(T_{2}-T_{1}\right)-C_{p}\left(T_{3}-T_{1}\right)}{C_{v}\left(T_{2}-T_{1}\right)}  \tag{14.83a}\\
\eta_{t h}=1-\frac{c_{p}\left(T_{3}-T_{1}\right)}{c_{v}\left(T_{2}-T_{1}\right)}  \tag{14.83b}\\
\eta_{\text {th }}=1-\frac{\gamma\left(\frac{T_{3}}{T_{1}}-1\right)}{\left(\frac{T_{2}}{T_{1}}-1\right)} \tag{14.83c}
\end{gather*}
$$

Since

$$
\begin{equation*}
\frac{T_{2}}{T_{1}}=\frac{P_{2}}{P_{1}}=r_{p}, \frac{T_{3}}{T_{1}}=\frac{V_{3}}{V_{1}} \text { and } P_{2} V_{2}^{\gamma}=P_{3} V_{3}^{\gamma} \tag{14.84}
\end{equation*}
$$

So

$$
\begin{equation*}
\frac{P_{2}}{P_{3}}=\left(\frac{V_{3}}{V_{2}}\right)^{\gamma}=\left(\frac{V_{3}}{V_{1}}\right)^{\gamma}=\frac{P_{2}}{P_{1}}=\frac{T_{2}}{T_{1}} \tag{14.85}
\end{equation*}
$$

Therefore

$$
\begin{align*}
& \eta_{t h}=1-\frac{\gamma\left(\frac{V_{3}}{V_{1}}-1\right)}{\left[\left(\frac{V_{3}}{V_{1}}\right)^{\gamma}-1\right]}  \tag{14.86a}\\
& \eta_{t h}=1-\frac{\gamma\left(r_{p}^{\frac{1}{\gamma}}-1\right)}{\left(r_{p}-1\right)}  \tag{14.86b}\\
& \eta_{t h}=1-\frac{\gamma\left(r_{e}-1\right)}{\left(r_{e}^{\gamma}-1\right)} \tag{14.86c}
\end{align*}
$$

Here, $r_{e}=V_{3} / V_{1}$, the volumetric expansion ratio. Eq. 3.18 indicates that the thermal efficiency of the Lenoir cycle depends primarily on the expansion ratio and the ratio of specific heats.

The intermittent-flow engine which powered the German V-1 buzz-bomb in 1942 during World War II operated on a modified Lenoir cycle. A few engines running on the Lenoir cycle were built in the late nineteenth century until the early twentieth century.

### 14.15 Deviation of Actual Cycles from Air Standard Cycles

The actual Otto and Diesel engines show marked deviations from the air-standard cycles described above. Above figure shows $p$ - $v$-diagram for a high-speed diesel engine would be very similar in appearance. The main differences between the actual and theoretical cycles are as follows.
a. Compression and expansion are not friction less adiabatic processes. A Certain amount of friction is always present and there is considerable heat transfer between the gases and cylinder wall.
b. Combustion does not occur either at constant volume or at constant pressure.
c. The thermodynamics properties of the gases after combustion are different than those of the fuel-air mixture before combustion.
d. The combustion may be incomplete.
e. The specific heats of the working fluid are not constant but increases with temperature.
f. The cylinder pressure during exhaust process is higher than the atmosphere. As a result, more work has to be done by the piston on the gases to expel them out of the cylinder, than work done by the gases on the piston during the intake stroke. This difference in work, called pumping work, is represented by the pumping loop shown by hatched area. Note that this work is negative and represents loss of work called pumping loss.

### 14.16 Recuperated Cycle

A recuperated turbine is similar to a simple-cycle gas turbine, except for the inclusion of a special heat exchanger-called a recuperator-that captures exhaust thermal energy to preheat compressed air before the burner. Capturing exhaust energy helps increase electrical efficiency compared to a simple-cycle gas turbine. Figure 14.28 is illustration of a typical Recuperated Gas Turbine.

Typical turbines can accommodate only a limited additional mass flow-from 5 to $15 \%$, depending on the design of the original gas turbine. Steam-injected gas

Fig. 14.28 Recuperated gas turbine

turbines enable the host to use the steam for industrial purposes, space heating, or for the generation of additional power.

A group of cycles under consideration for development involves the use of adiabatic saturators to provide steam at compressor discharge pressure to augment greatly the mass flow through the turbine, and consequently increase cycle power and efficiency. In the adiabatic saturator, water flows in a countercurrent path to the compressor discharge air in a mass transfer tower. Such equipment is often used in the chemical processing industries. The saturated air is preheated in a turbine exhaust heat recuperator. This cycle is called the Humid Air Turbine, or HAT, cycle. The HAT cycle is particularly useful in using the low-temperature heat generated in coal-gasification-fueled gas turbine power plants. As the mass flow through the turbine is significantly augmented, engineers can no longer use the expansion turbine, which was matched to the compressor in a conventional simple cycle gas turbine.

The critical cycle modification in an engine is the presence of heat exchanger modules in the hot exhausts, with the purpose of bringing back thermal energy from engine exit to combustion chamber. Given a fixed High Pressure Turbine Entry Temperature (HPT TET), this concept allows fuel savings, because the exhausts, which are discharged at a lower temperature, provide part of the required burner temperature rise. In order for the heat exchange process to be effective, there must be a sufficient temperature difference between compressor exit and turbine exit temperature at all operating points. A low High Pressure Compressor (HPC) exit temperature can be obtained with the use of inter-cooling, as can be clearly seen in Fig. 14.25. A high turbine exit temperature at different operating points can be obtained with a variable geometry turbine system (Sect. 5.4). The combined effect of the two heat-exchange processes maximizes the heat transfer in the recuperator, therefore improving the efficiency benefit. Figure 14.29 shows the thermodynamic cycle for a typical Intercooled Recuperated Aro (IRA) engine cycle in the $h$ - $S$ plane for Overall Pressure Ratio $(\mathrm{OPR}=30)$ and $\mathrm{T} 41=1800 \mathrm{~K}$. The chart illustrates that the amount of recuperated heat can be substantially increased by using the intercooler: the dotted line shows the compression process without inter-cooling.

Fig. 14.29 Engine cycle in $h$ - $S$ diagram

Fig. 14.30 Core efficiency illustrations

The effect of the different cycle innovations is shown in Fig. 14.30, where the core efficiency is calculated for different but consistent cycles (consistent technology level and same simulation tool). A considerable improvement in the performance of the recuperated engine can be achieved by adding the inter-cooling module, despite the detrimental effect of additional pressure losses.

## Chapter 15 <br> Vapor Power Cycles

Vapor (or Rankine) power cycles are by far the most common basis for the generation of electricity in large fixed plant operations. They were one of the first developed for steam engines and have been adapted to many applications. They have also been modified in a number of ways to improve their thermal efficiency and better utilize combustible fuels.

### 15.1 The Basic Rankine Cycle

Although the Carnot cycle is the most efficient cycle, but its work ratio is low and there are practical difficulties to follow it. Hence the ideal cycle, which is more suitable as a criterion for actual steam cycles than the Carnot cycle, is called Rankine cycle. The basic Rankine (vapor) Cycle consists of 4 processes. The state points are identified in Fig. 15.1.

## Process 1 to 2-Isentropic compression of a liquid in a pump.

Process 2 to 3-Constant pressure heat addition in a boiler or heat exchangercreates vapor.
Process 3 to 4-Isentropic expansion of the vapor in a turbine.
Process 4 to 1 -Constant pressure heat extraction in a condenser-returns vapor to liquid.

The general lay out of the components is pictured in Fig. 15.1. The steam generator, or boiler, consists of two generally separate heat exchangers-the economizer to heat the high pressure water to its boiling temperature, and the evaporator to convert the saturated liquid to steam. The heat transfer processes are different for the two different states of the liquid/vapor so this usually necessitates a different design for each region.

The temperature entropy diagram for the basic cycle is presented in Fig. 15.2. The work output of the system is represented by the area enclosed in the cycle on the T-s diagram by the curve 1-2-3-4-1. The heat input to the system is represented

[^6]

Fig. 15.1 Major components of a basic Rankine cycle

Fig. 15.2 T-s diagram for a basic Rankine cycle
by the curve $\mathbf{1}^{\mathbf{\prime}} \mathbf{- 1 - 2 - 3 - 4 - 4} \mathbf{' 1}^{\mathbf{\prime}}$. Therefore, the net thermal efficiency of the cycle is represented by the ratio of the two areas.

$$
\begin{equation*}
\eta_{t h}=\frac{\text { area } 1-2-3-4-1}{\text { area } 1^{\prime}-2-3-4^{\prime}-1^{\prime}} \tag{15.1}
\end{equation*}
$$

The efficiency of a Rankine cycle must be less than that of a Carnot cycle because the heat addition does not all occur at the peak temperature of the cycle.

One of the major advantages of the Rankine cycle is that the compression process in the pump takes place on a liquid. The energy consumption of this process is almost negligible compared to the work output of the turbine, so a less than isentropic efficiency for the liquid pump is not a major energy loss for the cycle.

Consider the two ways of improving the Rankine cycle efficiency by adding all of the heat at the peak temperature as indicated in Figs. 15.3a and b. In Fig. 15.3a,

Fig. 15.3 Alternative cycles
the cycle will require pumping on a vapor at state point 1 , which is much less efficient than pumping on a liquid. In Fig. 15.3b, to reach state point 3 at a constant temperature from the saturation line, the pressure will have to be continuously lowered, which is very difficult to accomplish. In the vapor region, a constant pressure curve departs the saturation line with a very significant upward slope as will soon be shown. Also by lowering the pressure to maintain a constant temperature with heat addition, some of the mechanical energy that was used in the pump would be sacrificed. There are several ways of increasing the work output of a Rankine cycle, but they do not improve on the efficiency relative to a Carnot cycle.

Now consider how the cycle efficiency is calculated. The heat input is given by

$$
\begin{equation*}
q_{i n}=h_{3}-h_{2} \tag{15.2}
\end{equation*}
$$

The turbine work is given by

$$
\begin{equation*}
w_{t}=h_{3}-h_{4} \tag{15.3}
\end{equation*}
$$

The enthalpy at state 4 is found by assuming an isentropic expansion process across the turbine so the entropy at state point 4 must be the same as the entropy at state point 3 . Once the pressure and entropy at state point 4 are known, the rest of the thermodynamic variables can be found including the enthalpy. Typically, a constant entropy expansion down to the pressure at state point 4 will put the fluid under the vapor dome and in the two-phase region. The entropy is then used to find the quality of the steam in the two-phase region. Once the quality is known, the enthalpy at state 4 can be easily obtained by the standard property expression for variables in the two phase regime.

The pump work is calculated by

$$
\begin{equation*}
w_{p}=h_{2}-h_{1}=\Delta p v=\left(p_{2}-p_{1}\right) v_{1} \tag{15.4}
\end{equation*}
$$

Therefore, the cycle thermal efficiency is given by

Note that for a closed system, the atmospheric pressure exiting the turbine and in the condenser will be significantly below atmospheric pressure as the liquid is being condensed to a temperature slightly above the cooling water temperature, which is near the ambient atmospheric temperature.

This can cause atmospheric gases to leak into the condenser and decrease the efficiency of the other components in the system, notably the pump. Therefore, a leak tight condenser is a very desirable component.
Example 15.1 Consider a basic Rankine power cycle with the saturated steam delivered to the turbine at 1000 psi and the condensate water delivered to the pump at 2.5 psi . Assume an isentropic turbine and pump. Calculate the cycle thermal efficiency.
Solution At 1000 psi $_{\text {sat }}=1004.3 \mathrm{R}, \mathrm{h}_{3}=1195.1 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{3}=1.39548 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$ at $2.5 \mathrm{psi}, \mathrm{T}_{\text {sat }}=594.1 \mathrm{R}, \mathrm{v}_{\mathrm{f}}=0.0163 \mathrm{~m}^{3} / \mathrm{kg}, \mathrm{h}_{\mathrm{f}}=102.6 \mathrm{Btu} / \mathrm{lbm}, \mathrm{h}_{\mathrm{fg}}=1019.1 \mathrm{Btu} / \mathrm{lbm}$, $\mathrm{s}_{\mathrm{f}}=0.18954 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{\mathrm{fg}}=1.71547 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

Then

$$
\begin{aligned}
& \text { Carnot Efficiency } \quad \eta_{C}=1-\frac{594.1}{1004.3}=0.4084 \\
& x_{4}=\frac{1.39548-0.18954}{1.71547}=0.7030 \quad h_{4}=102.6+0.7030 * 1019.1=819.0 \\
& \Delta h_{3-4}=1195.1-819.0=376.1 \mathrm{Btu} / \mathrm{lbm} \\
& \Delta h_{\text {pump }}=(1000-2.5) * 144 * 0.0163 / 778=3.0 \mathrm{Btu} / \mathrm{lbm} \\
& h_{2}=102.6+3.0=105.6 \mathrm{Btu} / \mathrm{lbm} \quad \Delta h_{2-3}=1195.1-105.6=1089.5 \mathrm{Btu} / \mathrm{lbm} \\
& \eta_{t h}=\frac{376.1-3.0}{1089.5}=0.3425 \quad \eta_{t h}=34.25 \% \quad \eta_{I I}=\frac{0.3425}{0.4084}=0.8386
\end{aligned}
$$

In addition to lossess required to drive the pump, inefficiencies in the turbine and pump can also affect the thermodynamic cycle efficiency. The change in enthalpy across a non-ideal turbine is given by

$$
\begin{equation*}
\Delta h_{\text {actual }}=\eta_{t} \Delta h_{\text {isentropic }} \tag{15.6}
\end{equation*}
$$

And for a non-ideal pump the actual change in enthalpy is given by

$$
\begin{equation*}
\Delta h_{\text {actual }}=\frac{\Delta h_{\text {isentropic }}}{\eta_{p}} \tag{15.7}
\end{equation*}
$$

Example 15.2 Re-evaluate the thermal efficiency of the Rankine cycle in Example 15.1 assuming a turbine with an adiabatic efficiency of $90 \%$ and a pump with an adiabatic efficiency of $80 \%$.

Solution The only changes are the $\Delta$ h's across the pump and the turbine.

$$
\begin{aligned}
\Delta h_{p u m p} & =\frac{3.0}{0.8}=3.75 \mathrm{Btu} / \mathrm{lbm} \quad \Delta h_{3-4}=0.9 * 376.1=338.5 \mathrm{Btu} / \mathrm{lbm} \\
\eta_{t h} & =\frac{338.5-3.75}{1089.5}=0.3073 \quad \eta_{t h}=30.73 \%
\end{aligned}
$$

Now consider possible ways of increasing the efficiency of the basic Rankine Cycle. There are really three possibilities-(1) increase the boiler pressure, (2) decrease the condensing temperature, and therefore the pressure, for the condensate entering the pump, and (3) increase the peak temperature of the cycle.

Example 15.3 Change the turbine inlet pressure for Example 15.1 to 1200 psi and re-evaluate the cycle efficiency.

Solution At $1200 \mathrm{psi}, \mathrm{T}_{\text {sat }}=1026.9, \mathrm{~h}_{3}=1186.8 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{3}=1.37253 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

Carnot Efficiency $\quad \eta_{C}=1-\frac{594.1}{1026.9}=0.4215$
$x_{4}=\frac{1.37253-0.18954}{1.71547}=0.6896 \quad h_{4}=102.6+0.6896 * 1019.7=805.8 \mathrm{Btu} / \mathrm{lbm}$
$\Delta h_{3-4}=1186.8-805.8=381.0 \mathrm{Btu} / \mathrm{lbm} \quad \Delta h_{2-3}=1186.8-105.6=1081.2 \mathrm{Btu} / \mathrm{lbm}$
$\eta_{t h}=\frac{381.0-3.0}{1081.2}=0.3496 \quad \eta_{\text {th }}=34.96 \% \quad \eta_{I I}=\frac{0.3496}{0.4215}=0.8294$

Example 15.4 Change the condensate pump input pressure in Example 15.1 to 1.5 psi and re-evaluate the thermal efficiency of the cycle.

Solution At $1.5 \mathrm{psi}, \mathrm{T}_{\text {sat }}=575.3 \mathrm{R}, \mathrm{v}_{\mathrm{f}}=0.0162 \mathrm{~m}^{3} / \mathrm{kg}, \quad \mathrm{h}_{\mathrm{f}}=83.8 \mathrm{Btu} / \mathrm{lbm}$, $\mathrm{h}_{\mathrm{fg}}=1029.9 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{\mathrm{f}}=0.15746 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{\mathrm{fg}}=1.79023 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

Carnot Efficiency $\quad \eta_{C}=1-\frac{575.3}{1004.3}=0.4272$
$x_{4}=\frac{1.39548-0.15746}{1.79023}=0.6915$
$h_{4}=83.8+0.6915 * 1029.9=796.0$ Btu/lbm
$\Delta h_{3-4}=1195.1-796.0=399.1 \mathrm{Btu} / \mathrm{lbm}$
$\Delta h_{\text {pump }}=(1000-1.5) * 144 * 0.0162 / 778=2.99$ Btu/lbm
$\Delta h_{2-3}=1195.1-(83.8+2.99)=1108.3 \mathrm{Btu} / \mathrm{lbm}$
$\eta_{t h}=\frac{399.1-2.99}{1108.3}=0.3574 \quad \eta_{t h}=35.74 \% \quad \eta_{I I}=\frac{0.3574}{0.4272}=0.8366$

### 15.2 Process Efficiency

Actual expansion process is irreversible, as shown by line 1-2 in Fig. 15.4 [1]. Similarly the actual compression of the water is irreversible, as indicated by line 3-4. The isentropic efficiency of a process is defined by;

$$
\text { Isentropic efficiency }=\frac{\text { actual work }}{\text { isentropic work }} \text { for an expansion process }
$$

and

$$
\text { Isentropicefficiency }=\frac{\text { isentropicwork }}{\text { actualwork }} \text { for an expansion process }
$$

Hence

$$
\begin{equation*}
\text { Turbineisentropicefficiency }=\frac{-W_{12}}{-W_{12 s}}=\frac{h_{1}-h_{2}}{h_{1}-h_{2 s}} \tag{15.8}
\end{equation*}
$$

In analyzing the performance of steam plant another criterion also known as Specific Steam Consumption (SSC). This relates the power output to the steam flow necessary to produce it. The steam flow indicates the size of plant and its component parts, and the SSC is a means whereby the relative sizes of different plants can be compared.

The ssc is the steam flow required to develop unit power output. The power output is given by $-m \sum W$, therefore we can write;

$$
\begin{equation*}
S S C=\frac{m}{-m \sum W}=\frac{1}{-\sum W} \tag{15.9}
\end{equation*}
$$

Fig. 15.4 Rankine cycle showing real processes on a $T-s$ diagram

Neglecting the feed pump work we have

$$
-\sum W=\left(h_{1}-h_{2}\right)-\left(h_{4}-h_{3}\right)
$$

Therefore

$$
S S C=\frac{1}{\left(h_{1}-h_{2}\right)-\left(h_{4}-h_{3}\right)}
$$

Note that when $h_{1}$ and $h_{2}$ are expressed in kilojoules per kilogram then the units of $S S C$ are $\mathrm{kg} / \mathrm{kJ}$ or $\mathrm{kg} / \mathrm{kW}$ h.

Example 15.5 A steam power plant operates between a boiler pressure of 609.126 psi and a condenser pressure of 0.507605 psi. Calculate for these limits the cycle efficiency, the work ratio, and the Specific Steam Consumption (SSC):
a. For a Carnot cycle using wet steam;
b. For a Rankine cycle with dry saturated steam at entry to the turbine;
c. For the Rankine cycle of (b), when the expansion process has an isentropic efficiency of $80 \%$.

## Solution

a. A Carnot cycle is shown in Fig. 15.5a

## a

Fig. 15.5 a Carnot cycle for Example 15.5. b Rankine cycle for Example 15.5. c Carnot cycle for Example 15.5

b

Consider the following;

$$
\begin{aligned}
T_{1} & =\text { saturation temperature at } 609.126 \mathrm{psi} \\
& =253.2+273=526.2 \mathrm{~K} \\
T_{2} & =\text { saturation temperature at } 0.507605 \mathrm{psi} \\
& =26.7+273=299.7 \mathrm{~K}
\end{aligned}
$$

Using Eq. 7.10 in the following form, we can write

$$
\eta_{\text {Carnot }}=1-\frac{T_{2}}{T_{1}}=\frac{T_{1}-T_{2}}{T_{1}}=\frac{526.2-299.7}{526.2}=0.432 \text { or } 43.2 \%
$$

Also heat supplied $=h_{1}-h_{4}=h_{\mathrm{fg}}$ at $42 \mathrm{bar}=1698 \mathrm{~kJ} / \mathrm{kg}$
Then

$$
\eta_{\text {Carnot }}=\frac{\text { Net work output } \left.\left(-\sum W\right)\right)}{\text { Turbineheatsupplied }}=0.432
$$

Therefore

$$
\left(-\sum W\right)=0.432 \times 1689
$$

i.e. Net work output,

$$
\left(-\sum W\right)=734 \mathrm{~kJ} / \mathrm{kg}
$$

To find the turbine work of the expansion process it is necessary to calculate $h_{2}$, using the fact that $\mathrm{s}_{1}=\mathrm{s}_{2}$. From steam tables we can see that $\mathrm{h}_{1}=2800 \mathrm{~kJ} / \mathrm{kg}$ and $\mathrm{s}_{1}=\mathrm{s}_{2}=6.049 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$. Using the entropy of wet steam that is given by the entropy of the water in the mixture plus the entropy of the dry steam in the mixture. For wet steam with quality $x$, we have

$$
s=s_{f}+x s_{f g}
$$

The quality is given by

$$
x=\frac{s-s_{f}}{s_{f g}}
$$

Applying all these relationship to part a of this example we can continue to write that;

$$
s_{2}=6.049=s_{f 2}+x_{2} s_{f g}=0.391+x_{2} 8.13
$$

Therefore

$$
x_{2}=\frac{6.049-0.391}{8.13}=0.696
$$

Therefore

$$
h=h_{f}+x h_{f g}
$$

Having the quality for an isotropic expansion the enthalpy is simply given by:

$$
h_{2}=h_{f 2}+x_{2} h_{f g 2}=112+(0.696 \times 2436)=1808 \mathrm{~kJ} / \mathrm{kg}
$$

So the turbine work for an isentropic expansion is given by:

$$
W_{12}=h_{2}-h_{1}
$$

Or work output is going to be $-W_{12}=h_{1}-h_{2}$, thus we can write

$$
-W_{12}=h_{1}-h_{2}=2800-1808=992 \mathrm{~kJ} / \mathrm{kg}
$$

Using Eq. 15.6 we can write that

$$
\begin{aligned}
S S C & =\frac{1}{\text { Net workoutput }\left(-\sum W\right)} \\
& =\frac{1}{734 \mathrm{~kJ} / \mathrm{kg}}=0.00136 \mathrm{~kg} / \mathrm{kWsec} \\
& =4.91 \mathrm{~kg} / \mathrm{kWh}
\end{aligned}
$$

b. The Rankine cycle is shown in Fig. 15.5b

As in part (a)

$$
h_{1}=2800 \mathrm{~kJ} / \mathrm{kg} \quad \text { and } \quad h_{2}=1808 \mathrm{~kJ} / \mathrm{kg}
$$

Also,

$$
h_{3}=h_{f} \text { at } 0.507605 \mathrm{psi}=112 \mathrm{~kJ} / \mathrm{kg}
$$

But for a reversible adiabatic process and using second law of thermodynamics, we can write that $d Q=d h-v d p=0$, therefore $d h=v d p$, and;

$$
\int_{3}^{4} d h=\int_{3}^{4} v d p \quad \text { and } \quad h_{4}-h_{3}=v \int_{3}^{4} d p=v\left(p_{4}-p_{3}\right)
$$

i.e.

$$
h_{4}-h_{3}=v\left(p_{4}-p_{3}\right)
$$

Therefore, the pump work input is given by;

$$
\text { Pump input work }=h_{4}-h_{3}=v\left(p_{4}-p_{3}\right)
$$

With assumption of $v=v_{f}$ at 0.507605 psi and using the above relation, we can write
Pump input work $=v_{f}\left(p_{4}-p_{3}\right)=0.001 \times(609.126-0.507605) \times \frac{10^{5}}{10^{3}}=4.2 \mathrm{~kJ} / \mathrm{kg}$
Using the relationship for turbine work output that we found in part (a) of this example, namely $-W_{12}=h_{1}-h_{2}$, we can write that

$$
-W_{12}=h_{1}-h_{2}=2800-1808=992 \mathrm{~kJ} / \mathrm{kg}
$$

If we define the Rankin efficiency is defined as $\eta_{R}$, then we can write

$$
\text { Rankine efficiency }=\eta_{R}=\frac{\text { Net work output }}{\text { Heatsupplied in the boiler }}
$$

or

$$
\eta_{R}=\frac{\left(h_{1}-h_{2}\right)-\left(h_{4}-h_{3}\right)}{\left(h_{1}-h_{3}\right)-\left(h_{4}-h 3\right)}=\frac{99.2-4.2}{(2800-112)-4.2}=0.368
$$

or

$$
\eta_{R}=36.8 \%
$$

And using Eq. 15.6 will give us the following result;

$$
\begin{aligned}
S S C & =\frac{1}{\text { Net work output }\left(-\sum W\right)} \\
& =\frac{1}{(992-4.2) \mathrm{kJ} / \mathrm{kg}}=0.00101 \mathrm{~kg} / \mathrm{kWsec} \\
& =3.64 \mathrm{~kg} / \mathrm{kWh}
\end{aligned}
$$

c. The cycle with an irreversible expansion process is shown in Fig. 15.5c. Using Eq. 15.6 we can write

$$
\text { Isentropic efficiency }=\frac{h_{1}-h_{2}}{h_{1}-h_{2 s}}=\frac{-W_{12}}{-W_{12 s}}
$$

Therefore

$$
0.8=\frac{-W_{12}}{992} \text { or }-W_{12}=0.8 \times 992=793.6 \mathrm{~kJ} / \mathrm{kg}
$$

Then the cycle efficiency is given by

$$
\begin{aligned}
\text { Cycle efficiency } & =\frac{\left(h_{1}-h_{2}\right)-\left(h_{4}-h_{3}\right)}{\text { gross heat supplied }} \\
& =\frac{793.6-4.2}{(2800-112)-4.2}=0.294 \\
& =29.4 \%
\end{aligned}
$$

Also, we can write for $S S C$ as before

$$
S S C=\frac{1}{793.6-4.2}=0.001267^{\mathrm{kg}} / \mathrm{kWsec}=4.56^{\mathrm{kg}} / \mathrm{kWh}
$$

The feed-pump term has been included in the above calculation, but an inspection of the comparative values shows that it could have been neglected without having a noticeable effect on the results.

### 15.3 The Rankine Cycle with a Superheater

The only way to increase the peak temperature of the Rankine cycle without increasing the boiler pressure is to heat the steam itself to a higher temperature. This requires the addition of another type of heat exchanger called a super heater. This third heat exchanger is added to the steam generator as described in Fig. 15.6. The T-s diagram is provided in Fig. 15.7.

The only difference that the superheated Rankine cycle presents when evaluating the cycle thermal efficiency is that the enthalpy at state point 3 , the inlet to the turbine, must be obtained from the superheated steam tables.

Fig. 15.6 Components for a superheated Rankine cycle

Fig. 15.7 T-s diagram for a Rankine cycle with a superheater

Example 15.6 Add a superheater to the cycle described in Example 15.1 that takes the turbine inlet temperature up to $1500^{\circ} \mathrm{R}$.

Solution At 1000 psi and $1500^{\circ} \mathrm{R}, \mathrm{h}_{3}=1532.5 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{3}=1.67285 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$ At $2.5 \mathrm{psi}, \mathrm{T}_{\text {sat }}=594.1 \mathrm{R}, \mathrm{v}_{\mathrm{f}}=0.0163 \mathrm{~m}^{3} / \mathrm{kg}, \mathrm{h}_{\mathrm{f}}=102.6 \mathrm{Btu} / \mathrm{lbm}, \mathrm{h}_{\mathrm{fg}}=1019.1 \mathrm{Btu} / \mathrm{lbm}$, $\mathrm{s}_{\mathrm{f}}=0.18954 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{\mathrm{fg}}=1.71547 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

Carnot Efficiency $\quad \eta_{C}=1-\frac{594.1}{1500}=0.6039$
$x_{4}=\frac{1.67258-0.18954}{1.71547}=0.8645$
$h_{4}=102.6+0.8645 * 10191=983.6 \mathrm{Btu} / \mathrm{lbm}$
$\Delta h_{3-4}=1535.5-983.6=548.9 \mathrm{Btu} / \mathrm{lbm}$
$\Delta h_{2-3}=1532.5-105.6=1426.9 \mathrm{Btu} / \mathrm{lbm}$
$\eta_{\text {th }}=\frac{548.9-3.0}{1426.9}=0.3826 \quad \eta_{t h}=38.26 \% \quad \eta_{I I}=\frac{0.3826}{0.6039}=0.6335$

Note that increasing the superheater outlet temperature further will increase the cycle efficiency further, but will decrease the second law efficiency relative to a Carnot cycle.
Example 15.7 Increase the superheater exit temperature from Example 15.6 to $1600^{\circ} \mathrm{R}$ and estimate the increase in cycle efficiency.

Solution At 1000 psi and $1600^{\circ} \mathrm{R}, \mathrm{h}_{3}=1589.3 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{3}=1.70929 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

Carnot Efficiency $\quad \eta=1-\frac{594.1}{1600}=0.6287$

$$
\begin{aligned}
x_{4} & =\frac{1.70929-0.18954}{1.71547}=0.8859 \\
h_{3} & =102.6+08859 * 1019.1=1005.4 \mathrm{Btu} / \mathrm{lbm} \\
\Delta h_{3-4} & =1589.3-1005.4=583.9 \mathrm{Btu} / \mathrm{lbm} \\
\Delta h_{2-3} & =1589.3-105.6=1492.7 \mathrm{Btu} / \mathrm{lbm} \\
\eta_{\text {th }} & =\frac{583.9-3.0}{1492.7}=0.3892 \quad \eta_{\text {th }}=38.92 \% \quad \eta_{I I}=\frac{0.3892}{0.6287}=0.6190
\end{aligned}
$$

Obviously, the reason the second law efficiency goes down is because the peak temperature of the cycle has been increased, but an even smaller fraction of the total heat input to the cycle has occurred near the peak temperature of the cycle.

### 15.4 External Reversibilities

No science or design can completely start at the beginning and proceed to develop everything in a uniform sequence. So backup and consider the two main heat exchange processes that go on in a typical Rankine cycle power plant. In the boiler, the feed water is heated to the turbine inlet conditions. In the condenser, the water is cooled from turbine exit conditions to a saturated liquid for delivery to the pump. In both processes, the heat transfer is driven by temperature differences. In the boiler, it is the difference between the hot gases in a combustion plant or primary coolant water in a nuclear reactor. In the condenser, it is the difference in temperature of the condensate and the external cooling water. These temperature differences are over plotted on a vapor dome representing a typical simple Rankine cycle in Fig. 15.8 below.

The hot side of the boiler is represented by the line $\boldsymbol{b}-\boldsymbol{a}$ and the external cooling flow is represented by the line $\boldsymbol{c}-\boldsymbol{d}$. There is very little that can be done about the irreversibilities in the external coolant flow other than to try to bring the differences $\mathrm{c}-3$ and d-2 closer together. This can be accomplished by building a bigger more effective condenser, but at some point the cost of the equipment takes over and further reductions in irreversibilities are not cost effective.

However, on the hot side there are some things that can be done. Note that the way the diagram is drawn, the flow of the hot gases or water in the boiler is from $\boldsymbol{a}$ to $\boldsymbol{b}$. It is essentially a counter flow heat exchanger. It would be possible to flow the hot fluids in the opposite direction as in a parallel flow heat exchanger, but that would only increase the temperature differences. This can be seen by comparing the two schematics below in Fig. 15.9, where the first (a) represents the temperature differences for a parallel flow exchanger and the second (b) represents a counter flow exchanger. The horizontal axis in both is the distance along the boiler.

Fig. 15.8 T-s diagram for basic Rankine cycle with overplot of external temperatures

Fig. 15.9 Temperature differences for parallel (a) and Counter (b) flow heat exchangers

PWR Steam Generator

Fossil/Gas Cooled Steam Generator

Fig. 15.10 Temperature gradients for nuclear and fossil steam generators

It should be clear why only the counter flow approach is ever considered. Now consider the difference between a nuclear steam generator and a fossil or gas steam generator. In the nuclear steam generator, the heat carried and transferred per unit volume is greater so the temperature slope on the hot side of the exchanger is significantly lower. The temperature drop on the hot side comes much closer to paralleling the constant temperature line across the vapor dome as can be seen in Fig. 15.10 below.

For a combustion or gas, cooled system there is a much stronger advantage to coming out of the vapor dome and superheating the working fluid.

Note that the minimum temperature drop between the two curves occurs at the point where the working fluid reaches the liquid saturation point identified on the graphs as the separation $\boldsymbol{e}-\boldsymbol{B}$. This point is called the "pinch point" and the fluid providing the heat must always maintain a positive separation here in order to stably transfer heat to the working fluid.

### 15.5 Superheated Rankine Cycle with Reheaters

In order to deliver more of the heat at a temperature close to the peak of the cycle, the steam is usually extracted from the turbine after a less than maximum expansion and reheated to a higher temperature. This involves splitting the turbine into a high pressure and a low pressure turbine or into high, intermediate, and low pressure turbines. Three turbines are not uncommon in many plants. They may all be on the same shaft to drive a common generator, but they will have separate cases. With a reheater, the flow is extracted after a partial expansion, run back through the boiler to heat it back up to the peak temperature, and then passed to the lower pressure turbine. A component diagram for a single reheater is provided in Fig. 15.11. The fluid is extracted after a partial expansion in the high pressure turbine at state 5 .

Fig. 15.11 Superheated Rankine cycle with single reheater

Typically, the extraction pressure is around one-fourth of the peak pressure. It is rerouted to the boiler and reheated to the peak temperature at state 6 . It may even be heated to a higher temperature as the components may be able to stand a higher temperature at the reduced pressure. It is then routed back to the intermediate or low-pressure turbine to be expanded to condenser pressure.

The temperature-entropy diagram is provided in Fig. 15.12. Note that state point 5 may or may not be under the vapor dome. If it is not under the vapor dome, the superheated steam tables must be interpolated based on the known pressure and entropy to find the enthalpy at state point 5 .

Most large steam plants today typically use three turbines and two reheaters. The analysis follows that for a single reheater but is repeated second time. In each case, a rule of thumb is that the pressure out of the turbine should be approximately onefourth of the inlet pressure.

Fig. 15.12 T-s diagram for superheated Rankine cycle with single reheater

Example 15.8 Add a reheater to the cycle of Example 15.6 after the superheated steam has been expanded to 250 psi .

Solution At 250 psi and $\mathrm{s}_{3}=1.67258 \mathrm{Btu} / \mathrm{lbm}$ interpolate to find $\mathrm{h}_{5}$

$$
\begin{aligned}
& s(200 \text { psi, 1000R })=1.65013, h(200 p s i, 1000 R)=1293.6 \\
& s(300 p s i, 1000 R)=1.59813, h(300 p s i, 1000 R)=1284.2 \\
& s(250 p s i, 1000 R)=1.64213, h(250 p s i, 1000 R)=1288.9 \\

& \eta_{t h}=\frac{144.4+472.1-3.0}{1426.9+164.7}=0.3855 \quad \eta_{t h}=38.55 \% \\
& \eta_{I I}=\frac{0.3855}{0.6039}=0.6384
\end{aligned}
$$

Note that the current generation of LWRs only produces saturated steam and cannot use nuclear driven superheaters or reheaters. Advanced reactors including liquid metal reactors, gas cooled reactors and molten salt reactors may be able to take advantage of superheating and reheating to improve their cycle efficiencies. From a cost of operation perspective, improvements in efficiency are not as important for nuclear plants as they are for fossil plants because the cost of fuel is a much smaller fraction of the total operating cost for a nuclear plant. However, it still pays to improve thermal efficiency in all cases.

### 15.6 Feed Water Heaters

With the addition of the reheaters, the external irreversibilities above the saturated water point break point, or pinch point, in the Rankine cycle have been dealt with as completely as possible. Next, the irreversibilities below the saturated water break point, or pinch point, can be addressed. This is normally taken care of with devices called Feed Water Heaters. There are three types of Feed Water Heaters and some plants use at least one of each. The three types are (1) Open or Direct Contact Feedwater Heaters, (2) Closed Feedwater Heaters with Drains Cascaded Backwards, and (3) Closed Feedwater Heaters with Drains Pumped Forward.

### 15.6.1 Open or Direct Contact Feedwater Heaters

A typical system with an Open Feedwater Heater is shown in Fig. 15.13 below.
The main turbine exit flow is drawn off at state point 4 as before. It passes through the condenser and enters the pump at state point 1 where its pressure is raised to the pressure of the bleed flow from the turbine at state point 2 . The small bleed flow for the heater is bled off at state point 5. It does not have to be at the exit of a turbine however. Since the flow is only being bled off and not to be returned, it can be bled off at any desired pressure. These two flows are then mixed in the open feed water heater. The resulting liquid then enters the feed water pump at state 7 .

Fig. 15.13 Open feed water heater cycle

Fig. 15.14 T-s diagram for a cycle with an open feed water heater

The feed water pump then raises the pressure of the hot water to the required system pressure to enter the boiler at state point 8 . Note that the boiler must heat the working fluid from the temperature at the exit of the feed water heater to the turbine throttle conditions at state point 3. But the heating from the condensate temperature to the temperature at state point 8 has been accomplished with lower temperature water (steam) so some of the irreversibility associated with the heat transfer has been eliminated (Fig. 15.14).

The main liability of the open feed water heater system is that it requires a pump after every heater that must pass most of the turbine flow. One advantage other than the decrease in heat transfer is that mixing of the two streams serves to release trapped gases in the feedwater and serves as an aerator. This is an advantage for fossil fueled plants but is normally not taken advantage of by nuclear plants due to concerns about releases of radioactivity.

Example 15.9 Add an open feed water heater to the cycle of Example 15.8 with the steam being extracted between the two turbines. Estimate the new cycle efficiency.

