ABSTRACT

This paper discusses the first year results of a screening procedure used to identify 92 kindergarten and first grade children who were at risk of developing serious emotional disturbance (SED), and presents additional data on the predictive validity of the screening procedure one year later. The Systematic Screening for Behavior Disorders (SSBD) is a three-stage, multiple-gated procedure for mass screening to determine whether a child should be referred for psycho-educational evaluation. This study adapted the procedure to assess level of risk status in order to better target instruction, behavioral, and community-based services based on need and applied to a population that is at-risk in general due to a variety of psychosocial factors. Students were ranked by teachers and classified as either low, moderate, or high risk for SED based on the number of gates passed during the screening process. Results from the study indicate the SSBD procedure appears to be well suited as an instrument for the classification of risk status, as well as for screening children who might be referred for evaluation for educational and mental health services. Purpose

The purposes of this presentation were to report the first year's results of a screening procedure used to identify kindergarten and first grade children who are at risk of developing Serious Emotional Disturbance (SED), and to present additional data on the predictive validity of the screening procedure one year later. The Systematic Screening for Behavior Disorders (SSBD) is a three-stage, multiple-gated procedure for mass screening to determine whether a child should be referred for psycho-educational evaluation (Walker and Severenson, 1992). We adapted this procedure to assess level of risk status in order to better target instructional, behavioral, and community-based services based on need and applied to a population that is at-risk in general due to a variety of psychosocial factors. This approach has the potential of providing more efficient and cost-effective means for allocating preventive services that vary in intensity and duration based on degree of risk.

Research Sample

The socio-demographic and educational characteristics of the sample are shown in tables 1 and 2, respectively.

Methods

Screening Procedure. The SSBD is designed to assess for both the presence of emotional and behavior problems and the effects of problem behavior on academic and social functioning in school. The three-stage procedure involves teacher's nominating ten children who fit a behavioral profile of externalizing behavior and ten who fit a profile of internalizing behavior; the nominated children are then ranked on the extent to which they display each type of behavior (Stage 1). In Stage 2 teachers rated the five highest

ranked children in each group (5 internalizers and 5 externalizers) on the Critical Events Checklist and the Adaptive/Maladaptive Behavior Rating Scale. Children who pass cut-off scores based on SSBD norms pass to Stage 3. In this stage trained professionals use observational measures in the classroom (Academic Engaged Time) and on the playground (Peer Social Behavior). Children who pass cut-off scores based on the stage 3 SSBD norms have passed through all three gates. When this occurs, the recommended assessment decision is to refer the child for a comprehensive psycho-educational evaluation.

In the present study we used this procedure to classify risk status as either low, moderate, or high based on the number of gates passed during the screening process. Children who were ranked by teachers who did not pass gate 2 were classified as low risk. Those who passed gate 2, but not gate 3, were considered to be at moderate risk, and those who passed all three gates were considered to be at high risk.

Other Measures. To assess concurrent validity of the screening procedure, we collected data from the Social Skills Rating (SSRS; Gresham & Elliot, 1990), Teacher and Parent forms, and teacher ratings on the Classroom Behavior Inventory (CBI, Schaefer, Edgerton, & Aronson, 1977). Apart from social skills, the SSRS also has a brief scale to assess externalizing, internalizing, and hyperactive behaviors and a scale which assesses compliance with school rules. The Parent Form measures the same social skills (cooperation, assertion, and self control) and Problem Behavior, but also includes a scale for measuring responsibility in relationships with others. The CBI broadly measures academic competence, temperament (extroversion and introversion), and social

department (considerateness versus hostility). Also, we collect school records data yearly in the project; but these data have not been analyzed at the present time.

Results

Screening Procedure

Table 3 shows that 92 (14%) of the children from the initial sample of 628 children were identified as having low risk for SED. Sixty-three (10%) of the children were identified as having moderate risk, and 28 (4.5%) were classified as high risk. Also, Table 3 shows that about 3% more children were identified as having moderate to high risk ($n = 91$, 14.5%) than would be predicted from the SSBD norms ($n = 73$, 11.6%) This finding was predictable given that the research sample was composed of mostly disadvantaged children who were at risk generally due to a variety of other psycho-social risk factors.

The difference between the obtained and expected frequencies for the moderate and high risk categories was due in part to the finding that relatively more children with externalizing behavior passed gate two. This might be attributed to the fact that externalizing behavior is more visible than internalizing behavior, or to selection bias on the part of teachers. However, it should be noted that the frequencies of both types of behavior problems were comparable among low-risk children and that the assessment criteria were more objective and stringent at the second and third stages of screening. Although the obtained frequencies for moderate and high risk externalizers were higher than expected, they were comparable for internalizing children.

Significant differences were obtained between the means for the Miami sample on the SSBD screening instruments and those for the SSBD normative sample for both

externalizers and internalizers. This suggests that the Miami research sample displayed greater levels of severity with respect to risk indicators than might be expected in a general population sample.

External Measures

Table 4 shows that internalizing children in the moderate and high risk groups were rated on SSRS as having better social skills than externalizing children. Externalizing children were rated as more externalizing and hyperactive than internalizing children on the Problem Behavior Scale. However, teachers tended to rate externalizing children as more internalizing as well. Also, as table 4 shows, externalizers were rated lower on the Academic Competence Scale than internalizers. Parents who completed the Parent Form of the SSRS did not perceive any differences between the children who were classified as having internalizing or externalizing behavior problems by the SSBD. This was the case with measures of both social skills and problem behavior. However, this was a small sample due to significant non-response, and 83% of the children whose parents completed the form had been classified as at moderate risk. Only 5 of the high risk externalizing children were represented, along with 5 on the internalizing scale.

Comparisons of externalizing and internalizing children on the CBI showed significant differences in the predicted direction on all scales except Creativity/Curiosity and Extroversion/Introversion. Externalizing children were perceived by teachers as less task-oriented, independent, and considerate of others and as more distractible, dependent, and hostile.

With respect to gender the SSBD identified 128 (62%) boys and 78 (38%) girls as having some level of risk. Relatively more boys were identified as having externalizing behaviors. However, a significant number of girls with internalizing and externalizing behaviors passed through the first stage of screening, and a proportional number of externalizing and internalizing girls were represented in the moderate and high risk groups (8% and 7%, and 2% each, respectively). Therefore, the procedures at stage 2 and 3 appeared to be successful in identifying a significant number of boys with internalizing problems.

Conclusions/Discussion

In general, the SSBD procedure appears to be well suited as an instrument for the classification of risk status, as well as for screening children who might be referred for evaluation for educational and mental health services. Also, this approach to assessment might have significant implications for refining the definition of risk for the purpose of planning and implementing preventive interventions, particularly of a comprehensive nature. Progress in the area of primary prevention has been impeded by the lack of reliable methods for assessing the level of risk for specific types of disorders (Forness, et al., 1996). We typically use rather gross measures that are subject to high rates of false positive cases. These results suggest that many of the children in our sample might benefit from universal interventions that target a defined population of at-risk children, while others might benefit to a greater extent from selective interventions that may meet the needs of particular subgroups of children who are at greater risk. Finally, a smaller group of high-risk children may require more intensive indicated interventions, given their more immediate needs. At the same time, the approach illustrated here has its

There are some technical problems assessing children as young as five years with this instrument, and it is not designed to detect comorbidity, which is part of the clinical portrait presented by high risk children. However, the Early Screening Project (ESP) instruments developed by Walker, Severson, and Feil (1995) to screen children aged 3-6 using the SSBD procedure have modified and now have been published.