## Solution

$$
\begin{aligned}
& h_{7}=\dot{m}_{5} h_{5}+\left(1-\dot{m}_{5}\right) h_{2} \quad \dot{m}_{5}=\frac{h_{7}-h_{2}}{h_{5}-h_{2}} \\
& h_{2}=102.6+(250-2.5) * 144 * 0.0162 / 778=102.6+0.742=103.3 \mathrm{Btu} / \mathrm{lbm} \\
& h_{5}=1388.1 \text { Btu } / \mathrm{lbm}(\text { Ex. } 6) \quad h_{7}=3.77 .0 \mathrm{Btu} / \mathrm{lbm}(\text { Sat Liquid }) \\
& \Delta h_{\text {feedwater pump }}=(1000-250) * 144 * 0.0187 / 778=2.596 \mathrm{Btu} / \mathrm{lbm} \\
& h_{8}=h_{7}+h_{\text {feedwater pump }}=3.77 .0+2.596=379.6 \mathrm{Btu} / \mathrm{lbm} \\
& m_{5}=\frac{377.0-103.3}{1388.1-103.3}=0.213
\end{aligned}
$$

$$
\begin{aligned}
\eta_{t h} & =\frac{144.4+(1.0-0.213) * 472.1-2.596-(1.0-0.213) * 0.742}{[1532.5-(379.6)]+(1.0-0.213) * 164.7} \\
& =\frac{512.76}{1282.52}=0.3998 \\
\eta_{t h} & =39.98 \% \quad \eta_{I I}=\frac{0.3998}{0.6039}=0.6620
\end{aligned}
$$

### 15.6.2 Closed Feed Water Heaters with Drain Pumped Forward Second Type

The second type of feed water heater is a closed feed water heater with drains cascaded backward. The closed feed water heater is simply a two fluid heat exchanger (Figs. 15.15 and 15.16).

Steam is extracted from the turbine and passed through the feed water heat exchanger. It then must pass through an expansion valve to get it back down to the condenser pressure or the next lower feed water heater in the chain. Typically the steam that is extracted is very close to saturation and so the dominant heat transfer activity is the condensation of this steam to heat the high pressure water out of the condensate pump. It is possible that the closed feed water heater could contain three separate types of heat exchanger. The first component would be a "de-superheater" that transfers heat from the superheated steam to the high-pressure water. The second component would be a condenser, which condenses the saturated steam to a liquid to heat the high-pressure water. The third component would be a "drain cooler"

Fig. 15.15 Closed feed water heater with drain cascaded backwards

Fig. 15.16 T-s diagram for closed feed water heater with drain cascaded backward
that heats to cold high-pressure water with the hot liquid condensate. The extracted steam would pass through each of these components in sequence. The cold highpressure water passes through them in the opposite sequence in the typical counter flow heat exchanger.

Because the dominant heat transfer mechanism is the condensation of the steam, the Terminal Temperature Difference (TTD) is defined as the difference in temperature between the high-pressure water exiting the heater and the condensation temperature of the high pressure steam. If there is no de-superheater component or a small one, this temperature difference will be positive. If there is a significant de-superheater section this temperature, difference could be negative which means that the high pressure water would exit the feed water heater at a higher temperature than the saturation temperature of the high pressure steam entering it.

Example 15.10 Replace the open feedwater heater of Example 15.9 with a closed feedwater heater with drain cascaded backward, extracting the steam between the two turbines. Assume a Terminal Temperature Difference (TTD) of $15^{\circ}$ R. Estimate the new cycle efficiency.

## Solution

$$
m_{5}\left(h_{5}-h_{7}\right)=\left(h_{8}-h_{2}\right)
$$

$T_{8}=800 R$ Interpolating in the sub - cooled liquid table
$h_{8}(1000 \mathrm{psi}, 800 \mathrm{R})=313.7 \mathrm{Btu} / \mathrm{lbm}$
$h_{7}$ comes from the sub - cooled liquid table for $594.1+15$

$$
=609 \mathrm{R} \text { and } 250 \mathrm{psi} h_{7}=119.2 \mathrm{Btu} / \mathrm{lbm}
$$

$$
h_{5}=1388.1 \mathrm{Btu} / \mathrm{lbm}(E x .6) h_{2}=105.6 \mathrm{Btu} / \mathrm{lbm}
$$

$$
\begin{aligned}
& m_{5}=\frac{\left(h_{8}=h_{2}\right)}{\left.h_{5}-h_{7}\right)}=\frac{313.7-105.6}{1388.1-119.2}=0.164 \\
& \Delta h_{3-8}=1532.5-313.7 \\
& \quad=1218.8 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

$$
\eta_{t h}=\frac{\Delta h_{3-5}+\left(1-m_{5}\right) \Delta h_{6-4}-\Delta h_{\text {pump }}}{\Delta h_{3-8}+\left(1-m_{5}\right) \Delta h_{5-6}}=\frac{144.4+0.836 * 472.1-3.0}{1218.8+0.836 * 164.7}=0.3952
$$

$$
\eta_{t h}=39.52 \% \quad \eta_{I I}=\frac{0.3952}{0.6039}=0.6544
$$

### 15.6.3 Closed Feed Water Heaters with Drain Pumped Forward Third Type

The third type of feed water heater is a closed feed water heater with the drain pumped forward. A layout of components is described in Fig. 15.17 and the T-s diagram in Fig. 15.18. For this configuration, the closed feed water heater is once again a two fluid counter flow heat exchanger. On the other hand, instead of the condensed steam being expanded back to condensate pressure, it is pumped up to the full system pressure with an added pump. This pump is smaller than the main condensate

Fig. 15.17 System layout for a closed feed water heater with drain pumped forward

Fig. 15.18 T-s diagram for closed feed water heater with drain pumped forward
pump because it processes a smaller amount of water and it starts at a much higher pressure. But it is another active component that could fail or require maintenance.

The cycle thermodynamic efficiency is improved very slightly over the closed feed water heater with the drain cascaded backward.

Example 15.11 Replace the closed feed water heater in Example 15.10 with a closed feed water heater with drain pumped forward extracting the steam between the two turbines. Estimate the new cycle efficiency.

## Solution

Balancing the heat transfer across the FWH

$$
\begin{aligned}
& \left(1-\dot{m}_{5}\right)\left(h_{8}=h_{2}\right)=\dot{m}_{5}\left(h_{5}-h_{7}\right) h_{8}=h_{7}+h_{c p} \\
& h_{c p}=(1000-250) * 0.0179 * 144 / 778=2.5 \mathrm{Btu} / \mathrm{lbm} \\
& \dot{m}_{5}=\frac{h_{8}-h_{2}}{h_{5}-h_{2}+h_{c p}}=\frac{313.7-105.6}{1388.1-105.6+2.5}=0.1619 \\
& \eta_{t h}=\frac{144.4+0.8381 * 472.1-0.8381 * 3-0.1619 * 2.5}{1421.5+0.8381 * 164.7}=0.3959 \\
& \eta_{t h}=39.59 \% \quad \eta_{I I}=\frac{0.3959}{0.6039}=0.6556
\end{aligned}
$$

Typically large steam power plants have multiple feed water heaters cascaded in increasing temperature ranges to heat the feed water from the temperature exiting the condensate pump up to near the system saturation pressure. As many as eight might be used in a typical $1000 \mathrm{MW}(\mathrm{t})$ plant. In a fossil plant one will be an open feed water heater to release dissolved gases, but nuclear plants have to contain the radioactivity so typically they are all closed feed water heaters.

The pressures at which the steam is extracted are usually arranged so that the temperature range between the saturated temperature of the condensate-exiting condenser and the saturated temperature at the full system pressure is divided into $\mathrm{n}+1$ equal intervals, where n is the number of feed water heaters. Then the extraction pressures are chosen to match these temperatures. For instance if the steam generator pressure is 1000 psi with a saturation temperature of $1004.3^{\circ} \mathrm{R}$ and the condenser pressure is 2.5 psi with a saturation pressure of $594.1^{\circ} \mathrm{R}$ and five feed water heaters will be used, the recommended saturation temperatures are,

$$
\begin{array}{ll}
\Delta T=(1004.3-594.1) /(5+1)=68.3^{\circ} R \\
T_{1}=662.5^{\circ} R & p_{1}=12.5 p s i \\
T_{2}=730.8^{\circ} R & p_{2}=42.5 p s i \\
T_{3}=799.2^{\circ} R & p_{3}=118.5 \mathrm{psi} \\
T_{4}=867.6^{\circ} R & p_{4}=268 p s i \\
T_{5}=935.9^{\circ} R & p_{5}=546.5 p s i
\end{array}
$$

Example 15.12 Reconsider the LWR circuit of Example 15.1. Add two feedwater heaters with drains cascaded backwards to this cycle and compute the new thermal efficiency. Assume the TTD for both heaters is $15^{\circ} \mathrm{R}$. Assume the hot fluid exiting both heaters is saturated liquid (Fig. 15.19).

Solution At $1000 \mathrm{psi}_{\text {sat }}=1004.3 \mathrm{R}, \mathrm{h}_{3}=1195.1 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{3}=1.39548 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$ at $2.5 \mathrm{psi}, \mathrm{T}_{\mathrm{sat}}=594.1 \mathrm{R}, \mathrm{v}_{\mathrm{f}}=0.0163 \mathrm{~m}^{3} / \mathrm{kg}, \mathrm{h}_{\mathrm{f}}=102.6 \mathrm{Btu} / \mathrm{lbm}, \mathrm{h}_{\mathrm{fg}}=1019.1 \mathrm{Btu} / \mathrm{lbm}$, $\mathrm{s}_{\mathrm{f}}=0.18954 \mathrm{Btu} / \mathrm{lbm}, \mathrm{s}_{\mathrm{fg}}=1.71547 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$

The extraction pressures will be given by dividingup the range from 594.1 to $1004.3^{\circ} \mathrm{R}$ into three intervals. The saturation temperatures would be 730.8 and $867.6^{\circ} \mathrm{R}$. These correspond to saturation pressures of 42 and 270 psi . Therefore, at 270 psi and $1.39548 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}$ the steam is in the saturated two-phase region.

$$
\begin{aligned}
& s_{f}=0.57675 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}, s_{f g}=0.94760 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R} \\
& h_{f}=373.7 \mathrm{Btu} / \mathrm{lbm}, h_{f g}=821.3 \mathrm{Btu} / \mathrm{lbm} \\
& x_{5}=\frac{1.39548-0.57675}{0.94760}=0.864 \\
& h_{5}=383.7+0.864 * 821.3=1093.3 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

And at 42 psi ,

$$
\begin{aligned}
s_{f} & =0.39734 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}, s_{f g}=1.27880 \mathrm{Btu} / \mathrm{lbm} / \mathrm{R}, \\
h_{f} & =239.8 \mathrm{Btu} / \mathrm{lbm}, h_{f g}=933.5 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

Fig. 15.19 LWR steam generator with two closed feed water heaters with drains cascaded backwards

$$
\begin{aligned}
x_{7} & =\frac{1.39548-0.39734}{1.27880}=0.781 \\
h_{7} & =239.8+0.781 * 933.5=968.4 \mathrm{Btu} / \mathrm{lbm} \\
T_{9} & =730.8-15=715^{\circ} \mathrm{R}, \mathrm{~h}_{9}=226.6 \mathrm{Btu} / \mathrm{lbm} T_{10}=867.5-15=852.5^{\circ} \mathrm{R}, \\
\mathrm{~h}_{10} & =369.1 \mathrm{Btu} / \mathrm{lbm}
\end{aligned}
$$

$$
\mathrm{h}_{6}=383.7 \mathrm{Btu} / \mathrm{lbm} \mathrm{~h} \mathrm{~h}_{8}=239.8 \mathrm{Btu} / \mathrm{lbm}
$$

Then

$$
\begin{aligned}
& m_{5}\left(h_{5}-h_{6}\right)=h_{10}-h_{9} m_{5}=\frac{h_{10}-h_{9}}{h_{5}-h_{6}}=\frac{369.1-226.6}{1093.3-383.7}=0.2008 \\
& m_{5} h_{6}+m_{7} h_{7}-\left(m_{5}+m_{7}\right) h_{8}=h_{9}-h_{2} m_{7}=\frac{h_{9}-h_{2}-m_{5}\left(h_{6}-h_{8}\right)}{h_{7}-h_{8}} \\
& m_{7}=\frac{226.6-105.6-0.2008 *(383.7-239.8)}{986.4-239.8}=0.1234 \\
& n_{t h}=\frac{1195.1-1093.3+(1.0-0.2008)(1093.3-968.4)}{1195.1-369.1}+ \\
& \quad \frac{(1.0-0.2008-0.1234) *(968.4-819.0)-3.0}{1195.1-369.1} \\
& \eta_{t h}=\frac{302.52}{826}=0.3662 \quad \eta_{t h}=36.62 \%
\end{aligned}
$$

### 15.7 The Supercritical Rankine Cycle

The major advantage of the Rankine cycle is that the compression process works on a liquid. It is certainly possible to compress the liquid to a pressure greater than its critical pressure and heat it above the critical temperature. The expansion process could completely take place above the vapor dome, only dropping into the twophase region near the exit from the turbine. The cycle efficiency would be improved slightly, but the stresses in the components would necessitate much more expensive structures. In addition, the safety consequences of a pipe rupture would increase significantly. So no supercritical cycle devices have been attempted with water as the working fluid, but other fluids, such as carbon dioxide, have been considered.

## Chapter 16 <br> Circulating Water Systems

Nuclear power plants are usually built next to lakes, rivers, and oceans. Not for the scenic views that such locales provide, but because water can absorb the waste heat produced by the plants. Nuclear power plants consume vast amounts of water during normal operation to absorb the waste heat left over after making electricity and to cool the equipment and buildings used in generating that electricity. In event of an accident, nuclear power plants need water to remove the decay heat produced by the reactor core and to cool the equipment and buildings used to provide the core's heat removal. This chapter describes the reliance of nuclear power plants on nearby bodies of water during normal operation and under accident conditions.

### 16.1 Introduction

A power plant generates electricity by boiling water to steam, which turns a turbine that then turns a generator. Cooling systems are required to cool the steam back to water so the cycle can continue.

Most power plants use one of two types of cooling water systems. The two modes of cooling are used to remove the waste heat from electrical generation:

1. Once through cooling and,
2. Closed cycle cooling.

In the once-through cooling system, water from the nearby lake, river or ocean flows through thousands of metal tubes inside the condenser. Steam flowing through the condenser outside the tubes gets cooled down and converted back into water. The condensed water is re-used by the plant to make more steam. The water exits the condenser tubes warmed up to $30^{\circ} \mathrm{F}$ higher than the lake, river, or ocean temperature and returns to that water body (Fig. 16.1).

As we said in once-through cooling withdraws water from a water body and circulates it within the plant to condense the steam from the turbine into water through heat absorption. In a wet cooling tower system, circulating water from the

[^7]

Fig. 16.1 Open cycle once through cooling system
plant moves through the tower and is cooled by evaporation, which is a closed-cycle cooling system.

In the closed-cycle cooling system, water flows through thousands of metal tubes inside the condenser. Steam flowing through the condenser outside the tubes gets cooled down and converted back into water. The condensed water is re-used by the plant to make more steam.

Water exits the condenser tubes warmed nearly $30^{\circ} \mathrm{F}$ higher than upon entry to the condenser tubes. The water leaving the condenser tubes flows to a cooling tower. Air moving upward past the water spraying downward inside the cooling tower cools the water. The water collected in the cooling tower basin is pumped back to the condenser for re-use. Water from the nearby lake, river, or ocean is needed to make-up for the water vapor carried away by the air leaving the cooling tower (Fig. 16.2).

For energy sources, water consumption is calculated in terms of the amount of water consumed to produce a standard measure of electricity generated-a mega-watt-hour (MWh).

Nuclear energy consumes 400 gallons/MWh with once-through cooling and 720 gallons/MWh with wet cooling towers. Coal consumes less, ranging from about 300 gallons/MWh for plants with minimal pollution controls and once-through cooling to 714 gallons/MWh for plants with advanced pollution control system and wet cooling towers. Natural gas-fueled power plants consume even less, at 100 gallons/ MWh for once-through, 370 gallons/MWh for combined-cycle plants with cooling towers and none for dry cooling.

Hydropower's typical water consumption is the most significant at 4500 gallons/ MWh, due in large part to evaporation from reservoirs. Renewable energy sources

Fig. 16.2 Typical closed cycle cooling system
such as geothermal and solar thermal consume two to four times more water than nuclear power plants.

All of the 104 nuclear reactors currently licensed to operate in the United States are light2 water reactors. Sixty-nine (69) are pressurized water reactors (PWRs) and 35 are boiling water reactors (BWRs).

In a BWR, water flowing through the reactor core is heated by its thermal energy and boils. The steam flows from the reactor vessel to the turbine. The steam spins the turbine, which is connected to a generator that produces electricity. The steam exits the turbine into the condenser.

Water from the nearby lake, river, or ocean flows through thousands of metal tubes in the condenser. Steam flowing past outside these tubes cools and changes back into water. The condensed water flows back to the reactor vessel for another cycle. The water leaves the condenser tubes nearly $30^{\circ} \mathrm{F}$ warmer and returns to the nearby lake, river, or ocean (Fig. 16.3).

In a PWR, water flowing through the reactor core is heated by its thermal energy. Because this water is maintained under high pressure (over 2000 pounds/sq in.), it does not boil even when heated to over $500^{\circ} \mathrm{F}$. The hot water flows from the reactor vessel and enters thousands of metal tubes within the steam generator. Heat passes through the thin tube walls to boil water at lower pressure that surrounds the tubes.

The water leaves the tubes about $10^{\circ} \mathrm{F}$ cooler and returns to the reactor vessel for another cycle. Steam leaves the steam generator and enters the turbine. The steam spins the turbine, which is connected to a generator that produces electricity. The steam exits the turbine into the condenser. Water from the nearby lake, river, or ocean flows through thousands of metal tubes in the condenser. Steam flowing past outside these tubes cools and changes back into water.

Fig. 16.3 Schematic of BWR. (In the boiling water reactor the same water loop serves as moderator, coolant for the core, and steam source for the turbine. Courtesy of DOE)

The condensed water flows back to the steam generator for another cycle. The water leaves the condenser tubes up to $30^{\circ} \mathrm{F}$ (Fig. 16.4).

The water needs of and usage by PWRs and BWRs are essentially identical. Both types of nuclear power reactors are about $33 \%$ efficient, meaning that for every three units of thermal energy generated by the reactor core, one unit of electrical energy goes out to the grid and two units of waste heat go out to the environment.

Note that An exception to the rule is the Palo Verde nuclear plant. Built in the arid region west of Phoenix, Arizona, cooling water is brought to the facility.

Also Note that Another type of reactor uses "heavy" water-water enriched in deuterium, an isotope of hydrogen that makes it heavier than regular or "light" water.

### 16.2 Cooling Power Plants

The most common types of nuclear power plants use water for cooling in two ways:

1. To convey heat from the reactor core to the steam turbines.
2. To remove and dump surplus heat from this steam circuit. (In any steam/ Rankine cycle plant such as present-day coal and nuclear plants there is a loss of about two-thirds of the energy due to the intrinsic limitations of turning heat into mechanical energy.)

The bigger the temperature difference between the internal heat source and the external environment (pinch point) where the surplus heat is dumped, the more

Fig. 16.4 Schematic of PWR. (In the pressurized water reactor, the water which flows through the reactor core is isolated from the turbine. Courtesy of DOE)
efficient is the process in achieving mechanical work-in this case, turning a generator [Carnot efficiency]. Hence the desirability of having a high temperature internally and a low temperature in the external environment. This consideration gives rise to desirably sitting power plants alongside very cold water.

Note that Many power plants, fossil and nuclear, have higher net output in winter than summer due to differences in cooling water temperature.

Also it is sufficed to say that;

- The amount of cooling required by any steam-cycle power plant (of a given size) is determined by its thermal efficiency. It has essentially nothing to do with whether it is fuelled by coal, gas or uranium.
- However, currently operating nuclear plants often do have slightly lower thermal efficiency than coal counterparts of similar age, and coal plants discharge some waste heat with combustion gases, whereas nuclear plants rely on water.
- Nuclear power plants have greater flexibility in location than coal-fired plants due to fuel logistics, giving them more potential for their sitting to be determined by cooling considerations.

### 16.2.1 Steam Cycle Heat Transfer

For the purpose of heat transfer from the core, the water is circulated continuously in a closed loop steam cycle and hardly any is lost. It is turned to steam by the primary heat source in order to drive the turbine to do work making electricity [Rankine Cycle], and it is then condensed and retuned under pressure to the heat source in a closed system [The function of the condenser is to condense exhaust steam
from the steam turbine by losing the latent heat of vaporization to the cooling water (or possibly air) passing through the condenser] A very small amount of make-up water is required in any such system. The water needs to be clean and fairly pure. [Within a nuclear reactor water or heavy water must be maintained at very high pressure ( $1000-2200 \mathrm{psi}, 7-15 \mathrm{MPa}$ ) to enable it to remain liquid above $100^{\circ} \mathrm{C}$, as in present reactors].

This function is much the same whether the power plant is nuclear, coal-fired, or conventionally gas-fired. Any steam cycle power plant functions in this way. At least $90 \%$ of the non-hydro electricity in every country is produced thus.

In a nuclear plant there is an additional requirement. When a fossil fuel plant is shut down, the source of heat is removed. When a nuclear plant is shut down some heat continues to be generated from radioactive decay, though the fission has ceased. This needs to be removed reliably, and the plant is designed to enable and assure this, both with routine cooling and also Emergency Core Cooling Systems (ECCS) provided in case of major problem with primary cooling. The routine cooling is initially with the main stream supply circuit bypassing the turbine and dumping heat into the condenser. After pressure drops, a residual heat removal system is relied upon with its own heat exchanger. The intensity of this decay heat diminishes with time, rapidly at first, and after a day or two ceases to be a problem if circulation is maintained.

Note that When Kashiwazaki-Kariwa seven nuclear reactor automatically shut down because of a severe earthquake in 2007, it took 16 h for the coolant temperature to diminish from 287 to $100^{\circ} \mathrm{C}$ so that it would no longer boil. "Cold shutdown" is when the primary circuit is at atmospheric pressure and not boiling (Fig. 16.5).

Fig. 16.5 Decay heat in fuel at Fukushima Daiichi reactors

### 16.2.2 Cooling to Condense the Steam and Discharge Surplus Heat

The second function for water in such a power plant is to cool the system so as to condense the low-pressure steam and recycle it. As the steam in the internal circuit condenses back to water, the surplus (waste) heat which is removed from it needs to be discharged by transfer to the air or to a body of water. This is a major consideration in sitting power plants, and in the UK sitting study in 2009 for nuclear plants all recommendations were for sites within 2 km of abundant water-sea or estuary.

This cooling function to condense the steam may be done in one of three ways:
Direct or "once-through" cooling. If the power plant is next to the sea, a big river, or large inland water body it may be done simply by running a large amount of water through the condensers in a single pass and discharging it back into the sea, lake or river a few degrees warmer and without much loss from the amount withdrawn. That is the simplest method. The water may be salt or fresh. Some small amount of evaporation will occur off site due to the water being a few degrees warmer.

- Recirculating or indirect cooling. If the power plant does not have access to abundant water, cooling may be done by passing the steam through the condenser and then using a cooling tower, where an up draught of air through water droplets cools the water. Sometimes an on-site pond or canal may be sufficient for cooling the water. Normally the cooling is chiefly through evaporation, with simple heat transfer to the air being of less significance. The cooling tower evaporates up to $5 \%$ of the flow and the cooled water is then returned to the power plant's condenser. The $3-5 \%$ or so is effectively consumed, and must be continually replaced. This is the main type of recirculating or indirect cooling.
- Dry cooling. A few power plants are cooled simply by air, without relying on the physics of evaporation. This may involve cooling towers with a closed circuit, or high forced draft air flow through a finned assembly like a car radiator.

With a fossil-fuel power plant some of the heat discharged is in the flue gases. With a large coal-fired plant some $15 \%$ of the waste heat is through the stack, whereas in a nuclear power plant virtually all the waste heat has to be dumped into the condenser cooling water. This gives rise to some difference in water consumption or use between a nuclear and a coal plant. (A gas turbine plant will discharge most of its waste heat in the exhaust.)

Beyond this, and apart from size, any differences between plants is due to thermal efficiency, i.e. how much heat has to be discharged into the environment, which in turn largely depends on the operating temperature in the steam generators. In a coal-fired or conventionally gas-fired plant it is possible to run the internal boilers at higher temperatures than those with finely-engineered nuclear fuel assemblies which must avoid damage. This means that the efficiency of modern coal-fired plants is typically higher than that of nuclear plants, though this intrinsic advantage may be offset by emission controls such as Flue Gas Desulfurization (FGD) and in the future, Carbon Capture and Storage (CCS) [2].

A nuclear or coal plant running at $33 \%$ thermal efficiency will need to dump about $14 \%$ more heat than one at $36 \%$ efficiency. Nuclear plants currently being built have about 34-36\% thermal efficiency, depending on site (especially water temperature). Older ones are often only $32-33 \%$ efficient. The relatively new Stanwell coal-fired plant in Queensland runs at $36 \%$, but some new coal-fired plants approach $40 \%$ and one of the new nuclear reactors claims $39 \%$.

### 16.3 Circulating Water Systems

Brief description of circulating water systems for any power plant is presented here [3].

## 1. Functions

Circulating Water Systems at any power plant have two important functions:

- Filter water before it is pumped to and through the condenser
- Cool the condenser

## 2. Major Components

Intake (Supply) Basin Water is supplied from an abundant source-river, lake, sea, or ocean-to a storage basin which, in turn, supplies the large pumps.

Trash Racks These racks remove large debris such as seaweed, grass, or logs. These racks must be periodically cleaned to remove debris that builds up.

Traveling Screens These are large steel screens up to 30 ft long that rotate and filter out larger debris that passes through the trash racks.

Condenser Cleaning System A system which usually uses small abrasive balls pumped through the condenser tubes for cleaning. Usually these systems are very effective at cleaning the tubes. Several times per year the plant power level must be reduced so that the tubes can be manually cleaned. This operation is performed when plant efficiency decreases to the point where the plant's operations and engineering staffs determine the tube cleaning is needed to improve plant performance (Fig. 16.6).

These large pumps supply water at over 100,000 gallons/min to the condenser. The pump is usually over 15 ft deep. The motor assembly may be $8-10 \mathrm{ft}$ high.

## 3. Simplified Diagram

The diagram below illustrates the arrangement of components within the system and the major flow paths (Fig. 16.7).

The green flow paths show how the water is taken from a river (yellow) to an intake supply basin (green) that the Circ Water Pumps take suction from. The water is then pumped to the Condenser where the water is heated. The water is then sent to an exit distribution basin where the water then can be returned to the river and/or pumped by the Cooling Tower Pumps to the Cooling Towers then the water returned

Fig. 16.6 Circulating water pumps [3]

Fig. 16.7 The arrangement of components within the system and the major flow paths [3]
to the intake supply basin where the water can be reused. The Cooling Tower System is discussed elsewhere in site materials.

### 16.4 Service or Cooling Water Systems

Brief description of service or cooling water systems for any power plant is presented here [3].

## 1. Functions

Service Water Systems at any power plant has one major function

- Cool the multitude of heat exchangers or coolers in the power house-other than the condenser.

This system is referred to by a variety of names-Service Water, Cooling Water, and Salt Water. Sometimes the system is broken into separate building systems as Turbine Building, Auxiliary Building, and Reactor Building. Often the system is broken into safety and non-safety portions. For a number of plants the safety portion is referred to as the Essential Service Water System. The equipment in the safety portion of the system is powered by independent sources, e.g. diesel-driven pumps and diesel generators to supply electrical power.

## 2. Major Components

Normal and Emergency Intake (Supply) Basins Water is supplied from an abundant source-river, lake, sea, or ocean-to a storage basin, which, in turn, supplies the large pumps.

Emergency Intake Pipe An emergency intake pipe may be used to provide a direct alternate path to the emergency portion of the system if the normal flow path is unavailable.

Emergency or Safeguards Traveling Screens These are large steel screens up to 30 ft long that rotate and filter out larger debris that passes through the trash racks.

Service Water Pumps For many plants there are an average of three pumps for single unit plants and five pumps for dual unit facilities. These pumps each supply water at about $10,000-15,000$ gallons $/ \mathrm{min}$ to a two (2) header system. Often the pumps are broken into safety and non-safety classes. For safety-related components this method assures redundancy.

Heat Exchangers or Coolers Components cooled or served by the Service Water System include:

- Generator Hydrogen Gas Cooler.
- Stator cooling.
- Generator exciter cooler.

## - Air compressor after cooler.

Fig. 16.8 Service water system

- Component Cooling Heat Exchanger.
- Containment Fan Cooler Units.
- Feed water Pump Oil and Motor Coolers.
- Condensate Pump Oil and motor Coolers.
- Turbine Oil Cooler
- Heater Drain Pump Oil and Motor Cooler.
- Diesel Generators
- Circulating Pump Seal Water

In addition, the Service Water system may provide the backup water source to the emergency feed water pump.

## 3. Simplified Diagrams

The diagram below illustrates the major flow paths for a typical Service Water System in the Turbine Building where major nonessential heat loads are cooled (Fig. 16.8).

## Chapter 17 <br> Electrical System

### 17.1 Introduction

A power reactor generates heat that is converted into steam. The steam can be used directly for power, as in a nuclear submarine. It can also be used to generate electric power-for example, in a commercial nuclear power plant. In the early twenty-first century more than 400 nuclear plants were generating

The interface between nuclear power plants (NPPs) and electric grids deserves careful attention especially in small electric power systems. Electric grids have an important impact on the safe and reliable operation as well as startup/shutdown of NPPs. Conversely, tripping a nuclear reactor may give rise to sizable disturbances in grid parameter (frequency and voltage), which require automated action on the part of grid to maintain the quality of electricity [1].

### 17.2 Balancing the Circuit to Maximize the Energy Delivered to the Load

The electrical generator driven by the steam, or gas, turbine is generally connected to a large electrical network with many components and branches. However for the sake of discussion this network can be reduced to a simple circuit as described in Fig. 17.1.

Vo represents the electrical generator. $L$ represents the lumped inductive load in the network. R represents the resistive load in the network. $C$ represents the lumped capacitance load in the network. Though there is a voltage drop across all three lumped parameters, the actual work is accomplished by the resistive load. The voltage drops across the lumped parameters must add up to the voltage introduced by the electrical generator.

Fig. 17.1 Simplified electrical circuit

L

C

$$
\begin{equation*}
V_{o}(t)=V_{L}(t)+V_{R}(t)+V_{C}(t) \tag{17.1}
\end{equation*}
$$

Since the generator is trying to maintain a constant frequency, either 50 Hz or 60 Hz , its voltage can be represented by

$$
\begin{equation*}
V_{o}(t)=V_{o} \sin \omega t \omega=2 \pi f \tag{17.2}
\end{equation*}
$$

The voltage drop across an inductive load is proportional to the rate of change of the current passing through the load.

$$
\begin{equation*}
V_{L}(t)=L \frac{d i(t)}{d t} \tag{17.3}
\end{equation*}
$$

The voltage drop across a resistive load is proportional to the current passing through the load.

$$
\begin{equation*}
V_{R}(t)=i(t) R \tag{17.4}
\end{equation*}
$$

The voltage generated across a capacitive load is proportional to the integral of the current into the capacitor.

$$
\begin{equation*}
V_{C}(t)=\frac{1}{C} \int i(t) d t \tag{17.5}
\end{equation*}
$$

Inserting each of these into the voltage drop equation gives,

$$
\begin{equation*}
V_{o} \sin \omega t=L \frac{d i(t)}{d t}+i(t) R+\frac{1}{C} \int i(t) d t \tag{17.6}
\end{equation*}
$$

Now the current must oscillate at the same frequency as the driving voltage at steady state, but it can be out of phase with the driving voltage so it can be represented by

$$
\begin{equation*}
i(t) I \cos \omega t+J \sin \omega t \tag{17.7}
\end{equation*}
$$

Then
$V_{o} \sin \omega t=L \omega(-\sin \omega t+J \cos \omega t)+R(I \cos \omega t+J \sin \omega t)+\frac{1}{\omega C}(I \sin \omega t-J \cos \omega t)$
Now since the $\sin \omega t$ and $\cos \omega t$ are independent functions, this equation can be split into two equations in their coefficients.

$$
\begin{equation*}
V_{o}=-I L \omega+R J+\frac{I}{\omega C} \quad 0=J L \omega+R I-\frac{J}{\omega C} \tag{17.9}
\end{equation*}
$$

Now let

$$
\begin{equation*}
\Delta=\frac{1}{\omega C}-L \omega \tag{17.10}
\end{equation*}
$$

This gives

$$
\begin{equation*}
V_{o}=I \Delta+R J \quad 0=J \Delta-R I \tag{17.11}
\end{equation*}
$$

and

$$
\begin{align*}
& I=\frac{J \Delta}{R}, \quad V_{o}=\frac{\Delta^{2} J}{R}+R J \quad V_{o}=\left(\frac{\Delta^{2} J}{R}+R\right) J  \tag{17.12}\\
& J=\frac{V_{o} R}{\Delta^{2}+R^{2}} \quad I=\frac{V_{o} \Delta}{\Delta^{2}+R^{2}} \\
& i(t)=V_{o}\left(\frac{\Delta}{\Delta^{2}+R^{2}} \cos \omega t+\frac{R}{\Delta^{2}+R^{2}} \sin \omega t\right)
\end{align*}
$$

Now the power delivered to the load is

$$
\begin{align*}
& P_{\text {Load }}=i^{2}(t) R \\
& P_{\text {Load }}=R V_{o}^{2}\left[\frac{\Delta^{2} \cos ^{2} \omega t+2 \Delta R \cos \omega t \sin \omega t+R^{2} \sin ^{2} \omega t}{\left(\Delta^{2}+R^{2}\right)^{2}}\right] \tag{17.13}
\end{align*}
$$

Now to get the work accomplished in one cycle,

$$
\begin{equation*}
W_{\text {Load }}=\int_{0}^{2 \pi} P_{\text {Load }} d t=R V_{o}^{2}\left[\frac{\Delta^{2} \pi+R^{2} \pi}{\left(\Delta^{2}+R^{2}\right)^{2}}\right]=\frac{\pi R V_{o}^{2}}{\left(\Delta^{2}+R^{2}\right)} \tag{17.14}
\end{equation*}
$$

This can be maximized by setting

$$
\Delta=0 \quad \text { or } \quad \omega L=\frac{1}{\omega C} \quad L C=\frac{1}{\omega^{2}}=\frac{1}{4 \pi^{2} f^{2}}
$$

The units on $f$ are $1 / s e c$, so the units on $L C$ should be $\sec ^{2}$. Typically, $C$ is measured in farads, and $L$ is measured in henrys.

$$
\begin{gathered}
1 \text { farad }=\frac{1 \text { coulomb }}{1 \text { volt }}=\frac{1 \text { coulomb }}{\frac{1 \text { joule }}{1 \text { coulomb }}}=\frac{1 \text { coulomb }^{2}}{1 \text { joule }} \\
1 \text { henry }=\frac{1 \text { joule }}{1 \text { amp }^{2}}=\frac{1 \text { joule }}{\left(\frac{1 \text { coulomb }}{1 \text { sec }}\right)^{2}} \\
1 \text { henry }^{*} 1 \text { farad }=\frac{1 \text { joule }^{*} \sec ^{2}}{1 \text { coulomb }^{2}} * \frac{1 \text { coulomb }}{}{ }^{2} \\
1 \text { joule }
\end{gathered} \mathrm{sec}^{2} .
$$

Then

$$
\begin{equation*}
W_{\text {Load }}=\frac{\pi V_{o}^{2}}{R} \tag{17.15}
\end{equation*}
$$

Typically the dominant industrial electric load for a utility consists of large motors that add inductance to the network. To compensate for this and meet the matching condition

$$
\begin{equation*}
\omega L=\frac{1}{\omega C} \tag{17.16}
\end{equation*}
$$

a utility will have on hand large capacitance banks that can be switched into and out of the circuit. This enables them to deliver the maximum work to the total load and efficiently use the electrical energy that has been produced

### 17.3 Optimizing the Transmission of Energy to the Load

The lumped resistance identified in the previous section includes all of the resistances in the network. The resistances in the consumer's devices are where the utility makes money. But the resistances in the network getting the electrical energy to the consumer also consume energy. So it is important to minimize transmission line losses. Transmission line losses are minimized by transmitting the electrical energy at the highest voltage possible consistent with safety and reliability. Note,

$$
\begin{equation*}
P=I V=I^{2} R \text { for a balanced network } \tag{17.17}
\end{equation*}
$$

Since $R$ is fixed for a particular transmission line material, it is important to have the minimum current. The power dissipated in the transmission line material is proportional to the square of the current. Since the power is also the product of the
current times the voltage, upping the voltage decreases the current. So long distance transmission lines carry the power at the highest voltage possible to minimize resistance losses in the lines.

The voltage can be increased or decreased by passage through a transformer. Typically the voltage coming out of the driven electrical generator is increased significantly to the transmission line voltage and then transmitted most of the distance to consumer centers. Then it passes through one or more transformers to drop it down to the levels required by individual consumers.

### 17.4 Overview of an Electrical Grid System

Since all electrical power plants cannot operate $100 \%$ of the time, they are hooked to a network grid that has multiple power plants supplying power to multiple consumers. Consumer requirements also fluctuate, so some power plants operate continuously and some only operate when the demand is high. Obviously utilities would like the power plants that operate the cheapest to be the ones that operate continuously and the ones that are cycled to meet peak demands can be more expensive to operate. Typically hydro, coal and nuclear are operated continuously and gas and oil plants are operated intermittently to satisfy peak demands. With increasing penetration by renewable energy systems into the market and the advent of consumer power plants (solar cells and small turbines) the management of a stable electricity supply will become more complicated.

Typically, the electricity supply system comprises a single interconnected alternating current network that connects together all the power plants and other sources of electrical power with electricity to consumers. The electricity supply system uses a range of voltage levels: extra high voltage lines (e.g. 400 kV and higher threephase) are used to transmit large amounts of power long distances; medium voltage lines are used to transmit power shorter distances and to connect large industrial consumers; and low voltages (such as 230 V single phase or 120 V single phase) are used to provide supplies to domestic consumers.

The main components of the electricity supply system include:

- Power plants of various kinds and sizes;
- Overhead lines operated at various voltages;
- Underground cables operated at various voltages;
- Substations (switchyards) with switching facilities where overhead lines and underground cables are interconnected, and where power plants may be connected;
- Transformers (often located in substations) to connect parts of the network operating at different voltages;
- HVDC connections (comprising a converter station at each end, and an overhead line or underground cable connection between them);
- Electrical protection, monitoring and metering equipment;
- Communication and control systems;
- One or more control centers.

The electricity system can be considered to comprise two significantly different kinds of networks: the transmission system(s), and the distribution systems(s). Because of their different purposes, the transmission systems and distribution systems are designed, operated and controlled in different ways.

The transmission system (also commonly called the 'grid system') comprises those parts of the system (overhead lines, underground cables, substations, transformers) operating at very high voltage (generally greater than 100 kV ), which are used to transmit large amounts of power long distances between large power plants and load centers. The large majority of circuits on the transmission system are overhead lines, because of the ease and speed of installation and the much lower cost compared to underground cables. Overhead lines on the transmission system are normally carried on tall steel lattice towers.

The distribution systems comprise those parts of the system operated at lower voltages (less than 100 kV ), and used to transmit smaller amounts of power shorter distances from the high voltage transmission network to individual customers at the voltage level the customer needs. The overhead lines on distribution systems may be carried on smaller steel lattice towers, or wooden or concrete poles. In urban areas underground cables are often used instead of overhead lines. Typically the transmission and distribution systems are owned and operated by different companies or organizations.

### 17.5 How Power Grids System Work

Power travels from the power plant to your house through a complex system called the power distribution grid. The grid system is exposed in public-if you live in a rural, urban and suburban area, chances are it is right out in the open for all to see. It is so public, in fact, that you probably do not even notice it anymore. Your brain likely ignores all of the power lines because it has seen them so often. In this section, we will look at all of the equipment that brings electrical power to your home.

Electrical power starts at the power plant. In almost all cases, the power plant consists of a spinning electrical generator. Something has to spin that generator-it might be a water wheel in a hydroelectric dam, a large diesel engine or a gas turbine. But in most cases, the element spinning the generator is a steam turbine. The steam might be created by burning coal, oil or natural gas. Or the steam may come from a nuclear reactor.

Extra high voltage electricity is delivered through the power grid from where it is generated and along the way converted into manageable voltage levels to be used by the consumer. No matter what it is that spins the generator, commercial electrical generators of any size generate what is called 3-phase AC power. To understand 3-phase AC power, it is helpful to understand single-phase power first (Fig. 17.2 and 17.3).

Fig. 17.2 Power grid distribution lines can be above or under ground. (Courtesy of American Electric Power)

### 17.5.1 Electrical Alternating (AC)

Most household electrical services are as single-phase, $120-\mathrm{V}$ AC service. If you use an oscilloscope and look at the power found at a normal wall-plate outlet in your house, what you will find is that the power at the wall plate looks like a sine wave, and that wave oscillates between -170 V and 170 V (the peaks are indeed at 170 V ; it is the effective (rms) voltage that is 120 V ). The rate of oscillation for the sine wave is 60 cycles per second.

Oscillating power like this is generally referred to as Alternating Current (AC), or alternating current. The alternative to AC is Direct Current (DC), or direct current. Batteries produce DC: A steady stream of electrons flows in one direction only, from the negative to the positive terminal of the battery. AC has at least three advantages over DC in a power distribution grid:

1. Large electrical generators happen to generate AC naturally, so conversion to DC would involve an extra step.
2. Transformers must have alternating current to operate, and we will see that the power distribution grid depends on transformers.
3. It is easy to convert AC to DC but expensive to convert DC to AC , so if you were going to pick one or the other AC would be the better choice.

The power plant, therefore, produces AC. On the next page, you will learn about the AC power produced at the power plant. Most notably, it is produced in three phases.

### 17.5.2 Three-Phase Power

The power plant produces three different phases of AC power simultaneously, and the three phases are offset $120^{\circ}$ from each other. There are four wires coming out of every power plant: the three phases plus a neutral or ground common to all three. If you were to look at the three phases on a graph, they would look like this relative to ground (Fig. 17.4):

Fig. 17.4 Graph of 3-Phase Power. (Courtesy of Group Builder, Inc.)

There is nothing magical about three-phase power. It is simply three single phases synchronized and offset by $120^{\circ}$.

Why three phases? Why not one or two or four? In 1-phase and 2-phase power, there are 120 moments per second when a sine wave is crossing zero volts. In 3-phase power, at any given moment one of the three phases is nearing a peak. High-power 3-phase motors (used in industrial applications) and things like 3-phase welding equipment therefore have even power output. Four phases would not significantly improve things but would add a fourth wire, so 3-phase is the natural settling point.

In addition, what about this "ground," as mentioned above? The power company essentially uses the earth as one of the wires in the power system. The earth is a pretty good conductor and it is huge, so it makes a good return path for electrons. (Car manufacturers do something similar; they use the metal body of the car as one of the wires in the car's electrical system and attach the negative pole of the battery to the car's body.) "Ground" in the power distribution grid is literally "the ground" that's all around you when you are walking outside. It is the dirt, rocks, groundwater, etc., of the earth.

### 17.5.3 Transmission System

Perhaps the most recognizable public part of the power grid is the high voltage network of transmission lines, supported by large metal pylons, that threads its way across the country. Other components of the grid include terminal stations, zone substations and sub-transmission lines, carrying low voltage electricity to the common consumers who may live in the city or the country, by using the power grid.

Extra high voltage transmission lines are needed to carry large amount of electricity over long distances. Most of the transmission lines operate at voltage of 500 kV . These extra high voltage lines have higher energy efficiency than a large number of lower voltage lines. They are more economic to construct, operate and maintain (Fig. 17.5).

Most transmission lines are overhead lines with conductors supported on steel lattice towers. The conductors are insulated from the towers by porcelain, glass or synthetic insulators. Transmission lines can also be constructed with underground cable. Extra high voltage underground cables are considerably more expensive than overhead lines of equivalent capacity; therefore they are not very cost effective form ownership point of view by utility companies.

### 17.5.4 Substation (Terminal Station) System

The power carried over the extra high voltage lines must be changed to a lower voltage before it can be used in the home or industry. This takes place in several stages. Firstly, the electricity is delivered to substations either to change the voltage level

Fig. 17.5 High voltage transmission lines. (Courtesy of STAV Publishing)

of the power or to provide a switching point for a number of transmission lines. The voltage of the electricity is lowered at the terminal station to $66,000 \mathrm{~V}(66 \mathrm{kV})$ by a transformer.

### 17.5.5 Zone Substation System

After the terminal station is where electricity distribution businesses such as city power and power core elements come into play. The electricity is distributed on the sub-transmission system, which is made up of very tall concrete or wooden power poles and power lines, or sometimes-underground power lines.

The sub-transmission system transports the electricity to one of zone substations where it is converted from $66,000 \mathrm{~V}(66 \mathrm{kV})$ to $22,000 \mathrm{~V}(22 \mathrm{kV})$ or $11,000 \mathrm{~V}$ $(11 \mathrm{kV})$. Electricity at this voltage can be then be distributed on smaller, lighter power poles.

From this point, high voltage distribution lines transfer the electricity from the zone substations to distribution substation, where it is transformed to $230-240 \mathrm{~V}$ for supply to customers (Fig. 17.6).

Fig. 17.6 A typical zone substation. (Courtesy of STAV Publishing)

Fig. 17.7 A typical regulator bank. (Courtesy of Langly Engineering)

### 17.5.6 Regulator Bank System

You will also find regulator banks located either along the line, underground or in the air. They regulate the voltage on the line to prevent undervoltage and overvoltage conditions (Fig. 17.7).

Up toward the top are three switches that allow this regulator bank to be disconnected for maintenance when necessary (Fig. 17.8):

Fig. 17.8 Regulator bank switches. (Courtesy of S\&C Electric Company)

Fig. 17.9 A typical line voltage. (Courtesy of Scott Engineering)

At this point, we have typical line voltage at something like 7200 V running through the neighborhood on three wires (with a fourth ground wire lower on the pole) (Fig. 17.9):

### 17.5.7 Taps System

A house needs only one of the three phases, so typically you will see three wires running down a main road, and taps for one or two of the phases running off on side streets. Pictured below is a 3-phase to 2-phase tap, with the two phases running off to the right (Fig. 17.10):

Here is a 2-phase to 1-phase tap, with the single phase running out to the right (Fig. 17.11):

Fig. 17.10 A 3-Phase or 2-Phase tap picture. (Courtesy of Cooper Power System)

Fig. 17.11 Pole mounted single-phase with three-wire center tapped picture. (Courtesy of Wikipedia)

### 17.5.8 At the House Level

Finally, we are down to the wire that brings power to your house! Past a typical house runs a set of poles with one phase of power (at 7200 V ) and a ground wire (although sometimes there will be two or three phases on the pole, depending on where the house is located in the distribution grid). At each house, there is a transformer drum attached to the pole, like this (Fig. 17.12):

In many suburban neighborhoods, the distribution lines are underground and there are green transformer boxes at every house or two. Here is some detail on what is going on at the pole (Fig. 17.13):

Fig. 17.12 Typical poles with 1-Phase power ( 7200 V ) at the house street picture. (Courtesy of epb)

Fig. 17.13 Distribution lines. (Courtesy of Wikipedia)

The transformer's job is to reduce the 7200 V down to the $240 / 230 \mathrm{~V}$ that makes up normal household electrical service. Let's look at this pole one more time, from the bottom, to see what is going on (Fig. 17.14):

There are two things to notice in this picture:

Fig. 17.14 Transformer pole. (Courtesy of Wikipedia)

1. There is a bare wire running down the pole. This is a grounding wire. Every utility pole on the planet has one. If you ever watch the power company install a new pole, you will see that the end of that bare wire is stapled in a coil to the base of the pole and therefore is in direct contact with the earth, running 6-10 ft $(1.8-3 \mathrm{~m})$ underground. It is a good, solid ground connection. If you examine a pole carefully, you will see that the ground wire running between poles (and often the guy wires) are attached to this direct connection to ground.
2. There are two wires running out of the transformer and three wires running to the house. The two from the transformer are insulated, and the third one is bare. The bare wire is the ground wire. The two insulated wires each carry 120 V , but they are $180^{\circ}$ out of phase so the difference between them is 240 V . This arrangement allows a homeowner to use both $120-\mathrm{V}$ and $240-\mathrm{V}$ appliances. The transformer is wired in this sort of configuration (Fig. 17.15):

The 240 V enters your house through a typical watt-hour meter like this one below (Fig. 17.16):

The meter lets the power company charge you for putting up all of these wires.

Fig. 17.15 Transformer wiring system

Fig. 17.16 Typical power meter. (Courtesy of PG\&E)

### 17.5.9 Safety Devices: Fuses, Circuit Breakers, Plugs and Outlets

Fuses and circuit breakers are safety devices. Let us say that you did not have fuses or circuit breakers in your house and something "went wrong." What could possibly go wrong? Here are some examples:

Fig. 17.17 Typical circuit breaker panel

- A fan motor burn out a bearing, seizes, overheats and melts, causing a direct connection between power and ground.
- A wire comes loose in a lamp and directly connects power to ground.
- A mouse chews through the insulation in a wire and directly connects power to ground.
- Someone accidentally vacuums up a lamp wire with the vacuum cleaner, cutting it in the process and directly connecting power to ground.
- A person is hanging a picture in the living room and the nail used for said picture happens to puncture a power line in the wall, directly connecting power to ground.

When a $120-\mathrm{V}$ power line connects directly to ground, its goal in life is to pump as much electricity as possible through the connection. Either the device or the wire in the wall will burst into flames in such a situation. (The wire in the wall will get hot as the element in an electric oven gets hot, which is to say very hot!). A fuse is a simple device designed to overheat and burn out extremely rapidly in such a situation. In a fuse, a thin piece of foil or wire quickly vaporizes when an overload of current runs through it. This kills the power to the wire immediately, protecting it from overheating. Fuses must be replaced each time they burn out. A circuit breaker uses the heat from an overload to trip a switch, and circuit breakers are therefore resettable (Fig. 17.17).

The power then enters the home through a typical circuit breaker panel like the one above.

Fig. 17.18 Typical circuit breaker or fuses. (Courtesy of Mission Electric Service)

Fig. 17.19 Typical circuit outlet in USA. (Courtesy of ACE Hardware Store)

Inside the circuit breaker panel, you can see the two primary wires from the transformer entering the main circuit breaker at the top. The main breaker lets you cut power to the entire panel when necessary. Within this overall setup, all of the wires for the different outlets and lights in the house each have a separate circuit breaker or fuse (Fig. 17.18):

If the circuit breaker is on, then power flows through the wire in the wall and makes its way eventually to its final destination, the outlet (Fig. 17.19).

Fig. 17.20 Control center operators monitor the flow of electricity

### 17.5.10 Control Centers

The flow of electricity through the power grid is controlled from several control centers throughout the State. These control centers use computers and communication systems to enable the operators to monitor both the flow of electricity and the condition of the power grid (Fig. 17.20).

### 17.5.11 Interstate Power Grids

Electricity power delivery does not recognize state boundaries. Power grid is joined to similar grids in entire net of power stations. This allows the buying and selling of electricity between states. The interconnection grid enables the more efficient use of resources and a reduced need for generating power plants because generation capacity can be shared between the stakeholders and states (Fig. 17.21).

### 17.6 United States Power Grid

Initially, power is delivered from one of about 10,000 power plants in the U.S. where the electricity itself is created, to a portion of the power distribution grid. Though we may have the idea that there is just one "grid" in the United States, in fact, there are many. What we refer to as the power grid is simply the interconnected lines of these transmission stations throughout the country.

Currently, the U.S. electrical grid is undergoing changes in the same way that cell phones have become "smart phones." Utility companies are looking at ways to use technology to increase the reliability and effectiveness of electricity supply. At

## How electricity is delivered

Fig. 17.21 How electricity is delivered (Courtesy of STAV Publishing)
this time, sections of the electrical grid are divided into Eastern, Western and Texas (ERCOT) areas, with electrical supply in all of those areas independently owned by many different companies.

One of the biggest challenges with the U.S. power grid and how it works is it's age and changes in regulation. With a base of development during the 1960's, power needs in America have changed radically. Originally, power was created and distributed locally. Now, large, multi-state organizations create and sell their power across vast regions of America. Adding to the confusion is the requirement that many states have created to deregulate power. Now, deregulation has caused confusion as to who is to maintain these transmission lines across the grid.

Ultimately, the electrical grid that we think of is nothing but a series of transmission lines that are all linked together into three separate regional areas in the US. While there is a government-led movement to update the way electricity is managed, currently, the grid operates quite simply. First, power is developed at a power plant, by burning fossil fuels, using solar power or even by positioning turbines under the falling water of a hydroelectric dam. Once the power is created, it is sent to a transmission sub-station near the power plant where it is broken down into smaller units, where it is then transmitted over high-voltage transmission lines. Once the electricity is moved over high-voltage transmission lines, it it deposited at a power substation. Because the power at the power substation is so potent, it is then transformed, using a "transformer," to be sent over local power lines. Finally, the power is transformed one more time, at either a transformer drum or ground-based transformer to be delivered into your home.

Fig. 17.22 Electrical grid distribution in United States Department of Energy Graphic. (Courtesy of Department of Energy)

Knowing that the electricity you use is part of the United States power grid simply gives you the information as to what region your electric service resides in. With upgrades into a "smart" power grid in the future, electric users can count on a more reliable and efficient electric supply throughout the United States.

As we said, the electric grid delivers electricity from points of generation to consumers, and the electricity delivery network functions via two primary systems: the transmission system and the distribution system. The transmission system delivers electricity from power plants to distribution substations, while the distribution system delivers electricity from distribution substations to consumers. The grid also encompasses myriads of local area networks that use distributed energy resources to serve local loads and/or to meet specific application requirements for remote power, village or district power, premium power, and critical loads protection.

It is important to note that there is no "national power grid" in the United States. In fact, the continental United States is divided into three main power grids (Fig. 17.22):

1. The Eastern Interconnected System, or the Eastern Interconnect.
2. The Western Interconnected System, or the Western Interconnect.
3. The Texas Interconnected System, or the Texas Interconnect.

Fig. 17.23 Dynamically controlled generation. (Courtesy of Department of Energy)
$\begin{array}{ll}\text { ECAR } & \text { East Central Area Reliability Coordination Agreement } \\ \text { ERCOT } & \text { Electric Reliability Council of Texas } \\ \text { FRCC } & \text { Florida Reliability Coordinating Council } \\ \text { MAAC } & \text { Mid-Atlantic Area Council } \\ \text { MAIN } & \text { Mid-America Interconnected Network } \\ \text { MAPP } & \text { Mid-Continent Area Power Pool } \\ \text { NPCC } & \text { Northeast Power Coordinating Council } \\ \text { SERC } & \text { Southeastern Electric Reliability Council } \\ \text { SPP } & \text { Southwest Power Pool } \\ \text { WSCC } & \text { Western Systems Coordinating Council }\end{array}$
The Eastern and Western Interconnects have limited interconnections to each other, and the Texas Interconnect is only linked to the others via direct current lines. Both the Western and Texas Interconnects are linked with Mexico, and the Eastern and Western Interconnects are strongly interconnected with Canada. All electric utilities in the mainland United States are connected to at least one other utility via these power grids.

The grid systems in Hawaii and Alaska are much different from on the U.S. mainland. Alaska has an interconnected grid system, but it connects only Anchorage, Fairbanks, and the Kenai Peninsula. Much of the rest of the state depends on small diesel generators, although there are a few minigrids in the state as well. Hawaii also depends on minigrids to serve each island's inhabitants (Fig. 17.23).

Power grids are inherently prone to big blackouts. The United States electric power grid is growing increasingly complex and interconnected, with a greater number of power buyers and sellers making a burgeoning number of transactions.

The U.S. power grid is outmoded, with too few transmission lines to handle Americans' ever-growing appetite for electricity.

### 17.7 Smart Power Grid (SG)

"Smart Grid" generally refers to a class of technology people are using to bring utility electricity delivery systems into the twenty-first century, using computer-based remote control and automation. These systems are made possible by two-way communication technology and computer processing that has been used for decades in other industries. They are beginning to be used on electricity networks, from the power plants and wind farms all the way to the consumers of electricity in homes and businesses. They offer many benefits to utilities and consumers-mostly seen in big improvements in energy efficiency on the electricity grid and in the energy users' homes and offices.

For a century, utility companies have had to send workers out to gather much of the data needed to provide electricity. The workers read meters, look for broken equipment and measure voltage, for example. Most of the devices utilities use to deliver electricity have yet to be automated and computerized. Now, many options and products are being made available to the electricity industry to modernize it.

The "grid" amounts to the networks that carry electricity from the plants where it is generated to consumers. The grid includes wires, substations, transformers, switches and much more.

Much in the way that a "smart" phone these days means a phone with a computer in it, smart grid means "computerizing" the electric utility grid. It includes adding two-way digital communication technology to devices associated with the grid. Each device on the network can be given sensors to gather data (power meters, voltage sensors, fault detectors, etc.), plus two-way digital communication between the device in the field and the utility's network operations center. A key feature of the smart grid is automation technology that lets the utility adjust and control each individual device or millions of devices from a central location (Fig. 17.24).

Smart Grid is about the big picture of improved energy delivery, informed consumption and reduced environmental impact. The new Smart Grid (SG) by various companies is offering a complete spectrum of products, solutions and services for the protection, automation, planning, monitoring and diagnosis of grid infrastructure, including products, complete solutions and services for rail electrification.

Companies in this technology are bringing to market Smart Grid solutions that can evolve over time, are scalable and are compliant with industry standards for interoperability and security. They are making the Smart Grid a reality by partnering with utilities and cities to implement their Smart Grid visions.

Fig. 17.24 Smart grid illustration

The number of applications that can be used on the smart grid once the data communications technology is deployed is growing as fast as inventive companies can create and produce them. Benefits include enhanced cyber-security, handling sources of electricity like wind and solar power and even integrating electric vehicles onto the grid. The companies making smart grid technology or offering such services include technology giants, established communication firms and even brand new technology firms.

## Chapter 18 Nuclear Power Plants

Currently, about half of all nuclear power plants are located in the US. There are many different kinds of nuclear power plants, and we will discuss a few important designs in this text. A nuclear power plant harnesses the energy inside atoms themselves and converts this to electricity. All of us use this electricity. In Sect. 18.1 of this chapter we show you should the idea of the fission process and how it works. A nuclear power plant uses controlled nuclear fission. In this chapter, we will explore how a nuclear power plant operates and the manner in which nuclear reactions are controlled. There are several different designs for nuclear reactors. Most of them have the same basic function, but one's implementation of this function separates it from another. There is several classification systems used to distinguish between reactor types. Below is a list of common reactor types and classification systems found throughout the world and they are briefly explained down below according to three types of classification either; (1) Classified by Moderator Material or (2) Classified by Coolant Material and (3) Classified by Reaction Type.

### 18.1 Fission Energy Generation

There is strategic as well as economic necessity for nuclear power in the United States and indeed most of the world. The strategic importance lies primarily in the fact that one large nuclear power plant saves more than 50,000 barrels of oil per day. At \$ 30-40 per barrel (1982), such a power plant would pay for its capital cost in a few short years. For those countries that now rely on but do not have oil, or must reduce the importation of foreign oil, these strategic and economic advantages are obvious. For those countries that are oil exporters, nuclear power represents an insurance against the day when oil is depleted. A modest start now will assure that they would not be left behind when the time comes to have to use nuclear technology.

The unit costs per kilowatt-hour for nuclear energy are now comparable to or lower than the unit costs for coal in most parts of the world. Other advantages are the lack of environmental problems that are associated with coal or oil-fired power
plants and the near absence of issues of mine safety, labor problems, and transportation bottlenecks. Natural gas is a good, relatively clean-burning fuel, but it has some availability problems in many countries and should, in any case, be conserved for small-scale industrial and domestic uses. Thus, nuclear power is bound to become the social choice relative to other societal risks and overall health and safety risks.

Nuclear fission is the process of splitting atoms, or fissioning them. This page will explain

### 18.2 The First Chain Reaction

Early in World War II the scientific community in the United States, including those Europeans now calling the US their safe home, pursued the idea that uranium fission and the production of excess neutrons could be the source of extraordinary new weapons. They knew Lisa Meitner's interpretation, in Sweden, of Hahn's experiments would likely be known in Germany. Clearly there might now be a race commencing for the development and production of a new, super weapon based on the fission of ${ }^{235} \mathrm{U}_{92}$ or ${ }^{239} \mathrm{Pu}_{94}$.

By early 1942, it was known that the two naturally occurring isotopes of uranium reacted with neutrons as follows:

$$
\begin{gathered}
{ }^{235} \mathrm{U}_{92}+{ }^{1} \mathrm{n}_{0} \quad \rightarrow \text { fission products }+(2.5)^{1} \mathrm{n}_{0}+200 \mathrm{MeV} \text { Energy } \\
\\
{ }^{238} \mathrm{U}_{92}+{ }^{1} \mathrm{n}_{0} \rightarrow{ }^{239} \mathrm{U}_{92} \\
{ }^{239} \mathrm{U}_{92} \quad \rightarrow{ }^{239} \mathrm{~Np}_{93}+\beta^{-1} \quad \mathrm{t}_{1 / 2}=23.5 \mathrm{~min} . \\
{ }^{239} \mathrm{~Np}_{93} \quad \rightarrow{ }^{239} \mathrm{Pu}_{94}+\beta^{-1} \quad \mathrm{t}_{1 / 2}=2.33 \text { days }
\end{gathered}
$$

Each U-235 that undergoes fission produces an average of 2.5 neutrons. In contrast, some U-238 nuclei capture neutrons, become U-239, and subsequently emit two beta particles to produce $\mathrm{Pu}-239$. The plutonium was fissile also and would produce energy by the same mechanism as the uranium. A flow sheet for uranium fission is shown in Fig. 18.1 below.

The answers to two questions were critical to the production of plutonium for atomic bombs:

1. Is it possible, using natural uranium ( $99.3 \% \mathrm{U}-238$ and $0.7 \% \mathrm{U}-235$ ), to achieve a controlled chain reaction on a large scale? If so, some of the excess neutrons produced by the fission of U- 235 would be absorbed by U-238 and produce fissile Pu-239.

Fig. 18.1 The first generations of a nuclear chain reaction
2. How can we separate (in a reasonable period of time) the relatively small quantities of $\mathrm{Pu}-239$ from the unreacted uranium and the highly radioactive fissionproduct elements?
Although fission had been observed on a small scale in many laboratories, no one had carried out a controlled chain reaction that would provide continuous production of plutonium for isolation.

Enrico Fermi thought that he could achieve a controlled chain reaction using natural uranium. He had started this work with Leo Szilard at Columbia University, but moved to the University of Chicago in early 1942.

The first nuclear reactor, called a pile, was a daring and sophisticated experiment that required nearly 50 t of machined and shaped uranium and uranium oxide pellets along with 385 t-the equivalent of four railroad coal hoppers-of graphite blocks, machined on site.

The pile itself was assembled in a squash court under the football field at the University of Chicago from the layered graphite blocks and uranium and uranium oxide lumps (Fermi's term) arranged roughly in a sphere with an anticipated

Fig. 18.2 CP-1-Graphite blocks with 3 inch diameter uranium cylinders inserted-part of a layer of CP-1, the first nuclear reactor. A layer of graphite blocks without inserted uranium is seen covering the active layer

13 foot radius. Neutron absorbing, cadmium coated control rods were inserted in the pile. By slowly withdrawing the rods, neutron activity within the pile was expected to increase and at some point, Fermi predicted, there would be one neutron produced for each neutron absorbed in either producing fission or by the control rods (Fig. 18.2).

On December 2, 1942, with 57 of the anticipated 75 layers in place, Fermi began the first controlled nuclear chain reaction occurred. At around 3:20 p.m. the reactor went critical; that is, it produced one neutron for every neutron absorbed by the uranium nuclei. Fermi allowed the reaction to continue for the next 27 min before inserting the neutron-absorbing control rods. The energy releasing nuclear chain reaction stopped as Fermi predicted it would.

In addition to excess neutrons and energy, the pile also produced a small amount of Pu-239, the other known fissile material (Fig. 18.3).

The achievement of the first sustained nuclear reaction was the beginning of a new age in nuclear physics and the study of the atom. Humankind could now use the tremendous potential energy contained in the nucleus of the atom. However, while a controlled chain reaction was achieved with natural uranium, and could produce plutonium, it would be necessary to separate U-235 from U-238 to build a uranium bomb.

On December 28, 1942, upon reviewing a report from his advisors, President Franklin Roosevelt recommended building full-scale plants to produce both U-235 and Pu-239.

Fig. 18.3 The first controlled chain reaction, Stagg Field, Chicago, December 2, 1942. (Courtesy of the Argonne National Laboratory)

This changed the effort to develop nuclear weapons from experimental work in academic laboratories administered by the U.S. Office of Scientific Research and Development to a huge effort by private industry. This work, supervised by the U.S. Army Corps of Engineers, was codenamed the Manhattan Project. It spread throughout the entire United States, with the facilities for uranium and plutonium production being located at Oak Ridge, Tennessee, and Hanford, Washington, respectively. Work on plutonium production continued at the University of Chicago, at what became known as the Metallurgical Laboratory or Met Lab. A new laboratory at Los Alamos, New Mexico, became the focal point for development of the uranium and plutonium bombs.

### 18.3 Concepts in Nuclear Criticality

A nuclear reactor works on the principle of a chain reaction. An initial neutron is absorbed by a fissile nuclide and during the process of fission; additional neutrons are released to replace the neutron that was consumed. If more neutrons are produced than are consumed, then the neutron population grows. If fewer neutrons are produced than are consumed, the neutron population shrinks. The number of fissions caused by the neutron population determines the energy released.

In order to quantify this concept let us define a multiplication factor $k$. We will define $k$ as the ratio of the production to consumption of neutrons.

$$
\begin{equation*}
k=\frac{\text { Production }}{\text { Consumption }} \tag{18.1}
\end{equation*}
$$

### 18.4 Fundamental of Fission Nuclear Reactors

Today many nations are considering an expanded role for nuclear power in their energy portfolios. This expansion is driven by concerns about global warming, growth in energy demand, and relative costs of alternative energy sources. In 2008, 435 nuclear reactors in 30 countries provided $16 \%$ of the world's electricity. In January 2009, 43 reactors were under construction in 11 countries, with several hundred more projected to come on line globally by 2030.

Concerns over energy resource availability, climate change, air quality, and energy security suggest an important role for nuclear power in future energy supplies. While the current Generation II and III nuclear power plant designs provide a secure and low-cost electricity supply in many markets, further advances in nuclear energy system design can broaden the opportunities for the use of nuclear energy. To explore these opportunities, the U.S. Department of Energy's Office of Nuclear Energy has engaged governments, industry, and the research community worldwide in a wide ranging discussion on the development of next generation nuclear energy systems known as "Generation IV." See Sect. 18.4 of this Chapter for more information on New Generation of Power Plant know as Gen IV (Fig. 18.4).

Nuclear reactors produce energy through a controlled fission chain reaction (See Sect 1.1 in above: The First Chain Reaction). While most reactors generate electric power, some can also produce plutonium for weapons and reactor fuel. Power reactors use the heat from fission to produce steam, which turns turbines to generate electricity. In this respect, they are similar to plants fueled by coal and natural gas. The components common to all nuclear reactors include a fuel assembly, control rods, a coolant, a pressure vessel, a containment structure, and an external cooling facility.

In a nuclear reactor neutrons interact with the nuclei of the surrounding atoms. For some nuclei (e.g. U-235) an interaction with a neutron can lead to fission: the nucleus is split into two parts, giving rise to two new nuclei (the so-called fission products), energy and a number of new highly energetic neutrons. Other possible interactions are absorption (the neutron is removed from the system), and simple collisions, where the incident neutron transfers energy to the nucleus, either elastically (hard sphere collision) or inelastically.

The speed of the neutrons in the chain reaction determines the reactor type (See Fig. 16.5). Thermal reactors use slow neutrons to maintain the reaction. These reactors require a moderator to reduce the speed of neutrons produced by fission. Fast

Fig. 18.4 A nuclear power plant. (Courtesy of R2 Controls)
和

Fig. 18.5 Types of nuclear reactors. (Courtesy of Chem Cases)

neutron reactors, also known as Fast Breeder Reactors (FBR), use high speed, unmoderated neutrons to sustain the chain reaction (Fig. 18.5).

Thermal reactors operate on the principle that uranium-235 undergoes fission more readily with slow neutrons than with fast ones. Light water $\left(\mathrm{H}^{2} \mathrm{O}\right)$, Heavy water $\left(\mathrm{D}_{2} \mathrm{O}\right)$, and carbon in the form of graphite are the most common moderators. Since slow neutron reactors are highly efficient in producing fission in uranium-235, they use fuel assemblies containing either natural uranium ( $0.7 \% \mathrm{U}-235$ ) or slightly enriched uranium ( $0.9-2.0 \% \mathrm{U}-235$ ) fuel. Rods composed of neutron-absorbing material such as cadmium or boron are inserted into the fuel assembly. The position of these control rods in the reactor core determines the rate of the fission chain reaction. The coolant is a liquid or gas that removes the heat from the core and produces steam to drive the turbines. In reactors using either light water or heavy water, the coolant also serves as the moderator. Reactors employing gaseous coolants ( $\mathrm{CO}_{2}$ or He ) use graphite as the moderator. The pressure vessel, made of heavy-duty steel, holds the reactor core containing the fuel assembly, control rods, moderator, and coolant. The containment structure, composed of thick concrete and steel, inhibits the release of radiation in case of an accident and also secures components of the reactor from potential intruders. Finally, the most obvious components of many nuclear power plants are the cooling towers, the external components, which provide cool water for condensing the steam to water for recycling into the containment structure. Cooling towers are also employed with coal and natural gas plants.

### 18.5 Reactor Fundamentals

It is important to realize that while the U-235 in the fuel assembly of a thermal reactor is undergoing fission, some of the fertile U-238 present in the assembly is also absorbing neutrons to produce fissile Pu-239. Approximately one third of the energy produced by a thermal power reactor comes from fission of this plutonium. Power reactors and those used to produce plutonium for weapons operate in dif-

Fig. 18.6 The fate of plutonium in a thermal reactor. (Courtesy of Chem Cases)

Production of plutonium in a nuclear reactor

ferent ways to achieve their goals. Production reactors produce less energy and thus consume less fuel than power reactors. The removal of fuel assemblies from a production reactor is timed to maximize the amount of plutonium in the spent fuel (See Fig. 15.6). Fuel rods are removed from production reactors after only several months in order to recover the maximum amount of plutonium-239. The fuel assemblies remain in the core of a power reactors for up to 3 years to maximize the energy produced. However, it is possible to recover some plutonium from the spent fuel assemblies of a power reactor (Fig. 18.6).

The power output or capacity of a reactor used to generate electricity is measured in megawatts of electricity, MW(e). However, due to the inefficiency of converting heat into electricity, this represents only about one third of the total thermal energy, $\mathrm{MW}(\mathrm{t})$, produced by the reactor. Plutonium production is related to MW(t). A production reactor operating at $100 \mathrm{MW}(\mathrm{t})$ can produce 100 g of plutonium per day or enough for one weapon every 2 months.

Another important property of a reactor is its capacity factor. This is the ratio of its actual output of electricity for a period of time to its output if it had been operated at its full capacity. The capacity factor is affected by the time required for maintenance and repair and for the removal and replacement of fuel assemblies. The average capacity factor for U.S. reactors has increased from $50 \%$ in the early 1970s to over $90 \%$ today. This increase in production from existing reactors has kept electricity affordable.

### 18.6 Thermal Reactors

Currently the majority of nuclear power plants in the world are water-moderated, thermal reactors. They are categorized as either light water or heavy water reactors. Light water reactors use purified natural water $\left(\mathrm{H}^{2} \mathrm{O}\right)$ as the coolant/moderator, while heavy water reactors employ heavy water, deuterium oxide ( $\mathrm{D}^{2} \mathrm{O}$ ). In
light water reactors, the water is either pressured to keep it in superheated form (in a pressurized water reactors, PWR) or allowed to vaporize, forming a mixture of water and steam (in a boiling water reactors, BWR). In a PWR (Fig. 16.10), superheated water flowing through tubes in the reactor core transfers the heat generated by fission to a heat exchanger, which produces steam in a secondary loop to generate electricity. None of the water flowing through the reactor core leaves the containment structure. In a BWR (Fig. 16.12), the water flowing through the core is converted to directly to steam and leaves the containment structure to drive the turbines. Light water reactors use low enriched Uranium as fuel. Enriched fuel is required because natural water absorbs some of the neutrons, reducing the number of nuclear fissions. All of the 103 nuclear power plants in the United States are light water reactors; 69 are PWRs and 34 are BWRs.

### 18.7 Nuclear Power Plants and Their Classifications

A nuclear power plant uses controlled nuclear fission. In this section, we will explore how a nuclear power plant operates and the manner in which, nuclear reactions are controlled. There are several different designs for nuclear reactors. Most of them have the same basic function, but one's implementation of this function separates it from another. There is several classification systems used to distinguish between reactor types. Below is a list of common reactor types and classification systems found throughout the world and they are briefly explained down below according to three types of classification either;

1. Classified by Moderator Material [i.e. Light Water Reactor, or Graphite Moderated Reactor, and Heavy Water Reactor].
2. Classified by Coolant Material [i.e. Pressurized Water Reactor, or Boiling Water Reactor, and Gas Cooled Reactor].
3. Classified by Reaction Type [i.e. Fast Neutron Reactor, or Thermal Neutron Reactor, and Liquid Metal Fast Breeder Reactor].

### 18.8 Classified by Moderator Material

These types of reactors and their general description are presented below;

### 18.8.1 Light Water Reactors (LWR)

A light water reactor is a type of thermal reactor that uses "light water" (plain water) as a neutron moderator or coolant instead of using deuterium oxide $\left({ }^{2} \mathrm{H}_{2} \mathrm{O}\right)$; light water reactors are the most commonly used among thermal reactors. Light water reactors are contained in highly pressurized steel vessels called reactor vessels. Heat

Fig. 18.7 A pumpless light water reactor

is generated by means of nuclear fission within the core of the reactor. The hundreds into a "fuel assembly" about 12 ft in length and about as thin as a pencil, group the nuclear fuel rods, each. Each fuel rod contains pellets of an oxidized form of Uranium $\left(\mathrm{UO}_{2}\right)$. A light water fuel reactor uses ordinary water to keep the system cool. The water is circulated past the core of the reactor to absorb the generated heat. The heated water then travels away from the reactor where it leaves the system as nothing more than water vapor. This is the method used in all LWRs except the BWR for in that specific system water is boiled directly by the reactor core (Fig. 18.7).

### 18.8.2 Graphite Moderated Reactors (GMR)

A Graphite Moderated Reactor (GMR) is a type of reactor that is moderated with graphite. The first ongoing nuclear reaction carried out by Enrico Fermi at The University of Chicago was of this type, as well as the reactor associated with the Chernobyl accident. GMRs share a valuable property with heavy water reactors, in that natural un-enriched Uranium may be used. Another highlight for the GMR is a low power density, which is ideal if power were to suddenly stop; this would not waste as much power/fuel. The common criticisms for this design are a lack

Fig. 18.8 A typical core layout of graphite moderated Reactor. (Courtesy Osterreichisches Ökologie-Institut)
of room for steam suppression and the limited safety precautions available to the design (Fig. 18.8).

### 18.8.3 Heavy Water Reactors (HWR)

Heavy water reactors (HWR) are a class of fission reactor that uses heavy water as a neutron moderator. Heavy water is deuterium oxide, $\mathrm{D}_{2} \mathrm{O}$. Neutrons in a nuclear reactor that uses uranium must be slowed down so that they are more likely to split other atoms and get more neutrons released to split other atoms. Light water can be used, as in a light water reactor (LWR), but since it absorbs neutrons, the uranium must be enriched for criticality to be possible. The most common pressurized heavy water reactor (PHWR) is the CANDU reactor.

Usually the heavy water is also used as the coolant but as example, the Lucens reactor was gas cooled. Advantages of this type reactor are that they can operate with unenriched uranium fuel. Although the opponents of heavy water reactors suggest that such reactors pose a much greater risk of nuclear proliferation because of two characteristics:

1. They use unenriched uranium as fuel, the acquisition of which is free from supervision of international institutions on uranium enrichment.
2. They produce more plutonium and tritium as by-products than light water reactors, these are hazardous radioactive substances that can be used in the produc-

Fig. 18.9 A typical outline layout of heavy water reactor (Courtesy of Atomic Energy of Canada Limited)
tion of modern nuclear weapons such as fission, boosted fission, and neutron bombs as well as the primary stages of thermonuclear weapons. For instance, India produced its plutonium for Operation Smiling Buddha, its first nuclear weapon test, by extraction from the spent fuel of a heavy water research reactor known as "CIRUS (Canada India Research Utility Services)". It is advocated that safeguards need to be established to prevent exploitation of heavy water reactors in such a fashion.

In heavy water reactors, both the moderator and coolant are heavy water $\left(\mathrm{D}_{2} \mathrm{O}\right)$. A great disadvantage of this type comes from this fact: heavy water is one of the most expensive liquids. However, it is worth its price: this is the best moderator. Therefore, the fuel of HWRs can be slightly ( $1-2 \%$ ) enriched or even natural uranium. Heavy water is not allowed to boil, so in the primary circuit very high pressure, similar to that of PWRs, exists (Fig. 18.9).

The main representative of the heavy water type is the Canadian CANDU reactor. In these reactors, the moderator and coolant are spatially separated: the moderator is in a large tank (calandria), in which there are pressure tubes surrounding the fuel assemblies. The coolant flows in these tubes only.

The advantage of this construction is that the whole tank need not be kept under high pressure; it is sufficient to pressurize the coolant flowing in the tubes. This arrangement is called pressurized tube reactor. Warming up of the moderator is much less than that of the coolant; it is simply lost for heat generation or steam production. The high temperature and high-pressure coolant, similarly to PWRs, goes to
the steam generator where it boils the secondary side light water. Another advantage of this type is that fuel can be replaced during operation and thus there is no need for outages.

The other type of heavy water reactor is the Pressurized Heavy Water Reactor (PHWR). In this type, the moderator and coolant are the same and the reactor pressure vessel has to stand the high pressure.

Heavy water reactors produce cca. $6 \%$ of the total NPP power of the world; however $13.2 \%$ of the under construction nuclear power plant capacity is accounted for by this type. One reason for this is the safety of the type; another is the high conversion factor, which means that during operation a large amount of fissile material is produced from U-238 by neutron capture.

### 18.9 Classified by Coolant Material

The descriptions of these types of reactors are as follow;

### 18.9.1 Pressurized Water Reactors (PWR)

A Pressurized Water Reactor (PWR) is Westinghouse Bettis Atomic Power Laboratory has used a type of light water reactor for decades in designs for military ship applications, now the primary manufacturers are Framatome-ANP and Westinghouse for present day power plant reactors. The pressurized water reactor is unique in that although water passes through the reactor core to act as moderator and coolant it does not flow in to the turbine. Instead of the conventional flow cycle, the water passes into a pressurized primary loop. This step in the PWR cycle produces steam in a secondary loop that drives the turbine. Advantages of the PWR include zero fuel leaks of radioactive material into the turbine or environment, and the ability to with stand higher pressures and temperatures to higher the Carnot efficiency. Disadvantages include complex reactor designs and costs. This reactor type accounts for the majority of reactors located in the U.S (Fig. 18.10).

Pressurized Water Reactor (PWR) is a type of a nuclear power reactor that uses enriched Uranium as a fuel which in turn heats the light water used for producing steam. The main feature which differentiates it from a BWR nuclear reactor is that a PWR has a separate arrangement to make steam in the form of a heat exchanger

### 18.9.1.1 The Arrangement of PWR

A Pressurized Water Reactor (PWR) is a type of power plant reactor consisting of two basic circuits having light water as the working fluid. In one of the circuits water is heated to a high temperature and kept at high pressure as well, so that it does

Fig. 18.10 A typical pressurized water reactor. (Courtesy of the Uranium Information Centre)
not get converted into a gaseous state. This superheated water is used as a coolant and a moderator for the nuclear reactor core hence the name PWR or pressurized water reactor.

The secondary circuit consists of water at high pressure in the gaseous state i.e. steam which is used to run the turbine-alternator arrangement. The point of interaction between these two circuits is the heat exchanger or the boiler wherein heat from the superheated high-pressure water converts the water in the secondary circuit to steam.

### 18.9.1.2 Advantages of PWR

- Much fewer control rods are required in a PWR. In fact, for a typical 1000 MW plant just around five dozen control rods are sufficient.
- Since the two circuits are independent of each other, it makes it very easy for the maintenance staff to inspect the components of the secondary circuit without having to shut down the power plant entirely.
- A PWR has got a high power density and this, combined with the fact that enriched Uranium is used as fuel instead of normal Uranium, leads to the construction of very compact core size for a given power output.
- One feature, which makes a PWR reactor very suitable for practical applications, is its positive demand coefficient, which serves to increase the output as a direct proportion to demand of power.
- The water used in the primary circuit is different from that used in the secondary circuit and there is no intermixing between the two, except for heat transfer, which takes place in the boiler or heat exchanger. This means that the water used
in the turbine side is free from radioactive steam hence the piping on that side is not required to be clad with special shielding materials.

### 18.9.1.3 Drawbacks of PWR

- The primary circuit consists of high temperature, high pressure water which accelerates corrosion. This means that the vessel should be constructed of very strong material such as stainless steel, which adds to construction costs of PWR.
- PWR fuel charging requires the plant to be shut down and this certainly requires a long time period of the order of at least a couple of months.
- The pressure in the secondary circuit is relatively quite low as compared to the primary circuit hence the thermodynamic efficiency of PWR reactors is quite low of the order of 20

### 18.9.1.4 Pressuriser

One important point to note here is that despite the changing loads the pressure in the primary circuit needs to be maintained at a constant value. This is achieved by installing a device known as pressuriser in the primary circuit. It basically, consists of a dome shaped structure which has heating coils which, are used to increase or decrease pressure as and when required depending on varied load conditions.

Note that in the Pressurized Water Reactor (PWR), the water, which passes over the reactor core to act as moderator and coolant, does not flow to the turbine, but is contained in a pressurized primary loop. The primary loop water produces steam in the secondary loop, which drives the turbine. The obvious advantage to this is that a fuel leak in the core would not pass any radioactive contaminants to the turbine and condenser (Fig. 18.11).

Another advantage is that the PWR can operate at higher pressure and temperature, about 160 atmospheres and about 315 C . This provides a higher Carnot efficiency than the BWR, but the reactor is more complicated and more costly to construct. Most of the U.S. reactors are pressurized water reactors.

### 18.9.2 Boiling Water Reactor (BWR)

The Boiling Water Reactor (BWR) date back to their General Electric introduction in the 1950s. The distinguishing feature in the BWR is the boiling method for steam. In this type of reactor, water passes over the core as a coolant to expand and become steam source for a turbine placed directly above. Advantages of this design type include a simpler reactor design, a smaller reactor system, and lower costs. Disadvantages found are the increase of radioactive materials in the turbine and a greater chance for fuel to burn out as water quickly evaporates to expose fuel rods to an atmosphere absent of a coolant. BWRs have found fame all over the world due to the cheap simple design.

Fig. 18.11 A typical outline of pressurized water reactor

In Fig. 18.12 (1) the core inside the reactor vessel creates heat, (2) a steam-water mixture is produced when very pure water (reactor coolant) moves upward through the core, absorbing heat, (3) the steam-water mixture leaves the top of the core and enters the two stages of moisture separation where water droplets are removed before the steam is allowed to enter the steam line, and (4) the steam line directs the steam to the main turbine, causing it to turn the turbine generator, which produces electricity.

Note that in the Boiling Water reactor (BWR), the water, which, passes over the reactor core to act as moderator and coolant, is also the steam source for the turbine. The disadvantage of this is that any fuel leak might make the water radioactive and that radioactivity would reach the turbine and the rest of the loop (Fig. 18.13).

A typical operating pressure for such reactors is about 70 atmospheres at which pressure the water boils at about $285^{\circ} \mathrm{C}$. This operating temperature gives a Carnot efficiency of only $42 \%$ with a practical operating efficiency of around $32 \%$, somewhat less than the PWR.

### 18.9.3 Gas Cooled Reactors (GCR)

The Gas Cooled Reactor (GCR) or the gas-graphite reactors operate using graphite as moderator and some gas (mostly $\mathrm{CO}_{2}$, lately helium) as coolant. This belongs to the oldest reactor types. The first GGR was the Calder Hall power plant reactor, which was built in 1955 in England. This type is called MAGNOX after the special magnesium alloy (Magnox), of which the fuel cladding was made. The fuel is natural uranium. These reactors account for $1.1 \%$ of the total NPP power of the world and are not built any more (Fig. 18.14).

The Advanced Gas cooled Reactor (AGR) is a development from MAGNOX: the cladding is not Magnox and the fuel is slightly enriched. The moderator is also graphite and the coolant is $\mathrm{CO}_{2}$. Contribution to total world capacity is $2.5 \%$. This type is not manufactured any longer (Fig. 18.15).

Control
Rod
Structure

Fig. 18.13 A typical layout of boiling water reactor

Fig. 18.14 A typical core layout of gas cooled reactor

Fig. 18.15 A typical outline layout of gas cooled reactor

The newest gas cooled reactor type is the High Temperature Gas cooled Reactor (HTGR), which is cooled by helium and moderated by graphite. In this reactor as high as $950^{\circ} \mathrm{C}$ coolant temperature can be achieved. The efficiency of a newly developed type, the Gas Turbine Modular Helium Reactor (GT-MHR) might be as high as almost $50 \%$.

Gas Cooled Reactors (GCR) and Advanced Gas Cooled Reactors (AGR) use carbon dioxide as the coolant to carry the heat to the turbine, and graphite as the moderator. Like heavy water, a graphite moderator allows natural uranium (GCR) or slightly enriched uranium (AGR) to be used as fuel.

### 18.10 Classified by Reaction Type

The descriptions of each of these reactors are given as follows;

### 18.10.1 Fast Neutron Reactor (FNR)

Fast Neutron Reactors (FNR), also known as Fast Breeder Reactors (FBR), use depleted nuclear waste as a form of energy. Uranium, which is composed of $0.7 \%$ Uranium-235 and $99.3 \%$ Uranium-238, is processed in the fast neutron reactors into isotopes of usable plutonium of plutonium 239 and 241. Fast neutron reactors are $60 \%$ more efficient than normal reactors; a fast neutron reactor uses liquid metal as its coolant as opposed to water, which makes the reactor safer to use and its fuel is metallic, which keeps the reactors under control more easily. Some cons of fast neutron reactors though are that they are very unpredictable, making them more tedious to use. Bubbles are more present in processes, so fast neutron reactors tend to heat up more rather than cool down and the coolant that it requires is much more exotic, such liquid sodium and bismuth eutectic.

Several countries have research and development programs for improved Fast Breeder Reactors (FBR), which are a type of Fast Neutron Reactors. These use the uranium-238 in reactor fuel as well as the fissile U-235 isotope used in most reactors.

Natural uranium contains about $0.7 \% \mathrm{U}-235$ and $99.3 \% \mathrm{U}-238$. In any reactor, the U-238 component is turned into several isotopes of plutonium during its operation. Two of these, Pu 239 and Pu 241, then undergo fission in the same way as U 235 to produce heat. In a fast neutron reactor this process is optimized so that it can 'breed' fuel, often using a depleted uranium blanket around the core. FBRs can utilize uranium at least 60 times more efficiently than a normal reactor.

Fast-neutron reactors could extract much more energy from recycled nuclear fuel, minimize the risks of weapons proliferation and markedly reduce the time nuclear waste must be isolated.

If developed sensibly, nuclear power could be truly sustainable and essentially inexhaustible and could operate without contributing to climate change. In particular, a relatively new form of nuclear technology could overcome the principal drawbacks of current methods-namely, worries about reactor accidents, the potential for diversion of nuclear fuel into highly destructive weapons, the management of dangerous, long-lived radioactive waste, and the depletion of global reserves of economically available uranium. This nuclear fuel cycle would combine two innovations: pyrometallurgical processing (a high-temperature method of recycling reactor waste into fuel) and advanced fast-neutron reactors capable of burning that fuel. With this approach, the radioactivity from the generated waste could drop to safe levels in a few hundred years, thereby eliminating the need to segregate waste for tens of thousands of years.

## Fast Reactor Technology: A Path to Long-Term Energy Sustainability Position Statement November 2005

"The American Nuclear Society believes that the development and deployment of advanced nuclear reactors based on fast-neutron fission technology is important to the sustainability, reliability, and security of the world's long-term energy supply. Of the known and proven energy technologies, only nuclear fission can provide the large quantities of energy required by industrial societies in a sustainable and environmentally acceptable manner".
"Natural uranium mined from the earth's crust is composed primarily of two isotopes: $99.3 \%$ is U-238, and $0.7 \%$ is the fissile U-235. Nearly all current power reactors are of the "thermal neutron" design, and their capability to extract the potential energy in the uranium fuel is limited to less than $1 \%$ of that available. The remainder of the potential energy is left unused in the spent fuel and in the uranium, depleted in U-235 that remains from the process of enriching the natural uranium in the isotope U-235 for use in thermal reactors. With known fast reactor technology, this unutilized energy can be harvested, thereby extending by a hundred-fold the amount of energy extracted from the same amount of mined uranium".
"Fast reactors can convert U-238 into fissile material at rates faster than it is consumed making it economically feasible to utilize ores with very low uranium concentrations and potentially even uranium found in the oceans [1-3]. A suitable technology has already been proven on a small scale [4]. Used fuel from thermal reactors and the depleted uranium from the enrichment process can be utilized in fast reactors, and that energy alone would be sufficient to supply the nation's needs for several hundred years".
"Fast reactors in conjunction with fuel recycling can diminish the cost and duration of storing and managing reactor waste with an offsetting increase in the fuel cycle cost due to reprocessing and fuel prefabrications. Virtually all long-lived heavy elements are eliminated during fast reactor operation, leaving a small amount of fission product waste that requires assured isolation from the environment for less than 500 years [5].
"Although fast reactors do not eliminate the need for international proliferation safeguards, they make the task easier by segregating and consuming the plutonium as it is created. The use of onsite reprocessing makes illicit diversion from within the process highly impractical. The combination of fast reactors and reprocessing is a promising option for reasons of safety, resource utilization, and proliferation resistance [5].
"Reaping the full benefits of fast reactor technology will take a decade or more for a demonstration reactor, followed by buildup of a fleet of operating power stations. For now and in the intermediate-term future, the looming short-term energy shortage must be met by building improved, proven thermal-reactor power plants. To assure longer-term energy sustainability and security, the American Nuclear Society sees a need for cooperative international efforts with the goal of building a fast reactor demonstration unit with onsite reprocessing of spent fuel."

### 18.10.2 Thermal Neutron Reactor

Thermal reactors go through the same process as fast neutron reactors, but in a thermal reactor the process of obtaining plutonium is slower. These types of reactors use a neutron moderator to slow neutrons until they approach the average kinetic energy of the surrounding particles, that is, to reduce the speed of the neutrons to low velocity thermal neutrons. The nuclear cross section of uranium- 235 for slow thermal neutrons is about 1000 barns. For fast neutrons, it is in the order of 1 barn. In a thermal reactor, the neutrons that undergo the reaction process have significantly lower electron-volt energy, so the neutrons are considered to be slower. A neutron's speed will determine its chances to interact with the nucleus of an atom; the slower its speed the bigger its fission cross section becomes and thus the higher its chance of interacting with the nucleus becomes (Fig. 18.16).

This figure gives the value of the fission cross section for some fissile isotopes. Note that both axes are logarithmic. The thermal and fast energy regions are indicated. For thermal energies, the fission cross section equals several thousand barn, at high energies the fission cross section is of the order of 1-10 barn.

Fig. 18.16 Fission cross section for some common nuclides vs. energy. (Courtesy of TUDelft)

The fact that the fission cross section is rather large for low-energy neutrons has an important effect on the design of a nuclear reactor: in a reactor where the neutrons have a low energy, not much fissile material is required, because the probability of an interaction is very large. The lowest energy a neutron can have in a nuclear reactor is the energy at which it is in equilibrium with its environment. The movement of the neutron is then identical to the thermal movement of the atoms that constitute the reactor. The neutrons have slowed down from the high energy ( 2 MeV ) where they are born to this equilibrium energy are called 'thermal neutrons'. The average energy of a neutron in thermal equilibrium is 0.025 eV -the neutron is slowed down over nine decades, more than a billion times. Reactors in which, most fissions are induced by thermal neutrons are called thermal reactors. Thermal reactors are by far the most widely used reactors in the world today. Most reactors use water, heavy water or graphite as moderator. The reason for the choice of thermal reactors is a simple one: a thermal reactor requires a small amount of fuel to become critical, and thus the fuel is cheap.

### 18.10.3 Liquid Metal Fast Breeder Reactors (LMFBR)

The plutonium-239 breeder reactor is commonly called a fast breeder reactor, and the cooling and a liquid metal does heat transfer. The metals, which can accomplish this, are sodium and lithium, with sodium being the most abundant and most commonly used. The construction of the fast breeder requires a higher enrichment of U-235 than a light-water reactor, typically $15-30 \%$. The reactor fuel is surrounded by a "blanket" of non-fissionable U-238. No moderator is used in the breeder reactor since fast neutrons are more efficient in transmuting U-238 to Pu-239. At this concentration of U-235, the cross-section for fission with fast neutrons is sufficient to sustain the chain-reaction. Using water as coolant would slow down the neutrons, but the use of liquid sodium avoids that moderation and provides a very efficient heat transfer medium (Fig. 18.17).

The Super-Phenix was the first large-scale breeder reactor. It was put into service in France in 1984. It ceased operation as a commercial power plant in 1997. Such a reactor can produce about $20 \%$ more fuel than it consumes by the breeding reaction. Enough excess fuel is produced over about 20 years to fuel another such reactor. Optimum breeding allows about $75 \%$ of the energy of the natural uranium to be used compared to $1 \%$ in the standard light water reactor (Fig. 18.18).

Under appropriate operating conditions, the neutrons given off by fission reactions can "breed" more fuel from otherwise non-fissionable isotopes. The most common breeding reaction is that of plutonium-239 from non-fissile uranium-238. The term "fast breeder" refers to the types of configurations, which can actually produce more fissionable fuel than they use, such as the LMFBR. This scenario is possible because the non-fissile uranium-238 is 140 times more abundant than the fissionable U-235 and can be efficiently converted into Pu-239 by the neutrons from a fission chain reaction.

Fig. 18.17 A typical layout of Liquid metal fast breeder reactor

Fig. 18.18 This is a photo of a model of the containment vessel of the Super-Phenix. It is displayed at the National Museum of Nuclear Science and Technology in Albuquerque, NM

France has made the largest implementation of breeder reactors with its large SuperPhenix reactor (today is not in production line) and an intermediate Russian scale reactor (BN-600) on the Caspian Sea for electric power and desalinization.

Breeding Plutonium- 239 can be accomplished from non-fissile uranium- 238 by the reaction illustrated.

The bombardment of Uranium-238 with neutrons triggers two successive beta decays with the production of plutonium. The amount of plutonium produced depends on the breeding ratio.

The concept of breading ratio of Plutonium-239 can be defined in following. In the breeding of plutonium fuel in breeder reactors, an important concept is the breeding ratio, the amount of fissile plutonium- 239 produced compared to the amount of fissile fuel (like U-235) used to produce it. In the liquid-metal, fastbreeder reactor (LMFBR), the target-breeding ratio is 1.4 but the results achieved have been about 1.2. This is based on 2.4 neutrons produced per U- 235 fission, with one neutron used to sustain the reaction.

This particular fission path yields three neutrons, but the average neutron yield is 2.4 neutrons.

The time required for a breeder reactor to produce enough material to fuel a second reactor is called its doubling time, and present design plans target about 10 years as a doubling time. A reactor could use the heat of the reaction to produce energy for 10 years, and at the end of that time have enough fuel to fuel another reactor for 10 years.

Liquid sodium is used as the coolant and heat-transfer medium in the LMFBR reactor. That immediately raised the question of safety since sodium metal is an extremely reactive chemical and burns on contact with air or water (sometimes explosively on contact with water). It is true that the liquid sodium must be protected from contact with air or water at all times, kept in a sealed system. However, it has been found that the safety issues are not significantly greater than those with highpressure water and steam in the light-water reactors.

Sodium is a solid at room temperature but liquefies at $98^{\circ} \mathrm{C}$. It has a wide working temperature since it does not boil until $892^{\circ} \mathrm{C}$. That brackets the range of operating temperatures for the reactor so that it does not need to be pressurized as does a water-steam coolant system. It has a large specific heat so that it is an efficient heat-transfer fluid.

In practice, those reactors, which have used liquid metal coolants, have been fast-neutron reactors. The liquid metal coolant has a major advantage there because water as a coolant also moderates or slows down the neutrons. Such fast-neutron reactors require a higher degree of enrichment of the uranium fuel than do the watermoderated reactors.

### 18.11 Nuclear Fission Power Generation

Nuclear fission energy is today a competitive and mature low-carbon technology, operating at very high levels of safety. The installed nuclear electricity capacity in the Europe (EU) for example, is 132 GWe , which provides one third of the EU's generated electricity. Most of the current designs are Light Water Reactors (LWR) of the second generation, capable of providing base-load electricity often with availability factors of over $90 \%$. There have been only a few new nuclear power plants
connected to the grid in the last two decades, and as a result of decommissioning of old plants the total number of reactors in Europe has decreased. Nevertheless, electricity supply from nuclear has remained constant and the levelised cost has decreased owing to improved efficiency, power upgrade and improved availability factor.

More recently, there has been a renewed interest in nuclear energy, referred to as "nuclear renaissance", mainly driven by concerns over climate change, security and independence of supply and energy costs.

### 18.12 Generation IV Nuclear Energy Systems

Concerns over energy resource availability, climate change, air quality, and energy security suggest an important role for nuclear power in future energy supplies. While the current Generation II and III nuclear power plant designs provide a secure and low-cost electricity supply in many markets, further advances in nuclear energy system design can broaden the opportunities for the use of nuclear energy. To explore these opportunities, the U.S. Department of Energy's Office of Nuclear Energy has engaged governments, industry, and the research community worldwide in a wide ranging discussion on the development of next generation nuclear energy systems known as "Generation IV".

The goal of the Gen IV Nuclear Energy Systems is to address the fundamental research and development (R\&D) issues necessary to establish the viability of nextgeneration nuclear energy system concepts to meet tomorrow's needs for clean and reliable electricity, and non-traditional applications of nuclear energy. Successfully addressing the fundamental Research and Development (R\&D) issues will allow Gen IV concepts that excel in safety, sustainability, cost-effectiveness, and proliferation risk reduction to be considered for future commercial development and deployment by the private sector (Fig. 18.19).

Gen IV reactor concepts are being developed to use advanced fuels, fashioned from recycled reactor fuel and capable of high-burnups. The corresponding fuel cycle strategies allow for efficient utilization of domestic uranium resources while minimizing waste. Reduction of proliferation risk and improvements in physical protection are being designed into Gen IV concepts to help thwart those who would target nuclear power plants for terrorist acts or use them improperly to develop materials for nuclear weapons. Gen IV concepts will feature advances in safety and reliability to improve public confidence in nuclear energy while providing enhanced investment protection for plant owners. Competitive life-cycle costs and acceptable financial risk are being factored into Gen IV concepts with high-efficiency electricity generation systems, modular construction, and shortened development schedules before plant startup.

Gen IV is also an active participant in the International Project on Innovative Nuclear Reactors and Fuel Cycles (INPRO). INPRO was established in 2001 in response to a resolution by the IAEA General Conference to help to ensure that

## Generations of Nuclear Energy

Fig. 18.19 The evolution of nuclear power
nuclear energy is available to contribute, in a sustainable manner, to meeting the energy needs of the twenty-first century and to bring together technology holders and users so that they can consider jointly the international and national actions required for achieving desired innovations in nuclear reactors and fuel cycles. INPRO provides a forum for discussion for experts and policy makers from industrialized and developing countries on all aspects of nuclear energy planning as well as on the development and deployment of innovative nuclear energy systems in the twentyfirst century.

The Generation IV International Forum (GIF) was chartered in May 2001, to lead the collaborative efforts of the world's leading nuclear technology nations to develop the next generation of nuclear energy systems. The initial efforts of GIF resulted in the identification of the six most promising reactor concepts to be investigated by this international research community and are documented in the Generation IV Technology Roadmap. Thirteen members have signed the GIF Charter: Argentina, Brazil, Canada, People's Republic of China, Euratom, France, Japan, Republic of Korea, the Russian Federation, Republic of South Africa, Switzerland, the United Kingdom and the United States. This unique international effort reached a major milestone on February 28, 2005, as five of the Forum's member countries (Canada, France, Japan, United Kingdom, and United States) signed the world's first multi-lateral agreement aimed at the international development of advanced nuclear energy systems-the Framework Agreement for International Collaboration on Research and Development of Generation IV Nuclear Energy Systems. Subsequent signatories to the Framework Agreement included People's Republic of China, Euratom, Republic of Korea, Republic of South Africa, and Switzerland.

Fig. 18.20 Map of member countries

The United Kingdom is a signatory of the Framework but is currently a non-active member. Argentina and Brazil have not ratified the Framework Agreement and are therefore considered non-active. The Russian Federation is working on the necessary approvals for its accession to the Framework (Fig. 18.20).

As detailed in its Charter and subsequent GIF Policy Statements, GIF is led by the Policy Group (PG), which is responsible for the overall coordination of GIF's Research and Development (R\&D) collaboration, policy formation and for interactions with other organizations. France with currently chairs the Policy Group vice chairs from the U.S. and Japan. An Experts Group and the Senior Industry Advisory Panel advises the Policy Group on (R\&D) strategy, priorities, and methodology and on evaluating research plans for each Generation IV System. The Framework Agreement establishes two levels of implementing arrangements in order to conduct the joint (R\&D). The first level consists of a System Arrangement for each Generation IV reactor concept directed by a System Steering Committee (SSC). Under each SSC, Project Arrangements are established with Project Management Boards to manage and implement the joint (R\&D).

### 18.13 Technological State of the Art and Anticipated Developments

It has been demonstrated that Generation-II plants can be safely and economically operated for up to 60 years through the development of improved harmonized Plant-Life Management technologies and Plant License Extension practices (PLIM/ PLEX) and that developments in fuel technologies can still lead to improvements
in reactor performance. The first Generation-III reactors, which are an evolution of thermal reactors with even further improved safety characteristics and economy, are now being built. In the coming decades, nuclear electricity generation should increase or at least maintain its current level by a combination of lifetime extension and power upgrades of Generation-II reactors and new build of Generation-III reactors. Two 1.6 GWe Generation-III reactors are presently under construction in Finland and France, targeted for connection to the grid in 2012.

The Finnish reactor was a First-of-a-Kind (FOAK) and the construction has suffered delays with the Overnight Cost increasing from 2000 to $3100 € / \mathrm{kWe}$, whereas the Overnight Cost for the second reactor in France is now $2400 € / \mathrm{kWe}$. In series production, the industry expects the cost to be $2000 \pm 500 € / \mathrm{GWe}$, which is in line with recent international studies. An additional capacity of 100 GWe of GenerationIII reactors over the next 25 years is a reasonable estimate, which would require an investment in the range of $€ 200-280$ billion. The capital costs represent typically $60-70 \%$ of the levelised cost for nuclear electricity, operation and maintenance 20$25 \%$ and fuel $10-15 \%$. The front-loaded cost profile means that the levelised cost is very sensitive to construction time and the financial schemes for the investment. Estimates in 2007 for UK resulted in range of $31-44 £ / \mathrm{MWh}(37-53 € / \mathrm{MWh})$.

Though uranium is relatively abundant in the Earth's crust and oceans, estimates of natural reserves are always related to the cost of mineral extraction. As the price of uranium increases on world markets, the number of economically exploitable deposits also increases. The most recent estimates [6] identified 5.5 Million $t$ of Uranium (MtU) that could be exploited below $130 \$ / \mathrm{kg}$. The total amount of undiscovered resources (reasonably assured and speculative) available at an extraction cost below $130 \$ / \mathrm{kgU}$ is estimated at 10.5 MtU . Unconventional resources, from which uranium is extracted as a by-product only, e.g. in phosphate production, lie between 7 and 22 MtU , and reserves in sea water are estimated to be 4000 MtU . Japanese studies suggest that uranium from sea water can be extracted at $300 € / \mathrm{kg}$. At a conservative estimate, $25,000 \mathrm{t}$ of the uranium are required to produce the fuel to generate 1000 TWhe in an open fuel cycle. The global electricity supplied by nuclear is 2600 TWhe, which means that the conventional resources below $130 \$ / \mathrm{kgU}$ at the current rate of consumption would last for at least 85 years with the already identified resources ( 5.5 MtU ) and 246 years, if the undiscovered are also included $(5.5+10.5 \mathrm{MtU})$. In addition to uranium, it is also possible to use thorium, which is three times more abundant in the Earth's crust, though would require different reactors and fuel cycles. Nonetheless, natural resources are plentiful and do not pose an immediate limiting factor for the development of nuclear energy.

However, in a scenario with a large expansion of nuclear energy, resources will become an issue much earlier, especially since new plants have at least a 60-year lifetime and utilities will need assurances when ordering new build that uranium supply can be maintained for the full period of operation. Eventually, known conventional reserves will all be earmarked for current plants or those under construction, and this could happen by the middle of this century. This underlines the need to develop the technology for a new generation, the so-called Generation-IV, of reactors and fuel cycles that are more sustainable. In particular, fast neutron breeder
reactors could produce up to 100 times more energy from the same quantity of uranium than current designs and may significantly reduce the amount of ultimate radioactive waste for disposal.

Fast reactors convert non-fissile material (U-238) in the fuel into fissile material (Pu-239) during reactor operation so that the net amount of fissile material increases (breeding). After re-processing of the spent fuel, the extracted fissile materials are then re-cycled as new fuels. Reduction of the radio-toxicity and heat load of the waste is achieved by separating some long-lived radionuclides, the minor actinides, which could then be "burned" in fast reactors or alternatively in Accelerator Driven Systems (ADS), through transmutation. The fast reactor concept has been demonstrated in research programs and national prototypes in the past, but further R\&D is needed to make it commercially viable and to develop the designs in compliance with true Generation-IV criteria. Major issues involve new materials that can withstand higher temperatures, higher burn-ups and neutron doses, corrosive coolants; reactor designs that eliminate severe accidents; and development of fuel cycles for waste minimization and elimination of proliferation risks. Fast Reactors are expected to be commercially available from 2040.

So far nuclear power has primarily been used to produce electricity, but it can also be used for process heat applications [7]. Currently, LWRs are already being used to a limited extent for some lower temperature applications $\left(200^{\circ} \mathrm{C}\right)$, such as district heating and desalination of seawater. Existing designs of High-Temperature Reactors (HTR) that can reach $800^{\circ} \mathrm{C}$ can be deployed in the coming decades and Very-High Temperature Reactors (VHTR) that can reach gas coolant temperatures beyond $1000^{\circ} \mathrm{C}$ are being studied as a Generation-IV concept for later deployment. Process heat applications include petroleum refinery applications $\left(400^{\circ} \mathrm{C}\right)$, recovery of oil from tar sands $\left(600-700^{\circ} \mathrm{C}\right)$, synthetic fuel from $\mathrm{CO}_{2}$ and hydrogen ( $600-$ $\left.1000^{\circ} \mathrm{C}\right)$, hydrogen production $\left(600-1000^{\circ} \mathrm{C}\right)$ and coal gasification $\left(900-1200^{\circ} \mathrm{C}\right)$. Small reactors that can be inherently safe and used to support specific high energy applications and often in remote areas are another very interesting application that is receiving more attention, in particular in the IAEA INPRO Initiative.

The management of radioactive waste, as either spent fuel or ultimate waste, depending on the national strategy, is a key issue for public acceptance of nuclear energy. There is scientific consensus that geological disposal is the only safe longterm solution for the management of ultimate waste. After a long period of intensive research and development coupled with in-depth political and social engagement, the world's first deep geological repositories for nuclear waste will be in operation in Sweden and Finland by 2020, with France following a few years later, demonstrating that practical solutions exist for the safe long-term management of hazardous waste from the operation of nuclear power plants. Though there will also be ultimate waste from Generation-IV fast reactor fuel cycles after reprocessing, the volumes and heat loads will be greatly reduced thereby facilitating disposal operations and optimizing use of space in available geological repositories.

### 18.14 Next Generation Nuclear Plant (NGNP)

The Next Generation Nuclear Plant (NGNP) demonstration project forms the basis for an entirely new generation of advanced nuclear plants capable of meeting the Nation's emerging need for greenhouse-gas-free process heat and electricity. The NGNP is based on the Very-High-Temperature gas-cooled Reactor (VHTR) technology, which was determined to be the most promising for the U.S. in the medium term. The determination is documented as part of the Generation IV implementation strategy in a report submitted to Congress in 20031 following an extensive international technical evaluation effort. The VHTR technology incorporates substantive safety and operational enhancements over existing nuclear technologies. As required by the Energy Policy Act of 2005 (EPAct), the NGNP will be a prototype nuclear power plant, built at the Idaho National Laboratory (INL). Future commercial versions of the NGNP will meet or exceed the reliability, safety, proliferationresistance, and economy of existing commercial nuclear plants.

It is envisioned that these advanced nuclear plants would be able to supply cost-competitive process heat that can be used to power a variety of energy intensive industries, such as the generation of electricity, hydrogen, enhanced oil recovery, refineries, coal-to-liquids and coal-to-gas plants, chemical plants, and fertilizer plants.

The U.S. Nuclear Regulatory Commission (NRC) is responsible for licensing and regulating the construction and operation of the NGNP. The EPAct authorizes the U.S. Department of Energy (DOE) to build the NGNP at the Idaho National Laboratory and charges INL with responsibility for leading the project development. The project's completion depends on the collaborative efforts of DOE and its national laboratories, commercial industry participants, U.S. universities, and international government agencies as well as successful licensing by the NRC. At present, and pending further evaluation as the NGNP proceeds through Phase 1 in cost-shared collaboration with industry as required by the EPAct, DOE has not made a final determination on whether the license applicant will be DOE or one or more entities that reflect a partnership between DOE and private sector firms.

Under the provisions of Section 644 of the EPAct, the Secretary of Energy and the Chairman of the Nuclear Regulatory Commission are to jointly submit to Congress a licensing strategy for the NGNP within 3 years of the enactment of the Act on August 8,2005 . This report addresses the requirement by outlining a NGNP licensing strategy jointly developed by the NRC and DOE. The scope of the document includes all four elements of the NGNP licensing strategy described in Section 644 (b) of the EPAct:

1. A description of the ways in which current NRC light-water reactor (LWR) licensing requirements need to be adapted for the types of reactors considered for the project.
2. A description of the analytical tools that the NRC will need to develop in order to independently verify the NGNP design and its safety performance.
3. A description of other research or development activities that the NRC will need to conduct for the review of an NGNP license application.
4. A budget estimate associated with the licensing strategy.

DOE has determined that the NGNP nuclear reactor will be a very-high-temperature gas-cooled reactor (VHTR) for the production of electricity, process heat, and hydrogen. The VHTR can provide high-temperature process heat (up to $950^{\circ} \mathrm{C}$ ) that can be used as a substitute for the burning of fossil fuels for a wide range of commercial applications. Since the VHTR is a new and unproven reactor design, the NRC will need to adapt its licensing requirements and process, which have historically evolved around light-water reactor (LWR) designs, for licensing the NGNP nuclear reactor. Thus, Section 644 of the EPAct recognized the need for an alternative licensing strategy. This report provides the recommended NGNP licensing strategy, jointly developed by the NRC and DOE. As the technology matures, the government/industry partnership evolves, and input is provided by the general public, revisions to the strategy may be necessary and appropriate.

The report addresses the four elements of the licensing strategy set forth in Section 644(b) of the EPAct. These elements are summarized above.

### 18.15 Generation IV Systems

The world's population is expected to expand from 6.7 billion people today to over 9 billion people by the year 2050, all striving for a better quality of life. As the earth's population grows, so does the demand for energy and the benefits that it brings: improved standards of living, better health and longer life expectancy, improved literacy and opportunity, and many others. Simply expanding the use of energy along the same mix of today's production options, however, does not satisfactorily address concerns over climate change and depletion of fossil resources. For the earth to support its population while ensuring the sustainability of humanity's development, we must increase the use of energy supplies that are clean, safe, cost effective, and which could serve for both basic electricity production and other primary energy needs. Prominent among these supplies is nuclear energy.

There is currently 370 GWe of nuclear power capacity in operation around the world, producing 3000 TWh each year- $15 \%$ of the world's electricity-the largest share provided by any non-greenhouse gas- emitting source. This reduces significantly the environmental impact of today's electricity generation and affords a greater diversity of electricity generation that enhances energy security.

For more than a decade, Generation IV International Forum (GIF) has led international collaborative efforts to develop next-generation nuclear energy systems that can help meet the world's future energy needs. Generation-IV designs will use fuel more efficiently, reduce waste production, be economically competitive, and meet stringent standards of safety and proliferation resistance.

As, we said the Generation IV International Forum (GIF) was initiated in May 2001 and formally chartered in mid 2001. It is an international collective representing government of 13 countries where nuclear energy is significant now and also seen as vital for the future. Most are committed to joint development of the next generation of nuclear technology. Led by the USA, Argentina, Brazil, Canada,

Fig. 18.21 Six reactor technologies of generation IV. (Courtesy of the Generation IV International Forum)

China, France, Japan, Russia, South Korea, South Africa, Switzerland, and the UK are charter members of the GIF, along with the EU (Euratom). Most of these are party to the Framework Agreement (FA), which formally commits them to participate in the development of one or more Generation IV systems selected by GIF for further R\&D. Argentina, and Brazil did not sign the FA, and the UK withdrew from it; accordingly, within the GIF, these three are designated as "inactive Members." Russia formalized its accession to the FA in August 2009 as its tenth member, with Rosatom as implementing agent. In 2011 the 13 members decided to modify and extend the GIF charter indefinitely

With these goals in mind, some 100 experts evaluated 130 reactor concepts before GIF selected six reactor technologies for further research and development.

These include:

1. Very High Temperature Reactor (VHTR)
2. the Molten Salt Reactor (MSR),
3. the Sodium-cooled Fast Reactor (SFR),
4. the Super Critical Water-cooled Reactor (SCWR),
5. the Gas-cooled Fast Reactor (GFR), and
6. the Lead-cooled Fast Reactor (LFR)

Figure 18.21 below, is illustration of the six types of reactors that are considered as part of Generation IV power plant. More details of each of these reactors are provided in later sections.

Fig. 18.22 Very high temperature reactor. (Courtesy of the Generation IV International Forum)

### 18.15.1 Very High Temperature Reactor (VHTR)

Among the six candidates of the Gen IV nuclear systems in the technical roadmap of Gen IV International Forum (GIF), the Very High Temperature Reactor (VHTR) is primarily dedicated to the cogeneration of electricity and hydrogen, the latter being extracted from water by using thermo-chemical, electro-chemical or hybrid processes. Its high outlet temperature makes it attractive also for the chemical, oil and iron industries. Original target of outlet temperature of $1000^{\circ} \mathrm{C}$ from VHTR can support the efficient production of hydrogen by thermo-chemical processes. The technical basis for VHTR is the TRISO coated particle fuel, the graphite as the core structure, helium coolant, as well as the dedicated core layout and lower power density to removal decay heat in a natural way. The VHTR has potential for inherent safety, high thermal efficiency, process heat application capability, low operation and maintenance costs, and modular construction (Fig. 18.22).

The VHTR is a next step in the evolutionary development of high-temperature gas-cooled reactors. It is a graphite-moderated, helium-cooled reactor with thermal neutron spectrum. It can supply nuclear heat and electricity over a range of core outlet temperatures between 700 and $950^{\circ} \mathrm{C}$, or more than $1000^{\circ} \mathrm{C}$ in future. The reactor core type of the VHTR can be a prismatic block core such as the Japanese HTTR, or a pebble-bed core such as the Chinese HTR-10. For electricity generation, a helium gas turbine system can be directly set in the primary coolant loop, which is called a direct cycle or at the lower end of the outlet temperature range, a steam generator can be used with a conventional rankine cycle. For nuclear heat applications such as process heat for refineries, petrochemistry, metallurgy, and hy-
drogen production, the heat application process is generally coupled with the reactor through an intermediate heat exchanger (IHX), the so-called indirect cycle. The VHTR can produce hydrogen from only heat and water by using thermochemical processes (such as the sulfur-iodine (S-I) process or the hybrid sulfur process), high temperature steam electrolysis (HTSE), or from heat, water, and natural gas by applying the steam reformer technology.

While, the original approach for VHTR at the start of the Generation IV program focused on very high outlet temperatures and hydrogen production, current market assessments have indicated that electricity production and industrial processes based on high temperature steam that require modest outlet temperatures $\left(700-850^{\circ} \mathrm{C}\right)$ have the greatest potential for application in the next decade. This also reduces technical risk associated with higher outlet temperatures. As a result, over the past decade, the focus has moved from higher outlet temperature designs such as GT-MHR and PBMR to lower outlet temperature designs such as HTR-PM in China and the NGNP in the US.

The VHTR has two typical reactor configurations, namely:

1. the pebble bed type and
2. the prismatic block type

Although the shape of the fuel element for two configurations are different, the technical basis for both configuration is same, such as the TRISO coated particle fuel in the graphite matrix, full ceramic (graphite) core structure, helium coolant, and low power density.

This will allow achieving high outlet temperature and the retention of fission production inside the coated particle under normal operation condition and accident condition. The VHTR can support alternative fuel cycles such as $\mathrm{U}-\mathrm{Pu}, \mathrm{Pu}, \mathrm{MOX}$, U-Th.

### 18.15.2 Molten Salt Reactor (MSR)

The MSR is distinguished by its core in, which the fuel is dissolved in molten fluoride salt. The technology was first studied more than 50 years ago. Modern interest is on fast reactor concepts as a long-term alternative to solid-fuelled fast neutrons reactors. The onsite fuel-reprocessing unit using pyrochemistry allows breeding plutonium or uranium-233 from thorium. R\&D progresses toward resolving feasibility issues and assessing safety and performance of the design concepts. Key feasibility issues focus on a dedicated safety approach and the development of salt redox potential measurement and control tools in order to limit corrosion rate of structural materials. Further work on the batch wise online salt processing is required. Much work is needed on molten salt technology and related equipments.

Molten Salt Reactor (MSR) technology was partly developed, including two demonstration reactors, in the 1950s and 1960s in the USA (Oak Ridge National Laboratory). The demonstrations MSRs were thermal-neutron-spectrum graphitemoderated concepts. Since 2005, R\&D has focused on the development of fast-
spectrum MSR concepts (MSFR) combining the generic assets of fast neutron reactors (extended resource utilization, waste minimization) with those relating to molten salt fluorides as fluid fuel and coolant (low pressure and high boiling temperature, optical transparency).

In contrast to most other molten salt reactors previously studied, the MSFR does not include any solid moderator (usually graphite) in the core. This design choice is motivated by the study of parameters such as feedback coefficient, breeding ratio, graphite lifespan and 233 U initial inventory. MSFR exhibit large negative temperature and void reactivity coefficients, a unique safety characteristic not found in solid-fuel fast reactors.

Compared with solid-fuel reactors, MSFR systems have lower fissile inventories, no radiation damage constraint on attainable fuel burn-up, no requirement to fabricate and handle solid fuel, and a homogeneous isotopic composition of fuel in the reactor. These and other characteristics give MSFRs potentially unique capabilities for actinide burning and extending fuel resources.

MSR developments in Russia on the Molten Salt Actinide Recycler and Transmuter (MOSART) aim to be used as efficient burners of transuranic (TRU) waste from spent UOX and MOX light water reactor (LWR) fuel without any uranium and thorium support and also with it. Other advanced reactor concepts are being studied, which use the liquid salt technology, as a primary coolant for Fluoride salt-cooled High-temperature Reactors (FHRs), and coated particle fuels similar to high temperature gas-cooled reactors (Fig. 18.23).

Fig. 18.23 Molten salt reactor. (Courtesy of the Generation IV International Forum)

More generally, there has been a significant renewal of interest in the use of liquid salt as a coolant for nuclear and non-nuclear applications. These salts could facilitate heat transfer for nuclear hydrogen production concepts, concentrated solar electricity generation, oil refineries, and shale oil processing facilities amongst other applications.

### 18.15.3 Sodium Cooled Fast Reactor (SFR)

The Sodium Cooled Fast Reactor (SFR) uses liquid sodium as the reactor coolant, allowing high power density with low coolant volume fraction and operation at low pressure. While the oxygen-free environment prevents corrosion, sodium reacts chemically with air and water and requires a sealed coolant system.

Plant size options under considerations are ranging from small, 50 to 300 MWe , modular reactors to larger plants up to 1500 MWe . The outlet temperature is $500-$ $550^{\circ} \mathrm{C}$ for the options, which allows the use of the materials developed and proven in prior fast reactor programs.

The SFR closed fuel cycle enables regeneration of fissile fuel and facilitates management of minor actinides. However, this requires that recycle fuels be developed and qualified for use. Important safety features of the Generation IV system include a long thermal response time, a reasonable margin to coolant boiling, a primary system that operates near atmospheric pressure, and an intermediate sodium system between the radioactive sodium in the primary system and the power conversion system. Water/steam, supercritical carbon-dioxide or nitrogen can be considered as working fluids for the power conversion system to achieve high performance in terms of thermal efficiency, safety and reliability. With innovations to reduce capital cost, the SFR is aimed to be economically competitive in future electricity markets. In addition, the fast neutron spectrum greatly extends the uranium resources compared to thermal reactors. The SFR is considered to be the nearest-term deployable system for actinide management (Fig. 18.24).

Much of the basic technology for the SFR has been established in former fast reactor programmes, and is being confirmed by the Phenix end-of-life tests in France, the restart of Monju in Japan and the lifetime extension of BN-600 in Russia. New programs involving SFR technology include the Chinese experimental fast reactor (CEFR) which was connected to the grid in July 2011, and India's prototype fast breeder reactor (PFBR) which is currently planned to go critical in 2013.

The SFR is an attractive energy source for nations that desire to make the best use of limited nuclear fuel resources and manage nuclear waste by closing the fuel cycle.

Fast reactors hold a unique role in the actinide management mission because they operate with high energy neutrons that are more effective at fissioning actinides. The main characteristics of the SFR for actinide management mission are:

- Consumption of transuranics in a closed fuel cycle, thus reducing the radiotoxicity and heat load, which facilitates waste disposal and geologic isolation.

Fig. 18.24 Sodium cooled fast reactor. (Courtesy of the Generation IV International Forum)

- Enhanced utilization of uranium resources through efficient management of fissile materials and multi-recycle.

High level of safety achieved through inherent and passive means also allows accommodation of transients and bounding events with significant safety margins.

The reactor unit can be arranged in a pool layout or a compact loop layout. Three options are considered:

- A large size ( $600-1500 \mathrm{MWe}$ ) loop-type reactor with mixed uranium-plutonium oxide fuel and potentially minor actinides, supported by a fuel cycle based upon advanced aqueous processing at a central location serving a number of reactors.
- An intermediate-to-large size (300-1500 MWe) pool-type reactor with oxide or metal fuel.
- A small size (50-150 MWe) modular-type reactor with uranium-plutonium-minor-actinide-zirconium metal alloy fuel, supported by a fuel cycle based on pyro-metallurgical processing in facilities integrated with the reactor.

### 18.15.4 Super Critical Water Cooled Reactor (SCWR)

The Super Critical Water Cooled (SCWRs) are high temperature, high-pressure, light-water-cooled reactors that operate above the thermodynamic critical point of water $\left(374^{\circ} \mathrm{C}, 22.1 \mathrm{MPa}\right)$.

The reactor core may have a thermal or a fast-neutron spectrum, depending on the core design. The concept may be based on current pressure vessel or on pressure tube reactors, and thus use light water or heavy water as moderator. Unlike current water-cooled reactors, the coolant will experience a significantly higher enthalpy rise in the core, which reduces the core mass flow for a given thermal power and increases the core outlet enthalpy to superheated conditions. For both pressure vessel and pressure-tube designs, a once through steam cycle has been envisaged, omitting any coolant recirculation inside the reactor. As in a boiling water reactor, the superheated steam will be supplied directly to the high-pressure steam turbine and the feed water from the steam cycle will be supplied back to the core. Thus, the SCWR concepts combine the design and operation experiences gained from hundreds of water-cooled reactors with those experiences from hundreds of fossil-fired power plants operated with supercritical water (SCW). In contrast to some of the other Generation IV nuclear systems, the SCWR can be developed incrementally step-by-step from current water-cooled reactors.

## a. Advantage and Challenges

Such SCWR designs have unique features that offer many advantages compared to state-of the-art water-cooled reactors:

- SCWRs offer increases in thermal efficiency relative to current-generation water-cooled reactors. The efficiency of a SCWR can approach $44 \%$ or more, compared to $34-36 \%$ for current reactors.
- Reactor coolant pumps are not required. The only pumps driving the coolant under normal operating conditions are the feed water pumps and the condensate extraction pumps.
- The steam generators used in pressurized water reactors and the steam separators and dryers used in boiling water reactors can be omitted since the coolant is superheated in the core.
- Containment, designed with pressure suppression pools and with emergency cooling and residual heat removal systems, can be significantly smaller than those of current water-cooled reactors can.
- The higher steam enthalpy allows to decrease the size of the turbine system and thus to lower the capital costs of the conventional island.

These general features offer the potential of lower capital costs for a given electric power of the plant and of better fuel utilization, and thus a clear economic advantage compared with current light water reactors.

However, there are several technological challenges associated with the development of the SCWR, and particularly the need to validate transient heat transfer models (for describing the depressurization from supercritical to sub-critical conditions), qualification of materials (namely advanced steels for cladding), and demonstration of the passive safety systems.

## b. GIF Progress up to 2012

Pre-conceptual core design studies for a core outlet temperature of more than $500^{\circ} \mathrm{C}$ have been performed in Japan, assuming either a thermal neutron
spectrum or a fast neutron spectrum. Both options are based on a coolant heat-up in two steps with intermediate mixing underneath the core. Additional moderator for a thermal neutron spectrum is provided by feed water inside water rods. The fast-spectrum option uses zirconium-hydride ( ZrH 2 ) layers to minimize hardening of the neutron spectrum in case of core voiding. A pre-conceptual design of safety systems for both options has been studied with transient analyses.
A pre-conceptual plant design with 1700 MW net electric power based on a pressure-vessel-type reactor has been studied by Yamada et al. and has been assessed with respect to efficiency, safety and cost. The study confirms the target net efficiency of $44 \%$ and estimates a cost reduction potential of $30 \%$ compared with current pressurized water reactors. Safety features are expected to be similar to advanced boiling water reactors.
A pre-conceptual design of a pressure-vessel-type reactor with a $500^{\circ} \mathrm{C}$ core outlet temperature and 1000 MW electric power has been developed in Europe, as summarized by Schulenberg and Starflinger. The core design is based on coolant heat-up in three steps. Additional moderator for the thermal neutron spectrum is provided in water rods and in gaps between assembly boxes. The design of the nuclear island and of the balance of the plant confirms results obtained in Japan, namely an efficiency improvement up to $43.5 \%$ and a cost reduction potential of $20-30 \%$ compared with latest boiling water reactors. Safety features as defined by the stringent European Utility Requirements are expected to be met.
Canada is developing a pressure-tube-type SCWR concept with a $625^{\circ} \mathrm{C}$ core outlet temperature at the pressure of 25 MPa . The concept is designed to generate 1200 MW electric power (a 300 MW concept is also being considered). It has a modular fuel channel configuration with separate coolant and moderator. A high-efficiency fuel channel is incorporated to house the fuel assembly. The heavy-water moderator directly contacts the pressure tube and is contained inside a low-pressure calandria vessel. In addition to providing moderation during normal operation, it is designed to remove decay heat from the high-efficiency fuel channel during long-term cooling using a passive moderator cooling system. A mixture of thorium oxide and plutonium is introduced as the reference fuel, which aligns with the GIF position paper on thorium fuel. The safety system design of the Canadian SCWR is similar to that of the ESBWR. However, the introduction of the passive moderator cooling system coupled with the highefficiency channel could reduce significantly the core damage frequency during postulated severe accidents such as large-break loss-of-coolant or station blackout events.
Pre-conceptual designs of three variants of pressure vessel supercritical reactors with thermal, mixed and fast neutron spectrum have been developed in Russia, which joined the SCWR System Arrangement in 2011.
Outside of the GIF framework, two conceptual SCWR designs with thermal and mixed neutron spectrum cores have been established by some research institutes in China. This is done, under framework of the Chinese national R\&D projects from 2007 to 2012, covering some basic research projects on materials and thermo hydraulics, the core/fuel design, the main system design (including
the conventional part), safety systems design, reactor structure design and fuel assembly structure design. The related feasibility studies have also been completed, and show that the design concept has promising prospects in terms of the overall performance, integration of design, component structure feasibility and manufacturability.
Prediction of heat transfer in SCW can be based on data from fossil fired power plants as discussed by Pioro et al. Computational tools for more complex geometries like fuel assemblies are available but still need to be validated with bundle experiments. System codes for transient safety analyses have been upgraded to include SCW, including depressurization transients to subcritical conditions. Flow stability in the core has been studied numerically. As in boiling water reactors, flow stability can be ensured using suitable inlet orifices in fuel assemblies. A number of candidate cladding materials have been tested in capsules, autoclaves and recirculating loops up to $700^{\circ} \mathrm{C}$ at a pressure of 25 MPa . Stainless steels with more than $20 \%$ chromium $(\mathrm{Cr})$ are expected to have the required corrosion resistance up to a peak cladding temperature of $650^{\circ} \mathrm{C}$. More work is needed to develop alloys suitable for use at the design peak cladding temperatures of $850^{\circ} \mathrm{C}$ for the Canadian SCWR concept. Further work is also needed to better identify the coolant conditions that lead to stress corrosion cracking. It has been shown that the creep resistance of existing alloys can be improved by adding small amounts of elements, such as zirconium ( Zr ), as reported by Kaneda et al. In the longer term, the steel experimental oxide dispersion strengthened (ODS) alloys offer an even higher potential, whereas nickel-base alloys are being considered for use in ultra supercritical fossil fired plants are less favorable for use in SCWRs due to their high neutron absorption and associated swelling and embrittlement.
Key water chemistry issues have been identified by Guzonas et al.; predicting and controlling water radiolysis and corrosion product transport (including fission products) remain the major $\mathrm{R} \& \mathrm{D}$ areas. In this regard, the operating experience using nuclear steam reheat at the Beloyarsk nuclear power plant in Russia is extremely valuable (Fig. 18.25).

### 18.15.5 Gas Cooled Fast Reactor (GFR)

The Gas Cooled Reactor (GFR) system is a high-temperature helium-cooled fastspectrum reactor with a closed fuel cycle. It combines the advantages of fast-spectrum systems for long-term sustainability of uranium resources and waste minimization (through fuel multiple reprocessing and fission of long-lived actinides), with those of high-temperature systems (high thermal cycle efficiency and industrial use of the generated heat, for hydrogen production for example).

The GFR uses the same fuel recycling processes as the SFR and the same reactor technology as the VHTR. Therefore, its development approach is to rely, in so far as feasible, on technologies developed for the VHTR for structures, materials, components and power conversion system. Nevertheless, it calls for specific R\&D

Fig. 18.25 Super critical water cooled reactor. (Courtesy of the Generation IV International Forum)
beyond the current and foreseen work on the VHTR system, mainly on core design and safety approach.

The reference design for GFR is based around a 2400 MWth reactor core contained within a steel pressure vessel. The core consists of an assembly of hexagonal fuel elements, each consisting of ceramic-clad, mixed-carbide-fuelled pins contained within a ceramic hex-tube. The favoured material at the moment for the pin clad and hex-tubes is silicon carbide fibre reinforced silicon carbide. The figure below shows the reactor core located within its fabricated steel pressure vessel surrounded by main heat exchangers and decay heat removal loops. The whole of the primary circuit is contained within a secondary pressure boundary, the guard containment (Figs. 18.26 and 18.27).

The coolant is helium and the core outlet temperature will be of the order of $850^{\circ} \mathrm{C}$. A heat exchanger transfers the heat from the primary helium coolant to a secondary gas cycle containing a helium-nitrogen mixture, which, in turn drives a closed cycle gas turbine. The waste heat from the gas turbine exhaust is used to raise steam in a steam generator, which is then used to drive a steam turbine. Such a combined cycle is common practice in natural gas-fired power plant so represents an established technology, with the only difference in the GFR case being the use of a closed cycle gas turbine.

Fig. 18.26 Gas cooled fast reactor. (Courtesy of the Generation IV International Forum)

Fig. 18.27 a GFR-reactor, decay heat loops, main heat exchangers and fuel handling equipment. b GFR spherical guard vessel. (Courtesy of the Generation IV International Forum)

### 18.15.6 Lead Cooled Fast Reactor (LFR)

The Lead-cooled Fast Reactor (LFR) features a fast neutron spectrum, high temperature operation, and cooling by molten lead or Lead-Bismuth Eutectic (LBE), low-pressure, chemically inert liquids with very good thermodynamic properties. It would have multiple applications including production of electricity, hydrogen and process heat. System concepts represented in plans of the Generation-IV International Forum (GIF) System Research Plan (SRP) are based on Europe's ELFR leadcooled system, Russia's BREST-OD-300 and the SSTAR system concept designed in the US.

The LFR has excellent materials management capabilities since it operates in the fast-neutron spectrum and uses a closed fuel cycle for efficient conversion of fertile uranium. It can also be used as a burner to consume actinides from spent LWR fuel and as a burner/breeder with thorium matrices. An important feature of the LFR is the enhanced safety that results from the choice of molten lead as a chemically inert and low-pressure coolant. In terms of sustainability, lead is abundant and hence available, even in case of deployment of a large number of reactors. More importantly, as with other fast systems, fuel sustainability is greatly enhanced by the conversion capabilities of the LFR fuel cycle. Because they incorporate a liquid coolant with a very high margin to boiling and benign interaction with air or water, LFR concepts offer substantial potential in terms of safety, design simplification, proliferation resistance and the resulting economic performance. An important factor is the potential for benign end state to severe accidents (Fig. 18.28).

The LFR has development needs in the areas of fuels, materials performance, and corrosion control. During the next 5 years progress is expected on materials, system design, and operating parameters. Significant test and demonstration activities are underway and planned during this period.

### 18.16 Next Generation of Nuclear Power Reactors for Power Production

Experts are projecting worldwide electricity consumption will increase substantially in the coming decades, especially in the development world, accompanying economic growth and social progress that has direct impact on rising electricity prices have focused fresh attention on nuclear power plants. New, safer and more economical nuclear reactors could not only satisfy many of our future energy needs but could combat global warming as well. Today's existing nuclear power plants on line in the United States provide fifth of the nation's total electrical output.

Taking into account the expected increase in energy demand worldwide and the growing awareness about global warming, climate change issues and sustainable development, nuclear energy will be needed to meet future global energy demand.

Fig. 18.28 Lead cooled fast reactor. (Courtesy of the Generation IV International Forum)

Nuclear power plant technology has evolved as distinct design generations as we mentioned in previous section and briefly summarized here again as follows:

- First Generation: prototypes, and first realizations (~1950-1970)
- Second Generation: current operating plants (~197-2030)
- Third generation: deployable improvements to current reactors ( $\sim 2000$ and on)
- Fourth generation: advanced and new reactor systems (2030 and beyond)

The Generation IV International Forum, or GIF, was chartered in July 2001 to lead the collaborative efforts of the world's leading nuclear technology nations to develop next generation nuclear energy systems to meet the world's future energy needs.

Eight technology goals have been defined for Generation IV systems in four broad areas:

1. Sustainability,
2. Economics,
3. Safety and Reliability, and finally,
4. Proliferation resistance and Physical protection.

A large number of countries share these ambitious goals as they aim at responding to economic, environmental and social requirements of the twenty-first century. They establish a framework and identify concrete targets for focusing GIF R\&D efforts

Eight technology goals have been defined for Generation IV systems in four broad areas: sustainability, economics, safety and reliability, and proliferation resistance and physical protection.

### 18.17 Goals for Generation IV Nuclear Energy Systems

The next generation ("Generation IV") of nuclear energy systems is intended to meet the below goals (while being at least as effective as the "third" generation in terms of economic competitiveness, safety and reliability) in order to provide a sustainable development of nuclear energy.

In principle, the Generation IV Systems should be marketable or deployable from 2030 onwards. The systems should also offer a true potential for new applications compatible with an expanded use of nuclear energy, in particular in the fields of hydrogen or synthetic hydrocarbon production, seawater desalination and process heat production.

It has been recognized that these objectives, widely and officially shared by a large number of countries, should be at the basis of an internationally shared R\&D program, which allows keeping open and consolidating the technical options, and avoiding any early or premature down selection.

| Sustainability-1 | Generation IV nuclear energy systems will provide sustainable energy <br> generation that meets clean air objectives and provides long term avail- <br> ability of systems and effective fuel utilization for worldwide energy <br> production. |
| :--- | :--- |
| Sustainability-2 | Generation IV nuclear energy systems will minimize and manage their <br> nuclear waste and notably reduce the long term stewardship burden, <br> thereby improving protection for the public health and the environment. |
| Economics-1 | Generation IV nuclear energy systems will have a clear life cycle cost <br> advantage over other energy sources. |
| Economics-2 | Generation IV nuclear energy systems will have a level of financial risk <br> comparable to other energy projects. |
| Safety and <br> reliability-1 | Generation IV nuclear energy systems operations will excel in safety and <br> reliability. |
| Safety and <br> reliability-2 | Generation IV nuclear systems will have a very low likelihood and <br> degree of reactor core damage. |
| Safety and <br> reliability-3 | Generation IV nuclear energy systems will eliminate the need for offsite <br> emergency response. |
| Proliferation resis- <br> tance and physical <br> protection | Generation IV nuclear energy systems will increase the assurance that <br> they are very unattractive and the least desirable route for diversion or <br> theft of weapons usable materials, and provide increased physical protec- <br> tion against acts of terrorism. |

## Evolution of Nuclear Power

Fig. 18.29 Evolution of nuclear power plants

In fact, because the next generation nuclear energy systems will address needed areas of improvement and offer great potential, many countries share a common interest in advanced R\&D that will support their development. The international research community should explore such development benefits from the identification of promising research areas and collaborative efforts that. The collaboration on R\&D by many nations on the development of advanced next generation nuclear energy systems will in principle aid the progress toward the realization of such systems, by leveraging resources, providing synergistic opportunities, avoiding unnecessary duplication and enhancing collaboration (Fig. 18.29).

In 2009, the Experts Group published an outlook on Generation IV R\&D, to provide a view of what GIF members hope to achieve collectively in the period 2010-2014. All Generation IV systems have features aiming at performance improvement, new applications of nuclear energy, and/or more sustainable approaches to the management of nuclear materials. High-temperature systems offer the possibility of efficient process heat applications and eventually hydrogen production. Enhanced sustainability is achieved primarily through adoption of a closed fuel cycle with reprocessing and recycling of plutonium, uranium and minor actinides using fast reactors; this approach provides significant reduction in waste generation and uranium resource requirements. The following Table summarizes the main characteristics of the six Generation IV systems.

| System | Neutron <br> spectrum | Coolant | Temp. ${ }^{\circ} \mathrm{C}$ | Fuel cycle | Size (MWe) |
| :--- | :--- | :--- | :--- | :--- | :--- |
| VHTR (Very high tem- <br> perature gas reactor) | Thermal | Helium | $900-1000$ | Open | $250-300$ |
| SFR (Sodium-cooled <br> fast reactor) | Fast | Sodium | 550 | Closed | $30-150$, <br> $300-1500$ <br> $1000-2000$ |
| SCWR (Supercritical <br> water-cooled reactor) | Thermal/fast | Water | $510-625$ | Open/Closed | $300-700$ <br> $1000-2000$ |
| GFR (Gas-cooled fast <br> reactor) | Fast | Helium | 850 | Closed | 1200 |
| LFR (Lead-cooled <br> fast reactor) | Fast | Lead | $480-800$ | Closed | $20-180$ |
| MSR (Molten salt <br> reactor) | Epithermal | Fluoride <br> salt | $700-800$ | Closed | 1000 |

### 18.18 Why We Need to Consider the Future Role of Nuclear Power Now

The following reasoning's are some arguments that show why we need to consider the future role in design of new nuclear power plant;

1. Nuclear power has been part of the global energy need mix for the past five decades. Currently it provides about $18 \%$ of the electricity we use in our homes and workplaces. For example in the UK, about one third of our emissions of carbon dioxide come from electricity generation. The vast majority of those emissions come from coal and gas power plants.
2. Energy companies will need to invest in around $30-35$ GW of new electricity generating capacity-as coal and nuclear plants retire-over the next two decades, with around two-thirds needed by 2020. This is equivalent to about one-third of our existing capacity. The world needs a clear and stable regulatory framework to reduce uncertainty for business to help ensure sufficient and timely investment in technologies that contribute to our energy goals.
3. Of the capacity that is likely to close over the two decades, two thirds is from carbon intensive fossil fuel generation and about 10 GW is nuclear and therefore low carbon. So companies' decisions on the type of power stations they invest in to replace this capacity will have significant implications for the level of carbon emissions. As an illustration, if our existing nuclear power stations were all replaced with fossil fuel fired power stations, our emissions would be between 8 and 16 MtC (million tons of carbon) a year higher as a result (depending on the mix of gas and coal-fired power stations). This would be equivalent to about $30-60 \%$ of the total carbon savings we project to achieve under our central
scenario from all the measures we are bringing forward in the Energy White Paper. Our gas demand would also be higher, at a time when we are becoming more dependent on imported sources of fossil fuels.
4. Electricity demand in the United States is expected to grow significantly in the future. Over the past decade, Americans used $17 \%$ more electricity, but domestic capacity rose only 2.3 \% (National Energy Policy, May 2001). Unless the United States significantly increases its generating capacity, the country will face an energy shortage that is projected to adversely affect our economy, our standard of living, and our national security. Coupled with this challenge is the need to improve our environment.
5. New nuclear power stations have long lead times. This time is necessary to secure the relevant regulatory and development consents, which must be obtained before construction can begin, and there is also a long construction period compared to other generating technologies. Our conservative assumption is that for the first new nuclear plant the pre-construction period would last around 8 years (to secure the necessary consents) and the construction period would last around 5 years. For subsequent plants, this is assumed to be 5 and 5 years; respectively. New nuclear power stations are therefore unlikely to make a significant contribution to the need for new capacity before 2020.
6. Even with our expectations that the share of renewable will grow, it is likely that fossil fuel generation will meet some of this need. However, beyond that date there are still significant amounts of new capacity needed; for example, in 2023 one third or 3 GW of our nuclear capacity will still be operational, based on published lifetimes. Given the likely increase in fossil fuel generation before this date, it is important that much of this capacity is replaced with low carbon technologies. New nuclear power stations could make an important contribution, as outlined in this consultation document, to meeting our needs for low carbon electricity generation and energy security in this period and beyond to 2050. Because of the lead-times, without clarity now we will foreclose the opportunity for nuclear power.
7. The existing approach on new nuclear build was set out in 200311:"Nuclear power is currently an important source of carbon-free electricity. However, its current economics make it an unattractive option for new, carbon-free generating capacity and there are also important issues of nuclear waste to be resolved. These issues include our legacy waste and continued waste arising from other sources. This white paper does not contain specific proposals for building new nuclear power stations. However, we do not rule out the possibility that at some point in the future new nuclear build might be necessary if we are to meet our carbon targets. Before any decision to proceed with the building of new nuclear power stations, there will need to be the fullest public consultation and the publication of a further white paper setting out our proposals."
8. Since 2003 there have been a number of developments, which have led the Government to consider afresh the potential contribution of new nuclear power stations. Firstly, there has been significant progress in tackling the legacy waste

- we have technical solutions for waste disposal that scientific consensus and experience from abroad suggest could accommodate all types of wastes from existing and new nuclear power stations;
- there is now an implementing body (the Nuclear Decommissioning Authority), with expertise in this area, and Government is reconstituting the Committee on Radioactive Waste Management (CoRWM) in order to provide continued independent scrutiny and advice; and
- a framework for implementing long-term waste disposal in a geological repository will be consulted on in the coming months.

9. The Government has also made progress in considering the issue of waste management in relation to potential new nuclear power stations:

- This consultation provides the opportunity to discuss the ethical, intergenerational and public acceptability issues associated with a decision to allow the private sector to invest in new nuclear power stations and generate new nuclear waste;
- The Government is developing specific proposals to protect the taxpayer. Under these proposals, private sector developers would meet the full decommissioning costs and full share of waste management costs. The proposals would be implemented in the event that we conclude that energy companies should be allowed to invest in new nuclear power stations. They would need to be in place before proposals for new power stations could go ahead.

10. Secondly, the high-level economic analysis of nuclear power, prepared for the Energy Review, concluded that under likely scenarios for gas and carbon prices and taking prudent estimates of nuclear costs, nuclear power would offer general economic benefit to the UK in terms of reduced carbon emissions and security of supply benefits. Therefore, the Government believes that it has a potential contribution to make, alongside other low-carbon generating technologies.
11. Thirdly, some energy companies have expressed a strong interest in investing in new nuclear power stations. They assess that new nuclear power stations could be an economically attractive low-carbon investment, which could help diversify their generation portfolios. Their renewed interest reflects assessments that with carbon being priced to reflect its impacts and gas prices likely to be higher than previously expected, the economics of new nuclear power stations are becoming more favorable.
12. Nuclear power stations have long lead times. If they are to be an option to replace the capacity closing over the next two decades, and in particular after 2020, a decision on whether allowing energy companies the option of investing in new nuclear power stations would be in the public interest, needs to be taken now. Energy companies would need to begin their initial preparations in the near future in order to have a reasonable prospect of building new generation in this period. Not taking the public interest decision now would foreclose the option of new nuclear being one of our options for tackling climate change and achieving energy security.

Fig. 18.30 The roadmap organization

### 18.19 The Generation IV Roadmap Project

As the Generation IV goals were being finalized, preparations were made to develop the Generation IV technology roadmap. The organization of the roadmap is shown in the Fig. 15.21 below. The Roadmap Integration Team (RIT) is the executive group. Groups of international experts were organized to undertake identification and evaluation of candidate systems, and to define R\&D to support them (Fig. 18.30).

In a first step, an Evaluation Methodology Group was formed to develop a process to systematically evaluate the potential of proposed Generation IV nuclear energy systems to meet the Generation IV goals. A discussion of the Evaluation Methodology Group's evaluation methodology is included in this report. At the same time, a solicitation was issued worldwide, requesting that concept proponents submit information on nuclear energy systems that they believe could meet some or all of the Generation IV goals. Nearly 100 concepts and ideas were received from researchers in a dozen countries [8].

Technical Working Groups (TWGs) were formed-covering nuclear energy systems employing water-cooled, gas-cooled, liquid-metal-cooled, and non-classical reactor concepts-to review the proposed systems and evaluate their potential using the tools developed by the Evaluation Methodology Group. Because of the large number of system concepts submitted, the TWGs collected their concepts into sets of concepts with similar attributes. The TWGs conducted an initial screening, termed screening for potential, to eliminate those concepts or concept sets that did not have reasonable potential for advancing the goals, or were too distant or technically infeasible [9].

A Fuel Cycle Crosscut Group (FCCG) was also formed at a very early stage to explore the impact of the choice of fuel cycle on major elements of sustain-ability-especially waste management and fuel utilization. Their members were equally drawn from the working groups, allowing them to compare their insights and findings directly. Later, other Crosscut Groups were formed covering economics, risk and safety, fuels and materials, and energy products. The Crosscut Groups reviewed the TWG reports for consistency in the technical evaluations and subject treatment, and continued to make recommendations regarding the scope and priority for crosscutting R\&D in their subject areas. Finally, the TWGs and Crosscut Groups worked together to report on the R\&D needs and priorities of the most promising concepts.

The international experts that contributed to this roadmap represented all ten GIF countries, the Organization for Economic Cooperation and Development Nuclear Energy Agency, the European Commission, and the International Atomic Energy Agency.

### 18.20 Licensing Strategy Components

A DOE and NRC working group was formed to develop the licensing strategy. This group conducted an in-depth analysis of LWR licensing process and technical requirements options, which was performed by the experienced senior staff of the two agencies. The methodology used in formulating the NGNP licensing strategy alternatives also included development of a phenomena identification and ranking table (PIRT) for a prototypical NGNP by subject matter experts in the nuclear field. The PIRT results assisted in the identification of key R\&D needs. Based on the detailed analysis of these alternatives and balancing schedule considerations with licensing risk and other pertinent factors, the Secretary of Energy and the Commission concluded that the following NGNP licensing strategy provides the best opportunity for meeting the 2021 date for initial operation of a prototype NGNP, which details of such analysis can be found in NGNP report to Congress.

NGNP reactor technology will differ from that of commercial LWRs currently used for electric power generation. LWRs have a well-established framework of regulatory requirements, a technical basis for these requirements, and supporting regulatory guidance on acceptable approaches an applicant can take to show that NRC requirements are met. The NRC uses a Standard Review Plan to review licensing applications for these reactor designs. Additionally, the NRC has a well-established set of validated analytical codes and methods and a well-established infrastructure for conducting safety research needed to support its independent safety review of an LWR plant design and the technical adequacy of a licensing application.

New nuclear power plants can be licensed under either of two existing regulatory approaches. The first approach is the traditional "two-step" process described in Title 10, Part 50, "Domestic Licensing of Production and Utilization Facilities," of the Code of Federal Regulations (10 CFR Part 50), which requires both a Construc-
tion Permit (CP) and a separate Operating License (OL). The second approach is the new "one-step" licensing process described in 10 CFR Part 52, "Licenses, Certifications, and Approvals for Nuclear Power Plants," which incorporates a combined Construction and Operating License (COL). Both of these processes allow a deterministic or risk-informed performance-based approach to technical requirements.

Many of the regulatory requirements and supporting review guidance for LWRs are technology-neutral; that is, they are applicable to non-LWR designs as well as LWR designs. However, certain LWR requirements may not apply to the unique aspects of a VHTR design. Accordingly, in developing the NGNP licensing strategy, the NRC and DOE considered the various options available to the NRC staff for adapting current NRC LWR licensing requirements for the NGNP VHTR. These options related to legal, process, technical, research, and regulatory infrastructure matters and included an examination of historical licensing activities. These considerations led to selection of a licensing strategy that would comply best with the considerations identified in the EPAct.

The licensing strategy outlined in this report is composed of two distinct aspects. The first aspect is a recommended approach for how the NRC will adapt the current LWR technical requirements to apply to a VHTR. The second aspect is a recommended licensing process alternative that identifies which of the procedural alternatives in the NRC regulations would be best for licensing the NGNP. To arrive at these recommendations, NRC and DOE evaluated a number of options and alternatives.

### 18.21 Market and Industry Status and Potentials

Europe plays a leading role in the development of nuclear energy and has $35 \%$ of the globally installed capacity. The reactors in Europe have been in operation for 27 years on average. Current plans in most EU member countries are to extend their lifetime on a case by case basis beyond 40 years, and even beyond 60 years in some cases, in combination with power upgrades. The first two Generation-III reactors, European Pressurized-water Reactor (EPR) are currently being constructed.

The global growth of the nuclear energy can be measured by the increasing number of reactors (three more in 2005 and 2006; seven in 2007 and ten in 2008), but with a strong concentration in Asia. Nevertheless a number of these reactors are of European design. There are presently four reactors under construction in Europe: the EPRs in Finland and France and two smaller reactors of Generation-II type (VVER 440) in Slovakia and with plans to build new reactors in France, Romania, Bulgaria and Lithuania. Perhaps more importantly the UK has taken concrete steps towards new build with bidding beginning in 2009 from leading utilities, and Italy has declared that it intends to start a nuclear program with a target to produce $25 \%$ of the electricity by 2030. The estimated maximum potential installed capacities of nuclear fission power for the EU-27, ( 150 GWe by 2020 and 200 GWe by 2030) appear more realistic than the baseline ( 115 GWe in 2020 and 100 GWe in 2030).

Programs to build fast reactor and high-temperature reactor demonstrators are being implemented in Russia and several Asian countries. Although these are not Generation-IV designs, transfer of knowledge and experience from operation will contribute significantly to future Generation-IV development. In Europe, a concerted effort is proposed in the form of a European Industrial Initiative in sustainable nuclear fission as part of the Community's SET-Plan. The EII has singled out the Sodium Fast Reactor (SFR) as its primary system with the basic design selected by 2012 and construction of a prototype of 250-600 MWe that is connected to the grid and operational by 2020.

In parallel, a gas- or lead-cooled fast reactor (GFR/LFR) will also be investigated. The selection of the alternative fast reactor technology is scheduled for 2012 on the basis of a current program of pre-conceptual design research. The reactor will be a $50-100$ MWth demonstrator reactor that should also be in operation by 2020. The SFR prototype and LFR/GFR demonstrator will be complemented by a fuel fabrication workshop that should serve both systems, and by a range of new or refurbished supporting experimental facilities for qualification of safety systems, components, materials and codes. A commercial deployment for a SFR reactor is expected from 2040 and for the alternative design a decade later.

High temperature reactors dedicated to cogeneration of process heat for the production of synthetic fuels or industrial energy products could be available to meet market needs by 2025, which would trigger requirements to construct "first of a kind" demonstrators in the next few years. Indeed, such programs are currently being set up in some countries (USA, Japan, South Africa and China). The key aspect is the demonstration of the coupling with the conventional industrial plant. Supercritical water reactors and molten salt reactors, as well as accelerator driven sub-critical systems dedicated to transmutation of nuclear waste, are currently being assessed in terms of feasibility and performance, though possible industrial applications have yet to be clearly identified.

### 18.22 Barriers

The high capital cost of nuclear energy in combination with uncertain long-term conditions constitutes a financial risk for utilities and investors. The lack of widespread support in the EU Member States may undermine the strength of EU industry for the development of new technologies. Harmonized regulations, codes and standards at the EU-level would strengthen the competitiveness of Europe's nuclear sector and promote deployment of Generation-III technology in the near term. The industry, infrastructures and services that support nuclear power has shrunk significantly during the last decades. This situation in Europe is not unique but it may pose a bottleneck for the deployment of reactors in the relatively near future. One example is large forgings needed for pressure vessel heads. World capacity is limited and even at the present new build construction rate there is a waiting list for delivery of these components.

Public acceptance remains an important issue, but even though opinion is not very favorable in a number of Member States, there are signs that the mood is changing. Nevertheless, concerted efforts are still required, based on objective and open dialogue amongst all stakeholders. International cooperation currently exists at the level of research, and this is being facilitated in the area of Generation-IV systems by the Generation-IV International Forum (GIF). However, EU industry is facing stiff competition, especially in Asia where strong corporate support for R\&D is putting industry in a better position to gain leadership in the near future. Another significant potential barrier for nuclear fission is the shortage of qualified engineers and scientists as a result of the lack of interest in nuclear careers during the 1990s and the reduced availability of specialist courses at universities. Preservation of nuclear knowledge remains a major issue, especially since most of the current generations of nuclear experts are nearing retirement.

### 18.23 Needs

The high initial capital investments and sensitive nature of the technology involved means that renewed deployment of currently available nuclear technology can only take place in a stable (or, at least, predictable) regulatory, economic and political environment. In June 2009, the EU established a common binding framework on nuclear safety with the adoption of the Council Directive establishing a Community framework for the safety of nuclear installations [8, 9]. This is the first binding EU legislation in this field.

In order to retain its leading position and to overcome bottlenecks in the supply chain, Europe also needs to re-invigorate the industrial supply chains supporting the nuclear sector. Apart from this overriding requirement for a clear European strategy on nuclear energy, a new research and innovation system is needed that can assure additional funding, especially for the development of Generation-IV technology. In this context the Sustainable Nuclear Energy Technology Platform plays a key role. The timescales involved, and the fact that key political and strategic decisions are yet to be taken regarding this technology, mean that a significant part of this additional funding must be public. The launch of the European Sustainable Nuclear Industrial Initiative under the Community's SET-Plan, bringing together key industrial and R\&D organizations would be a very significant step towards the construction and operation of the necessary demonstrators and prototypes.

High temperature reactors based on existing technology can also be deployed in the near future with the aim of demonstrating the co-generation of process heat and the coupling with industrial processes. This would need to be built and funded through a European or International consortium, which should also include the process heat end-user industries. In the meantime, an enhanced research effort is needed to ensure Europe's leadership in sustainable nuclear energy technologies that include continuous innovation in LWRs, qualification and development of materials, closed fuel cycle with U-Pu multi-recycling and (very) high temperature reactors and related fuel technology.

Breakthroughs are especially sought in the fields of materials to enhance safety, nuclear fuels and fuel cycle processes. Additionally, there is a need for harmonization of European standards and a strategic planning of national and European research infrastructures for use by the European research community. The implementation of geological disposal of high-level waste is also being pursued as part of national waste management programs, though some countries are not as advanced as others. The new Implementing Geological Disposal Technology Platform, launched in November 2009, is coordinating the remaining necessary applied research in Europe leading up to the start of operation of the first geological repositories for high-level and long-lived waste around 2020, and will facilitate progress in and technology transfer with other national programs.

More effort is needed to inform and interact with the public and other stakeholders, and the education and training of a new generation of nuclear scientists and engineers and transfer of knowledge from the generation that designed and built reactors in the seventies and eighties needs urgent attention. The European Nuclear Energy Forum (ENEF) provides a unique platform for a broad open discussion on the role nuclear power plays today and could play in the low carbon economy of the future. ENEF analyses and discusses the opportunities (competitiveness, financing, grid, etc) and risks (safety, waste) and need for education and training associated with the use of nuclear power and proposes effective ways to foster communication with and participation of the public.

### 18.24 Synergies with Other Sectors

Nuclear energy provides a very stable base-load electricity supply and can therefore work in synergy with renewable energies that are more intermittent. Nuclear energy should also contribute significantly to a low-carbon transport sector as high temperature applications can provide synthetic fuel and hydrogen, while generated electricity could provide a large share of the energy for electrical cars. Interactions are anticipated with activities in "Hydrogen Energy and Fuel Cells" through the potential of nuclear hydrogen production and with "grids" from the characteristics of nuclear electricity generation. With respect to basic materials research, there should be synergies with other applications, such as "Biofuels" and "Clean Coal", where materials are subjected to extreme environments. In addition, the opportunities for important common research with the fusion program, especially in the area of materials, need to be fully exploited. The European Energy Research Alliance under the SET-Plan is also expected to provide opportunities for synergies and collaborative work in the area of nuclear materials. In general, cross cutting research would benefit from more clearly defined channels of interaction, responsibilities and increased flexibility regarding funding and programming.

## Chapter 19 Nuclear Fuel Cycle

Nuclear power has unresolved challenges in long-term management of radioactive wastes. A critical factor for the future of an expanded nuclear power industry is the choice of the fuel cycle - what type of fuel is used, what types of reactors 'burn' the fuel, and the method of disposal of spent fuel.

### 19.1 The Nuclear Fuel Cycle

The nuclear fuel cycle is dealing with all steps in the life history of the reactor fuel, starting with the mining of the uranium ore. The nuclear fuel cycle, which is an industrial process involving various activities to produce electricity from uranium in nuclear power reactors. The nuclear fuel cycle starts with the mining of uranium and ends with the disposal of nuclear waste. With the reprocessing of used fuel as an option for nuclear energy, the stages form a true cycle. The complete fuel cycle loop can be divided into two fold steps and they are classified as (Fig. 19.1);

1. Front End: The steps that are making up this cycle are starting with to prepare uranium for use in a nuclear reactor, and it undergoes the steps of mining and milling, conversion, enrichment and fuel fabrication. These steps make up the 'front end' of the nuclear fuel cycle.
2. Back End: The steps that are making up this part of cycle are ending up with uranium that has been spent about 3 years in a reactor to produce electricity, and then used fuel may undergo a further series of steps including temporary storage, reprocessing, and recycling before wastes are disposed. Collectively these steps are known as the 'back end' of the fuel cycle.

As it mentioned the cycle starts with the mining of uranium and ends with the disposal of nuclear waste.

The uranium is extracted from the ore and is converted in a series of steps into actual fuel material, usually pure uranium dioxide and the raw material for today's most commercial nuclear reactors fuel is uranium. The conclusion of these series of

Fig. 19.1 The nuclear fuel cycle
steps will produce an efficient fuel for generating electricity. Therefore, a lengthily isotope separation process is part of the fuel preparation effort. Natural uranium consists primarily of two isotopes, $99.3 \%$ is $\mathrm{U}_{238}$ and $0.7 \%$ is $\mathrm{U}_{235}$.

Uranium is a common metal that can be found throughout the world. It is present in most rocks and soils, in many rivers and in sea water. Uranium is about 500 times more abundant than gold and about as common as tin and it is a common, slightly radioactive material that occurs naturally in the Earth's crust.

There are three ways to mine uranium:

1. Open pit mines,
2. Underground mines and
3. In situ leaching where the uranium is leached directly from the ore.

The largest producers of uranium ore are Kazakhstan, Canada and Australia. The concentration of uranium in the ore could range from 0.03 up to $20 \%$.

Uranium is enriched in $\mathrm{U}_{235}$ by introducing the gas in fast-spinning cylinders ('centrifuges'), where heavier isotopes are pushed out to the cylinder walls. Uranium can also be enriched using older technology by pumping $\mathrm{UF}_{6}$ gas through porous membranes that allow $\mathrm{U}_{235}$ to pass through more easily than heavier isotopes, such as $\mathrm{U}_{238}$. Enrichment increases the proportion of the $\mathrm{U}_{235}$ isotope.

Fig. 19.2 Enrichment increases the proportion of the $\mathrm{U}_{235}$ isotope

The fission process which heat releases energy in a nuclear reactor, takes place mainly in $\mathrm{U}_{235}$. Most nuclear power plants require fuel with $\mathrm{U}_{235}$ enriched to a level of $3-5 \%$. To increase the concentration of $\mathrm{U}_{235}$, uranium must be enriched. Since enrichment happens in gaseous form, yellow cake is converted to uranium hexafluoride gas $\left(\mathrm{UF}_{6}\right)$ at a conversion facility. $\mathrm{UF}_{6}$ gas is filled into large cylinders where it solidifies. The cylinders are loaded into strong metal containers and shipped to an enrichment plant (Fig. 19.2).

Enriched uranium ( $\mathrm{UF}_{6}$ ) cannot be directly used in reactors, as it does not withstand high temperatures or pressures. It is therefore, converted into uranium oxide $\left(\mathrm{UO}_{2}\right)$. Fuel pellets are formed by pressing $\mathrm{UO}_{2}$, which is sintered (baked) at temperatures of over $1400^{\circ} \mathrm{C}$ to achieve high density and stability.

The pellets are cylindrical and are typically $8-15 \mathrm{~mm}$ in diameter and $10-15 \mathrm{~mm}$ long. They are packed in long metal tubes to form fuel rods, which are grouped in 'fuel assemblies' for introduction into a reactor (Fig. 19.3).

Once the fuel is loaded inside a nuclear reactor, controlled fission can occur. Fission means that the $\mathrm{U}_{235}$ atoms are split. The splitting releases heat energy that is used

to heat water and produce high-pressure steam. The steam turns a turbine connected to a generator, which generates electricity. The fuel is used in the reactor for 3-6 years. About once a year, $25-30 \%$ of the fuel is unloaded and replaced with fresh fuel.

A nuclear power plant produces electricity by:

1. Heating water to
2. Generate steam that
3. Makes the turbine rotate to
4. Enable the generator to produce electricity.

The useful lifetime of the fuel in a reactor may be limited by dimensional changes in solid fuel elements, by the accumulation of neutron absorbing fission product poisons (especially in thermal reactors), and by deletion of the fissile material. As a rule of thumb, the fuel will require replacement when only a few percent of the total fissile and fertile species have been consumed.

If the unused materials were to be recovered and recycled, the spent fuel would be subjected to a complex, chemical reprocessing procedure. The spent fuel assemblies removed from the reactor are very hot and radioactive. Therefore the spent fuel is stored under water, which provides both cooling and radiation shielding. After a few years, spent fuel can be transferred to an interim storage facility. This facility can involve either wet storage, where spent fuel is kept in water pools, or dry storage, where spent fuel is kept in casks (Fig. 19.4).

Both the heat and radioactivity decrease over time and after 40 years in storage, the fuel's radioactivity will be about a thousand times lower than when it was removed from the reactor. The intense radioactivity of the fission products present introduces a special problem and a "cooling period" of at least 120 days must generally be allowed for the radioactivity to decay to a sufficient extent to permit the reprocessing operations.

Used fuel also needs to be taken care of for reuse and disposal. The nuclear fuel cycle includes the 'front end', i.e. preparation of the fuel, the 'service period' in which fuel is used during reactor operation to generate electricity, and the 'back end', i.e. the safe management of spent nuclear fuel including reprocessing and reuse and disposal. If spent fuel is not reprocessed, the fuel cycle is referred to as an 'open' or 'once-through' fuel cycle; if spent fuel is reprocessed, and partly reused, it is referred to as a 'closed' nuclear fuel cycle.

Fig. 19.4 During temporary storage, the radioactivity and heat of spent nuclear fuel decreases

Fig. 19.5 Spent fuel can be recycled to produce more power

The spent fuel contains uranium (96\%), plutonium (1\%) and high-level waste products ( $3 \%$ ).

The uranium, with less than $1 \%$ fissile $\mathrm{U}_{235}$ and the plutonium can be reused. Some countries chemically reprocess usable uranium and plutonium to separate them from unusable waste. Recovered uranium from reprocessing can be returned to the conversion plant, converted to $\mathrm{UF}_{6}$ and subsequently re-enriched. Recovered plutonium, mixed with uranium, can be used to fabricate mixed oxide fuel (MOX) (Fig. 19.5).

### 19.2 Fuel Cycle Choices

In the world today, nuclear energy comprises $\sim 15 \%$ of the total electricity mix. This power source produces no $\mathrm{CO}^{2}$ during the operation of the plants and can provide bulk power to industry and households $24 / 7$. Concerns about $\mathrm{CO}^{2}$ emissions from burning fossil fuels (coal, oil and natural gas) have caused the world demand of nuclear power to rise. With increasing interest in nuclear energy, we are facing a problem of sharing the readily available uranium resources. To increase the energy utilization and decrease the radio toxicity of the waste advanced concepts for fuel reprocessing are being investigated on a global scale. This is a multi disciplinary research field spanning from organic synthesis to particle physics and no single research group can hope to cover all aspects.

Collaboration is crucial to the success of these projects. For a successful advanced nuclear fuel cycle, one or several chemical separations steps are required to fractionate the different elements in spent fuel. These separations processes are of varying complexity and use a range of different chemicals making it challenging to implement them on industrial scale. Furthermore, some of the processes under development are still in the experimental stage and require supporting fundamental studies to succeed. In this presentation, similarities and differences between the different separations schemes are discussed and emphasizing the challenges that will be faced before an advanced nuclear fuel cycle can be implemented in industry.

Nuclear fuel cycle policies have been rather inconsistent throughout history, arguably due to the complex interdependencies of technical, social, economic and
environmental issues involved. Sophisticated fuel cycle simulation tools are being developed to aid the decision makers with defining future fuel cycle strategies. However, the value of these tools for policy making has yet to be demonstrated. This limited success may be partially attributed to the fact that the large amount of technical data generated by these tools obscures the actual policy tradeoffs. From the recent simplified analyses, it was discovered, not surprisingly, that in order to address nuclear waste and resource sustainability issues, the construction of fuel reprocessing infrastructure along with fast spectrum reactors has to be pursued as soon as possible. This policy, however, has a significant economic penalty due to the high cost of fast reactors and reprocessing plants. Decoupling these two parts of the infrastructure would thus allow their gradual introduction, reducing the economic burden and increasing the chances of success.

Collaboration is crucial to the success of these projects. These separations processes are of varying complexity and use a range of different chemicals making it challenging to implement them on industrial scale. Furthermore, some of the processes under development are still in the experimental stage and require supporting fundamental studies to succeed. In this presentation, similarities and differences between the different separations schemes are discussed and emphasizing the challenges that will be faced before an advanced nuclear fuel cycle can be implemented in industry.

Nuclear fuel cycle policies have been rather inconsistent throughout history, arguably due to the complex interdependencies of technical, social, economic and environmental issues involved. Sophisticated fuel cycle simulation tools are being developed to aid the decision makers with defining future fuel cycle strategies. However, the value of these tools for policy making has yet to be demonstrated. This limited success may be partially attributed to the fact that the large amount of technical data generated by these tools obscures the actual policy tradeoffs. From the recent simplified analyses, it was discovered, not surprisingly, that in order to address nuclear waste and resource sustainability issues, the construction of fuel reprocessing infrastructure along with fast spectrum reactors has to be pursued as soon as possible. This policy, however, has a significant economic penalty due to the high cost of fast reactors and reprocessing plants. Decoupling these two parts of the infrastructure would thus allow their gradual introduction, reducing the economic burden and increasing the chances of success.

One study and analysis by team of experts at MIT separates fuel cycle into two classes of choices and they are as;

1. Open Cycle, and
2. Closed Cycle.

In the open or once-through fuel cycle, the spent fuel discharged from the nuclear reactor is treated as waste. Figure 19.6 is depiction of an open or one-through fuel that is projected to year 2050.

In the closed fuel cycle today, the spent fuel discharged from the reactor is reprocessed, and the products are partitioned into Uranium ( U ) and Plutonium ( Pu )

Current Burnup: 50 GWD/MTIHM:

High Burnup: 100 GWD/MTIHM:

Fig. 19.6 Open fuel cycle or once through fuel-projected to 2050
suitable for fabrication into oxide fuel or Mixed Oxide fuel (MOX) for recycle back into a reactor (See Fig. 19.7). The rest of the spent fuel is treated as High-Level Waste (HLW). In the future, closed fuel cycles could include use of a dedicated reactor that would be used to transmute selected isotopes that have been separated from spent fuel (See Fig. 19.8). The dedicated reactor also may be used as a breeder to produce new fissile fuel by neutron absorption at a rate that exceeds the consumption of fissile fuel by the neutron chain reaction. In such fuel cycles the waste stream will contain less actinides which, will significantly reduce the long-term radioactivity of the nuclear waste.

Fig. 19.7 Closed fuel cycle for Plutonium recycle (MOX option—one cycle)—projected 2050

Fig. 19.8 Closed fuel cycle a full actinide recycle-projected to 2050

In general these MIT experts expect that the once-through fuel cycle to have an advantage in terms of cost and proliferation resistance (since there is no reprocessing and separation of actinides), compared to the closed cycle. Closed cycles have an advantage over the once-through cycle in terms of resource utilization (since the recycled actinides reduce the requirement for enriched uranium), which in the limit of very high ore prices would be more economical. Some argue that closed cycles also have an advantage for long-term waste disposal, since long-lived actinides can be separated from the fission products and transmuted in a reactor.

Both once-through and closed cycles can operate on U (Uranium) or Th (Thorium) fuel and can involve different reactor types, e.g., Light Water Reactors (LWRs), Heavy Water Reactors (HWRs), Supercritical water reactors (SCWRs), High Temperature and Very High Temperature Gas Cooled Reactors (HTGRs), Liquid Metal and Gas Fast Reactors (LMFRs and GFRs), or Molten Salt Reactors (MSR) of various sizes. Today, almost all deployed reactors are of the LWR type. The introduction of new reactors or fuel cycles will require considerable development resources and some period of operating experience before initial deployment.

### 19.3 In Core Fuel Management

The primary aim for the in-core fuel management in a nuclear reactor is to achieve higher fuel utilization without compromising the safety during operation. Loading pattern optimization during each refueling stage is the main challenge in light water reactors like pressurized water reactors (PWRs) and boiling water reactors (BWRs). Whereas, in case of heavy water reactors like pressurized heavy water
reactors (PHWRs), the development of refueling scheme is relatively simple mainly due to on-line refueling, use of small length bundle and natural uranium as fuel. The use of small length bundle and flexibility of multi-bundle shift scheme helps in controlling the ripples in power due to refueling.

As part of nuclear fuel cycle process, considerations of fuel management elements are in order and they are indicating as follow:

- Deliver the required power level at lowest costs.
- Meet the safety requirements (SAR) for the core.
- Mechanical and thermal design of fuel assemblies.
- Amount and attributes of fresh assemblies to purchase.
- Reuse of partially burnt fuel.
- Core loading pattern.
- Achieve the desired burn-up.
- Consider impact on subsequent reload cycle.
- With one exception all elements need to be considered for each reload cycle.

There are computer codes written to validate all these points in order to obtain operation license commercially as part of the process. This includes, fuel cycle considerations, reactor core parameters, average power per assembly, fuel management and its objectives, and complying with nuclear waste policies in place.

### 19.4 Nuclear Fuel and Waste Management

All the steps of the nuclear fuel cycle generate radioactive waste. Nuclear waste is classified according to the level of radioactivity into four broad categories: Very Low Level Waste (VLLW), Low Level Waste (LLW), Intermediate Level Waste (ILW) and High Level Waste (HLW). Each of these categories at very high level can be describes as follows;

1. Very Low Level Waste: (VLLW) is an exempt waste (VLLW) contains radioactive materials at a level which is not considered harmful to people or the surrounding environment. It consists mainly of demolished material (such as concrete, plaster, bricks, metal, valves, piping etc.) produced during rehabilitation or dismantling operations on nuclear industrial sites. Other industries, such as food processing, chemical, steel etc also produce VLLW because of the concentration of natural radioactivity present in certain minerals used in their manufacturing processes. The waste is therefore disposed of with domestic refuse, although countries such as France are currently developing facilities to store VLLW in specifically designed VLLW disposal facilities. Radioactive materials which, occur naturally and where human activities increase the exposure of people to ionizing radiation are known by the acronym 'NORM'. NORM is an acronym for Naturally Occurring Radioactive Material, which potentially includes all radioactive elements found in the environment. Long-lived radioactive elements such as uranium, thorium and potassium and any of their decay products,
such as radium and radon are examples of NORM. These elements have always been present in the Earth's crust and atmosphere. The term NORM exists also to distinguish 'natural radioactive material' from anthropogenic sources of radioactive material, such as those produced by nuclear power and used in nuclear medicine, where incidentally the radioactive properties of a material maybe what make it useful. However, from the perspective of radiation doses to people, such a distinction is completely arbitrary.
2. Low Level Waste: (LLW) is generated from hospitals and industry, as well as the nuclear fuel cycle. It comprises paper, rags, tools, clothing, and filters, etc., which contain small amounts of mostly short-lived radioactivity. It does not require shielding during handling and transport and is suitable for shallow land burial. To reduce its volume, it is often compacted or incinerated before disposal. It comprises some $90 \%$ of the volume but only $1 \%$ of the radioactivity of all radioactive waste.
3. Intermediate Level Waste: (ILW) contains higher amounts of radioactivity and some requires shielding. It typically comprises resins, chemical sludges and metal fuel cladding, as well as contaminated materials from reactor decommissioning. Smaller items and any non-solids may be solidified in concrete or bitumen for disposal. It makes up some $7 \%$ of the volume and has $4 \%$ of the radioactivity of all radwaste.
4. High Level Waste: (HLW) arises from the 'burning' of uranium fuel in a nuclear reactor. HLW contains the fission products and transuranic elements generated in the reactor core. It is highly radioactive and hot, so requires cooling and shielding. It can be considered as the 'ash' from 'burning' uranium. HLW accounts for over $95 \%$ of the total radioactivity produced in the process of electricity generation.

There are two distinct kinds of HLW:

- Used fuel itself.
- Separated waste from reprocessing the used fuel (as described in section on Managing HLW from used fuel below).

HLW has both long-lived and short-lived components, depending on the length of time it will take for the radioactivity of particular radionuclide's to decrease to levels that are considered no longer hazardous for people and the surrounding environment. If generally short-lived fission products can be separated from long-lived actinides, this distinction becomes important in management and disposal of HLW.

### 19.4.1 Managing HLW from Used Fuel

Most countries operating nuclear power plants have developed or continue to develop strategies to deal with waste. In many countries, disposal facilities are already available for LLW and, in some, for ILW.

More than $95 \%$ of the total radioactivity in radioactive wastes is contained in HLW (spent nuclear fuel or the most radioactive residues of reprocessing), even though HLW accounts for less than $5 \%$ of the total volume of waste. A typical 1000-MW nuclear power plant produces $10 \mathrm{~m}^{3}$ of spent fuel per year, when packaged for disposal. If this spent fuel is reprocessed, about $2.5 \mathrm{~m}^{3}$ of vitrified waste is produced. Today, spent fuel and HLW are stored in special purpose interim storage facilities.

Large-scale reprocessing facilities are currently operational in France, Russia and the United Kingdom. The main Japanese reprocessing plant is still being commissioned; although a small plant is in operation, (most of Japanese reprocessing to date has taken place in France and the UK). Utilities in a few European countries (including Belgium, Germany, the Netherlands, Sweden and Switzerland) have had a significant amount of spent fuel reprocessed in France and the UK. In most cases, these contracts have now ended, following changes in policy in these countries, but the power companies or countries concerned have a contractual obligation to take back the HLW produced for eventual disposal (as well as the separated plutonium and uranium). India has plans for commercial reprocessing as part of a thorium-uranium fuel cycle, but this is at the development stage. Other countries may reconsider the reprocessing option in future if alternative reprocessing technologies are developed or if reprocessing appears to be more economically attractive than direct disposal.

New reactor designs and fuel cycles are being developed with this consideration in mind. There are relevant international cooperation programmers, with the United States taking a major role, as well as those countries, which today reprocess.

Used fuel gives rise to HLW, which may be either the used fuel itself in fuel rods, or the separated waste arising from reprocessing this (see next section on Recycling used fuel). In either case, the amount is modest-as noted above, a typical reactor generates about 27 t of spent fuel or $3 \mathrm{~m}^{3} /$ year of vitrified waste. Both can be effectively and economically isolated, and have been handled and stored safely since nuclear power began.

Storage is mostly in ponds at reactor sites, or occasionally at a central site. See later section below.

If the used fuel is reprocessed, as is that from UK, French, Japanese and German reactors, HLW comprises highly radioactive fission products and some transuranic elements with long-lived radioactivity. These are separated from the used fuel, enabling the uranium and plutonium to be recycled. Liquid HLW from reprocessing must be solidified. The HLW also generates a considerable amount of heat and requires cooling. It is vitrified into borosilicate (Pyrex) glass, encapsulated into heavy stainless steel cylinders about 1.3 m high and stored for eventual disposal deep underground. This material has no conceivable future use and is unequivocally waste. The hulls and end-fittings of the reprocessed fuel assemblies are compacted, to reduce volume, and usually incorporated into cement prior to disposal as ILW. France has two commercial plants to vitrify HLW left over from reprocessing oxide fuel, and there are plants in the UK and Belgium as well. The capacity of these Western European plants is 2500 canisters ( 1000 t ) a year and some have been operating for three decades.

Fig. 19.9 Decay in radioactivity of fission products

If used reactor fuel is not reprocessed, it will still contain all the highly radioactive isotopes, and then the entire fuel assembly is treated as HLW for direct disposal. It too generates a lot of heat and requires cooling. However, since it largely consists of uranium (with a little plutonium), it represents a potentially valuable resource and there is an increasing reluctance to dispose of it irretrievably.

Either way, after 40-50 years the heat and radioactivity have fallen to one thousandth of the level at removal. This provides a technical incentive to delay further action with HLW until the radioactivity has reduced to about $0.1 \%$ of its original level.

After storage for about 40 years the used fuel assemblies are ready for encapsulation or loading into casks ready for indefinite storage or permanent disposal underground.

Direct disposal of used fuel has been chosen by the USA and Sweden among others, although evolving concepts lean towards making it recoverable if future generations see it as a resource. This means allowing for a period of management and oversight before a repository is closed (Fig. 19.9).

HLW disposal is more contentious than disposal of lower-level wastes and no country today has an operating disposal site for high-level waste. Though wide technical consensus exists on the adequacy of geological disposal of HLW, it has not yet won general public consent. In some countries, however, there are volunteer

Table 19.1 Examples of high-level waste disposal strategies

|  | Facilities and progress towards final repositories |

### 19.4.2 Recycling Used Fuel

Any used fuel will still contain some of the original $U_{235}$ as well as various plutonium isotopes, which have been formed inside the reactor core, and the $\mathrm{U}_{238}$. In total, these account for some $96 \%$ of the original uranium and over half of the original energy content (ignoring $\mathrm{U}_{238}$ ). Reprocessing, undertaken in Europe and Russia, separates this uranium and plutonium from the wastes so that they can be recycled for re-use in a nuclear reactor. Plutonium arising from reprocessing is recycled through a MOX fuel fabrication plant where it is mixed with depleted uranium oxide to make fresh fuel. European reactors currently use over 5 t of plutonium a year in fresh MOX fuel.

Major commercial reprocessing plants operate in France, UK, and Russia with a capacity of some 5000 t /year and cumulative civilian experience of $80,000 \mathrm{t}$ over

Fig. 19.10 Storage pond for used fuel at the thermal oxide reprocessing plant at the UK's Sellafield site (Sellafield Ltd)

50 years. A new reprocessing plant with an 800 t /year capacity at Rokkasho in Japan is undergoing commissioning.

France and UK also undertake reprocessing for utilities in other countries, notably Japan, which has made over 140 shipments of used fuel to Europe since 1979. Until now most Japanese used fuel has been reprocessed in Europe, with the vitrified waste and the recovered uranium and plutonium (as MOX fuel) being returned to Japan to be used in fresh fuel. Russia also reprocesses some spent fuel from Soviet-designed reactors in other countries.

There are several proposed developments of reprocessing technologies (Described in the section of this chapter on Processing of Used Nuclear Fuel). One technology under development would separate plutonium along with the minor actinides as one product. This however cannot be simply put into MOX fuel and recycled in conventional reactors; it requires fast neutron reactors, which are yet few and far in between. On the other hand, it would make disposal of high-level wastes easier (Fig. 19.10).

### 19.4.3 Storage and Disposal of Used Fuel and Other HLW

Spent nuclear fuel or high-level waste can be safely disposed of deep underground, in stable rock formations such as granite, thus eliminating the health risk to people and the environment. The first disposal facilities will be in operation around 2020.

HLW is the liquid waste that results when spent fuel is reprocessed to recover unfissioned uranium and plutonium. During this process, strong chemicals, and these results in liquid HLW dissolve the fuel. Plans are to solidify these liquids into a

Fig. 19.11 Waste management disposal facilities
form that is suitable for disposal. Solidification is still in the planning stages. While currently there are no commercial facilities in this country that reprocess spent fuel, spent fuel from defense program reactors has been routinely reprocessed for use in producing nuclear weapons or for reuse in new fuel (Fig. 19.11).

Compared to the total inventory of HLW, the volume of commercial HLW from the reprocessing of commercial spent fuel is almost insignificant, less than one percent. Defense-related HLW comprises greater than ninety-nine percent of the volume of HLW. Figure 19.12 shows the historical and projected volume of de-

Fig. 19.12 Historical and projected inventories of defense high-level radioactive waste. (Reference: DOE/RW-0006, Rev. 7)

Fig. 19.13 Nuclear waste can be buried deep underground
fense-related HLW through the year 2020. The effect of the end of the "Cold War" on these projections is uncertain.

HLW is now stored in underground tanks or stainless steel silos on federal reservations in South Carolina, Idaho, and Washington and at the Nuclear Fuel Services Plant in West Valley, NY. These facilities have begun programs to solidify and structurally stabilize the waste in preparation for disposal at a national repository.

Waste will be packed in long-lasting containers and buried deep in the geological formations chosen for their favorable stability and geochemistry, including limited water movement. These geological formations have stability over hundreds of millions of years, far longer than the waste is dangerous (Fig. 19.13).

Historically the United States has not considered Spent Nuclear Fuel (SNF) storage as a major component of fuel cycle policy. However, repository programs worldwide have adopted a policy of storing SNF (or the HLW from reprocessing) for $40-60$ years before disposal in a geological repository to reduce the radioactivity and decay heat. This reduces repository costs and performance uncertainties. Countries such as France with its partly closed fuel cycle and Sweden with its open fuel cycle built storage facilities several decades ago for this purpose. The failure to include long-term storage as part of the spent fuel management has had major impacts on the design of the proposed Yucca Mountain Repository (YMR). Due to the heat load of SNF, the repository was required to be ventilated to remove decay heat while the SNF cooled. The YMR would have, after 30 years of filling, become functionally an underground storage facility with active ventilation for an additional 50 years prior to closure. Fuel cycle transitions require a half-century or more. It is likely to be several decades before the U.S. deploys alternative fuel cycles. Long-term interim storage provides time to assure proper development of repositories and time to decide whether LWR SNF is a waste that ultimately requires disposal or whether it is a valuable resource. For multiple reasons, planning for long term interim storage of spent nuclear fuel-on the scale of a century-should be an integral part of nuclear fuel cycle design. In recommending century-scale storage, one should not precluding earlier reprocessing or geological disposal of SNF or much longer term managed storage if the technology permits. These options are preserved. The key point is that fuel cycle decisions should be taken over the next decade or two in the context of a century time scale for managed storage.

Fig. 19.14 Projected accumulated radioactivity of commercial spent fuel discharges for the DOE/ EIA No-New-Orders and lower reference cases. Integrated data base for 1991: U.S. spent fuel and radioactive waste inventory projections and characteristics, DOE/ORNL, Oct 1991. (DOE/ RW-0006, Rev. 7)

Until a disposal or long-term storage facility is operational, most spent fuel is stored in water pools at the reactor site where it was produced. The water removes leftover heat generated by the spent fuel and serves as a radiation shield to protect workers at the site.

The operation of nuclear reactors over the last 20 years has substantially added to the amount of radioactive waste in this country. As shown in Fig. 19.14, by the year 2020, the total amount of spent fuel is expected to increase significantly.

The process of selecting appropriate deep geological repositories is now underway in several countries. Finland and Sweden are well advanced with plans for direct disposal of used fuel, since their parliaments decided to proceed on the basis that it was safe, using existing technology. Both countries have selected sites, in Sweden, after competition between two municipalities. The USA has opted for a final repository at Yucca Mountain in Nevada, though this is now stalled due to political decision. There have also been proposals for international HLW repositories in optimum geology (Fig. 19.15).

A pending question is whether wastes should be emplaced so that they are readily retrievable from repositories. There are sound reasons for keeping such options open-in particular, it is possible that future generations might consider the buried waste to be a valuable resource. On the other hand, permanent closure might increase long-term security of the facility. After being buried for about 1000 years most of the radioactivity will have decayed. The amount of radioactivity then remaining would be similar to that of the naturally occurring uranium ore from which it originated, though it would be more concentrated.

Fig. 19.15 Decay in radioactivity of high level waste. (Courtesy of DOE)

### 19.4.4 Regulation of Disposal

The fuel for most nuclear reactors consists of pellets of ceramic uranium dioxide that are sealed in hundreds of metal rods. These rods are bundled together to form what is known as a "fuel assembly." Depending upon the type and size of the reactor, a fuel assembly can weigh up to 1500 pounds. As the nuclear reactor operates, uranium atoms fission (split apart) and release energy.

When most of the usable uranium has fissioned, the "spent" fuel assembly is removed from the reactor. Some elements, such as plutonium, in HLW and spent fuel are highly radioactive and remain so for thousands of years. Therefore, the safe disposal of this waste is one of the most controversial environmental subjects facing the federal government and affected states.

The federal government (the EPA, the DOE, and the NRC) has overall responsibility for the safe disposal of HLW and spent fuel. The EPA is responsible for developing environmental standards that apply to both DOE-operated and NRC-licensed facilities. Currently, the NRC is responsible for licensing such facilities and ensuring their compliance with the EPA standards. DOE is responsible for developing the deep geologic repository, which has been authorized by Congress for disposing of spent fuel
and high level waste. Both the NRC and the Department of Transportation are responsible for regulating the transportation of these wastes to storage and disposal sites.

### 19.5 Processing of Used Nuclear Fuel

Over the last 50 years, the principal reason for reprocessing used fuel has been to recover unused uranium and plutonium in the used fuel elements and thereby close the fuel cycle, gaining some $25 \%$ more energy from the original uranium in the process and thus contributing to energy security. A secondary reason is to reduce the volume of material to be disposed of as high-level waste to about one fifth. In addition, the level of radioactivity in the waste from reprocessing is much smaller and after about 100 years falls much more rapidly than in used fuel itself.

A key, nearly unique, characteristic of nuclear energy is that used fuel may be reprocessed to recover fissile and fertile materials in order to provide fresh fuel for existing and future nuclear power plants. Several European countries, Russia and Japan have had a policy to reprocess used nuclear fuel, although government policies in many other countries have not yet addressed the various aspects of reprocessing.

In the last decade interest has grown in recovering all long-lived actinides together (i.e. with plutonium) to recycle them in fast reactors so that they end up as short-lived fission products. This policy is driven by two factors: reducing the longterm radioactivity in high-level wastes, and reducing the possibility of plutonium being diverted from civil use-thereby increasing proliferation resistance of the fuel cycle. If used fuel is not reprocessed, then in a century or two the built-in radiological protection will have diminished, allowing the plutonium to be recovered for illicit use (though it is unsuitable for weapons due to the non-fissile isotopes present).

Reprocessing used fuel to recover uranium (as reprocessed uranium, or RepU) and plutonium ( Pu ) avoids the wastage of a valuable resource. Most of it-about $96 \%$-is uranium, of which less than $1 \%$ is the fissile $\mathrm{U}_{235}$ (often $0.4-0.8 \%$ ); and up to $1 \%$ is plutonium. Both can be recycled as fresh fuel, saving up to $30 \%$ of the natural uranium otherwise required. The materials potentially available for recycling (but locked up in stored used fuel) could conceivably run the US reactor fleet of about 100 GWe for almost 30 years with no new uranium input.

So far, almost 90,000 t (of 290,000 t discharged) of used fuel from commercial power reactors has been reprocessed. Annual reprocessing capacity is now some 4000 t /year for normal oxide fuels, but not all of it is operational.

Between now and 2030 some $400,000 \mathrm{t}$ of used fuel is expected to be generated worldwide, including $60,000 \mathrm{t}$ in North America and $69,000 \mathrm{t}$ in Europe (Table 19.2).

### 19.5.1 Reprocessing Policies

Conceptually reprocessing can take several courses, separating certain elements from the remainder, which becomes high-level waste. Reprocessing options include:

## ات <br> "

| Total civil capacity |  |  | 5630 |

- Separate U, Pu, (as today).
- Separate $\mathrm{U}, \mathrm{Pu}+\mathrm{U}$ (small amount of U$)$.
- Separate U, Pu, minor actinides.
- Separate $\mathrm{U}, \mathrm{Pu}+\mathrm{Np}, \mathrm{Am}+\mathrm{Cm}$.
- Separate $U+P u$ all together.
- Separate $\mathrm{U}, \mathrm{Pu}+$ actinides, certain fission products.

In today's reactors, reprocessed uranium (RepU) needs to be enriched, whereas plutonium goes straight to mixed oxide (MOX) fuel fabrication. This situation has two perceived problems: the separated plutonium is a potential proliferation risk, and the minor actinides remain in the separated waste, which means that its radioactivity is longer-lived than if it comprised fission products only.

As there is no destruction of minor actinides, recycling through light water reactors delivers only part of the potential waste management benefit. For the future, the focus is on removing the actinides from the final waste and burning them with the recycled uranium and plutonium in fast neutron reactors. (The longer-lived fission products may also be separated from the waste and transmuted in some other way.) Hence, the combination of reprocessing followed by recycling in today's reactors should be seen as an interim phase of nuclear power development, pending widespread use of fast neutron reactors.

All but one of the six Generation IV reactors being developed has closed fuel cycles, which recycle all the actinides. Although US policy has been to avoid reprocessing, the US budget process for 2006 included $\$ 50$ million to develop a plan for "integrated spent fuel recycling facilities", and a program to achieve this with fast reactors has become more explicit since.

### 19.6 Back End of Fuel Cycle

As part of back-end of fuel cycle is concerned the study that is done by World Nuclear Association talks about nuclear fuel and waste management that was discussed in previous section of this chapter and they can be summarized as;

- Nuclear power is the only large-scale energy-producing technology which, takes full responsibility for all its wastes and fully costs this into the product.
- The amount of radioactive wastes is very small relative to wastes produced by fossil fuel electricity generation.
- Used nuclear fuel may be treated as a resource or simply as a waste.
- Nuclear wastes are neither particularly hazardous nor hard to manage relative to other toxic industrial wastes.
- Safe methods for the final disposal of high-level radioactive waste are technically proven; the international consensus is that this should be geological disposal.

All parts of the nuclear fuel cycle produce some radioactive waste (radwaste) and the relatively modest cost of managing and disposing of this is part of the electricity cost, i.e. it is internalised and paid for by the electricity consumers.

At each stage of the fuel cycle there are proven technologies to dispose of the radioactive wastes safely. For low- and intermediate-level wastes these are mostly being implemented. For high-level wastes some countries await the accumulation of enough of it to warrant building geological repositories; others, such as the USA, have encountered political delays.

Unlike other industrial wastes, the level of hazard of all nuclear waste-its ra-dioactivity-diminishes with time. Each radionuclide contained in the waste has a half-life-the time taken for half of its atoms to decay and thus for it to lose half of its radioactivity. Radionuclides with long half-lives tend to be alpha and beta emitters-making their handling easier-while those with short half-lives tend to emit the more penetrating gamma rays. Eventually all radioactive wastes decay into non-radioactive elements. The more radioactive an isotope is, the faster it decays.

The main objective in managing and disposing of radioactive (or other) waste is to protect people and the environment. This means isolating or diluting the waste so that the rate or concentration of any radionuclides returned to the biosphere is harmless. To achieve this, practically all wastes are contained and managed-some clearly need deep and permanent burial. From nuclear power generation, none is allowed to cause harmful pollution.

All toxic wastes need to be dealt with safely, not just radioactive wastes. In countries with nuclear power, radioactive wastes comprise less than $1 \%$ of total industrial toxic wastes (the balance of which remains hazardous indefinitely).

## Chapter 20 <br> The Economic Future of Nuclear Power

From the global viewpoint and urgent need to support rising demand for electricity, many countries recognize the substantial role which nuclear power has played in satisfying various policy objectives, including energy security of supply, reducing import dependence and reducing greenhouse gas or polluting emissions. Nevertheless, as such considerations are far from being fully accounted for in liberalized power markets, nuclear plants must demonstrate their viability on normal commercial criteria as well as their life cycle advantages.

### 20.1 Introduction

Of all factors affecting prospects for the substantial growth of nuclear power in the twenty-first century, cost is the most fundamental. What are the essential economics associated with the construction and operation of advanced state-of-the-art nuclear power plants?.

Certainly, other factors will affect the pace of the global nuclear renaissance now under way. The nuclear debate continues to feature expressions of concern about nuclear arms, terrorism, operational and transport safety, and effective waste management and disposal. In addressing all of these concerns, however, the combined efforts of science, diplomacy and industry have achieved substantial advance in ensuring that civil nuclear power can be used without substantial human or environmental risk.

Studies by organizations such as Nuclear Energy Institute (NEI) and World Nuclear Association (WNA) are showing an excellent demonstration and analysis of the economic future of nuclear power plants both from total cost of ownership and return on investment of such plants and some of these analyses are showing here. For further detailed and more up to date, we urge readers to refer to the sites of these two organizations.

Today, given the urgent environmental imperative of achieving a global cleanenergy revolution, public policy has sound and urgent justification for placing a
sizeable premium on clean technologies. Such environmentally driven incentives can come through carbon taxes, emissions trading, or subsidies for non-emitting generators of power.

This achievement in meeting legitimate public concerns has provided the foundation for the nuclear renaissance by prompting governments in countries representing the preponderance of world population and economic activity to consider a wider exploitation of the benefits of nuclear energy.

These benefits fall into two categories:

- National: price stability and security of energy supply
- Global environmental: near-zero greenhouse gas emissions tolerances.

Nuclear energy is, in many places, competitive with fossil fuels for electricity generation, despite relatively high capital costs and the need to internalize all waste disposal and decommissioning costs. If the social, health and environmental costs of fossil fuels are also taken into account, the economics of nuclear power are outstanding.

The research and development work that was undertaken in the early stages of nuclear power development was a challenging project for government research organizations as well as the industrial sector. The optimum technical solutions were progressively uncovered through multiple and various demonstration programs developed in the 1950s and 1960s under government funding and, at the same time, by increasingly scaling up the reactor ratings to compete more easily with fossil fuels. Designs were mainly motivated by the search for higher thermal efficiency, lower system pressure, the ability to stay on line continuously and better utilization of uranium resources. The breakthrough in the commercialization of nuclear power was reached when unit ratings exceeded several hundreds of MWe in the mid-1960s.

Since the late 1980s, on the electricity power supply side, governments have steadily moved away from direct regulation in energy markets to concentrate on establishing the framework for a competitive supply system. There are significant differences in regulatory regimes with some countries retaining a substantial regulated element. Electricity market liberalization itself comes in many guises, but the industry today recognizes that all plants must demonstrate that they are costeffective and that this must be achieved while still maintaining very high safety and environmental standards. Safety and the best economic operation tend, in any case, to go hand in hand.

### 20.2 Overall Costs: Fuel, Operation and Waste Disposal

With nuclear energy's higher capital cost and longer development and construction period, investors will focus on how risks can be managed, mitigated and risk allocations optimized. The business case for nuclear will ultimately depend on the structure of risk allocation between operators, investors, suppliers and customers.

Although new nuclear power plants require large capital investment, they are hardly unique by the standards of the overall energy industry, where oil platforms
and Liquefied Natural Gas (LNG) liquefaction facilities cost many billions of dollars. Main aspects of these costs are due to imposed federal and state government's regulation for standard operating procedures and safety factors that are required be implemented and followed. Projects of similar magnitude can be found in the building of new roads, bridges and other elements of infrastructure. Many of the risk-control and project management techniques developed for these projects are equally applicable to building nuclear power stations.

Risks that are specific to nuclear plants are those surrounding the management of radioactive waste and used fuel and the liability for nuclear accidents. As with many other industrial risks, public authorities must be involved in setting the regulatory framework. The combined goal must be public safety and the stable policy environment necessary for investment.

Assessing the relative costs of new generating plants utilizing different technologies is a complex matter and the results depend crucially on location. Coal is, and will probably remain, economically attractive in countries such as China, the USA and Australia with abundant and accessible domestic coal resources as long as carbon emissions are cost-free. Gas is also competitive for base-load power in many places, particularly using combined-cycle plants, though rising gas prices have removed much of the advantage.

As part cost study analyzing WNA and NEI organizations, the following points were considered and taken into account as;

- Nuclear power is cost competitive with other forms of electricity generation, except where there is direct access to low-cost fossil fuels.
- Fuel costs for nuclear plants are a minor proportion of total generating costs, though capital costs are greater than those for coal-fired plants are and much greater than those for gas-fired plants.
- In assessing the economics of nuclear power, decommissioning and waste disposal costs are fully taken into account.

To support new-build projects, projects must be structured to share risks amongst key stakeholders in a way that is both equitable and that encourages each project participant to fulfill its responsibilities.

### 20.2.1 Fuel Costs

This is the total annual cost associated with the "burn-up" of nuclear fuel resulting from the operation of the unit. This cost is based upon the amortized costs associated with the purchasing of uranium, conversion, enrichment, and fabrication services along with storage and shipment costs, and inventory (including interest) charges less any expected salvage value.

For a typical 1000 MWe BWR or PWR, the approximate cost of fuel for one reload (replacing one third of the core) is about $\$ 40$ million, based on an 18 -month refueling cycle. The average fuel cost at a nuclear power plant in 2011 was 0.68 cents/ kWh.

Fig. 20.1 Monthly fuel cost to U.S. electric utilities

Because nuclear plants refuel every 18-24 months, they are not subject to fuel price volatility like natural gas and oil power plants. The following chart is presentation of 'Monthly Fuel Cost to U.S. Electric Utilities'. This line graph shows U.S. electric utilities' monthly fuel costs for nuclear, coal, gas, and oil between 1995 and 2011 (Fig. 20.1).

From the outset, the basic attraction of nuclear energy has been its low fuel costs compared with coal, oil and gas-fired plants. Uranium, however, has to be processed, enriched and fabricated into fuel elements, and about half of the cost is due to enrichment and fabrication. In the assessment of the economics of nuclear power allowances must also be made for the management of radioactive used fuel and the ultimate disposal of this used fuel or the wastes separated from it. But even with these included, the total fuel costs of a nuclear power plant in the Convention on the Organization for Economic Co-operation and Development (OECD) are typically about a third of those for a coal-fired plant and between a quarter and a fifth of those for a gas combined-cycle plant. The US Nuclear Energy Institute suggests that for a coal-fired plant $78 \%$ of the cost is the fuel, for a gas-fired plant the figure is $89 \%$, and for nuclear the uranium is about $14 \%$, or double that to include all front end costs.

In March 2011, the approx. US $\$$ cost to get 1 kg of uranium as $\mathbf{U O} \mathbf{O}_{2}$ reactor fuel (at current spot uranium price) (Table 20.1):

At 45,000 MWd/t burn-up this gives $360,000 \mathrm{kWh}$ electrical per kg , hence fuel cost: 0.77 cents $/ k W h$.

Table 20.1 Source World Nuclear Association

| Uranium | $8.9 \mathrm{~kg} \mathrm{U}_{3} \mathrm{O}_{8} \times \$ 146$ | US\$ 1300 |
| :--- | :--- | :--- |
| Conversion | $7.5 \mathrm{~kg} \mathrm{U} \times \$ 13$ | US\$ 98 |
| Enrichment | $7.3 \mathrm{SWU} \times \$ 155$ | US\$ 1132 |
| Fuel fabrication | per kg | US\$ 240 |
| Total, approx |  | US\$ 2770 |

Fig. 20.2 Finish study of 'The Impact of Fuel Costs on Electricity Generation Costs'

Fuel costs are one area of steadily increasing efficiency and cost reduction. For instance, in Spain the nuclear electricity cost was reduced by $29 \%$ over 1995-2001. This involved boosting enrichment levels and burn-up to achieve $40 \%$ fuel cost reduction. Prospectively, a further $8 \%$ increase in burn-up will give another $5 \%$ reduction in fuel cost.

Uranium has the advantage of being a highly concentrated source of energy, which is easily and cheaply transportable. The quantities needed are very much less than for coal or oil. One kilogram of natural uranium will yield about 20,000 times as much energy as the same amount of coal. It is therefore intrinsically a very portable and tradable commodity.

The fuel's contribution to the overall cost of the electricity produced is relatively small, so even a large fuel price escalation will have relatively little effect (see below).

A Finnish study in 2000 also quantified fuel price sensitivity to electricity costs (Fig. 20.2):

Fig. 20.3 Effect of Uranium price on fuel cost

These show that a doubling of fuel prices would result in the electricity cost for nuclear rising about $9 \%$, for coal rising $31 \%$ and for gas $66 \%$. Gas prices have since risen significantly.

The impact of varying the uranium price in isolation is shown below in a worked example of a typical US plant, assuming no alteration in the tails assay at the enrichment plant (Fig. 20.3).

Doubling the uranium price (say from $\$ 25$ to $50 / 1 \mathrm{~b} \mathrm{U}_{308}$ ) takes the fuel cost up from 0.50 to 0.62 US cents $/ \mathrm{kWh}$, an increase of one quarter, and the expected cost of generation of the best US plants from 1.3 to 1.42 US cents/ $/ \mathrm{kWh}$ (an increase of almost $10 \%$ ). So while there is some impact, it is comparatively minor, especially by comparison with the impact of gas prices on the economics of gas generating plants. In these, $90 \%$ of the marginal costs can be fuel. Only if uranium prices rise to above $\$ 100 / \mathrm{lb} \mathrm{U}_{308}(\$ 260 / \mathrm{kgU})$ and stay there for a prolonged period (which seems very unlikely) will the impact on nuclear generating costs be considerable.

Nevertheless, for nuclear power plants operating in competitive power markets where it is impossible to pass on any fuel price increases (i.e. the utility is a pricetaker), higher uranium prices will cut corporate profitability. Yet fuel costs have been relatively stable over time - the rise in the world uranium price between 2003 and 2007 added to generation costs, but conversion, enrichment and fuel fabrication costs did not followed the same trend.

For prospective new nuclear plants, the fuel element is even less significant (see below). The typical front-end nuclear fuel cost is typically only $15-20 \%$ of the total, as opposed to $30-40 \%$ for operating nuclear plants.

There are other possible savings. For example, if used fuel is reprocessed and the recovered plutonium and uranium is used in mixed oxide (MOX) fuel, more energy can be extracted. The costs of achieving this are large, but are offset by MOX fuel not needing enrichment and particularly by the smaller amount of high-level wastes produced at the end. Seven $\mathrm{UO}_{2}$ fuel assemblies give rise to one MOX assembly plus some vitrified high-level waste, resulting in only about $35 \%$ of the volume, mass and cost of disposal.

### 20.2.2 Future Cost Competitiveness

Understanding the cost of new generating capacity and its output requires careful analysis of what is in any set of figures. There are three broad components: capital, finance and operating costs. Capital and financing costs make up the project cost.

Capital costs comprise several things: the bare plant cost (usually identified as Engineering-Procurement-Construction-EPC-cost), the owner's costs (land, cooling infrastructure, administration and associated buildings, site works, switchyards, project management, licenses, etc), cost escalation and inflation. Owner's costs may include transmission infrastructure. The term "overnight capital cost" is often used, meaning EPC plus owners' costs and excluding financing, escalation due to increased material and labor costs, and inflation. Construction cost-sometimes called "all-in cost", adds to overnight cost any escalation and interest during construction and up to the start of construction. It is expressed in the same units as overnight cost and is useful for identifying the total cost of construction and for determining the effects of construction delays. In general the construction costs of nuclear power plants are significantly higher than for coal- or gas-fired plants because of the need to use special materials, and to incorporate sophisticated safety features and back-up control equipment. These contribute much of the nuclear generation cost, but once the plant is built the cost variables are minor.

Long construction periods will push up financing costs, and in the past they have done so spectacularly. In Asia construction times have tended to be shorter, for instance the new-generation 1300 MWe Japanese reactors which began operating in 1996 and 1997 were built in a little over 4 years, and 48-54 months is typical projection for plants today.

Decommissioning costs are about $9-15 \%$ of the initial capital cost of a nuclear power plant. But when discounted, they contribute only a few percent to the investment cost and even less to the generation cost. In the USA, they account for $0.1-$ 0.2 cents $/ \mathrm{kWh}$, which is no more than $5 \%$ of the cost of the electricity produced.

Financing costs will depend on the rate of interest on debt, the debt-equity ratio, and if it is regulated, how the capital costs are recovered. There must also be an allowance for a rate of return on equity, which is risk capital.

Operating costs include operating and maintenance (O\&M) plus fuel. Fuel cost figures include used fuel management and final waste disposal. These costs, while usually external for other technologies, are internal for nuclear power (i.e. they have to be paid or set aside securely by the utility generating the power, and the cost passed on to the customer in the actual tariff).

This "back-end" of the fuel cycle, including used fuel storage or disposal in a waste repository, contributes up to $10 \%$ of the overall costs per kWh, -rather less if there is direct disposal of used fuel rather than reprocessing. The $\$ 26$ billion US used fuel program is funded by a 0.1 cents $/ \mathrm{kWh}$ levy.

Calculations of relative generating costs are made using levelised costs, meaning average costs of producing electricity including capital, finance, and owner's costs on site, fuel and operation over a plant's lifetime, with provision for decommissioning and waste disposal.

It is important to note that capital cost figures quoted by reactor vendors, or which are general and not site-specific, will usually just be for EPC costs. This is because owner's costs will vary hugely, most of all according to whether a plant is Greenfield or at an established site, perhaps replacing an old plant.

There are several possible sources of variation, which preclude confident comparison of overnight, or EPC (Engineering, Procurement and Construction) capital costs-e.g. whether initial core load of fuel is included. Much more obvious is whether the price is for the nuclear island alone (Nuclear Steam Supply System) or the whole plant including turbines and generators-all the above figures include these. Further differences relate to site works such as cooling towers as well as land and permitting-usually they are all owners' costs as outlined earlier in this section. Financing costs are additional, adding typically around $30 \%$, and finally there is the question of whether cost figures are in current (or specified year) dollar values or in those of the year in which spending occurs.

### 20.2.3 Major Studies on Future Cost Competitiveness

There have been many studies carried out examining the economics of various future generation options, and the following are merely the most important and also focus on the nuclear element.

The 2010 OECD study Projected Costs of generating Electricity compared 2009 data for generating base-load electricity by 2015 as well as costs of power from renewables, and showed that nuclear power was very competitive at $\$ 30 / \mathrm{t} \mathrm{CO}_{2}$ cost and low discount rate. The study comprised data for 190 power plants from 17 OECD countries as well as some data from Brazil, China, Russia and South Africa. It used levelised lifetime costs with carbon price internalized (OECD only) and discounted cash flow at 5 and $10 \%$, as previously. The precise competitiveness of different base-load technologies depended very much on local circumstances and the costs of financing and fuels.

Nuclear overnight capital costs in OECD ranged from US\$ 1556/kW for APR1400 in South Korea through $\$ 3009$ for ABWR in Japan, $\$ 3382 / \mathrm{kW}$ for Gen III + in USA, \$ 3860 for EPR at Flamanville in France to $\$ 5863 / \mathrm{kW}$ for EPR in Switzerland, with world median $\$ 4100 / \mathrm{kW}$. Belgium, Netherlands, Czech Rep and Hungary were all over $\$ 5000 / \mathrm{kW}$. In China, overnight costs were $\$ 1748 / \mathrm{kW}$ for CPR-1000 and $\$ 2302 / \mathrm{kW}$ for AP1000, and in Russia $\$ 2933 / \mathrm{kW}$ for VVER-1150. EPRI (USA) gave $\$ 2970 / \mathrm{kW}$ for APWR or ABWR Eurelectric gave $\$ 4724 / \mathrm{kW}$ for EPR. OECD black coal plants were costed at $\$ 807-2719 / \mathrm{kW}$, those with carbon capture and compression (tabulated as CCS, but the cost not including storage) at \$ 3223-5811/kW, brown coal \$ 1802-3485, gas plants \$ 635-1747/kW and onshore wind capacity \$ $1821-3716 / \mathrm{kW}$. (Overnight costs were defined here as EPC, owner's costs and contingency, but excluding interest during construction) (Table 20.2).

Table 20.2 OECD electricity generating cost projections for year 2010 on-5 \% discount rate, cents/kWh. (Source: [1])

| Country | Nuclear | Coal | Coal with <br> CCS | Gas CCGT | Onshore wind |
| :--- | :--- | :--- | :--- | :--- | :---: |
| Belgium | 6.1 | 8.2 | - | 9.0 | 9.6 |
| Czech R | 7.0 | $8.5-9.4$ | $8.8-9.3$ | 9.2 | 14.6 |
| France | 5.6 | - | - | - | 9.0 |
| Germany | 5.0 | $7.0-7.9$ | $6.8-8.5$ | 8.5 | 10.6 |
| Hungary | 8.2 | - | - | - | - |
| Japan | 5.0 | 8.8 | - | 10.5 | - |
| Korea | $2.9-3.3$ | $6.6-6.8$ | - | 9.1 | - |
| Netherlands | 6.3 | 8.2 | - | 7.8 | 8.6 |
| Slovakia | 6.3 | 12.0 | - | - | - |
| Switzerland | $5.5-7.8$ | - | - | 9.4 | 16.3 |
| USA | 4.9 | $7.2-7.5$ | 6.8 | 7.7 | 4.8 |
| China | $3.0-3.6$ | 5.5 | - | 4.9 | $5.1-8.9$ |
| Russia | 4.3 | 7.5 | 8.7 | 7.1 | 6.3 |
| EPRI (USA) | 4.8 | 7.2 | - | 7.9 | 6.2 |
| Eurelectric | 6.0 | $6.3-7.4$ | 7.5 | 8.6 | 11.3 |

${ }^{\text {a }}$ For China and Russia: 2.5 c is added to coal and 1.3 c to gas as carbon emission cost to enable sensible comparison with other data in those fuel/technology categories, though within those countries coal and gas will in fact be cheaper than the Table above suggests

At $5 \%$ discount rate comparative costs are as shown above. Nuclear is comfortably cheaper than coal and gas in all countries. At $10 \%$ discount rate (below) nuclear is still cheaper than coal in all but the Eurelectric estimate and three EU countries, but in these three gas becomes cheaper still. Coal with carbon capture is mostly more expensive than either nuclear or paying the $\$ 30 / \mathrm{t}$ for $\mathrm{CO}_{2}$ emissions, though the report points out "great uncertainties" in the cost of projected CCS. Also, investment cost becomes a much greater proportion of power cost than with $5 \%$ discount rate (Table 20.3).

A 2004 report from the University of Chicago, funded by the US Department of Energy, compared the levelised power costs of future nuclear, coal, and gas-fired power generation in the USA. Various nuclear options were covered, and for an initial ABWR or AP1000 they range from 4.3 to 5.0 cents $/ \mathrm{kWh}$ on the basis of overnight capital costs of $\$ 1200$ to $1500 / \mathrm{kW}$, 60 year plant life, 5 year construction and $90 \%$ capacity. Coal gives $3.5-4.1$ cents $/ \mathrm{kWh}$ and gas (CCGT) $3.5-4.5$ cents $/ \mathrm{kWh}$, depending greatly on fuel price.

The levelised nuclear power cost figures include up to $29 \%$ of the overnight capital cost as interest, and the report notes that up to another $24 \%$ of the overnight capital cost needs to be added for the initial unit of a first-of-a-kind advanced design such as the AP1000, defining the high end of the range above. For more advanced plants such as the EPR or SWR1000, overnight capital cost of $\$ 1800 / \mathrm{kW}$ is as-

Table 20.3 OECD electricity generating cost projections for year 2010 on- $10 \%$ discount rate, cents/kWh. (Source: [1])

| Country | Nuclear | Coal | Coal with <br> CCS | Gas CCGT | Onshore wind |
| :--- | :--- | :--- | :--- | :--- | :---: |
| Belgium | 10.9 | 10.0 | - | $9.3-9.9$ | 13.6 |
| Czech R | 11.5 | $11.4-13.3$ | $13.6-14.1$ | 10.4 | 21.9 |
| France | 9.2 | - | - | - | 12.2 |
| Germany | 8.3 | $8.7-9.4$ | $9.5-11.0$ | 9.3 | 14.3 |
| Hungary | 12.2 | - | - | - | - |
| Japan | 7.6 | 10.7 | - | 12.0 | - |
| Korea | $4.2-4.8$ | $7.1-7.4$ | - | 9.5 | - |
| Netherlands | 10.5 | 10.0 | - | 8.2 | 12.2 |
| Slovakia | 9.8 | 14.2 | - | - | - |
| Switzerland | $9.0-13.6$ | - | - | 10.5 | 23.4 |
| USA | 7.7 | $8.8-9.3$ | 9.4 | 8.3 | 7.0 |
| China | $4.4-5.5$ | 5.8 | - | 5.2 | $7.2-12.6$ |
| Russia | 6.8 | 9.0 | 11.8 | 7.8 | 9.0 |
| EPRI (USA) | 7.3 | 8.8 | - | 8.3 | 9.1 |
| Eurelectric | 10.6 | $8.0-9.0$ | 10.2 | 9.4 | 15.5 |

${ }^{\text {a }}$ For China and Russia: 2.5 c is added to coal and 1.3 c to gas as carbon emission cost to enable sensible comparison with other data in those fuel/technology categories, though within those countries coal and gas will in fact be cheaper than the Table above suggests
sumed and power costs are projected beyond the range above. However, considering a series of eight units of the same kind and assuming increased efficiency due to experience which lowers overnight capital cost, the levelised power costs drop $20 \%$ from those quoted above and where first-of-a-kind engineering costs are amortized (e.g. the $\$ 1500 / \mathrm{kW}$ case above), they drop $32 \%$, making them competitive at about 3.4 cents/kWh (Table 20.4).

The study also shows that with a minimal carbon control cost impact of 1.5 cents/ kWh for coal and 1.0 cents/kWh for gas superimposed on the above figures, nuclear is even more competitive. But more importantly it goes on to explore other policy options which would offset investment risks and compensate for first-of-a-kind engineering costs to encourage new nuclear investment, including investment tax breaks, and production tax credits phasing out after 8 years. (US wind energy gets a production tax credit which, has risen to 2.1 cents $/ \mathrm{kWh}$.)

In May 2009, an update of a heavily referenced 2003 MIT study was published. This said that "since 2003 construction costs for all types of large-scale engineered projects have escalated dramatically. The estimated cost of constructing a nuclear power plant has increased at a rate of $15 \%$ per year heading into the current economic downturn. This is based both on the cost of actual builds in Japan and Korea and on the projected cost of new plants planned for in the United States. Capital costs for both coal and natural gas have increased as well, although not by as much.

Table 20.4 Nuclear plant: projected electricity costs (cents/kWh). (Source: [1])

| Overnight capital cost $\$ / \mathrm{kW}$ | 1200 | 1500 | 1800 |  |
| :--- | :--- | :--- | :--- | :--- |
| First unit | 7 year build, 40 year life | 5.3 | 6.2 | 7.1 |
|  | 5 year build, 60 year life | 4.3 | 5.0 | 5.8 |
| Fourth unit | 7 year build, 40 year life | 4.5 | 4.5 | 5.3 |
|  | 5 year build, 60 year life |  |  |  |
| Eighth unit | 7 year build, 40 year life | 3.7 | 3.7 | 4.3 |
|  | 5 year build, 60 year life $^{\mathrm{a}}$ | 3.4 | 4.2 | 4.9 |
|  |  | 3.4 | 4.0 |  |

${ }^{\text {a }}$ calculated from above data

The cost of natural gas and coal that peaked sharply is now receding. Taken together, these escalating costs leave the situation [of relative costs] close to where it was in 2003." The overnight capital cost was given as $\$ 4000 / \mathrm{kW}$, in 2007 dollars. Applying the same cost of capital to nuclear as to coal and gas, nuclear came out at 6.6 cents $/ \mathrm{kWh}$, coal at 8.3 cents and gas at 7.4 cents, assuming a charge of $\$ 25 / \mathrm{t}$ CO 2 on the latter.

Escalating capital costs were also highlighted in the US Energy Information Administration (EIA) 2010 report "Updated Capital Cost Estimates for Electricity Generation Plants". The US cost estimate for new nuclear was revised upwards from $\$ 3902 / \mathrm{kW}$ by $37 \%$ to a value of $\$ 5339 / \mathrm{kW}$ for 2011 by the EIA. This is in contrast to coal, which increases by only $25 \%$, and gas, which actually shows a $3 \%$ decrease in cost. Renewables estimates show solar dropping by $25 \%$ while onshore wind increases by about $21 \%$. The only option to increase faster than nuclear is offshore wind at $49 \%$, while the increase in coal with CCS is about the same as nuclear. In the previous year's estimate, EIA assumed that the cost of nuclear would drop with time and experience, and that by 2030 the cost of nuclear would drop by almost $30 \%$ in constant dollars.

By way of contrast, China is stating that it expects its costs for plants under construction to come in at less than $\$ 2000 / \mathrm{kW}$ and that subsequent units should be in the range of $\$ 1600 / \mathrm{kW}$. These estimates are for the AP1000 design, the same as used by EIA for the USA. This would mean that an AP1000 in the USA would cost about three times as much as the same plant built in China. Different labor rates in the two countries are only part of the explanation. Standardized design, numerous units being built, and increased localization are all significant factors in China.

The French Energy and Climate Directorate published in November 2008 an update of its earlier regular studies on relative electricity generating costs. This shied away from cash figures to a large extent due to rapid changes in both fuel and capital, but showed that at anything over 6000 h production per year ( $68 \%$ capacity factor), nuclear was cheaper than coal or gas combined cycle (CCG). At $100 \%$ capacity CCG was $25 \%$ more expensive than nuclear. At less than $4700 \mathrm{~h} /$ year CCG was cheapest, all without taking $\mathrm{CO}_{2}$ cost into account.

With the nuclear plant, fixed costs were almost $75 \%$ of the total, with CCG they were less than $25 \%$ including allowance for $\mathrm{CO}_{2}$ at $\$ 20 / \mathrm{t}$. Other assumptions were $8 \%$ discount rate, gas at $6.85 \$ / \mathrm{GJ}$, coal at EUR $60 / \mathrm{t}$. The reference nuclear unit is the EPR of 1630 MWe net, sited on the coast, assuming all development costs being borne by Flamanville 3, coming on line in 2020 and operating only 40 of its planned 60 years. Capital cost apparently EUR $2000 / \mathrm{kW}$. Capacity factor $91 \%$, fuel enrichment is $5 \%$, burnup $60 \mathrm{GWd} / \mathrm{t}$ and used fuel is reprocessed with MOX recycle. In looking at overall fuel cost, uranium at $\$ 52 / \mathrm{lb}$ made up about $45 \%$ of it, and even though $3 \%$ discount rate was used for back-end, the study confirmed the very low cost of waste in the total-about $13 \%$ of fuel cost, mostly for reprocessing.

At the end of 2008 EdF updated the overnight cost estimate for Flamanville 3 EPR (the first French EPR, but with some supply contracts locked in before escalation) to EUR 4 billion in 2008 Euros (EUR 2434/kW), and electricity cost 5.4 cents/ kWh (compared with 6.8 cents $/ \mathrm{kWh}$ for CCGT and 7.0 cents $/ \mathrm{kWh}$ for coal, "with lowest assumptions" for $\mathrm{CO}_{2}$ cost). These costs were confirmed in mid 2009, when EdF had spent nearly EUR 2 Billion. In July 2010, EdF revised the overnight cost to about EUR 5 Billion.

In May 2008, South Carolina Electric and Gas Co. and Santee Cooper locked in the price and schedule of new reactors for their summer plant in South Carolina at $\$ 9.8$ billion. (The budgeted cost earlier in the process was $\$ 10.8$ billion, but some construction and material costs ended up less than projected.) The EPC contract for completing two 1117-MW AP1000s is with Westinghouse and the Shaw Group. Beyond the cost of the actual plants, the figure includes forecast inflation and owners' costs for site preparation, contingencies and project financing. The units are expected to be in commercial operation in 2016 and 2019.

In November 2008, Duke Energy Carolinas raised the cost estimate for its Lee plant ( $2 \times 1117$ MWe AP1000) to $\$ 11$ billion, excluding finance and inflation, but apparently including other owners costs.

In November 2008, TVA updated its estimates for Bellefonte units 3 and 4 for which it had submitted a COL application for twin AP1000 reactors, total 2234 MWe. It said that overnight capital cost estimates ranged from \$ 2516 to 4649/ kW for a combined construction cost of $\$ 5.6-10.4$ billion. Total cost to the owners would be \$ 9.9-17.5 billion.

In 2013, the Nuclear Energy Institute announced the results of its financial modeling of comparative costs in the USA, based on figures from the US Energy Information Administration's 2013 Annual Energy Outlook. NEI assumed $5 \%$ cost of debt, $15 \%$ return on equity and a $70 / 30$ debt equity capital structure. The figures are tabulated below. The report went on to show that with nuclear plant license renewal beyond 60 years, power costs would be $\$ 53-60 / \mathrm{MWh}$ (Table 20.5).

Table 20.5 NEI 2013 financial modeling

|  | EPC cost (per kW) | Capacity (\%) | Electricity cost <br> (per MWh) |
| :--- | :--- | :--- | :--- |
| Gas combined cycle, gas @ \$ 3.70/GJ | $\$ 1000$ | 90 | $\$ 44.00$ |
| Gas combined cycle, gas @ \$ 5.28/GJ | $\$ 1000$ | 90 | $\$ 54.70$ |
| Gas combined cycle, gas @ \$ 6.70/GJ | $\$ 1000$ | 90 | $\$ 61.70$ |
| Gas combined cycle, gas @ \$ 6.70/GJ, <br> $50-50$ debt-equity | $\$ 1000$ | 90 | $\mathrm{c} \$ 70$ |
| Supercritical pulverised coal, <br> 1300 MWe | $\$ 3000$ | 85 | $\$ 75.70$ |
| Integrated gasification combined cycle <br> coal, 1200 MWe | $\$ 3800$ | 85 | $\$ 94.30$ |
| Nuclear, 1400 MWe (EIA's EPC <br> figure) | $\$ 5500$ | 90 | $\$ 121.90$ |
| Nuclear, 1400 MWe (NEI suggested <br> EPC figure) | $\$ 4500-5000$ | 30 | 112.90 |
| Wind farm, 100 MWe | $\$ 1000$ | $85-90$ |  |

$5 \%$ cost of debt, $15 \%$ return on equity and a $70-30$ debt equity capital structure

Regarding bare plant costs, some recent figures apparently for overnight capital cost (or Engineering, Procurement and Construction-EPC-cost) quoted from reputable sources but not necessarily comparable are:

- EdF Flamanville EPR: EUR 4 billion/\$ 5.6 billion, so EUR 2434/kW or \$ 3400/ kW
- Bruce Power Alberta $2 \times 1100$ MWe ACR, $\$ 6.2$ billion, so $\$ 2800 / \mathrm{kW}$
- CGNPC Hongyanhe $4 \times 1080$ CPR-1000 $\$ 6.6$ billion, so $\$ 1530 / \mathrm{kW}$
- AEO Novovronezh 6 and 72136 MWe net for $\$ 5$ billion, so $\$ 2340 / \mathrm{kW}$
- AEP Volgodonsk 3 and $4,2 \times 1200$ MWe VVER $\$ 4.8$ billion, so $\$ 2000 / \mathrm{kW}$
- KHNP Shin Kori 3 and 41350 MWe APR-1400 for $\$ 5$ billion, so $\$ 1850 / \mathrm{kW}$
- FPL Turkey Point $2 \times 1100$ MWe AP1000 \$ 2444-3582/kW
- Progress Energy Levy county $2 \times 1105$ MWe AP1000 \$ 3462/kW
- NRG South Texas $2 \times 1350$ MWe ABWR $\$ 8$ billion, so $\$ 2900 / \mathrm{kW}$
- ENEC for UAE from Kepco, $4 \times 1400$ MWe APR-1400 \$ 20.4 billion, so $\$ 3643 /$ kW

A striking indication of the impact of financing costs is given by Georgia Power, which said in mid 2008 that twin 1100 MWe AP1000 reactors would cost $\$ 9.6$ billion if they could be financed progressively by ratepayers, or $\$ 14$ billion if not. This gives $\$ 4363$ or $6360 / \mathrm{kW}$ including all other owners' costs.

Finally, in the USA the question of whether a project is subject to regulated cost recovery or is a merchant plant is relevant, since it introduces political, financial and tactical factors. If the new build cost escalates (or is inflated), some cost recovery may be possible through higher rates can be charged by the utility if those costs are deemed prudent by the relevant regulator. By way of contrast, a merchant plant has to sell all its power competitively, so must convince its shareholders that it has a good economic case for moving forward with a new nuclear unit.

### 20.2.4 Operations and Maintenance (O\&M) Costs

This is the annual cost associated with the operation, maintenance, administration, and support of a nuclear power plant. Included are costs related to labor, material and supplies, contractor services, licensing fees, and miscellaneous costs such as employee expenses and regulatory fees. The average non-fuel O\&M cost for a nuclear power plant in 2011 was 1.51 cents $/ \mathrm{kWh}$.

These costs are much easier to quantify and are independently verified as they relate directly to the profitability of the Utilities, which operate them. Any discrepancies are soon discovered through accounting audits. Companies that operate the USA's nuclear power reactors have made excellent profits over the last 5 years. The US Nuclear Power industry has at last lived up to its promise made in 1970's to produce electricity reliably and cheaply. Since 1987 the cost of producing electricity has decreased from 3.63 to 1.68 cents $/ \mathrm{kWh}$ in 2004 and plant availability has increased from 67 to over $90 \%$. The operating cost includes a charge of 0.2 cents/ kWh to fund the eventual disposal of waste from the reactor and for decommissioning the reactor. The price of Uranium Ore contributes approximately 0.05 cents/ kWh.

As part of management of nuclear power plant operations, it is clear from both the French and US experience that pro-active Industry organizations are vital in obtaining efficient plant utilization and in minimizing running costs. In the US in the late 1980s and early 1990s there was little pooling of knowledge and experience amongst Nuclear Power Operators. A combination of industry inexperience, the lack of standardized designs and the fragmentation of the industry caused this.

Once again, this was in contrast to the French experience where the uniform design and the single state-owned organization allowed knowledge to be more easily shared.

The US industry has since gone through several cycles of consolidation and the operation of the USA's fleet of Nuclear Reactors has mostly been taken over by specialist companies that specialize in this activity. In addition, the industry has learned the benefits of pooling knowledge. This combination has demonstrably improved the performance of the US reactor fleet and is reflected in the share price of the nuclear operation companies.

### 20.3 Production Costs

Operation and Maintenance (O\&M) and Fuel Costs are part of production cost at a power plant. Since 2001, nuclear power plants have achieved the lowest production costs between coal, natural gas and oil.

Fuel costs make up $30 \%$ of the overall production costs of nuclear power plants. Fuel costs for coal, natural gas and oil, however, make up about $80 \%$ of the production costs. The following charts and plots are summary of all costs for United States

Fig. 20.4 Fuel as a percentage of electric power industry production costs (2011)
electric companies that, one need to take under consideration in order to own and operate a power plant to generate electricity.

- Fuel as a Percentage of Electric Power Industry Production Costs
- U.S. Nuclear Industry Production Costs by Quartile
- U.S. Electricity Production Costs
- U.S. Electricity Production Costs and Components (Table)

Note The following bar chart shows the percentage of electric industry production costs attributable to fuel for nuclear, coal, gas and oil in 2011 (Fig. 20.4).
Note The following bar chart depicts a 3-year rolling average of production costs by quartile in 2011 cents/kWh between 2007 and 2011 (Fig. 20.5).

Note The following line graph shows average U.S. electricity production costs between 1995 and 2011 for nuclear, coal, gas, and oil (Fig. 20.6).

US figures for 2013 published by NEI show the general picture, with nuclear generating power at 1.87 cents $/ \mathrm{kW}$ (See Fig. 20.7).
Note The data given in Fig. 20.7 refer to fuel plus the operation and maintenance costs only; they exclude capital, since this varies greatly among utilities and states, as well as with the age of the plant.

Note The following table shows annual average U.S. electricity production, operations and maintenance (O\&M), and fuel costs-from 1995 to 2011 for nuclear, coal, gas and oil (Table 20.6).

### 20.3.1 Costs Related to Waste Management

In the USA, Nuclear Power operators are charged 0.1 cents $/ \mathrm{kWh}$ for the disposal of Nuclear Waste. In Sweden, this cost is 0.13 US cents $/ \mathrm{kWh}$. These Countries have utilized these funds to pursue research into Geologic disposal of waste and both now have mature proposals for the task.

In France, the cost of waste disposal and decommissioning is estimated to be $10 \%$ of the construction cost. So far, provisions of 71 billion Euros have been acquired for this from the sale of electricity. As part of the cost related to waste management, two following important key issues should be take under consideration and they are;

1. Committed Funds for the Nuclear Waste Management
$\$ 35.8$ billion ( $1 / 10$ th of a cent per kWh of electricity generated at nuclear power plants plus interest since 1983). Of the $\$ 35.8$ billion, $\$ 10.8$ billion has been spent. Payments to the Nuclear Waste Fund are included in the fuel costs. See the table below (Table 20.7).
Table 20.6 U.S. electricity production costs and components (1995-2011). (Source: Ventyx velocity suite)

| Year | Total production costs |  |  |  | Operations and maintenance costs |  |  |  | Fuel costs |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## 2. Estimated Cost of Decommissioning

The US industry average cost for decommissioning a power plant is USD $\$ 300$ million. The funds for this activity are accumulated in the operating cost of the plant. The French and Swedish Nuclear Industries expect decommissioning costs to be $10-15 \%$ of the construction costs and budget this into the price charged for electricity. On the other hand, the British decommissioning costs have been projected to be around 1 billion pounds/reactor. Cleaning up the Hanford Nuclear Weapons reactor is budgeted at $\$ 5.6$ billion but may cost two to three times this much.
Per plant \$ 300-500 million-includes estimated radiological, used fuel and site restoration costs-about \$ 300 million, $\$ 100-150$ million and $\$ 50$ million, respectively.
Industry $\$ 31.9$ billion—about \$ 300 million/reactor. Decommissioning costs are not included in production costs.
Of the total \$ 31.9 billion estimated to decommission all eligible nuclear plants at an average cost of $\$ 300$ million, $\$ 22.5$ billion or about two-thirds have already been funded. The remaining $\$ 9.4$ billion will be funded over the next 20 years (the average nuclear plant is licensed for 40 years).

### 20.3.2 Life-Cycle Costs (U.S. Figures)

These are the estimated total costs versus the electricity output over the lifetime of a new power plant. Costs include construction, operations and maintenance, fuel and decommissioning. For life cycle costs of nuclear, coal, and gas, NEI's white paper, The Cost of New Generating Capacity in Perspective is a good source to refer to it.

Although nuclear project costs are undeniably large, total project cost does not measure a project's economic viability. The relevant metric is the cost of the electricity produced by the nuclear project relative to alternative sources of electricity and relative to the market price of electricity at the time the nuclear plant comes into service. As illustrated by the detailed financial modeling cited above, new nuclear power plants can be competitive, even with total project costs exceeding \$6000/ kWe, including EPC and owners' costs and financing costs.

### 20.3.3 Construction Costs

Construction costs are very difficult to quantify but dominate the cost of Nuclear Power. The main difficulty is that third generation power plants now proposed are claimed to be both substantially cheaper and faster to construct than the secondgeneration power plants now in operation throughout the world. The Nuclear Industry says its learned the lessons of economy-of-volume demonstrated by the French Nuclear Program, and that these will be employed for the new power plants. In 2005, Westinghouse claimed its Advanced PWR reactor, the AP1000, will cost USD \$ $1400 / \mathrm{kW}$ for the first reactor and fall in price for subsequent reactors. A
more technical description is here. Proponents of the CANDU ACR and Gas Cooled pebble bed reactors made similar or stronger claims. However, the first wave of new generation plants in the USA is expected to cost over $\$ 3500 / \mathrm{kW}$ of capacity. Additional costs increase the price even more.

The General Electric ABWR was the first third generation power plant approved. The first two ABWR's were commissioned in Japan in 1996 and 1997. These took just over 3 years to construct and were completed on budget. Their construction costs were around $\$ 2000 / \mathrm{kW}$. Two additional ABWR's are being constructed in Taiwan. However, these have faced unexpected delays and are now at least 2 years behind schedule.

Meanwhile the Chinese Nuclear Power Industry has won contracts to build new plants of their own design at capital costs reported to be $\$ 1500$ and $1300 / \mathrm{kW}$ at sites in Southeast and North-East China. If completed on budget these facilities will be formidable competitors to the Western Nuclear Power Industry.

Given the history of Nuclear Plant construction in the U.S.A., the financial industry sees the construction of the new generation of reactors as a risky investment and demands a premium on capital lent for the purpose. The Energy Bill recently passed by the US Congress assumes this risk and provides production credits of 1.8 cents $/ \mathrm{kWh}$ for the first 3 years of operation. This subsidy is equivalent to what is paid to Wind Power companies and is designed to encourage new nuclear reactor construction in the USA.

If the AP1000 lives up to, its promises of $\$ 1000 / \mathrm{kW}$ construction cost and 3 year construction time, it will provide cheaper electricity than any other Fossil Fuel based generating facility, including Australian Coal power, even with no sequestration charges. This promise appears to have been unfulfilled. The cost of the first AP1000 is expected to be over $\$ 3500 / \mathrm{kW}$.

### 20.4 Comparing the Economics of Different Forms of Electricity Generation

A 2010 OECD study Projected Costs of generating Electricity set out some actual costs of electricity generation, from which the following figures are taken (Table 20.8):

It is important to distinguish between the economics of nuclear plants already in operation and those at the planning stage. Once capital investment costs are effectively "sunk", existing plants operate at very low costs and are effectively "cash machines". Their operations and maintenance (O\&M) and fuel costs (including used fuel management) are, along with hydropower plants, at the low end of the spectrum and make them very suitable as base-load power suppliers. This is irrespective of whether the investment costs are amortized or depreciated in corporate financial accounts. This cost is based on, assuming the forward or marginal costs of operation are below the power price and the plant will operate.

Table 20.8 Actual costs of electricity (US cents $/ \mathrm{kWh}$ ). (Source: [1], projected costs of generating electricity, Tables 3.7 this shows the levelized cost, which is the average cost of producing electricity including capital, finance, owner's costs on site, fuel and operation over a plant's lifetime)

| Technology | Region or country | At $10 \%$ discount rate | At 5 \% discount rate |
| :--- | :--- | :--- | :--- |
| Nuclear | OECD Europe | $8.3-13.7$ | $5.0-8.2$ |
|  | China | $4.4-5.5$ | $3.0-3.6$ |
| Black coal with CCS | OECD Europe | 11.0 | 8.5 |
| Brown coal with CCS | OECD Europe | $9.5-14.3$ | $6.8-9.3$ |
| CCGT with CCS | OECD Europe | 11.8 | 9.8 |
| Large hydro-electric | OECD Europe | $14.0-45.9$ | $7.4-23.1$ |
|  | China: Three gorges | 5.2 | 2.9 |
|  | China: other | $2.3-3.3$ | $1.2-1.7$ |
| Onshore wind | OECD Europe | $12.2-23.0$ | $9.0-14.6$ |
|  | China | $7.2-12.6$ | $5.1-8.9$ |
| Offshore wind | OECD Europe | $18.7-26.1$ | $13.8-18.8$ |
| Solar photovoltaic | OECD Europe | $38.8-61.6$ | $28.7-41.0$ |
|  | China | $18.7-28.3$ | $12.3-18.6$ |

### 20.5 System Cost

System Costs are external to the building and operation of any power plant, but must be paid by the electricity consumer, usually as part of the transmission and distribution cost. From a government policy point of view they are just as significant as the actual generation cost, but are seldom factored in to comparisons among different supply options, especially comparing base-load with dispersed renewables. In fact that the total system cost should be analysed when introducing new power generating capacity on the grid. Any new power plant likely requires changes to the grid, and hence incurs a significant cost for power supply that must be accounted for. But this cost for large base-load plants is small compared with integrating renewables to the grid.

See also paper on Electricity Transmission Grids.

### 20.6 External costs

External costs are not included in the building and operation of any power plant, and are not paid by the electricity consumer, but by the community generally. The external costs are defined as those actually incurred in relation to health and the environment, and which are quantifiable but not built into the cost of the electricity.

The report of a major European study of the external costs of various fuel cycles, focusing on coal and nuclear, was released in mid 2001-ExternE. It shows that in clear cash terms nuclear energy incurs about one tenth of the costs of coal. If these
costs were in fact included, the EU price of electricity from coal would double and that from gas would increase $30 \%$. These are without attempting to include the external costs of global warming.

The European Commission launched the project in 1991 in collaboration with the US Department of Energy, and it was the first research project of its kind "to put plausible financial figures against damage resulting from different forms of electricity production for the entire EU". The methodology considers emissions, dispersion and ultimate impact. With nuclear energy the risk of accidents is factored in along with high estimates of radiological impacts from mine tailings (waste management and decommissioning being already within the cost to the consumer). Nuclear energy averages 0.4 -euro cents $/ \mathrm{kWh}$, much the same as hydro, coal is over 4.0 cents (4.1-7.3), gas ranges $1.3-2.3$ cents and only wind shows up better than nuclear, at $0.1-0.2$ cents $/ \mathrm{kWh}$ average. NB these are the external costs only.

As part of Energy Subsidies and External Costs, the following points are in process

- Substantial amounts have been invested in energy R\&D over the last 30 years. Much of this has been directed at developing nuclear energy-which now supplies $14 \%$ of world electricity.
- Today, apart from Japan and France, there is about twice as much R\&D investment in renewables than nuclear, but with rather less to show for it and with less potential for electricity supply.
- Nowhere in the world is nuclear power subsidized per unit of production. In some countries however it is taxed because production costs are so low.
- Renewables receive heavy direct subsidies in the market, fossil fuels receive indirect subsidies in their waste disposal as well as some direct subsidies.
- Nuclear energy fully accounts for its waste disposal and decommissioning costs in financial evaluations.

There are three main areas where, broadly speaking, subsidies or other support for energy may apply:

1. Government R\&D for particular technologies,
2. Subsidies for power generation per unit of production (or conceivably per unit of capacity), including costs imposed on disincentivised alternatives, and the
3. Allowance of external costs, which are either paid by the community at large or picked up later by governments.

In recent years, some controversy has surrounded the question of the relative levels of R\&D expenditure on nuclear energy and on new renewables (essentially technologies to harness wind and solar energy). Unfortunately, IEA data available for the first edition of this paper is no longer available, hence some of the following is dated. There are some plots and data resources presented here, for more detailed, and update information readers should refer themselves to web site of world nuclear organization at http://www.world-nuclear.org

Serbia published new FITs early in 2013, which will be valid for 12 years from project commissioning and will be corrected annually every February in line

Table 20.9 Expenditure by IEA countries on energy R\&D

| Year | 1975 | 1980 | 1985 | 1990 | 1995 | 2000 | 2005 |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | :---: |
| Conservation | 333 | 955 | 725 | 510 | 1240 | 1497 | 1075 |
| Fossil fuels | 587 | 2564 | 1510 | 1793 | 1050 | 612 | 1007 |
| Renewables | 208 | 1914 | 843 | 563 | 809 | 773 | 1113 |
| Nuclear <br> fission | 4808 | 6794 | 6575 | 4199 | 3616 | 3406 | 3168 |
| Nuclear <br> fusion | 597 | 1221 | 1470 | 1055 | 1120 | 893 | 715 |
| Other | 893 | 1160 | 787 | 916 |  |  |  |
| Total energy <br> R\&D | 7563 | 15034 | 12186 | 9394 | 9483 | 9070 | 9586 |

| Total: <br> excluding <br> Japan | 6055 | 11596 | 8448 | 5842 | 5811 | 5349 | 5681 |

Energy R\&D Expenditures

Fig. 20.8 Energy research and development expenditures
with the level of inflation in the Eurozone. They include EUR 9.2 cents $/ \mathrm{kWh}$ for wind and 16.25 cents $/ \mathrm{kWh}$ for solar, but with low caps on the capacity covered (Table 20.9) (Fig. 20.8).

The above table and graph are from the OECD International Energy Agency's database (IEA, 2001 and 2006) regarding government expenditure in the 26 IEA member countries. The database does not include information about private companies' expenditure, nor funds spent by non-IEA countries, such as China, Russia or India.

The total amount of energy R\&D expenditure by governments of IEA countries rose in response to the oil price shocks of the early 1970s and then fell away as associated concerns abated, with the conspicuous exception of Japan. Private R\&D investment has apparently followed the same pattern outside Japan.

Table 20.10 Expenditure by IEA countries on fission R\&D. (2005 US\$ millions)

|  | UK | France | Japan | USA | Other IEA <br> countries | All IEA <br> countries |
| :--- | ---: | :--- | :--- | :--- | :--- | :--- |
| 1975 | 929 | 0 | 763 | 2164 | 952 | 4808 |
| 1980 | 741 | 0 | 2098 | 2410 | 1160 | 6794 |
| 1985 | 638 | 895 | 2259 | 1241 | 1542 | 6575 |
| 1990 | 253 | 555 | 2298 | 737 | 356 | 4199 |
| 1995 | 17 | 599 | 2455 | 103 | 442 | 3616 |
| 2000 | 0 | 666 | 2393 | 39 | 308 | 3406 |
| 2005 | 4 | $?$ | 2398 | 171 | $?$ | 3168 |

Throughout the period, the expenditure on nuclear fission dominated the overall figures, though falling from $64 \%$ of the total in 1975 to $33 \%$ in 2005. However, Table 20.10 shows that in most IEA countries (apart from Japan), government R\&D expenditure on nuclear fission fell significantly through the 1990s, to trivial levelsin fact below that spent on renewables, which has averaged about US\$ 700 million per year for the last two decades but is now rising (Table 20.10).

IEA data shows R\&D on nuclear fission peaking around 1980 and after 1985 declining steadily to less than half that level. Since 1990, Japan alone has been responsible for some two thirds of IEA R\&D expenditure on nuclear fission, with France accounting for most of the remainder. If the French and Japanese figures are excluded, fission $R \& D$ expenditure in the rest of the IEA countries totaled US\$ 308 million in 2000 (Fig. 20.9).

IEA Energy R\&D Expenditures

Fig. 20.9 IEA energy research and development expenditures

Table 20.11 Other US DOE R\&D data is as follows (\$ millions). (EIA 2008 and 2011)

| Years | Currency | Renewables | Coal | Nuclear | End use |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $1988-2007$ | $\$ 2007$ | 6271 | 7593 | 13,500 | 5737 |
| FY 2007 | $\$ 2010$ | 717 | 582 | 1017 | 509 |
| FY 2010 | $\$ 2010$ | 1409 | 663 | 1169 | 832 |

US Department of Energy figures show the renewables total in the US R\&D budget as $\$ 505$ million in FY2007 and energy efficiency $\$ 676$ million, compared with nuclear power at $\$ 300$ million (double the 2003 level) and fossil fuels at $\$ 397$ million. Nuclear fusion is additional at \$ 319 million (Table 20.11).

In FY 2007, relating the support to actual energy produced, the figures are: wind 2.34 cents $/ \mathrm{kWh}$, "clean coal" 2.98 cents $/ \mathrm{kWh}$, gas, coal 0.044 cents $/ \mathrm{kWh}$, nuclear 0.16 cents/kWh.

Outside the IEA, Russia, India and China have substantial nuclear fission programs and as the European Union also funds an amount of fission R\&D, the worldwide totals for fission will be rather higher than the figure above. Nonetheless, given that the bulk of government-sponsored R\&D into nuclear fission focuses on waste management and other fuel cycle back-end processes, it is clear that little is being spent at present by governments on new reactor designs.

## Chapter 21 <br> Safety, Waste Disposal, Containment, and Accidents

The public acceptance of nuclear energy is still greatly dependent on the risk of radiological consequences in case of severe accidents. Such consequences were recently emphasized with the Fkushima-Daiichi accident in 2011. The nation's nuclear power plants are among the safest and most secure industrial facilities in the United States. Multiple layers of physical security, together with high levels of operational performance, protect plant workers, the public and the environment.

### 21.1 Safety

As a matter of fact, despite the highly-efficient prevention measures adopted for the current plants, some accident scenarios may, with a low probability, result in a severe accident, potentially leading to core melting, plant damage and dispersal of radioactive materials out of the plant containment.

Even if the Japanese power station was not equipped with the newest devices for the prevention or mitigation of severe accidents, Fukushima, as well as the Three Mile Island accident in 1979, confirmed the key role of the containment barrier in the significant mitigation of radioactive releases.

The improvement of the nuclear designs and the set-up of adequate accident management trategies require confinement structures and emergency system that must be properly dimensioned (configuration, choice of materials and cooling circuits), to guarantee the integrity of the safety barriers and avoid the release of radioactive gasses and aerosols to the outside environment.

In this chapter, schematics of typical nuclear power plants are preliminarily shown, together with the main concepts of nuclear reactions and the formation of radioactive isotopes.

The risk of radioactive release to the external environment because of accidents is then pointed out, in order to explain the reasons of safety criteria that characterize these kinds of installations.

Attention is paid to the needs of maintaining the structural integrity of both cooling circuits and confinement structures. Seismic analyses are cited, as well as the risk of containment building damaging due to over-pressurization in case of severe accident.
U.S. nuclear plants are well designed, operated by trained personnel, defended against attack and prepared in the event of an emergency and following measurements are taken under consideration;

1. Emergency Preparedness: Every nuclear power plant in the country has a detailed plan for responding in the event of an emergency. Operators test that plan regularly, with the participation of local and state emergency response organizations.
2. Operational Safety: Stringent federal regulation, automated, redundant safety systems and the industry's commitment to comprehensive safety procedures keep nuclear power plants and their communities safe.
3. Personnel Training and Screening: Operators receive rigorous training and must hold valid federal licenses. All nuclear power plant staff are subject to background and criminal history checks before they are granted access to the plant.
4. Plant Security: Each nuclear power plant has extensive security measures in place to protect the facility from intruders. Since Sept. 11, 2001, the nuclear energy industry has substantially enhanced security at nuclear plants.

An illustration of the area of a nuclear power plant protected by armed guards, physical barriers and surveillance equipment from top-level point of view is depicted below (Fig. 21.1).

### 21.2 Nuclear Waste Disposal

Most used fuel from nuclear power plants is stored in steel-lined concrete pools filled with water, or in airtight steel or concrete-and-steel containers as pictured below (Fig. 21.2).

Used nuclear fuel is a solid material safely stored at nuclear plant sites. This storage is only temporary - one component of an integrated used fuel management system that addresses all facets of storing, recycling and disposal. In summary all the measurements that are being looked at are as follows;

1. Integrated Used Fuel Management: Under an integrated management approach, used nuclear fuel will remain stored at nuclear power plants in the near term. Eventually, the government will recycle it and place the unusable end product in a deep geologic repository.
2. Low-Level Radioactive Waste: Low-level waste is a byproduct of the beneficial uses of a wide range of radioactive materials. These include electricity generation, medical diagnosis and treatment, and various other medical processes.

Fig. 21.1 Nuclear plant security zones. (Source NEI)

Fig. 21.2 Nuclear waste disposal container. (Source NEI)
3. Recycling Used Nuclear Fuel: The federal government plans to develop advanced recycling technologies to take full advantage of the unused energy in the used fuel and reduce the amount and toxicity of byproducts requiring disposal.
4. Storage of Used Nuclear Fuel: Currently, used nuclear fuel is stored at the nation's nuclear power plants in steel-lined, concrete pools or basins filled with water or in massive, airtight steel or concrete-and-steel canisters.
5. Transportation: The U.S. Department of Energy will transport used nuclear fuel to the repository by rail and road, inside massive, sealed containers that have undergone safety and durability testing.

Fig. 21.3 Aerial view of Yucca mountain. (Source NEI)
6. Repository Development: Under any used fuel management scenario, disposal of high-level radioactive byproducts in a permanent geologic repository is necessary.

The following image is the aerial view of Yucca Mountain, Nevada, site of national repository (Fig. 21.3).

### 21.3 Contamination

Environmental effects and impacts in recent years has been a main concerns of any major construction including new planning for deployment of nuclear power plant within United Sates or throughout the world. Therefore, before taking a nuclear power plant effects and impacts with environment, under consideration, it would be fruitful to have some understanding of contamination and what we mean, by environmental contamination both form nuclear and fossil fueled energy sources.

There is a synonymous common denominator between contamination and pollution yet from environmental point of view there is distinction between them. Introduction of a foreign substance within environment can be known as contamination, while pollution is a level of contamination, which is harmful to human and its environment.

Every human being is continuously exposed to different forms of radiation every moment of their life. In fact, the use of radiation in medicine, electricity generation and many other common applications has improved, extended and saved the
lives of millions of Americans. Studies by the United Nations Scientific Committee on the Effects of Atomic Radiation, the National Research Council's BEIR VII study group and the National Council on Radiation Protection and Measurements all show that the risk associated with low-dose radiation from natural and manmade sources, including nuclear power plants, is extremely small. Researchers with the U.S. Department of Energy's Lawrence Berkeley National Laboratory, through a combination of state-of-the-art time-lapse live imaging and mathematical modeling of a special line of human breast cells, found evidence that for low-dose levels of ionizing radiation, cancer risks may not be directly proportional to dose. The data show that at lower doses of ionizing radiation, DNA repair mechanisms work much better than at higher doses. This contradicts the standard model for predicting biological damage from ionizing radiation-the linear-no-threshold hypothesis or LNT-that holds that risk is directly proportional to dose at all levels of irradiation.

Nuclear power plants have controlled and monitored emissions of radiation, but the amount is extremely small and poses no threat to the public or the environment. The Nuclear Regulatory Commission reports that people living close to a nuclear power plant receive, at most, an additional 1 millirem of radiation exposure a year. To put this in perspective, 1 millirem is one thousandth of the radiation exposure from a single whole-body CAT scan. The average American is exposed to 620 millirem of radiation every year. Three hundred millirem comes from natural sources, such as cosmic rays, uranium in the Earth's crust and radon gas in the atmosphere. Most of the rest comes from medical procedures such as CAT scans and consumer products. The radiation exposure from living near a nuclear power plant is insignificant and is no threat to the health of the public. After more than 3600 reactor years of operation, there is no scientific or medical evidence that shows anyone has been harmed by the radiation from any of America's commercial nuclear energy facilities, including the accident at Three Mile Island 32 years ago.

After more than a half-century of radiological monitoring and medical research, there is no evidence linking U.S. nuclear energy plants to negative effects on the health of the public or workers. Claims that radioactivity from nuclear plants has caused negative health effects on public/workers, have been refuted by the United Nations Scientific Committee of the Effects of Atomic Radiation, National Research Council's BEIR VII study group, the National Cancer Institute, the American Cancer Society, the American Academy of Pediatrics, numerous state departments of health and other independent studies.

After 32 years, there is no evidence that the nation's worst nuclear power plant accident harmed a single person or had any negative effect on the environment. More than a dozen health studies and continuous environmental monitoring have found no effect on the health of the people or the environment around the Three Mile Island nuclear plant in Pennsylvania.

Radioactive materials from nuclear plants, including used nuclear fuel, are highly regulated, strictly controlled and monitored and can be safely stored indefinitely. No member of the public has ever been harmed by the handling, transportation, storage or disposal of any of the radioactive material from the nation's nuclear power plants.

Note At the same concentration, industrial waste products such as hydrogen cyanide and arsenic are more toxic to humans than any of the materials used or produced at a nuclear plant.

There is no evidence that any person has died because of radiation exposure associated with the accident at the Fukushima Daiichi nuclear facility. In Japan, a small group of nuclear workers received radiation doses that may increase the risk of cancer over their lifetimes, but none of the workers' exposure is considered life threatening. Protective actions being taken by the Japanese government, including long-term evacuation of nearby residents, area decontamination and extensive radiation monitoring, are expected to avert significant radiological health consequences among the citizens of Japan. In the United States, extensive radiation monitoring by the U.S. Environmental Protection Agency's national radiation monitoring network at American commercial nuclear power plants and U.S. Department of Energy facilities detected extremely low levels of radiation thousands of times below government limits that pose no threat to human health.

### 21.4 Accidents

Nuclear power reactors are repository of enormous fission products and possible potential for a major accidents whether natural disaster or manmade. Fortunately, there have been no such accidents to date.

In addition to engineering and procedures, which reduce the risk and severity of accidents, all plants have guidelines for Severe Accident Management or Mitigation (SAM). These conspicuously came into play after the Fukushima accident, where staff had immense challenges in the absence of power and with disabled cooling systems following damage done by the tsunami. The experience following that accident is being applied not only in design but also in such guidelines, and peer reviews on nuclear plants will focus more on these than previously.

In mid 2011, the IAEA Incident and Emergency Centre launched a new secure web-based communications platform to unify and simplify information exchange during nuclear or radiological emergencies. The Unified System for Information Exchange on Incidents and Emergencies (USIE) has been under development since 2009 but was actually launched during the emergency response to the accident at Fukushima.

At Fukushima Daiichi in March 2011 the three operating reactors shut down automatically, and were being cooled as designed by the normal residual heat removal system using power from the back-up generators, until the tsunami swamped them an hour later. The emergency core cooling systems then failed. Days later, a separate problem emerged as spent fuel ponds lost water. Detailed analysis of the accident continues, but the main results include more attention being given to siting criteria and the design of back-up power and post-shutdown cooling, as well as provision for venting the containment of that kind of reactor and other emergency management procedures.

Nuclear plants have Severe Accident Mitigation Guidelines (SAMG, or in Japan: SAG), and most of these, including all those in the USA, address what should be done for accidents beyond design basis, and where several systems may be disabled. See section below.

In 2007, the US NRC launched a research program to assess the possible consequences of a serious reactor accident. Its draft report was released nearly a year after the Fukushima accident had partly confirmed its findings. The State-of-the-Art Reactor Consequences Analysis (SOARCA) showed that a severe accident at a US nuclear power plant (PWR or BWR) would not be likely to cause any immediate deaths, and the risks of fatal cancers would be vastly less than the general risks of cancer. SOARCA's main conclusions fall into three areas: how a reactor accident progresses; how existing systems and emergency measures can affect an accident's outcome; and how an accident would affect the public's health. The principal conclusion is that existing resources and procedures can stop an accident, slow it down or reduce its impact before it can affect the public, but even if accidents proceed without such mitigation they take much longer to happen and release much less radioactive material than earlier analyses suggested.

This was borne out at Fukushima, where there was ample time for evacuation-3 days-before any significant radioactive releases.

The April 1986 disaster at the Chernobyl nuclear power plant in the Ukraine was the result of major design deficiencies in the RBMK type of reactor, the violation of operating procedures and the absence of a safety culture. One peculiar feature of the RBMK design was that coolant failure could lead to a strong increase in power output from the fission process (positive void coefficient). However, this was not the prime cause of the Chernobyl accident.

The accident destroyed the reactor and killed 56 people, 28 of whom died within weeks from radiation exposure. It also caused radiation sickness in a further 200300 staff and firefighters, and contaminated large areas of Belarus, Ukraine, Russia and beyond. It is estimated that at least $5 \%$ of the total radioactive material in the Chernobyl-4 reactor core was released from the plant, due to the lack of any containment structure. Most of this was deposited as dust close by. Some was carried by wind over a wide area.

About 130,000 people received significant radiation doses (i.e. above internationally accepted ICRP limits) and continue to be monitored. About 4000 cases of thyroid cancer in children have been linked to the accident. Most of these were curable, though about nine were fatal. No increase in leukemia or other cancers have yet shown up, but some is expected. The World Health Organization is closely monitoring most of those affected.

The Chernobyl accident was a unique event and the only time in the history of commercial nuclear power that radiation-related fatalities occurred.

The destroyed unit 4 was enclosed in a concrete shelter, which now requires remedial work.

An OECD expert report on it concluded that "the Chernobyl accident has not brought to light any new, previously unknown phenomena or safety issues that are not resolved or otherwise covered by current reactor safety programs for commer-
cial power reactors in OECD Member countries". In other words, the concept of 'defense in depth' was conspicuous by its absence, and tragically shown to be vitally important.

Apart from the RBMK reactor design, an early Russian PWR design, the VVER-440/V-230, gave rise to concerns in Europe, and a program was initiated to close these down as a condition of EU accession, along with Lithuania's two RBMK units. See related papers on Early Soviet Reactors and EU Accession, and RBMK Reactors.

## Appendix A: Table and Graphs Compilations

The following tables provide samples of engineering data for materials of interest to Thermodynamics. For any detailed design work, more extensive handbooks should be consulted. The thermophysical property data for water, carbon dioxide and sodium were generated for this book. They represent the best fit to the latest physical measurements. More extensive tables are available from the National Institutes of Standards and Technology (NIST).

The Ideal Gas constant pressure specific heat is given by

$$
\theta=\left(\frac{T(K)}{100}\right)=\left(\frac{T\left({ }^{\circ} R\right)}{180}\right) \quad C_{p}=\sum_{i=0}^{i=4} C_{i}(\theta)^{i / 2}=\frac{\mathrm{kcal}}{\mathrm{kgmole}-K}=\frac{\mathrm{Btu}}{\mathrm{lbm}-{ }^{\circ} R} \quad C_{0}=C_{0}^{*}\left(\frac{\theta^{2}}{\theta^{2}+\tau}\right)
$$

## Index

## A

Absolute pressure, 12
Absolute zero, 16, 82, 184, 197
Acentric factor, 34
Adiabatic cooling, 125
Adiabatic Flame Temperature, 239, 240
Adiabatic heating, 125
Advanced Gas cooled Reactor (AGR), 452
Alternating Current (AC), 420
Amagat's law, 48
Argentina, 464
Atkinson Cycle, 366
Avogadro's Number, 45

## B

Back End Fuel Cycle, 497
Beattie-Bridgemen equation of state, 30
Benedict-Webb-Rubin (BWR) equation of state, 31
Boiling, 275, 279
Boiling Water reactor (BWR), 452
Boiling Water Reactor (BWR), 451
Boiling Water Reactors (BWR), 445
Brayton Cycle, 325, 329
Brazil, 464

## C

Canadian CANDU reactor, 448
Carnot Cycle, 377
Carnot engine, 156, 158, 159, 341, 342, 343
CAT scan, 549
Chemical fuels, 228
Chernobyl, 446, 551
Circuit Breakers, 428
Classical thermodynamics, 7, 8, 46, 57, 131, 213
Closed systems, 8

Coefficient of viscosity, 146, 149
Combustion, 229
Conduction, 82, 244
Contamination, 548
Control Centers, 431
Control cost, 528
Control volume, 10
Convection, 81, 82, 244, 253
Convention on the Organization for Economic
Co-operation and Development
(OECD), 522
Cooling towers, 443
cost, 524
Critical Heat Flux (CHF), 276
Critical Point, 21, 38
Cycle, 61, 62

## D

Dalton' s Law, 47
Dead state, 176, 178
Degenerate, 200
Density, 11
Department of Energy, 442
Diesel Cycle, 350
Direct Current (DC), 420

## E

Eastern Interconnects, 434
Effects of Atomic Radiation, 549
Electrical Grid System, 417
Energy interactions, 53
Energy transfer, 53
English (E) system, 5
Enriched fuel, 445
Enrico Fermi, 439
Enthalpy, 86, 113, 115, 117-119, 165, 215, 224, 235, 239

Entropy, 86, 160, 160, 162, 163, 165, 166, $169,170,198,197,206,207,210,216$, 218, 219, 326, 375, 377
Equation of state, 19, 22, 24, 25, 28-31, 33, $57,61,65,108,112,117,118,122$, 127, 217
Equivalent Air Cycle, 339
Ericsson Cycle, 361, 364
Euratom, 463
European Nuclear Energy Forum (ENEF), 492
European Pressurized-water Reactor (EPR), 489
European Sustainable Nuclear Industrial Initiative, 491
Europe (EU), 461
Evaluation Methodology Group, 487
Exact or Perfect Differentials, 63
Exergy, 176
Extensive security measures, 546
External flows, 253

## F

Fast Breeder Reactors (FBR), 443, 455
Fast Neutron Reactors (FNR), 455
Fault Detectors, 435
Film boiling region, 281
First Law of Thermodynamics, 16, 53, 86, 88, 89, 107, 85
First-of-a-Kind (FOAK), 465
Fission, 438, 439, 442
Fluoride salt-cooled High-temperature Reactors (FHR), 472
France, 463
Front End Fuel Cycle, 497
Fuel cost, 524
Fuel costs, 521
Fuel Costs, 532
Fuel Cycle Crosscut Group (FCCG), 488
Fuel management scenario, 548
Fukushima, 545, 550, 551

## G

Gage pressure, 12
Gas Cooled Reactor (GCR), 452, 454
Gas Cooled Reactor (GFR), 477
Gas Law, 136
Gas Mixtures, 45
Gas Turbine Modular Helium Reactor (GT-MHR), 454
Generation II, 462
Generation III, 462
Generation IV, 442, 462-464, 467, 487, 516

Generation IV International Forum (GIF), 463
Generation Nuclear Plant (NGNP), 467
Gen IV, 442, 462
Gibbs Free Energy, 214
Gibbs Potential, 214
Graphite Moderated Reactor(GMR), 446
Grid Systems, 434

## H

Hanford, 441
Heat Capacities of Ideal Gas, 122
Heat of Combustion, 239
Heat of Fusion, 19, 115
Heat of Vaporization, 19
Heat Pump, 154
Heavy water (D2O), 443
Heavy water reactors (HWR), 447
Heavy Water Reactors (HWR), 444, 446
Helmholtz Free Energy, 209, 214
Helmholtz Potential, 214, 215
Heterogeneous mixture, 18
Higher Heating Value, 239
High Level Waste (HLW), 505-508, 510, 511, 512, 513, 514
High-Level Waste (HLW), 503
High Pressure Compressor (HPC), 371
High Temperature Gas cooled Reactor (HTGR), 454
High-Temperature Reactors (HTR), 466
Homogeneous mixture, 18
Hydraulic diameter, 259
Hydrogen Energy and Fuel Cells, 492

## I

Ideal Gas, 19, 22-25, 28, 31-33, 37, 45, 47, $49,50,117,118,122,126,127,161$, 140, 162-164, 203, 205, 218, 221, 222, 205, 207, 209, 225
Ideal Gas Mixtures, 45, 49
Inexact or Imperfect Differential, 63
Innovative Nuclear Reactors and Fuel Cycles (INPRO), 462
Integrated management approach, 546
Intensive variables, 10
Intermediate Level Waste (ILW), 505
Internal energy, 79, 86
Irreversibility, 174
Isentropic efficiency, 380
J
Japan, 463
Joule-Thompson, 225

## K

Kay's rule, 49
Kelvins degree, 14
L
Lawrence Berkeley National Laboratory, 549
Laws of Thermodynamics, 16
Lead-Bismuth Eutectic (LBE), 480
Lead-cooled Fast Reactor (LFR), 480
Lenoir Cycle, 368
Leo Szilard, 439
Light water (H2O), 443
Light Water Reactors (LWR), 445
Linear-No-Threshold (LNT), 549
Liquefied Natural Gas (LNG), 521
Liquid Metal Fast Breeder Reactors (LMFBR), 458
Los Alamos, 441
Low Level Waste (LLW), 505

## M

Macroscopic systems, 8
Manhattan Project, 441
Maxwell Boltzmann, 212
Mean Efficiency Pressure (MEP), 348
Mean Free Path, 144
Medical diagnosis, 546
Million Tons of Uranium (MtU), 465
Mixed Oxide fuel (MOX), 501, 503, 509, 516, 530
Mixture in equilibrium, 37
Mixtures of pure substances, 10, 45
Molten Salt Reactor (MSR), 471
Monthly Fuel Cost, 522

## N

Natural gas, 438
Naturally Occurring Radioactive Material (NORM), 505
Nernst Postulate, 199
New Generation of Power Plant, 442
New Mexico, 441
Newtonian mechanics, 3
Non-equilibrium states, 57, 142
Nuclear criticality, 441
Nuclear Energy Institute (NEI), 519
Nuclear Fuel Cycle, 455, 497, 500, 501, 502, 505, 506, 512, 517
Nuclear Power Plants, 401, 403, 404, 413, 437, 443, 444, 461, 462, 466, 488, 499, $506,515,519,520,524,525,532,535$, $538,545,546,549,550$
Nuclear Regulatory Commission (NRC), 467

Nucleate boiling (DNB), 276
Nusselt number, 259-262, 266, 267

## 0

Oak Ridge, 441
Open systems, 8
Otto Cycle, 344

## P

Path function, 63, 64
Pellets, 499, 514
Peng-Robinson coefficients, 36
Peng-Robinson equation of state, 29
People's Republic of China, 463
Pinch Point, 389
Plank's constant, 185
Plant-Life Management technologies and Plant License Extension practices (PLIM/ PLEX), 464
Prandtl number, 259, 260, 277
President Franklin Roosevelt, 440
Pressurized Heavy Water Reactor (PHWR), 449
Pressurized Water Reactor (PWR), 1, 449, 451
Pressurized Water Reactors, PWR, 445
Pure substances, 10, 17, 21, 28, 45, 46, 165

## Q

Quasi-equilibrium process, 8
Quasi-static, 57, 59-61, 63, 65, 74, 77, 156, 94

## R

Radiation, 82, 245
Rankine Cycle, 375, 376, 385, 400
Rankine degree, 14
Recuperated Cycle, 370
Redlich-Kwong equation of state, 28, 49
Reversible process, 77
Reversible work, 173
Reynolds number, 255, 256, 259, 260, 265, 266, 271
Risk of radioactive release, 545
Roadmap Integration Team (RIT), 487
Rohsenow, 276
Russian Federation, 464

## S

Schrodinger's wave equation, 207
Second Law of Thermodynamics, 16, 153, 167
Severe Accident Management (SAM), 550
Severe Accident Mitigation Guidelines (SAMG), 551
Smart Grid, 435

Sodium Cooled Fast Reactor (SFR), 473
Sodium Fast Reactor (SFR), 490
South Africa, 463
Specific volume, 11, 18, 20, 22, 23, 25, 37
Spent Nuclear Fuel (SNF), 512
Standard Cycle, 335
Stanton number, 260
State emergency response, 546
State functions, 63
Stirling Cycle, 361
Stoichiometric Air, 231
Substation System, 421
Super Critical Water Cooled (SCWR), 474
Supercritical water reactors (SCWR), 504
Switzerland, 463
System Costs, 540
System International (SI), 5
System Steering Committee (SSC), 464

## T

Taps Ssystem, 424
Technical Working Group (TWG), 487
Temperature, 13
Tennessee, 441
Terminal Temperature Difference (TTD), 395
Theoretical Air, 231
Thermal energy, $2,3,6,8,16,17,53,79,82$, $89,100,114,139,138,153,156,336$, 370-372, 444,
Thermal reactor, 443, 445, 457, 458
Third Law of Thermodynamics, 16, 198
Three Phase Power, 420
Transport used nuclear fuel, 547
True Heat Engine, 154
Turbulent flow, 255

## U

Unified System for Information Exchange (USIE), 550
United Kingdom, 464
United States, 1, 437, 441, 445, 463
United States Power Grid, 431
University of Chicago, 439, 441, 446, 527
Uranium Ore, 532
Used Nuclear Fuel, 510

## V

Vacuum pressure, 12
Van der Waals equation, 27
Vapor dome, 21, 28, 40, 137, 220, 377, 387, 389, 390, 400
Very-High Temperature Reactors (VHTR), 466
Very High Temperature Reactor (VHTR), 470
Very Low Level Waste (VLLW), 505
Virial equation of state, 31
Voltage sensors, 435

## W

Washington, 441
Western Interconnects, 434
West Valley, NY, 512
World Nuclear Association (WNA), 519

Y
Yucca Mountain, 512, 513, 548

## Z

Zeroth Law of Thermodynamics, 16, 97

[^0]:    This chapter deals with the relationship between pressure, specific volume, and temperature for a pure substance.
